Package ‘marmap’
March 24, 2023

Type Package
Title Import, Plot and Analyze Bathymetric and Topographic Data
Version 1.0.10
Date 2023-03-24
Author Eric Pante, Benoit Simon-Bouhet, and Jean-Olivier Irisson
Maintainer Benoit Simon-Bouhet <besibo@gmail.com>
Depends R (>= 2.10)
Imports DBI, RSQLite, gdistance, geosphere, sp, raster, ncdf4, plotrix, shape, reshape2, adehabitatMA, ggplot2, methods
Suggests maps, mapdata, lattice, mapproj, R.rsp
BugReports https://github.com/ericpante/marmap/issues
Description Import xyz data from the NOAA (National Oceanic and Atmospheric Administration, <https://www.noaa.gov>), GEBCO (General Bathymetric Chart of the Oceans, <https://www.gebco.net>) and other sources, plot xyz data to prepare publication-ready figures, analyze xyz data to extract transects, get depth / altitude based on geographical coordinates, or calculate z-constrained least-cost paths.

aleutians

Bathymetric data for the Aleutians (Alaska)

Description

Bathymetric matrix of class bathy created from NOAA GEODAS data.

Usage

data(aleutians)

Details

Data imported from the NOAA GEODAS Grid Translator webpage (https://maps.ngdc.noaa.gov/viewers/wcs-client/) and transformed into an object of class bathy by as.bathy.

Value

A text file.

Author(s)

see https://maps.ngdc.noaa.gov/viewers/wcs-client/

See Also

as.bathy, read.bathy, antimeridian.box

Examples

# load celt data
data(aleutians)

# class "bathy"
class(aleutians)
supply(aleutians)

# test plot.bathy
plot(aleutians, image = TRUE,
    bpal = list(c(0,max(aleutians),"grey"),
                c(min(aleutians),0,"darkblue","lightblue"),
                land = TRUE, lwd = 0.1, axes = FALSE)
antimeridian.box(aleutians, 10)
antimeridian.box

---

**Description**

Adds a box on maps including the antimeridian (180 degrees).

**Usage**

```r
antimeridian.box(object, tick.spacing)
```

**Arguments**

- **object**
  - matrix of class bathy
- **tick.spacing**
  - spacing between tick marks (in degrees, default=20)

**Value**

The function adds a box and tick marks to an existing plot which contains the antimeridian line (180 degrees).

**Author(s)**

Eric Pante & Benoit Simon-Bouhet

**See Also**

- `plot.bathy`

**Examples**

```r
data(aleutians)

# default plot:
plot(aleutians,n=1)

# plot with corrected box and labels:
plot(aleutians,n=1,axes=FALSE)
antimeridian.box(aleutians, 10)
```
as.bathy

Convert to bathymetric data in an object of class bathy

Description
Reads either an object of class RasterLayer, SpatialGridDataFrame or a three-column data.frame containing longitude (x), latitude (y) and depth (z) data and converts it to a matrix of class bathy.

Usage
as.bathy(x)

Arguments
x Object of RasterLayer or SpatialGridDataFrame, or a three-column data.frame with longitude (x), latitude (y) and depth (z) (no default)

Details
x can contain data downloaded from the NOAA GEODAS Grid Translator webpage (http://www.ngdc.noaa.gov/mgg/gdas/gd_designagrid.html) in the form of an xyz table. The function as.bathy can also be used to transform objects of class raster (see package raster) and SpatialGridDataFrame (see package sp).

Value
The output of as.bathy is a matrix of class bathy, which dimensions and resolution are identical to the original object. The class bathy has its own methods for summarizing and plotting the data.

Author(s)
Benoit Simon-Bouhet

See Also
summary.bathy, plot.bathy, read.bathy, as.xyz, as.raster, as.SpatialGridDataFrame.

Examples
# load NW Atlantic data
data(nw.atlantic)

# use as.bathy
atl <- as.bathy(nw.atlantic)

# class "bathy"
class(atl)

# summarize data of class "bathy"
summary(atl)
as.raster  

Convert bathymetric data to a raster layer

Description
Transforms an object of class bathy to a raster layer.

Usage
as.raster(bathy)

Arguments
bathy an object of class bathy

Details
as.raster transforms bathy objects into objects of class RasterLayer as defined in the raster package. All methods from the raster package are thus available for bathymetric data (e.g. rotations, projections...).

Value
An object of class RasterLayer with the same characteristics as the bathy object (same longitudinal and latitudinal ranges, same resolution).

Author(s)
Benoit Simon-Bouhet

See Also
as.xyz, as.bathy, as.SpatialGridDataFrame

Examples
# load Hawaii bathymetric data
data(hawaii)

# use as.raster
r.hawaii <- as.raster(hawaii)

# class "RasterLayer"
class(r.hawaii)

# Summaries
summary(hawaii)
summary(r.hawaii)
as.SpatialGridDataFrame

Convert bathymetric data to a spatial grid

Description
Transforms an object of class bathy to a SpatialGridDataFrame object.

Usage
as.SpatialGridDataFrame(bathy)

Arguments
bathy  an object of class bathy

Details
as.SpatialGridDataFrame transforms bathy objects into objects of class SpatialGridDataFrame as defined in the sp package. All methods from the sp package are thus available for bathymetric data (e.g. rotations, projections...).

Value
An object of class SpatialGridDataFrame with the same characteristics as the bathy object (same longitudinal and latitudinal ranges, same resolution).

Author(s)
Benoit Simon-Bouhet

See Also
as.xyz, as.bathy, as.raster
Examples

# load Hawaii bathymetric data
data(hawaii)

# use as.SpatialGridDataFrame
sp.hawaii <- as.SpatialGridDataFrame(hawaii)

# Summaries
summary(hawaii)
summary(sp.hawaii)

# structure of the SpatialGridDataFrame object
str(sp.hawaii)

# Plots
plot(hawaii,image=TRUE,lwd=.2)
image(sp.hawaii)

---

as.xyz  

Convert to xyz format

Description

Converts a matrix of class bathy into a three-column data.frame containing longitude, latitude and depth data.

Usage

as.xyz(bathy)

Arguments

bathy  

matrix of class bathy.

Details

The use of as.bathy and as.xyz allows to switch back and forth between the long format (xyz) and the wide format of class bathy suitable for plotting bathymetric maps, computing least cost distances, etc. as.xyz is especially useful for exporting xyz files when data are obtained using subsetSQL, i.e. bathymetric matrices of class bathy.

Value

Three-column data.frame with a format similar to xyz files downloaded from the NOAA GEODAS Grid Translator webpage (https://maps.ngdc.noaa.gov/viewers/wcs-client/). The first column contains longitude data, the second contains latitude data and the third contains depth/elevation data.
**autoplot.bathy**

**Description**

Plots contour or image map from bathymetric data matrix of class `bathy` with ggplot2

**Usage**

```r
## S3 method for class 'bathy'
autoplot(x, geom="contour", mapping=NULL, coast=TRUE, ...)
```

**Arguments**

- `x`: bathymetric data matrix of class `bathy`, imported using `read.bathy`
- `geom`: geometry to use for the plot, i.e. type of plot; can be ‘contour’, ‘tile’ or ‘raster’. contour does a contour plot. tile and raster produce an image plot. tile allows true geographical projection through `coord_map`. raster only allows approximate projection but is faster to plot. Names can be abbreviated. Geometries can be combined by specifying several in a vector.
- `mapping`: additional mappings between the data obtained from calling `fortify.bathy` on `x` and the aesthetics for all geoms. When not NULL, this is a call to `aes()`.
- `coast`: boolean; whether to highlight the coast (isobath 0 m) as a black line
- `...`: passed to the chosen geom(s)
Details

`fortify.bathy` is called with argument `x` to produce a data.frame compatible with ggplot2. Then layers are added to the plot based on the argument `geom`. Finally, the whole plot is projected geographically using `coord_map` (for `geom="contour"`) or an approximation thereof.

Author(s)

Jean-Olivier Irisson

`fortify.bathy`, `plot.bathy`, `read.bathy`, `summary.bathy`

Examples

```r
# load NW Atlantic data and convert to class bathy
data(nw.atlantic)
atl <- as.bathy(nw.atlantic)

    # basic plot
    ## Not run:
    library("ggplot2")
    autoplot.bathy(atl)

    # plot images
    autoplot.bathy(atl, geom=c("tile"))
    autoplot.bathy(atl, geom=c("raster")) # faster but not resolution independant

    # plot both!
    autoplot.bathy(atl, geom=c("raster", "contour"))

    # geom names can be abbreviated
    autoplot.bathy(atl, geom=c("r", "c"))

    # do not highlight the coastline
    autoplot.bathy(atl, coast=FALSE)

    # better colour scale
    autoplot.bathy(atl, geom=c("r", "c")) +
        scale_fill_gradient2(low="dodgerblue4", mid="gainsboro", high="darkgreen")

    # set aesthetics
    autoplot.bathy(atl, geom=c("r", "c"), colour="white", size=0.1)

    # topographical colour scale, see ?scale_fill_etopo
    autoplot.bathy(atl, geom=c("r", "c"), colour="white", size=0.1) + scale_fill_etopo()

    # add sampling locations
    data(metallo)
    last_plot() + geom_point(aes(x=lon, y=lat), data=metallo, alpha=0.5)

    # an alternative contour map making use of additional mappings
```
# see ?stat_contour in ggplot2 to understand the ..level.. argument
autoplot.bathy(atl, geom="contour", mapping=aes(colour=..level..))

## End(Not run)

---

**celt**  
*Bathymetric data for the North Est Atlantic*

---

## Description

Bathymetric matrix of class `bathy` created from NOAA GEODAS data.

## Usage

data(celt)

## Details

Data imported from the NOAA GEODAS Grid Translator webpage ([https://maps.ngdc.noaa.gov/viewers/wcs-client/](https://maps.ngdc.noaa.gov/viewers/wcs-client/)) and transformed into an object of class `bathy` by `as.bathy`.

## Value

A text file.

## Author(s)

see [https://maps.ngdc.noaa.gov/viewers/wcs-client/](https://maps.ngdc.noaa.gov/viewers/wcs-client/)

## See Also

`as.bathy`, `read.bathy`

## Examples

```r
# load celt data
data(celt)

# class "bathy"
class(celt)
summary(celt)

# test plot.bathy
plot(celt, deep=-300, shallow=-50, step=25)
```
check.bathy

Sort bathymetric data matrix by increasing latitude and longitude

Description

Reads a bathymetric data matrix and orders its rows and columns by increasing latitude and longitude.

Usage

check.bathy(x)

Arguments

x a matrix

Details

check.bathy allows to sort rows and columns by increasing latitude and longitude, which is necessary for plotting with the function image (package graphics). check.bathy is used within the marmap functions read.bathy and as.bathy (it is also used in getNOAA.bathy through as.bathy).

Value

The output of check.bathy is an ordered matrix.

Author(s)

Eric Pante

See Also

read.bathy, as.bathy, getNOAA.bathy

Examples

matrix(1:100, ncol=5, dimnames=list(20:1, c(3,2,4,1,5))) -> a
check.bathy(a)
col2alpha

Adds alpha transparency to a (vector of) color(s)

Description

Adds transparency to a color or a vector of colors by specifying one or several alpha values.

Usage

col2alpha(color, alpha = 0.5)

Arguments

- **color**: a (vector of) color codes or names
- **alpha**: a value (or vector of values) between 0 (full transparency) and 1 (no transparency).

Details

When the size of color and alpha vectors are different, alpha values are recycled.

Value

A (vector) of color code(s).

Author(s)

Benoit Simon-Bouhet

Examples

```r
# Generate random data
dat <- rnorm(4000)

# plot with plain color for points
plot(dat, pch=19, col="red")

# Add some transparency to get a better idea of density
plot(dat, pch=19, col=col2alpha("red", .3))

# Same color for all points but with increasing alpha (decreasing transparency)
plot(dat, pch=19, col=col2alpha(rep("red", 4000), seq(0, 1, len=4000)))

# Two colors, same alpha
plot(dat, pch=19, col=col2alpha(rep(c("red", "purple"), each=2000), .2))

# Four colors, gradient of transparency for each color
plot(dat, pch=19, col=col2alpha(rep(c("blue", "purple", "red", "orange"), each=1000), seq(.1, .6, len=1000)))
```
# Alpha transparency applied to a gradient of colors
plot(dat,pch=19,col=col2alpha(rainbow(4000),.5))

collate.bathy Collates two bathy matrices with data from either sides of the antimeridian

Description
Collates two bathy matrices, one with longitude 0 to 180 degrees East, and the other with longitude 0 to 180 degrees West

Usage
collate.bathy(east,west)

Arguments
east matrix of class bathy with eastern data (West of antimeridian)
west matrix of class bathy with western data (East of antimeridian)

Details
This function is meant to be used with read.bathy() or readGEBCO.bathy(), when data is downloaded from either sides of the antimeridian line (180 degrees longitude). If, for example, data is downloaded from GEBCO for longitudes of 170E-180 and 180-170W, collate.bathy() will create a single matrix of class bathy with a coordinate system going from 170 to 190 degrees longitude.

getNOAA.bathy() deals with data from both sides of the antimeridian and does not need further processing with collate.bathy().

Value
A single matrix of class bathy that can be interpreted by plot.bathy. When plotting collated data (with longitudes 0 to 180 and 180 to 360 degrees), plots can be modified to display the conventional coordinate system (with longitudes 0 to 180 and -180 to 0 degrees) using function antimeridian.box().

Author(s)
Eric Pante

See Also
getNOAA.bathy, summary.bathy, plot.bathy, antimeridian.box

### Examples

```r
## faking two datasets using aleutians, for this example
## "a" and "b" simulate two datasets downloaded from GEBCO, for ex.
data(aleutians)
aleutians[1:181,] -> a ; "bathy" -> class(a)
aleutians[182:601,] -> b ; "bathy" -> class(b)
-(360-as.numeric(rownames(b))) -> rownames(b)

## check these objects with summary(): pay attention of the Longitudinal range
summary(aleutians)
summary(a)
summary(b)

## merge datasets:
collate.bathy(a,b) -> collated
summary(collated) # should be identical to summary(aleutians)
```

#### combine.buffers

Create a new, (non circular) composite buffer from a list of existing buffers.

**Description**

Creates a new bathy object from a list of existing buffers of compatible dimensions.

**Usage**

```r
combine.buffers(...)
```

**Arguments**

- `...` 2 or more buffer objects as produced by `create.buffer`. All bathy objects within the buffer objects must be compatible: they should have the same dimensions (same number of rows and columns) and cover the same area (same longitudes and latitudes).

**Value**

An object of class bathy of the same dimensions as the original bathy objects contained within each buffer objects. The resulting bathy object contains only NAs outside of the combined buffer and values of depth/altitude inside the combined buffer.

**Author(s)**

Benoit Simon-Bouhet

**See Also**

`create.buffer`, `plot.buffer`, `plot.bathy`
create.buffer

Create a buffer of specified radius around one or several points

Description

Create a circular buffer of user-defined radius around one or several points defined by their longitudes and latitudes.

Usage

create.buffer(x, loc, radius, km = FALSE)

Arguments

x
an object of class bathy

loc
a 2-column data.frame of longitudes and latitudes for points around which the buffer is to be created.

radius
numeric. Radius of the buffer in the same unit as the bathy object (i.e. usually decimal degrees) when km=FALSE (default) or in kilometers when radius=TRUE.

km
logical. If TRUE, the radius should be provided in kilometers. When FALSE (default) the radius is in the same unit as the bathy object (i.e. usually decimal degrees).
Details

This function takes advantage of the buffer function from package adehabitatMA and several functions from packages sp to define the buffer around the points provided by the user.

Value

An object of class bathy of the same size as mat containing only NAs outside of the buffer and values of depth/altitude (taken from mat) within the buffer.

Author(s)

Benoit Simon-Bouhet

See Also

outline.buffer, combine.buffers, plot.bathy

Examples

# load and plot a bathymetry
data(florida)
plot(florida, lwd = 0.2)
plot(florida, n = 1, lwd = 0.7, add = TRUE)

# add a point around which a buffer will be created
loc <- data.frame(-80, 26)
points(loc, pch = 19, col = "red")

# compute and print buffer
buf <- create.buffer(florida, loc, radius=1.5)
buf

# highlight isobath with the buffer and add outline
plot(buf, outline=FALSE, n = 10, col = 2, lwd=.4)
plot(buf, lwd = 0.7, fg = 2)

-----------------------------------
diag.bathy                      Finds matrix diagonal for non-square matrices
-----------------------------------

Description

Finds either the values of the coordinates of the non-linear diagonal of non-square matrices.

Usage

diag.bathy(mat,coord=FALSE)
Arguments

mat a data matrix
coord whether of not to output the coordinates of the diagonal (default is FALSE)

Details

diag.bathy gets the values or coordinates from the first element of a matrix to its last elements. If the matrix is non-square, that is, its number of rows and columns differ, diag.bathy computes an approximate diagonal.

Value

A vector of diagonal values is coord is FALSE, or a table of diagonal coordinates if coord is FALSE

Author(s)

Eric Pante

See Also

get.transect.diag

Examples

# a square matrix: diag.bathy behaves as diag
top <- matrix(1:25, 5, 5) -> a ; a
diag(a)
diag.bathy(a)

# a non-square matrix: diag.bathy does not behaves as diag
top <- matrix(1:15, 3, 5) -> b ; b
diag(b)
diag.bathy(b)

# output the diagonal or its coordinates:
rownames(b) <- seq(32,35, length.out=3)
colnames(b) <- seq(-100,-95, length.out=5)
diag.bathy(b, coord=FALSE)
diag.bathy(b, coord=TRUE)
**dist2isobath**

*Computes the shortest great circle distance between any point and a given isobath*

---

**Description**

Computes the shortest (great circle) distance between a set of points and an isoline of depth or altitude. Points can be selected interactively by clicking on a map.

**Usage**

```r
dist2isobath(mat, x, y=NULL, isobath=0, locator=FALSE, ...)
```

**Arguments**

- `mat` Bathymetric data matrix of class `bathy`, as imported with `read.bathy`.
- `x` Either a list of two elements (numeric vectors of longitude and latitude), a 2-column matrix or data.frame of longitudes and latitudes, or a numeric vector of longitudes.
- `y` Either `NULL` (default) or a numerical vector of latitudes. Ignored if `x` is not a numeric vector.
- `isobath` A single numerical value indicating the isobath to which the shortest distance is to be computed (default is set to 0, *i.e.* the coastline).
- `locator` Logical. Whether to choose data points interactively with a map or not. If `TRUE`, a bathymetric map must have been plotted and both `x` and `y` are both ignored.
- `...` Further arguments to be passed to `locator` when the interactive mode is used (`locator=TRUE`).

**Details**

dist2isobath allows the user to compute the shortest great circle distance between a set of points (selected interactively on a map or not) and a user-defined isobath. dist2isobath takes advantage of functions from packages `sp` (`Lines()` and `SpatialLines()`) and `geosphere` (`dist2Line`) to compute the coordinates of the nearest location along a given isobath for each point provided by the user.

**Value**

A 5-column data.frame. The first column contains the distance in meters between each point and the nearest point located on the given isobath. Columns 2 and 3 indicate the longitude and latitude of starting points (*i.e.* either coordinates provided as `x` and `y` or coordinates of points selected interactively on a map when `locator=TRUE`) and columns 4 and 5 contains coordinates (longitudes and latitudes) arrival points *i.e.* the nearest points on the isobath.

etopo  

Etopo colours

Description

Various ways to access the colors on the etopo color scale

Usage

etopo.colors(n)

scale_fill_etopo(...)

scale_color_etopo(...)

Arguments

n  number of colors to get from the scale. Those are evenly spaced within the scale.

...  passed to scale_fill_gradientn or scale_color_gradientn

Details

etopo.colors is equivalent to other color scales in R (e.g. grDevices::heat.colors, grDevices::cm.colors).
scale_fill/color_etopo are meant to be used with ggplot2. They allow consistent plots in various subregions by setting the limits of the scale explicitly.

florida

Bathymetric data around Florida, USA

Description

Bathymetric object of class bathy created from NOAA GEODAS data.

Usage

data(florida)
fortify.bathy

Details

Data imported from the NOAA GEODAS Grid Translator webpage (https://maps.ngdc.noaa.gov/viewers/wcs-client/) and transformed into an object of class `bathy` by `read.bathy`.

Value

A bathymetric object of class `bathy` with 539 rows and 659 columns.

Author(s)

see https://maps.ngdc.noaa.gov/viewers/wcs-client/

See Also

`plot.bathy`, `summary.bathy`

Examples

```r
# load florida data
data(florida)

# class "bathy"
class(florida)
summary(florida)

# test plot.bathy
plot(florida,asp=1)
plot(florida,asp=1,image=TRUE,drawlabels=TRUE,land=TRUE,n=40)
```

Description

Extract bathymetry data in a data.frame

Usage

```r
## S3 method for class 'bathy'
fortify(model, data, ...)
```

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>model</td>
<td>bathymetric data matrix of class <code>bathy</code>, imported using <code>read.bathy</code></td>
</tr>
<tr>
<td>data</td>
<td>ignored</td>
</tr>
<tr>
<td>...</td>
<td>ignored</td>
</tr>
</tbody>
</table>
Details

`fortify.bathy` is really just calling `as.xyz` and ensuring consistent names for the columns. It then allows to use `ggplot2` functions directly.

`autoplot.bathy`, `as.xyz`

Examples

```r
# load NW Atlantic data and convert to class bathy
data(nw.atlantic)
atl <- as.bathy(nw.atlantic)

library("ggplot2")
# convert bathy object into a data.frame
head(fortify(atl))

# one can now use bathy objects with ggplot directly
ggplot(atl) + geom_contour(aes(x=x, y=y, z=z)) + coord_map()

# which allows complete plot configuration
atl.df <- fortify(atl)
ggplot(atl.df, aes(x=x, y=y)) + coord_quickmap() +
  geom_raster(aes(fill=z), data=atl.df[atl.df$z <= 0,]) +
  geom_contour(aes(z=z),
              breaks=c(-100, -200, -500, -1000, -2000, -4000),
              colour="white", size=0.1
            ) +
  scale_x_continuous(expand=c(0,0)) +
  scale_y_continuous(expand=c(0,0))
```

get.area  

Get projected surface area

Description

Get projected surface area for specific depth layers

Usage

```r
get.area(mat, level.inf, level.sup=0, xlim=NULL, ylim=NULL)
```
get.area

Arguments

- **mat**: bathymetric data matrix of class bathy, imported using `read.bathy` (no default)
- **level.inf**: lower depth limit for calculation of projected surface area (no default)
- **level.sup**: upper depth limit for calculation of projected surface area (default is zero)
- **xlim**: longitudinal range of the area of interest (default is NULL)
- **ylim**: latitudinal range of the area of interest (default is NULL)

Details

`get.area` calculates the projected surface area of specific depth layers (e.g. upper bathyal, lower bathyal), the projected plane being the ocean surface. The resolution of `get.area` depends on the resolution of the input bathymetric data. `xlim` and `ylim` can be used to restrict the area of interest. Area calculation is based on `areaPolygon` of package `geosphere` (using an average Earth radius of 6,371 km).

Value

A list of four objects: the projected surface area in squared kilometers, a matrix with the cells used for calculating the projected surface area, the longitude and latitude of the matrix used for the calculations.

```
get.box

Get bathymetric information of a belt transect

Description

get.box gets depth information of a belt transect of width width around a transect defined by two points on a bathymetric map.

Usage

get.box(bathy, x1, x2, y1, y2, width, locator=FALSE, ratio=FALSE, ...)

get.box

Arguments

- **bathy**
  Bathymetric data matrix of class `bathy`.
- **x1**
  Numeric. Start longitude of the transect. Requested when `locator=FALSE`.
- **x2**
  Numeric. Stop longitude of the transect. Requested when `locator=FALSE`.
- **y1**
  Numeric. Start latitude of the transect. Requested when `locator=FALSE`.
- **y2**
  Numeric. Stop latitude of the transect. Requested when `locator=FALSE`.
- **width**
  Numeric. Width of the belt transect in degrees.
- **locator**
  Logical. Whether to choose transect bounds interactively with a map or not. When `FALSE` (default), a bathymetric map (`plot.bathy(bathy,image=TRUE)`) is automatically plotted and the position of the belt transect is added.
- **ratio**
  Logical. Should aspect ratio for the `wireframe` plotting function (package `lattice`) be computed (default is `FALSE`).
- **...**
  Other arguments to be passed to `locator` and `lines` to specify the characteristics of the points and lines to draw on the bathymetric map for both the transect and the bounding box of belt transect.

Details

get.box allows the user to get depth data for a rectangle area of the map around an approximate linear transect (belt transect). Both the position and size of the belt transect are user defined. The position of the transect can be specified either by inputing start and stop coordinates, or by clicking on a map created with `plot.bathy`. In its interactive mode, this function uses the `locator` function (`graphics` package) to retrieve and plot the coordinates of the selected transect. The argument `width` allows the user to specify the width of the belt transect in degrees.

Value

A matrix containing depth values for the belt transect. `rownames` indicate the kilometric distance from the start of the transect and `colnames` indicate the distance form the central transect in degrees. If `ratio=TRUE`, a list of two elements: `depth`, a matrix containing depth values for the belt transect similar to the description above and `ratios` a vector of length two specifying the ratio between (i) the width and length of the belt transect and (ii) the depth range and the length of the belt transect. These ratios can be used by the function `wireframe` to produce realistic 3D bathymetric plots of the selected belt transect.

`plot.bathy`, `get.transect`, `get.depth`
**get.depth**

*Get depth data by clicking on a map*

**Description**

Outputs depth information based on points selected by clicking on a map

**Usage**

```r
get.depth(mat, x, y=NULL, locator=TRUE, distance=FALSE, ...)
```

**Arguments**

- **mat**: Bathymetric data matrix of class bathy, as imported with `read.bathy`.
- **x**: Either a list of two elements (numeric vectors of longitude and latitude), a 2-column matrix or `data.frame` of longitudes and latitudes, or a numeric vector of longitudes.
- **y**: Either `NULL` (default) or a numerical vector of latitudes. Ignored if `x` is not a numeric vector.
- **locator**: Logical. Whether to choose data points interactively with a map or not. If `TRUE` (default), a bathymetric map must have been plotted and both `x` and `y` are both ignored.
- **distance**: Whether to compute the haversine distance (in km) from the first data point on (default is `FALSE`). Only available when at least two points are provided.
- **...**: Further arguments to be passed to `locator` when the interactive mode is used (`locator=TRUE`).

**Examples**

```r
# load and plot bathymetry
data(hawaii)
plot(hawaii,im=TRUE)

# get the depth matrix for a belt transect
depth <- get.box(hawaii,x1=-157,y1=20,x2=-155.5,y2=21,width=0.5,col=2)

# plotting a 3D bathymetric map of the belt transect
require(lattice)
wireframe(depth,shade=TRUE)

# get the depth matrix for a belt transect with realistic aspect ratios
depth <- get.box(hawaii,x1=-157,y1=20,x2=-155.5,y2=21,width=0.5,col=2,ratio=TRUE)

# plotting a 3D bathymetric map of the belt transect with realistic aspect ratios
require(lattice)
wireframe(depth[[1]],shade=TRUE,aspect=depth[[2]])
```
get.depth

Details

get.depth allows the user to get depth data by clicking on a map created with plot.bathy or by providing coordinates of points of interest. This function uses the locator function (graphics package); after creating a map with plot.bathy, the user can click on the map once or several times (if locator=TRUE), press the Escape button, and get the depth of those locations in a three-column data.frame (longitude, latitude and depth). Alternatively, when locator=FALSE, the user can submit a list of longitudes and latitudes, a two-column matrix or data.frame of longitudes and latitudes (as input for x), or one vector of longitudes (x) and one vector of latitudes (y). The non-interactive mode is well suited to get depth information for each point provided by GPS tracking devices. While get.transect gets every single depth value available in the bathymetric matrix between two points along a user-defined transect, get.depth only provides depth data for the specific points provided as input by the user.

Value

A data.frame with at least, longitude, latitude and depth with one line for each point of interest. If distance=TRUE, a fourth column containing the kilometric distance from the first point is added.

Examples

# load NW Atlantic data and convert to class bathy
data(nw.atlantic)
atl <- as.bathy(nw.atlantic)

# create vectors of latitude and longitude
lon <- c(-70, -65, -63, -55)
lat <- c(33, 35, 40, 37)

# a simple example
plot(atl, lwd=.5)
points(lon, lat, pch=19, col=2)

# Use get.depth to get the depth for each point
get.depth(atl, x=lon, y=lat, locator=FALSE)

# alternatively once the map is plotted, use the interactive mode:
## Not run:
get.depth(atl, locator=TRUE, pch=19, col=3)
## End(Not run)

# click several times and press Escape
get.sample

Get sample data by clicking on a map

Description
Outputs sample information based on points selected by clicking on a map

Usage
get.sample(mat, sample, col.lon, col.lat, ...)

Arguments
mat           bathymetric data matrix of class bathy, imported using read.bathy (no default)
sample        data.frame containing sampling information (at least longitude and latitude) (no default)
col.lon       column number of data frame sample containing longitude information (no default)
col.lat       column number of data frame sample containing latitude information (no default)
...           further arguments to be passed to rect for drawing a box around the selected area

Details
get.sample allows the user to get sample data by clicking on a map created with plot.bathy. This function uses the locator function (graphics package). After creating a map with plot.bathy, the user can click twice on the map to delimit an area (for example, lower left and upper right corners of a rectangular area of interest), and get a dataframe corresponding to the sample points present within the selected area.

Value
a dataframe of the elements of sample present within the area selected

Warning
clicking once or more than twice on the map will return a warning message: "Please choose two points from the map"

### get.transect

**Compute approximate cross section along a depth transect**

#### Description

Compute the depth along a linear transect which bounds are specified by the user.

#### Usage

```r
get.transect(mat, x1, y1, x2, y2, locator=FALSE, distance=FALSE, ...)
```

#### Arguments

- `mat`: bathymetric data matrix of class `bathy`, imported using `read.bathy` (no default)
- `x1`: start longitude of the transect (no default)
- `x2`: stop longitude of the transect (no default)
- `y1`: start latitude of the transect (no default)
- `y2`: stop latitude of the transect (no default)
- `locator`: whether to use locator to choose transect bounds interactively with a map (default is `FALSE`)
- `distance`: whether to compute the haversine distance (in km) from the start of the transect, along the transect (default is `FALSE`)
- `...`: other arguments to be passed to `locator()` to specify the characteristics of the points and lines to draw on the bathymetric map when `locator=TRUE`.  

get.transect

Details

get.transect allows the user to compute an approximate linear depth cross section either by inputting start and stop coordinates, or by clicking on a map created with plot.bathy. In its interactive mode, this function uses the locator function (graphics package); after creating a map with plot.bathy, the user can click twice to delimit the bound of the transect of interest (for example, lower left and upper right corners of a rectangular area of interest), press Escape, and get a table with the transect information.

Value

A table with, at least, longitude, latitude and depth along the transect, and if specified (distance=TRUE), the distance in kilometers from the start of the transect. The number of elements in the resulting table depends on the resolution of the bathy object.

Warning

Clicking once or more than twice on the map will return a warning message: "Please choose only two points from the map". Manually entering coordinates that are outside the geographical range of the input bathy matrix will return a warning message.

Note

The distance option of get.transect is calculated based on the haversine formula for getting the great circle distance (takes into account the curvature of the Earth). get.transect uses an internal function called diag.bathy that extracts the approximate diagonal of a matrix, when that matrix has uneven dimensions (different numbers of columns and rows).

lines(nw.atlantic.coast)
getNOAA.bathy

Import bathymetric data from the NOAA server

Description

Imports bathymetric data from the NOAA server, given coordinate bounds and resolution.

Usage

getNOAA.bathy(lon1, lon2, lat1, lat2, resolution = 4,
               keep = FALSE, antimeridian = FALSE, path = NULL)

Arguments

lon1
  first longitude of the area for which bathymetric data will be downloaded
lon2
  second longitude of the area for which bathymetric data will be downloaded
lat1
  first latitude of the area for which bathymetric data will be downloaded
lat2
  second latitude of the area for which bathymetric data will be downloaded
resolution
  resolution of the grid, in minutes (default is 4)
keep
  whether to write the data downloaded from NOAA into a file (default is FALSE)
antimeridian
  whether the area should include the antimeridian (longitude 180 or -180). See
details.
path
  Where should bathymetric data be downloaded to if keep = TRUE? Where should
getNOAA.bathy() look up for bathymetric data already downloaded? Defaults
to the current working directory.
getNOAA.bathy

Details

getNOAA.bathy queries the ETOPO 2022 database hosted on the NOAA website, given the coordinates of the area of interest and desired resolution. Users have the option of directly writing the downloaded data into a file (keep = TRUE argument; see below). If an identical query is performed (i.e. using identical lat-long and resolution), getNOAA.bathy will load data from the file previously written to the disk instead of querying the NOAA database. This behavior should be used preferentially (1) to reduce the number of unnecessary queries to the NOAA website, and (2) to reduce data load time. If the user wants to make multiple, identical queries to the NOAA website without loading the data written to disk, the data file name must be modified by the user. Alternatively, the data file can be moved outside of the present working directory.

getNOAA.bathy allows users to download bathymetric data in the antimeridian region when antimeridian = TRUE. The antimeridian is the 180th meridian and is located about in the middle of the Pacific Ocean, east of New Zealand and Fidji, west of Hawaii and Tonga. For a given pair of longitude values, e.g. -150 (150 degrees West) and 150 (degrees East), you have the possibility to get data for 2 distinct regions: the area centered on the antimeridian (60 degrees wide, when antimeridian = TRUE) or the area centered on the prime meridian (300 degrees wide, when antimeridian = FALSE). It is recommended to use keep = TRUE in combination with antimeridian = TRUE since gathering data for an area around the antimeridian requires two distinct queries to NOAA servers.

Value

The output of getNOAA.bathy is a matrix of class bathy, which dimensions depends on the resolution of the grid uploaded from the NOAA server. The class bathy has its own methods for summarizing and plotting the data. If keep=TRUE, a csv file containing the downloaded data is produced. This file is named using the following format: 'marmap_coord_COORDINATES_res_RESOLUTION.csv' (COORDINATES separated by semicolons, and the RESOLUTION in degrees).

## griddify

**Fill a grid with irregularly spaced data**

### Description

Transforms irregularly spaced xyz data into a raster object suitable to create a bathy object with regularly spaced longitudes and latitudes.

### Usage

```r
g Kiddify(xyz, nlon, nlat)
```

### Arguments

- **xyz**: 3-column matrix or data.frame containing (in this order) arbitrary longitude, latitude and altitude/depth values.
- **nlon**: integer. The number of unique regularly-spaced longitude values that will be used to create the grid.
- **nlat**: integer. The number of unique regularly-spaced latitude values that will be used to create the grid.

### Details

`griddify` takes anys dataset with irregularly spaced xyz data and transforms it into a raster object (i.e. a grid) with user specified dimensions. `griddify` relies on several functions from the `raster` package, especially `rasterize` and `resample`. If a cell of the user-defined grid does not contain any depth/altitude value in the original xyz matrix/data.frame, a NA is added in that cell. A bilinear interpolation is then applied in order to fill in most of the missing cells. For cells of the user-defined grid containing more than one depth/altitude value in the original xyz matrix/data.frame, the mean depth/altitude value is computed.

### Value

The output of `griddify` is an object of class `raster`, with `nlon` unique longitude values and `nlat` unique latitude values.

hawaii

Bathymetric data for Hawaii, USA

Description

Bathymetric object of class bathy created from NOAA GEODAS data and arbitrary locations around the main Hawaiian islands.

Usage

data(hawaii)
data(hawaii.sites)

Details

hawaii contains data imported from the NOAA GEODAS Grid Translator webpage (https://maps.ngdc.noaa.gov/viewers/wcs-client/) and transformed into an object of class bathy by read.bathy. hawaii.sites is a 2-columns data.frame containing longitude and latitude of 6 locations spread at sea around Hawaii.
irregular

Irregularly spaced bathymetric data.

Description

Three-column data.frame of irregularly-spaced longitudes, latitudes and depths.

Usage

data(irregular)
is.bathy

Value
A three-columns data.frame containing longitude, latitude and depth/elevation data.

Author(s)
Data modified form a dataset kindly provided by Noah Lottig from the university of Wisconsin https://limnology.wisc.edu/staff/lottig-noah/ in the framework of the North Temperate Lakes Long Term Ecological Research program https://lter.limnology.wisc.edu

**lc.dist**

*Computes least cost distances between two or more locations*

Description

Computes least cost distances between two or more locations

Usage

```r
lc.dist(trans, loc, res = c("dist", "path"), meters = FALSE, round = 0)
```

Arguments

- **trans**: transition object as computed by `trans.mat`
- **loc**: A two-columns matrix or data.frame containing latitude and longitude for 2 or more locations.
- **res**: either "dist" or "path". See details.
- **meters**: logical. When `res = "dist"`, should the results be returned in kilometers (default) or in meters.
- **round**: integer indicating the number of decimal places to be used for printing results when `res = "dist"`. 
lc.dist computes least cost distances between 2 or more locations. This function relies on the package gdistance (van Etten, 2011. https://CRAN.R-project.org/package=gdistance) and on the trans.mat function to define a range of depths where the paths are possible.

Value

Results can be presented either as a kilometric distance matrix between all possible pairs of locations (argument res="dist") or as a list of paths (i.e. 2-columns matrices of routes) between pairs of locations (res="path").

linesGC

Add Great Circle lines on a map

Description

linesGC draws Great Circle lines between a set of start and end points on an existing map.

Usage

linesGC(start.points, end.points, n = 10, antimeridian = FALSE, ...)

Arguments

- **start.points**: Two-column data.frame or matrix of longitudes and latitudes for start points.
- **end.points**: Two-column data.frame or matrix of longitudes and latitudes for end points. The dimensions of start.points and end.points must be compatible (i.e. they must have the same number of rows).
- **n**: Numeric. The number of intermediate points to add along the great circle line between the start and end points.
- **antimeridian**: Logical indicating if the map on which the great circle lines will be plotted covers the antimeridian region. The antimeridian (or antemeridian) is the 180th meridian and is located in the middle of the Pacific Ocean, east of New Zealand and Fidji, west of Hawaii and Tonga.
- **...**: Further arguments to be passed to `lines` to control the aspect of the lines to draw.
Details

linesGC takes advantage of the gcIntermediate function from package geosphere to plot lines following a great circle. When working with marmap maps encompassing the antimeridian, longitudes are numbered from 0 to 360 (as opposed to the classical numbering from -180 to +180). It is thus critical to set antimeridian=TRUE to avoid plotting incoherent great circle lines.

**Description**

marmap is a package designed for downloading, plotting and manipulating bathymetric and topographic data in R. It can query the ETOPO 2022 bathymetry and topography database hosted by the NOAA, use simple latitude-longitude-depth data in ascii format, and take advantage of the advanced plotting tools available in R to build publication-quality bathymetric maps. Functions to query data (bathymetry, sampling information, etc...) are available interactively by clicking on marmap maps. Bathymetric and topographic data can also be used to calculate projected surface areas within specified depth/altitude intervals, and constrain the calculation of realistic shortest path distances.

**Details**

- **Package:** marmap
- **Type:** Package
- **Version:** 1.0.10
- **Date:** 2023-03-24

*Coral sampling information from the North West Atlantic*

**Description**

Coral sampling data from Thoma et al 2009 (MEPS)

**Usage**

`data(nw.atlantic)`
Details

Sampling locations (longitude, latitude, depth in meters) for the deep-sea octocoral species Metallogorgia melanotrichos (see Thoma et al 2009 for details, including cruise information).

Value

A 3-column data frame

# load NW Atlantic data and convert to class bathy
data(nw.atlantic, metallo)
atl <- as.bathy(nw.atlantic)

## the function plot below plots:
## - the coastline in blue,
## - isobaths between 8000-4000 in light grey,
## - isobaths between 4000-500 in dark grey (to emphasize seamounts)

# 1st example: function points uses first two columns ; 3rd column contains depth info
plot(atl, deep=c(-8000,-4000,0), shallow=c(-4000,-500,0), step=c(500,500,0),
    lwd=c(0.5,0.5,1.5), lty=c(1,1,1),
    col=c("grey80", "grey20", "blue"),
    drawlabels=c(FALSE,FALSE,FALSE) )
points(metallo, cex=1.5, pch=19,col=rgb(0,0,1,0.5))

# 2nd example: plot points according to coordinates
plot(atl, deep=c(-8000,-4000,0), shallow=c(-4000,-500,0), step=c(500,500,0),
    lwd=c(0.5,0.5,1.5), lty=c(1,1,1),
    col=c("grey80", "grey20", "blue"),
    drawlabels=c(FALSE,FALSE,FALSE) )
subset(metallo, metallo$lon>-55) -> s # isolate points from the Corner Rise seamounts:
points(s, cex=1.5, pch=19,col=rgb(0,0,1,0.5)) # only plot those points

# 3rd example: point colors corresponding to a depth gradient:
par(mai=c(1,1,1,1.5))
plot(atl, deep=c(-6500,0), shallow=c(-50,0), step=c(500,0),
    lwd=c(0.3,1), lty=c(1,1),
    col=c("black", "black"),
    drawlabels=c(FALSE,FALSE,FALSE))
nw.atlantic

Bathymetric data for the North West Atlantic

Description

Data imported from the NOAA GEODAS server

Usage

data(nw.atlantic)

Details

Data imported from the NOAA GEODAS Grid Translator webpage (https://maps.ngdc.noaa.gov/viewers/wcs-client/). To prepare data from NOAA, fill the custom grid form, and choose "XYZ (lon,lat,depth)" as the "Output Grid Format", "No Header" as the "Output Grid Header", and either of the space, tab or comma as the column delimiter (either can be used, but "comma" is the default import format of read.bathy). Choose "omit empty grid cells" to reduce memory usage.

Value

A three-columns data.frame containing longitude, latitude and depth/elevation data.

Author(s)

see https://maps.ngdc.noaa.gov/viewers/wcs-client/

nw.atlantic.coast

summary(atl)

# test plot.bathy
plot(atl, deep=-8000, shallow=-1000, step=1000)

nw.atlantic.coast  Coastline data for the North West Atlantic

Description

Coastline data for the North West Atlantic, as downloaded using the NOAA Coastline Extractor tool.

Usage

data(nw.atlantic.coast)

Details

Coastline data for the NW Atlantic was obtained using the NOAA Coastline Extractor tool. To get more coastline data, go to https://www.ngdc.noaa.gov/mgg/shorelines/.

Value

A 2-column data frame

References

see https://www.ngdc.noaa.gov/mgg/shorelines/

nw.atlantic

Examples

# load NW Atlantic data and convert to class bathy
data(nw.atlantic,nw.atlantic.coast)
atl <- as.bathy(nw.atlantic)

## the function plot below plots only isobaths:
## - isobaths between 8000-4000 in light grey,
## - isobaths between 4000-500 in dark grey (to emphasize seamounts)
plot(atl, deep=c(-8000,-4000), shallow=c(-4000,-500), step=c(500,500),
     lwd=c(0.5,0.5,1.5),lty=c(1,1,1),
     col=c("grey80", "grey20", "blue"),
     drawlabels=c(FALSE,FALSE,FALSE) )
##
## the coastline can be added from a different source,
## and can therefore have a different resolution:
## add a geographical reference on the coast:
lines(mw.atlantic.coast)
points(-71.064,42.358, pch=19); text(-71.064,42.358,"Boston", adj=c(1.2,0))

---

### outline.buffer

Get a composite buffer in a format suitable for plotting its outline.

#### Description

Get a buffer (i.e. a non-circular buffer as produced by `combine.buffers()`) in a format suitable for plotting its outline. `outline.buffer()` replaces any NA values in a buffer or bathy object by 0 and non-NA values by -1.

#### Usage

```r
outline.buffer(buffer)
```

#### Arguments

- `buffer` a buffer object of class bathy (i.e. bathy matrix containing depth/altitude values within the buffer and NAs outside)

#### Details

This function is essentially used to prepare a composite buffer for plotting its outline on a bathymetric map. Plotting a single circular buffer should be done using the `plot.buffer()` function since it offers a more straightforward method for plotting and much smoother outlines, especially for low-resolution bathymetries.

#### Value

An object of class bathy of the same dimensions as `buffer` containing only zeros (outside the buffer area) and -1 values (within the buffer).

#### Author(s)

Benoit Simon-Bouhet

#### See Also

`create.buffer, combine.buffers, plot.bathy`
palette.bathy

**Examples**

```r
data(florida)
plot(florida, lwd = 0.2)
plot(florida, n = 1, lwd = 0.7, add = TRUE)

# add points around which a buffer will be computed
loc <- data.frame(c(-80,-82), c(26,24))
points(loc, pch = 19, col = "red")

# create 2 distinct buffer objects with different radii
buf1 <- create.buffer(florida, loc[1,], radius=1.9)
buf2 <- create.buffer(florida, loc[2,], radius=1.2)

# combine both buffers
buf <- combine.buffers(buf1,buf2)
```

```r
## Not run:
# Add outline of the resulting buffer in red
# and the outline of the original buffers in blue
plot(outline.buffer(buf), lwd = 3, col = 2, add=TRUE)
plot(buf1, lwd = 0.5, fg="blue")
plot(buf2, lwd = 0.5, fg="blue")
## End(Not run)
```

---

**palette.bathy**

*Builds a bathymetry- and/or topography-constrained color palette*

**Description**

Builds a constrained color palette based on depth / altitude bounds and given colors.

**Usage**

`palette.bathy(mat, layers, land=FALSE, default.col="white")`

**Arguments**

- `mat` a matrix of bathymetric data, class bathy not required.
- `layers` a list of depth bounds and colors (see below)
- `land` logical. Whether to consider land or not (default is FALSE)
- `default.col` a color for the area of the matrix not bracketed by the list supplied to `layers`
palette.bathy allows the production of color palettes for specified bathymetric and/or topographic layers. The layers argument must be a list of vectors. Each vector corresponds to a bathymetry/topography layer (for example, one layer for bathymetry and one layer for topography). The first and second elements of the vector are the minimum and maximum bathymetry/topography, respectively. The other elements of the vector (3, onward) correspond to colors (see example below). palette.bathy is called internally by plot.bathy when the image argument is set to TRUE.

Value

A vector of colors which size depends on the depth/altitude range of the bathy matrix.

newcol <- palette.bathy(mat=atl,
layers = list(c(min(atl), 0, "purple", "blue", "lightblue")),
land = FALSE, default.col = "grey")
plot(atl, land = FALSE, n = 10, lwd = 0.5, image = TRUE,
bpal = newcol, default.col = "grey")

# same:
plot(atl, land = FALSE, n = 10, lwd = 0.5, image = TRUE,
bpal = list(c(min(atl), 0, "purple", "blue", "lightblue")),
default.col = "gray")

# creating depth-constrained palette for 3 ocean "layers"
newcol <- palette.bathy(mat = atl, layers = list(
c(min(atl), -3000, "purple", "blue", "grey"),
c(-3000, -150, "white"),
c(-150, 0, "yellow", "green", "brown")),
land = FALSE, default.col = "grey")
plot(atl, land = FALSE, n = 10, lwd = 0.7, image = TRUE,
bpal = newcol, default.col = "grey")

# same
plot(atl, land = FALSE, n = 10, lwd = 0.7, image = TRUE,
bpal = list(c(min(atl), -3000, "purple", "blue", "grey"),
c(-3000, -150, "white"),
c(-150, 0, "yellow", "green", "brown")),
land = FALSE, default.col = "grey")
c(-150, 0, "yellow", "green", "brown"),
default.col = "grey")

# creating depth-constrained palette for land and ocean
newcol <- palette.bathy(mat= atl, layers = list(
c(min(atl),0,"purple","blue","lightblue"),
c(0, max(atl), "gray90", "gray10"),
land = TRUE)
plot(atl, land = TRUE, n = 10, lwd = 0.5, image = TRUE, bpal = newcol)

# same
plot(atl, land = TRUE, n = 10, lwd = 0.7, image = TRUE,
bpal = list(  
c(min(atl), 0, "purple", "blue", "lightblue"),
c(0, max(atl), "gray90", "gray10")))

---

### path.profile

**Geographic coordinates, kilometric distance and depth along a path**

#### Description

Computes and plots the depth/altitude along a transect or path

#### Usage

```r
path.profile(path,bathy,plot=FALSE, ...)
```

#### Arguments

- `path`: 2-columns matrix of longitude and latitude as obtained from `lc.dist` with argument `dist=TRUE`.
- `bathy`: bathymetric data matrix of class `bathy`.
- `plot`: logical. Should the depth profile be plotted?
- `...`: when `plot=TRUE`, other arguments to be passed to `plotProfile`, such as graphical parameters (see `par` and `plotProfile`).

#### Value

a four-columns matrix containing longitude, latitude, kilometric distance from the start of a route and depth for a set of points along a route. Optionally (i.e. when `plot=TRUE`) a bivariate plot of depth against the kilometric distance from the starting point of a transect or least cost path.

summary(profile)

plot.bathy

Plotting bathymetric data

Description

Plots contour map from bathymetric data matrix of class bathy

Usage

## S3 method for class 'bathy'
plot(x, image=FALSE, bpal=NULL, land=FALSE,
     deepest.isobath, shallowest.isobath, step, n=20,
     lwd=1, lty=1, col="black", default.col="white", drawlabels = FALSE,
     xlab="Longitude", ylab="Latitude", asp=1, ...)

Arguments

x         bathymetric data matrix of class bathy, imported using read.bathy
image     whether or not to color depth layers (default is FALSE)
bpal      if image is TRUE, either NULL (default: a simple blue color palette is used), a
          vector of colors, or a list of depth bounds and colors (see below)
land      whether or not to use topographic data that may be available in the bathy dataset
          (default is FALSE)
**plot.bathy**

- **deepest.isobath**: deepest isobath(s) to plot
- **shallowest.isobath**: shallowest isobath(s) to plot
- **step**: distance(s) between two isobaths
- **n**: if the user does not specify the range within which isobaths should be plotted, about \( n \) isobaths are automatically plotted within the depth range of the bathy matrix (default is 20).
- **lwd**: isobath line(s) width (default is 1)
- **lty**: isobath line type(s) (default is 1)
- **col**: isobath line color(s) (default is black)
- **default.col**: if image is TRUE, a color for the area of the matrix not bracketed by the list supplied to bpal (see below; default is white)
- **drawlabels**: whether or not to plot isobath depth as a label (default is FALSE); may contain several elements
- **xlab**: label for the x axis of the plot
- **ylab**: label for the y axis of the plot
- **asp**: numeric, giving the aspect ratio \( y/x \) of the plot. See **plot.window**
- **...**: Other arguments to be passed either to contour (default) or to image when argument image=TRUE.

**Details**

`plot.bathy` uses the base `contour` and `image` functions. If a vector of isobath characteristics is provided, different types of isobaths can be added to the same plot using a single call of `plot.bathy` (see examples)

If image=TRUE, the user has three choices for colors: (1) bpal can be set to NULL, in which case a default blue color palette is generated; (2) colors can be user-defined as in example 4, in which case the palette can be generated with function `colorRampPalette` (colors are then supplied as a vector to `plot.bathy`); (3) colors can be constrained to bathymetry- and/or topography. In this last case, a list of vectors is supplied to `plot.bathy` (example 7): each vector corresponds to a bathymetry/topography layer (for example, one layer for bathymetry and one layer for topography). The first and second elements of the vector are the minimum and maximum bathymetry/topography, respectively. The other elements of the vector (3, onward) correspond to colors (see example 7).

**Value**

A bathymetric map with isobaths

**Note**

`plot.bathy` uses a matrix of class `bathy`, and can therefore be substituted for `plot`.

**Author(s)**

Eric Pante and Benoit Simon-Bouhet

Examples

# load NW Atlantic data and convert to class bathy
data(nw.atlantic)
atl <- as.bathy(nw.atlantic)
## Example 1: a simple marine chart
plot(atl) # without specifying any isobath parameters
plot(atl, n=5, drawlabels=TRUE) # with about 5 isobaths
plot(atl, deep=-8000, shallow=0, step=1000) # with isobath parameters

## Example 2: taking advantage of multiple types of isobaths
plot(atl, deep=c(-8000,-2000,0), shallow=c(-2000,-100,0), step=c(1000,100,0),
    lwd=c(0.5,0.5,1), lty=c(1,1,1), col=c("grey80","red","blue"),
    drawlabels=c(FALSE,FALSE,FALSE) )

## Example 3: plotting a colored map with the default color palette
plot(atl, image=TRUE, deep=c(-8000,0), shallow=c(-1000,0), step=c(1000,0),
    lwd=c(0.5,1), lty=c(1,1), col=c("grey","black"), drawlabels=c(FALSE,FALSE))

## Example 4: make a pretty custom color ramp
colorRampPalette(c("purple","lightblue","cadetblue2","cadetblue1","white")) -> blues
plot(atl, image=TRUE, bpal=blues(100), deep=c(-6500,0), shallow=c(-50,0), step=c(500,0),
    lwd=c(0.3,1), lty=c(1,1), col=c("black","black"), drawlabels=c(FALSE,FALSE))

scaleBathy(atl, deg=3, x="bottomleft", inset=5)

## Example 5: add points corresponding to sampling locations
## point colors correspond to the sampling depth
par(mai=c(1,1,1,1.5))
plot(atl, deep=c(-4500,0), shallow=c(-50,0), step=c(500,0),
    lwd=c(0.3,1), lty=c(1,1), col=c("black","black"), drawlabels=c(FALSE,FALSE))

# add a title to the plot
title(main="Distribution of coral samples\non the New England and Corner Rise seamounts")
# add a scale
scaleBathy(atl, deg=3, x="bottomleft", inset=5)

# add a geographical reference on the coast:
points(-71.064,42.358, pch=19)
text(-71.064,42.358,"Boston", adj=c(1.2,0))
# prepare colors for the sampling locations:
data(metallo) ## see dataset metallo
max(metallo$depth, na.rm=TRUE) -> mx
colorRampPalette(c("white","lightyellow","lightgreen","blue","lightblue1","purple")) -> ramp
blues <- ramp(max(metallo$depth))

# plot sampling locations:
points(metallo, col="black", bg=blues[metallo$depth], pch=21,cex=1.5)
library(shape)
colorlegend(zlim=c(-mx,0), col=rev(blues), main="depth (m)",posx=c(0.85,0.88))

## Example 6: use packages maps and mapdata in combination with marmap
# use maps and mapdata to plot the coast
library(maps)
library(mapdata)
map(Var, Var, xlim=c(-75,-46),ylim=c(32,44), fill=TRUE, col="grey")
box();axis(1);axis(2)

# add bathymetric data from 'bathy' data
plot(atl, add=TRUE, lwd=.3, deep=-4500, shallow=-10, step=500,
drawlabel=FALSE, col="grey50")

## Example 7: provide a list of depths and colors to argument bpal to finely tune palette
# check out ?palette.bathy to see details on how the palette is handled

# creating depth-constrained palette for the ocean only
plot(atl, land = FALSE, n = 10, lwd = 0.5, image = TRUE,
bpal = list(c(min(atl), 0, "purple", "blue", "lightblue")),
default.col = "gray")

# creating depth-constrained palette for 3 ocean "layers"
plot(atl, land = FALSE, n = 10, lwd = 0.7, image = TRUE,
bpal = list(c(min(atl), -3000, "purple","blue","grey"),
c(-3000, -150, "white"),
c(-150, 0, "yellow", "green", "brown")),
default.col = "grey")

# creating depth-constrained palette for land and ocean
plot(atl, land = TRUE, n = 10, lwd = 0.7, image = TRUE,
bpal = list(c(min(atl), 0, "purple", "blue", "lightblue"),
c(0, max(atl), "gray90", "gray10")))

---

**plot.buffer**

*Plots a circular buffer and or its outline*

**Description**

plot.buffer is a generic function that allows the plotting of objects of class buffer, either as new plots or as a new layer added on top of an existing one. The plotting of both the bathymetry/hypsometry as well as the outline of the buffer is possible.
## S3 method for class 'buffer'
plot(x, outline = TRUE, add = TRUE, ...)

### Arguments

- **x**: an object of class buffer as produced by the create.buffer() function.
- **outline**: Should the outline of the buffer be plotted (default) or the bathymetric/hypsometric data within the buffer.
- **add**: Should the plot be added on top of an existing bathymetric/hypsometric plot (default) or as a new plot.
- **...**: Further arguments to be passed to the symbols() function from the graphics package when outline = TRUE (default) or to plot.bathy() when outline = FALSE.

### Value

Either a plot of the outline of a buffer (default) or a bathymetric map with isobaths of a buffer when outline = FALSE.

### Author(s)

Benoit Simon-Bouhet

### See Also

create.buffer, combine.buffers, plot.bathy

### Examples

```r
# load and plot a bathymetry
data(florida)
plot(florida, lwd = 0.2)
plot(florida, n = 0, lwd = 0.7, add = TRUE)

# add points around which a buffer will be computed
loc <- data.frame(-80, 26)
points(loc, pch = 19, col = "red")

# compute buffer
buf <- create.buffer(florida, loc, radius=1.5)

# plot buffer bathymetry
plot(buf, outline=FALSE, n=10, lwd=.5, col=2)

# add buffer outline
plot(buf, lwd=.7, fg=2)
```
plotArea

Plotting projected surface areas

Description

Highlights the projected surface area for specific depth layers on an existing bathymetric/hypsometric map.

Usage

plotArea(area, col)

Arguments

area a list of 4 elements as produced by get.area.
col color of the projected surface area on the map.

Author(s)

Benoit Simon-Bouhet

get.area, plot.bathy, areaPolygon

Examples

# load and plot a bathymetry
data(florida)
plot(florida, lwd = 0.2)
plot(florida, n = 1, lwd = 0.7, add = TRUE)

# Create a point and a buffer around this point
loc <- data.frame(-80, 26)
buf <- create.buffer(florida, loc, radius=1.8)

# Get the surface within the buffer for several depth slices
surf1 <- get.area(buf, level.inf=-200, level.sup=-1)
surf2 <- get.area(buf, level.inf=-800, level.sup=-200)
surf3 <- get.area(buf, level.inf=-3000, level.sup=-800)

s1 <- round(surf1$Square.Km)
s2 <- round(surf2$Square.Km)
s3 <- round(surf3$Square.Km)

# Add buffer elements on the plot
col.surf1 <- rgb(0.7, 0.7, 0.3, 0.3)
col.surf2 <- rgb(0, 0.7, 0.3, 0.3)
col.surf3 <- rgb(0.7, 0, 0, 0.3)
plotArea(surf1, col = col.surf1)
plotArea(surf2, col = col.surf2)
plotArea(surf3, col = col.surf3)
plot(buf, lwd = 0.7)
points(loc, pch = 19, col = "red")

## Add legend
legend("topleft", fill = c(col.surf1, col.surf2, col.surf3),
    legend = c(paste("]-200 ; -1] -","s1","km2"),
    paste("]-800 ; -200] -","s2","km2"),
    paste("]-3000 ; -800] -","s3","km2"))

```
plotProfile

Ploting bathymetric data along a transect or path
```

### Description

Plots the depth/altitude along a transect or path

### Usage

```
plotProfile(profile, shadow=TRUE, xlim, ylim, col.sea, col.bottom, xlab, ylab, ...)
```

### Arguments

- **profile**: 4-columns matrix obtained from `get.transect` with argument `dist=TRUE`, or from `path.profile`.
- **shadow**: logical. Should the depth profile cast a shadow over the plot background?
- **xlim, ylim**: numeric vectors of length 2, giving the x and y coordinates ranges. If unspecified, `xlim` values are based on the length of the transect or path and `ylim` values are based on the depth range of the bathymetric matrix `bathy`.
- **col.sea**: color for the sea area of the plot. Defaults to `rgb(130/255,180/255,212/255)`.
- **col.bottom**: color for the bottom area of the plot. Defaults to `rgb(198/255,184/255,151/255)`.
- **xlab, ylab**: titles for the x and y axes. If unspecified, `xlab="Distance from start of transect (km)"` and `ylab="Depth (m)"`
- **...**: arguments to be passed to methods, such as _graphical parameters_ (see `par`)

### Value

A bivariate plot of depth against the kilometric distance from the starting point of a transect or least cost path.

### Note

`path.profile` with argument `plot` set to `TRUE` plots depth profiles with default values for all arguments of `plotProfile`.

read.bathy

Read bathymetric data in XYZ format

Description

Reads a three-column table containing longitude (x), latitude (y) and depth (z) data.
Usage

read.bathy(xyz, header = FALSE, sep = ",", ...)  

Arguments

xyz three-column table with longitude (x), latitude (y) and depth (z) (no default)
header whether this table has a row of column names (default = FALSE)
sep character separating columns, (default=",")
... further arguments to be passed to read.table()

Details

Allows direct import of data from the NOAA GEODAS Grid Translator webpage (https://maps.ngdc.noaa.gov/viewers/wcs-client/). To prepare data from NOAA, fill the custom grid form, and choose "XYZ (lon,lat,depth)" as the "Output Grid Format", "No Header" as the "Output Grid Header", and either of the space, tab or comma as the column delimiter (either can be used, but "comma" is the default import format of read.bathy). Choose "omit empty grid cells" to reduce memory usage.

Value

The output of read.bathy is a matrix of class bathy, which dimensions depends on the resolution of the grid uploaded from the NOAA GEODAS server (Grid Cell Size). The class bathy has its own methods for summarizing and plotting the data.

summary(atl)

readGEBCO.bathy

Read bathymetric data from a GEBCO file

Description
Imports 30-sec and 1-min bathymetric data from a .nc file downloaded on the GEBCO website.

Usage
readGEBCO.bathy(file, resolution = 1, sid = FALSE)

Arguments
- file: name of the .nc file
- resolution: resolution of the grid, in units of the selected database (default is 1; see details)
- sid: logical. Is the data file containing SID information?

Details
readGEBCO.bathy reads a 30 arcseconds or 1 arcminute bathymetry file downloaded from the GEBCO (General Bathymetric Chart of the Oceans) website (British Oceanographic Data Center). The website allows the download of bathymetric data in the netCDF format. readGEBCO.bathy uses the ncdf4 package to load the data into R, and parses it into an object of class bathy.

Data can be downloaded from the 30 arcseconds database (GEBCO_08) or the 1 arcminute database (GEBCO_1min, the default). A third database type, GEBCO_08 SID, is available from the website. This database includes a source identifier specifying which grid cells have depth information based on soundings; it does not include bathymetry or topography data. readGEBCO.bathy can read this type of database when sid is set to TRUE. Then only the SID information will be included in the object of class bathy. Therefore, to display a map with both the bathymetry and the SID information, you will have to download both datasets from GEBCO, and import and plot both independently.

The argument resolution specifies the resolution of the object of class bathy. Because the resolution of GEBCO data is rather fine, we offer the possibility of downsizing the dataset with resolution. resolution is in units of the selected database: in "GEBCO_1min", resolution is in minutes; in "GEBCO_08", resolution is in 30 arcseconds (that is, resolution = 3 corresponds to 3x30sec, or 1.5 arcminute).

Value
The output of readGEBCO.bathy is a matrix of class bathy, which dimensions depends on the resolution specified (one-minute, the original GEBCO resolution, is the default). The class bathy has its own methods for summarizing and plotting the data.
scaleBathy

Adds a scale to a map

Description

Uses geographic information from object of class bathy to calculate and plot a scale in kilometer.
scaleBathy

Usage

scaleBathy(mat, deg=1, x="bottomleft", y=NULL, inset=10, angle=90, ...)

Arguments

mat         bathymetric data matrix of class bathy, imported using read.bathy
deg         the number of degrees of longitudes to convert into kilometers (default is 1)
x, y         the coordinates used to plot the scale on the map (see Details)
inset        when x is a keyword (e.g. "bottomleft"), inset is a percentage of the plotting
             space controlling the relative position of the plotted scale (see Examples)
angle        angle from the shaft of the arrow to the edge of the arrow head
...          further arguments to be passed to text

Details

scaleBathy is a simple utility to add a scale to the lower left corner of a bathy plot. The
distance in kilometers between two points separated by 1 degree longitude is calculated based
on the minimum latitude of the bathy object used to plot the map. Option deg allows the
user to plot the distance separating more than one degree (default is one).

The plotting coordinates x and y either correspond to two points on the map (i.e.
longitude and latitude of the point where the scale should be plotted), or correspond to a
keyword (set with x, y being set to NULL) from the list "bottomright", "bottomleft", "topright", "topleft". When a keyword
is used, the option inset controls how far the scale will be from the edges of the plot.

Value

a scale added to the active graphical device

Note

The calculation formula is from function map.scale of package maps. 6372.798 km is used as the
Earth radius.

atl <- as.bathy(nw.atlantic)

# a simple example
space.pies

Automatic placement of piecharts on maps

Description

Attempts to automatically place piecharts on maps, avoiding overlap. Work in progress...

Usage

```r
space.pies(x, y, pie.slices, pie.colors=NULL, pie.radius=1, pie.space=5,
           link=TRUE, seg.lwd=1, seg.col=1, seg.lty=1, coord=NULL)
```

Arguments

- **x**: the longitude of the anchor point for the piechart
- **y**: the latitude of the anchor point for the piechart
- **pie.slices**: a table with the counts to draw pies (col: pie categories, or slices; rows: sites on the map)
- **pie.colors**: a table with the colors to draw pies (col: pie categories, or slices; rows: sites on the map)
- **pie.radius**: size of the piechart
- **pie.space**: factor of spacing between the anchor and the pie (the larger, the farther the pie from the anchor)
- **link**: logical; whether to add a segment to link pie and anchor
- **seg.lwd**: the line width of the link
- **seg.col**: the line color of the link
- **seg.lty**: the line type of the link
- **coord**: when coord = NULL (default), placement is automatic. Otherwise, a 2-col table of lon/lat for pies.
Details

space.pies tries to position piecharts on a map while avoiding overlap between them. The function heavily relies on two other functions. floating.pie from package plotrix is used to draw individual piecharts. floating.pie treats one pie at a time; space.pies can handle one or multiple pies by looping floating.pie. pointLabels from package maptools was modified to find the best placement for the pies, given their size and distance from their anchor point. pointLabels was originally meant to automatically place text labels, not objects; the modified version contained in space.pies uses the coordinates chosen by pointLabels for text. The algorithm used is simulating annealing (SANN). You can get a different result each time you run space.pies, because pointLabel finds one good solution out of many. If you are not satisfied by the solution, you can try running the function again.

The argument coord allows to choose between the automatic placement outlined above, and a user-defined list of longitudes and latitudes (in a two-column table format) for plotting the piecharts. Anchor point: spatial location of the data corresponding to the piechart (e.g. a sampling point).

Value

Piechart(s) added to a plot.

Author(s)

Eric Pante, using functions plotrix::floating.pie and maptools::pointLabel.

Examples

# fake frequencies to feed to space.pies()
sample(seq(10,90,5), 11) -> freq.a
100-freq.a -> freq.b
rep("lightblue",11) -> col.a
rep("white",11) -> col.b

# some coordinates on the NW Atlantic coast, and on seamounts
x = c(-74.28487,-73.92323,-73.80753,-72.51728,-71.12418,
     -69.81176,-69.90715,-70.43201,-70.17135,-69.43912,-65.49608)
y = c(39.36714,39.98515,40.40316,40.79654,41.49872,41.62076,
     41.99805,42.68061,43.40714,43.81499,43.36471)
SubsetBathy

Generates rectangular or non-rectangular bathy objects by extracting bathymetric data from larger bathy objects.

Usage

SubsetBathy(mat, x, y=NULL, locator=TRUE, ...)

Arguments

- `mat`: Bathymetric data matrix of class `bathy`, as imported with `read.bathy`.
- `x`: Either a list of two elements (numeric vectors of longitude and latitude), a 2-column matrix or data.frame of longitudes and latitudes, or a numeric vector of longitudes.
- `y`: Either `NULL` (default) or a numerical vector of latitudes. Ignored if `x` is not a numeric vector.
- `locator`: Logical. Whether to choose data points interactively with a map or not. If TRUE (default), a bathymetric map must have been plotted and both `x` and `y` are both ignored.
- `...`: Further arguments to be passed to `locator` when the interactive mode is used.
subsetBathy

Details

subsetBathy allows the user to generate new bathy objects by extracting data from larger bathy objects. The extraction of bathymetric data can be done interactively by clicking on a bathymetric map, or by providing longitudes and latitudes for the boundaries for the new bathy object. If two data points are provided, a rectangular area is selected. If more than two points are provided, a polygon is defined by linking the points and the bathymetric data is extracted within the polygon only. subsetBathy relies on the point.in.polygon function from package sp to identify which points of the initial bathy matrix lie within the boundaries of the user-defined polygon.

Value

A matrix of class bathy.

## End(Not run)
# click several times and press Escape

---

**subsetSQL**

Creating and querying local SQL database for bathymetric data

**Description**

subsetSQL queries the local SQL database created with `setSQL` to extract smaller data subsets.

**Usage**

```r
setSQL(bathy, header = TRUE, sep = " ", db.name = "bathy_db")
subsetSQL(min_lon, max_lon, min_lat, max_lat, db.name = "bathy_db")
```

**Arguments**

- `bathy`: A text file containing a comma-separated, three-column table with longitude, latitude and depth data (no default)
- `header`: does the xyz file contains a row of column names (default = TRUE)
- `sep`: character separating columns in the xyz file, (default=" ")
- `min_lon`: minimum longitude of the data to be extracted from the local SQL database
- `max_lon`: maximum longitude of the data to be extracted from the local SQL database
- `min_lat`: minimum latitude of the data to be extracted from the local SQL database
- `max_lat`: maximum latitude of the data to be extracted from the local SQL database
- `db.name`: The name of (or path to) the SQL database to be created on disk by `setSQL` or from which `subsetSQL` will extract data ("bathy_db" by default)

**Details**

Functions `setSQL` and `subsetSQL` were built to work together. `setSQL` builds an SQL database and saves it on disk. `subsetSQL` queries that local database and the fields `min_lon`, `max_lon`, etc, are used to extract a subset of the database. The functions were built as two entities so that multiple queries can be done multiple times, without re-building the database each time. These functions were designed to access the very large (>5Go) ETOPO 2022 file that can be downloaded from the NOAA website ([https://www.ncei.noaa.gov/products/etopo-global-relief-model](https://www.ncei.noaa.gov/products/etopo-global-relief-model))

**Value**

`setSQL` returns `TRUE` if the database was successfully created. `subsetSQL` returns a matrix of class `bathy` that can directly be used with `plot.bathy`. 
Note

If unspecified, db.name is set to "bathy_db" by default. Thus, there must be no database file called bathy_db in the working directory prior to running setSQL unless a different name is used for the new database. Make sure that your "bathy" input is a xyz text file (for function setSQL) with 3 columns containing longitude, latitude and depth data, in that order. setSQL and subsetSQL were modified on Nov. 2, 2014 to comply with RSQLite 1.0.0.

summary.bathy

Summary of bathymetric data of class bathy

Description

Summary of bathymetric data of class bathy. Provides geographic bounds and resolution (in minutes) of the dataset, statistics on depth data, and a preview of the bathymetric matrix.
trans.mat

Usage

## S3 method for class 'bathy'
summary(object, ...)

Arguments

object object of class bathy
... additional arguments affecting the summary produced (see base function summary).

Value

Information on the geographic bounds of the dataset (minimum and maximum latitude and longitude), resolution of the matrix in minutes, statistics on the depth data (e.g. min, max, median...), and a preview of the data.

trans.mat  Transition matrix

Description

Creates a transition object to be used by lc.dist to compute least cost distances between locations.

Usage

g trans.mat(bathy, min.depth=0, max.depth=NULL)
Arguments

- **bathy**: A matrix of class `bathy`.
- **min. depth, max. depth**: Numeric. The range of depth between which the path will be possible. The default (min. depth=0 and max. depth=NULL) indicates that the transition between cells of the grid is possible between 0 meters depth and the maximum depth of `bathy`. See details.

Details

`trans.mat` creates a transition object usable by `lc.dist` to computes least cost distances between a set of locations. `trans.mat` rely on the function `raster` from package `raster` (Hijmans & van Etten, 2012. [https://CRAN.R-project.org/package=raster](https://CRAN.R-project.org/package=raster)) and on `transition` from package `gdistance` (van Etten, 2011. [https://CRAN.R-project.org/package=gdistance](https://CRAN.R-project.org/package=gdistance)).

The transition object contains the probability of transition from one cell of a bathymetric grid to adjacent cells and depends on user defined parameters. `trans.mat` is especially useful when least cost distances need to be calculated between several locations at sea. The default values for `min. depth` and `max. depth` ensure that the path computed by `lc.dist` will be the shortest path possible at sea avoiding land masses. The path can be constrained to a given depth range by setting manually `min. depth` and `max. depth`. For instance, it is possible to limit the possible paths to the continental shelf by setting `max. depth`=-200. Inaccuracies of the bathymetric data can occasionally result in paths crossing land masses. Setting `min. depth` to low negative values (e.g. -10 meters) can limit this problem.

`trans.mat` takes also advantage of the function `geoCorrection` from package `gdistance` (van Etten, 2012. [https://CRAN.R-project.org/package=gdistance](https://CRAN.R-project.org/package=gdistance)) to take into account map distortions over large areas.

Value

A transition object.

Warning

Please be aware that the use of `trans.mat` can be time consuming for large bathymetric datasets. The function takes about one minute to compute a transition matrix for the `hawaii` bathymetric data (bathymetric data of class `bathy` with 599 rows and 419 columns, see `hawaii`) on a MacBook Pro with a 2.66 GHz Intel Core i7 processor and 4 Go of RAM.
