Package ‘matsbyname’

December 5, 2019

Type Package
Title An Implementation of Matrix Mathematics
Version 0.4.11
Date 2019-12-04
Maintainer Matthew Heun <matthew.heun@me.com>
Description An implementation of matrix mathematics wherein operations are performed "by name."
License MIT + file LICENSE
Language en-US
Encoding UTF-8

abs_byname

Description

Absolute value of matrix elements

Usage

abs_byname(a)

Arguments

a

a matrix or list of matrices

Value

a with each element replaced by its absolute value

Examples

abs_byname(1)
abs_byname(-1)
m <- matrix(c(-10,1,1,100), nrow = 2, dimnames = list(paste0("i", 1:2), paste0("c", 1:2))) \%\% setrowtype("Industry") \%\% setcoltype("Commodity")
abs_byname(m)
**all_byname**

*Are all matrix elements TRUE?*

**Description**

Tells whether all elements in matrix `a` are true.

**Usage**

```r
all_byname(a)
```

**Arguments**

- `a` : a matrix or list of matrices

**Details**

`a` can be a matrix or a list of matrices.

**Value**

TRUE if all elements of `a` are TRUE, FALSE otherwise

**Examples**

```r
all_byname(matrix(rep(TRUE, times = 4), nrow = 2, ncol = 2))
all_byname(matrix(c(TRUE, FALSE), nrow = 2, ncol = 1))
```

---

**and_byname**

*And "by name"*

**Description**

Operands should be logical, although numerical operands are accepted. Numerical operands are interpreted as FALSE when 0 and TRUE for any other number.

**Usage**

```r
and_byname(...)```

**Arguments**

- `...` : operands to the logical and function

**Value**

logical and applied to the operands
any_byname

Examples

```r
and_byname(TRUE)
and_byname(FALSE)
and_byname(list(TRUE, FALSE), list(TRUE, TRUE), list(TRUE, TRUE), list(TRUE, TRUE))
m1 <- matrix(c(TRUE, TRUE, TRUE, FALSE), nrow = 2, ncol = 2,
              dimnames = list(c("r1", "r2"), c("c1", "c2")))
m2 <- matrix(c(TRUE, FALSE, TRUE, TRUE), nrow = 2, ncol = 2,
              dimnames = list(c("r1", "r2"), c("c1", "c2")))
and_byname(m1, m1)
and_byname(m1, m2)
and_byname(list(m1, m1), list(m1, m1), list(m2, m2))
```

---

any_byname  Are any matrix elements TRUE?

Description

Tells whether any elements in matrix `a` are true.

Usage

```r
any_byname(a)
```

Arguments

`a`  
A matrix or list of matrices

Details

`a` can be a matrix or a list of matrices.

Value

TRUE if any elements of `a` are TRUE, FALSE otherwise

Examples

```r
any_byname(matrix(c(TRUE, FALSE), nrow = 2, ncol = 1))
any_byname(matrix(rep(FALSE, times = 4), nrow = 2, ncol = 2))
```
Apply a binary function "by name"

Description

If either a or b is missing or NULL, 0 is passed to FUN in its place. Note that if either a and b are lists, elements must be named the same. The names of list elements of a are applied to the output.

Usage

binaryapply_byname(
  FUN,
  a,
  b,
  .FUNdots = NULL,
  match_type = c("all", "matmult", "none"),
  set_rowcoltypes = TRUE,
  .organize = TRUE
)

Arguments

FUN  a binary function to be applied "by name" to a and b.
a  the first operand for FUN.
b  the second operand for FUN.
.FUNdots  a list of additional named arguments passed to FUN.
match_type  one of "all", "matmult", or "none". When both a and b are matrices, "all" (the default) indicates that rowtypes of a must match rowtypes of b and coltypes of a must match coltypes of b. If "matmult", coltypes of a must match rowtypes of b. If "none", neither coltypes nor rowtypes are checked.
set_rowcoltypes  tells whether to apply row and column types from a and b to the output. Set TRUE (the default) to apply row and column types to the output. Set FALSE, to not apply row and column types to the output.
.organize  a boolean that tells whether or not to automatically complete a and b relative to each other and sort the rows and columns of the completed matrices. Normally, this should be TRUE (the default). However, if FUN takes over this responsibility, set to FALSE.

Value

the result of applying FUN "by name" to a and b.
**Examples**

```r
productnames <- c("p1", "p2")
industrynames <- c("i1", "i2")
U <- matrix(1:4, ncol = 2, dimnames = list(productnames, industrynames)) %>%
  setrowtype("Products") %>% setcoltype("Industries")
Y <- matrix(1:4, ncol = 2, dimnames = list(rev(productnames), rev(industrynames))) %>%
  setrowtype("Products") %>% setcoltype("Industries")
sum_byname(U, Y)
```

```r
binaryapply_byname(`+`, U, Y)
```

**clean_byname**

*Cleans (deletes) rows or columns of matrices that contain exclusively clean_value*

**Description**

Cleans (deletes) rows or columns of matrices that contain exclusively `clean_value`.

**Usage**

```r
clean_byname(a, margin = c(1, 2), clean_value = 0)
```

**Arguments**

- **a**: the matrix to be cleaned.
- **margin**: the dimension over which cleaning should occur, 1 for rows, 2 for columns, or c(1,2) for both rows and columns. Default is c(1,2).
- **clean_value**: the undesirable value. Default is 0.

When a row (when `margin = 1`) or a column (when `margin = 2`) contains exclusively `clean_value`, the row or column is deleted from the matrix.

**Value**

A "cleaned" matrix, expunged of rows or columns that contain exclusively `clean_value`.

**Examples**

```r
m <- matrix(c(-20, 1, -20, 2), nrow = 2, dimnames = list(c("r1", "r2"), c("c1", "c2")))
```

```r
m %>% clean_byname(margin = 1, clean_value = -20) # Eliminates -20, -20 row
# Nothing cleaned, because no columns contain all 0's (the default clean_value).
```

```r
m %>% clean_byname(margin = 2)
```

```r
list(m, m) %>% clean_byname(margin = 1, clean_value = -20)
```

```r
DF <- data.frame(m = I(list()))
DF[[1,"m"]]<- m
DF[[2,"m"]]<- m
```
DF %>% clean_byname(margin = 1, clean_value = -20)
m2 <- matrix(c(-20, -20, 0, -20, -20, -20, -20, -20, -20), nrow = 3, dimnames = list(c("r1", "r2", "r3"), c("c1", "c2", "c3")))
clean_byname(m2, margin = c(1,2), clean_value = -20)
DF2 <- data.frame(m2 = I(list()))
DF2[[1, "m2"]]<- m2
DF2[[2, "m2"]]<- m2
DF2 %>% clean_byname(margin = c(1, 2), clean_value = -20)

---

### colprods_byname

**Column products, sorted by name**

**Description**

Calculates column products (the product of all elements in a column) for a matrix. An optional rowname for the resulting row vector can be supplied. If rowname is NULL or NA (the default), the row name is set to the row type as given by rowtype(a).

**Usage**

```r
colprods_byname(a, rowname = NA)
```

**Arguments**

- `a` a matrix or data frame from which column products are desired.
- `rowname` name of the output row containing column products.

**Value**

a row vector of type matrix containing the column products of a.

**Examples**

```r
library(dplyr)
M <- matrix(c(1:6), nrow = 2, dimnames = list(paste0("i", 1:2), paste0("c", 3:1))) %>% setrowtype("Industries") %>% setcoltype("Commodities")
colprods_byname(M)
colprods_byname(M, rowname = "E.ktoe")
M %>% colprods_byname %>% rowprods_byname
# This also works with lists
colprods_byname(list(M, M))
colprods_byname(list(M, M), rowname = "E.ktoe")
colprods_byname(list(M, M), rowname = NA)
colprods_byname(list(M, M), rowname = NULL)
DF <- data.frame(M = I(list()))
DF[1,"M"]<- M
DF[2,"M"]<- M
colprods_byname(DF$M[[1]])
```
colprods_byname(DF$M)
colprods_byname(DF$M, "prods")
res <- DF %>% mutate(
  cs = colprods_byname(M),
  cs2 = colprods_byname(M, rowname = "prod")
)
res$cs2

colsums_byname

Column sums, sorted by name

Description
Calculates column sums for a matrix by premultiplying by an identity vector (containing all 1’s). In contrast to colSums (which returns a numeric result), the return value from colsums_byname is a matrix. An optional rowname for the resulting row vector can be supplied. If rowname is NULL or NA (the default), the row name is set to the row type as given by rowtype(a).

Usage

colsums_byname(a, rowname = NA)

Arguments

- a: a matrix or list of matrices from which column sums are desired.
- rowname: name of the output row containing column sums.

Value

A row vector of type matrix containing the column sums of a.

Examples

library(dplyr)
m <- matrix(c(1:6), nrow = 2, dimnames = list(paste0("i", 1:2), paste0("c", 3:1))) %>%
  setrowtype("Industries") %>% setcoltype("Commodities")
colsums_byname(m)
colsums_byname(m, rowname = "E.ktoe")
m %>% colsums_byname %>% rowsums_byname
# This also works with lists
colsums_byname(list(m, m))
colsums_byname(list(m, m), rowname = "E.ktoe")
colsums_byname(list(m, m), rowname = NA)
colsums_byname(list(m, m), rowname = NULL)
DF <- data.frame(m = I(list()))
DF[1,"m"] <- m
DF[2,"m"] <- m
colsums_byname(DF$m[1]))
colsums_byname(DF$m)
```r
colsums_byname(DF$m, "sums")
res <- DF %>% mutate(
  cs = colsums_byname(m),
  cs2 = colsums_byname(m, rowname = "sum")
)
res$cs2

<table>
<thead>
<tr>
<th>coltype</th>
<th>Column type</th>
</tr>
</thead>
</table>

**Description**
Extracts column type of a.

**Usage**
coltype(a)

**Arguments**
a the object from which you want to extract column types

**Value**
the column type of a

**Examples**
```r
commoditynames <- c("c1", "c2")
industrynames <- c("i1", "i2")
U <- matrix(1:4, ncol = 2, dimnames = list(commoditynames, industrynames)) %>%
  setrowtype(rowtype = "Commodities") %>% setcoltype("Industries")
coltype(U)
# This also works for lists
coltype(list(U,U))
```

```r
compare_byname(a, compare_fun = c("==", "!=", "<", "<=", ">=", ">"), val = 0)
```

**Description**
Compares matrix entries to a value, returning a matrix of same size as a containing TRUE or FALSE values as the result of applying compare_fun and val to all entries in a.

**Usage**
compare_byname(a, compare_fun = c("==", "!=", "<", "<=", ">=", ">"), val = 0)
Arguments

a
a matrix or list of matrices whose values are to be counted according to compare_fun

compare_fun
the comparison function, one of "==", "!=" or "<", "<=" or ">". Default is ">=".

val
a single value against which entries in matrix a are compared. Default is 0.

Value

a logical matrix of same size as a containing TRUE where the criterion is met, FALSE otherwise

Examples

m <- matrix(c(0, 1, 2, 3, 4, 0), nrow = 3, ncol = 2)
compare_byname(m, "<", 3)
compare_byname(list(m,m), "<", 3)

complete_and_sort

Complete matrices relative to one another and sort into same row, column order

Description

Completes each matrix relative to each other, thereby assuring that both matrices have same row and column names. Missing rows and columns (relative to the other matrix) are filled with fill. Thereafter, rows and columns of the matrices are sorted such that they are in the same order (by name). To complete rows of m1 relative to columns of m2, set the m2 argument to transpose_byname(m2).

Usage

complete_and_sort(
  a,
  b,
  fill = 0,
  margin = c(1, 2),
  roworder = NA,
  colorder = NA
)

Arguments

a
The first matrix

b
The second (optional) matrix.

fill
rows and columns added to a and b will contain the value fill. (a double)

margin
Specifies the dimension(s) of a and b over which completing and sorting will occur
roworder

Specifies a custom ordering for rows of returned matrices. Unspecified rows are dropped.

colorder

Specifies a custom ordering for columns of returned matrices. Unspecified columns are dropped.

Details

margin has nearly the same semantic meaning as in apply. For rows only, give 1; for columns only, give 2; for both rows and columns, give c(1,2), the default value.

If only m1 is specified, rows of m1 are completed and sorted relative to columns of m1. If neither m1 nor m2 have dimnames, m1 and m2 are returned unmodified. If only one of m1 or m2 has dimnames, an error is thrown.

Value

A named list containing completed and sorted versions of a and b.

Examples

m1 <- matrix(c(1:6), nrow=3, dimnames = list(c("r1", "r2", "r3"), c("c2", "c1")))
m2 <- matrix(c(7:12), ncol=3, dimnames = list(c("r3", "r4"), c("c2", "c3", "c4")))
complete_and_sort(m1)
complete_and_sort(m1, m2)
complete_and_sort(m1, m2, roworder = c("r3", "r2", "r1"))
complete_and_sort(m1, m2, colorder = c("c4", "c3")) # Drops un-specified columns
complete_and_sort(m1, m2, margin = 1)
complete_and_sort(m1, m2, margin = 2)
complete_and_sort(m1, t(m2))
complete_and_sort(m1, t(m2), margin = 1)
complete_and_sort(m1, t(m2), margin = 2)
v <- matrix(1:6, ncol=2, dimnames=list(c("r3", "r1", "r2"), c("c2", "c1")))
complete_and_sort(v, v)
# Also works with lists
complete_and_sort(list(m1,m1), list(m2,m2))
complete_rows_cols

Usage

```r
complete_rows_cols(
  a = NULL,
  mat = NULL,
  fill = 0,
  fillrow = NULL,
  fillcol = NULL,
  margin = c(1, 2)
)
```

Arguments

- **a**: a matrix or list of matrices to be completed.
- **mat**: a matrix from which dimnames will be extracted for the purposes of completing a with respect to mat.
- **fill**: rows and columns added to a will contain the value fill. (Default is 0.)
- **fillrow**: a row vector of type matrix with same column names as a. Any rows added to a will be fillrow. If non-NULL, fillrow takes precedence over both fillcol and fill in the case of conflicts.
- **fillcol**: a column vector of type matrix with same row names as a. Any columns added to a will be fillcol. If non-NULL, fillcol takes precedence over fill in the case of conflicts.
- **margin**: specifies the subscript(s) in a over which completion will occur. margin has nearly the same semantic meaning as in `apply` For rows only, give 1; for columns only, give 2; for both rows and columns, give c(1, 2), the default value.

Details

Note that `complete_rows_cols(mat1,mat2)` and `complete_rows_cols(mat2,mat1)` are not guaranteed to have the same order for rows and columns. (Nor are the values in the matrix guaranteed to have the same positions.) If dimnames(mat) is NULL, a is returned unmodified. If either a or matrix are missing names on a margin (row or column), an error is given. Matrices can be completed relative to themselves, meaning that a will be made square, containing the union of row and column names from a itself. All added rows and columns will be created from one of the fill* arguments. When conflicts arise, precedence among the fill* arguments is fillrow then fillcol then fill. Self-completion occurs if a is non-NULL and both is.null(matrix) and is.null(names). Under these conditions, no warning is given. If is.null(names) and dimnames of matrix cannot be determined (because, for example, matrix doesn’t have any dimnames), a is completed relative to itself and a warning is given.

Value

A modified version of a possibly containing additional rows and columns whose names are obtained from matrix
Examples

```r
m1 <- matrix(c(1:6), nrow=3, dimnames = list(c("r1", "r2", "r3"), c("c1", "c2")))
m2 <- matrix(c(7:12), ncol=3, dimnames = list(c("r2", "r3"), c("c2", "c3", "c4")))
complete_rows_cols(m1, m2) # Adds empty column c4
complete_rows_cols(m1, t(m2)) # Creates r2, r3 columns; c2, c3, c4 rows
complete_rows_cols(m1, m2, margin = 1) # No changes because r2 and r3 already present in m1
complete_rows_cols(m1, m2, margin = 2) # Adds empty columns c3 and c4
complete_rows_cols(m1, t(m2), margin = 1) # Adds empty rows c2, c3, c4
complete_rows_cols(m1, m2, fill = 100) # Adds columns c3 and c4 with 100's
complete_rows_cols(m1, m1) # Nothing added, because everything already present
complete_rows_cols(m1, t(m1)) # Adds empty r1, r2, r3 columns
complete_rows_cols(m1) # Adds rows r10, r11; cols c10, c11
```

### count_vals_byname

**Count the number of matrix entries that meet a criterion**

**Description**

Expressions can be written in a natural way such as `count_vals_byname(m,"<=".1)`.

**Usage**

```r
count_vals_byname(
  a,
  val = 0
)```
count_vals_incols_byname

Arguments

a a matrix or list of matrices whose values are to be counted according to compare_fun
compare_fun the comparison function, one of "==", "!="", "<", "<="", ">", or ">=". Default is "==".
val the value against which matrix entries are compared. Default is 0.

Details

Either a single matrix or a list of matrices can be given as the a argument. compare_fun can be specified as a string ("!=") or as a back-quoted function ('!=').

Value

an integer indicating the number of entries in a that meet the specified criterion

Examples

m <- matrix(c(0, 1, 2, 3, 4, 0), nrow = 3, ncol = 2)
count_vals_byname(m) # uses defaults: compare_fun = "==" and val = 0
count_vals_byname(m, compare_fun = "!=")
count_vals_byname(m, compare_fun = `!=`) # Write expressions in a natural way
count_vals_byname(m, "<=" , 1)
# Also works for lists
count_vals_byname(list(m,m), "<=" , 1)

count_vals_incols_byname

Count the number of matrix entries in columns that meet a criterion

Description

Expressions can be written in a natural way such as count_vals_incols_byname(m,"<=" , 1).

Usage

count_vals_incols_byname(
  a,
  compare_fun = c("==", "!=", "<", "<="",">",">"),
  val = 0
)

Arguments

a a matrix or list of matrices whose values are to be counted by columns according to compare_fun
compare_fun the comparison function, one of "==", "!="", "<", "<="", ">", or ">=". Default is "=="
val the value against which matrix entries are compared. Default is 0.
count_vals_inrows_byname

Count the number of matrix entries in rows that meet a criterion

Details

Either a single matrix or a list of matrices can be given as the a argument. compare_fun can be specified as a string ("!=") or as a back-quoted function ('!=').

Value

an matrix with a single row indicating the number of entries in a that meet the specified criterion in each column of a

Examples

m <- matrix(c(0, 1, 2, 3, 4, 0), nrow = 3, ncol = 2)
count_vals_incols_byname(m) # uses defaults: compare_fun = "==" and val = 0
count_vals_incols_byname(m, compare_fun = "!=")
count_vals_incols_byname(m, compare_fun = '!=')
# Write expressions in a natural way
count_vals_incols_byname(m, "<=" , 1)
# Also works for lists
count_vals_incols_byname(list(m,m), "<=" , 1)

count_vals_inrows_byname

Count the number of matrix entries in rows that meet a criterion

Description

Expressions can be written in a natural way such as count_vals_inrows_byname(m,"<=" , 1).

Usage

count_vals_inrows_byname( 
a, compare_fun = c("==", "!=" , "<" , "<=" , ">" , ">=") , val = 0 
)

Arguments

a a matrix or list of matrices whose values are to be counted by rows according to compare_fun
compare_fun the comparison function, one of "==", "!=" , "<" , "<=" , ">" , or ">=". Default is "==".
val the value against which matrix entries are compared. Default is 0.

Details

Either a single matrix or a list of matrices can be given as the a argument. compare_fun can be specified as a string ("!=") or as a back-quoted function ('!=').
cumapply_byname

Value

an **matrix** with a single column indicating the number of entries in a that meet the specified criterion in each row of a

Examples

```r
m <- matrix(c(0, 1, 2, 3, 4, 0), nrow = 3, ncol = 2)
count_vals_inrows_byname(m) # uses defaults: compare_fun = "==" and val = 0
count_vals_inrows_byname(m, compare_fun = "!=")
# Write expressions in a natural way
count_vals_inrows_byname(m, "!<", 1)
# Also works for lists
count_vals_inrows_byname(list(m,m), "!<", 1)
```

---

**cumapply_byname**  
Apply a function cumulatively to a list of matrices or numbers

Description

FUN must be a binary function that also accepts a single argument. The result is a list with first element **FUN(a[[1]]).** For i >= 2, elements are **FUN(a[[i]], out[[i-1]])**, where out is the result list.

Usage

cumapply_byname(FUN, a)

Arguments

**FUN**  
the function to be applied

**a**  
the list of matrices or numbers to which FUN will be applied cumulatively

Details

**naryapply_byname** and **cumapply_byname** are similar. Their differences can be described by considering a data frame. **naryapply_byname** applies FUN to several columns (variables) of the data frame. For example, **sum_byname** applied to several variables gives another column containing the sums across each row of the data frame. **cumapply_byname** applies FUN to successive entries in a single column. For example **sum_byname** applied to a single column gives the sum of all numbers in that column.

Value

a list of same length as a containing the cumulative application of FUN to a
cumprod_byname

**Examples**

```
cumapply_byname(sum, list(1, 2, 3, 4))
cumapply_byname(sum_byname, list(1, 2, 3, 4))
cumapply_byname(prod, list(1, 2, 3, 4))
cumapply_byname(hadamardproduct_byname, list(1, 2, 3, 4))
```

cumprod_byname

**Cumulative element-product that respects row and column names**

**Description**

Provides cumulative element-products along a list or column of a data frame. If a is a single number, a is returned. If a is a list of numbers, a list representing the cumulative product of the numbers is returned. If a is a single matrix, a is returned. If a is a list of matrices, a list representing the cumulative product of the matrices is returned. In this case, each entry in the returned list is product "by name," such that row and column names of the matrices are respected.

**Usage**

```
cumprod_byname(a)
```

**Arguments**

a

a number, list of numbers, matrix or list of matrices for which cumulative element product is desired

**Details**

This function respects groups if a is a variable in a data frame.

**Value**

a single number, list of numbers, a single matrix, or a list of matrices, depending on the nature of a

**Examples**

```
cumprod_byname(list(1, 2, 3, 4, 5))
m1 <- matrix(c(1), nrow = 1, ncol = 1, dimnames = list("r1", "c1")) %>%
  setrowtype("row") %>% setcoltype("col")
m2 <- matrix(c(2), nrow = 1, ncol = 1, dimnames = list("r2", "c2")) %>%
  setrowtype("row") %>% setcoltype("col")
m3 <- matrix(c(3), nrow = 1, ncol = 1, dimnames = list("r3", "c3")) %>%
  setrowtype("row") %>% setcoltype("col")
cumprod_byname(list(m1, m2, m3))
```
**cumsum_byname**

**Cumulative sum that respects row and column names**

**Description**

Provides cumulative sums along a list or column of a data frame. If \( a \) is a single number, \( a \) is returned. If \( a \) is a list of numbers, a list representing the cumulative sum of the numbers is returned. If \( a \) is a single matrix, \( a \) is returned. If \( a \) is a list of matrices, a list representing the cumulative sum of the matrices is returned. In this case, each entry in the returned list is sum "by name," such that row and column names of the matrices are respected.

**Usage**

```r
cumsum_byname(a)
```

**Arguments**

- **a**
  
  a number, list of numbers, matrix or list of matrices for which cumulative sum is desired

**Details**

If cumulative sums are desired in the context of a data frame, groups in the data frame are respected if `mutate` is used. See examples.

**Value**

a single number, list of numbers, a single matrix, or a list of matrices, depending on the nature of \( a \)

**Examples**

```r
library(dplyr)
m1 <- matrix(c(1), nrow = 1, ncol = 1, dimnames = list("r1", "c1")) %>%
  setrowtype("row") %>% setcoltype("col")
m2 <- matrix(c(2), nrow = 1, ncol = 1, dimnames = list("r2", "c2")) %>%
  setrowtype("row") %>% setcoltype("col")
m3 <- matrix(c(3), nrow = 1, ncol = 1, dimnames = list("r3", "c3")) %>%
  setrowtype("row") %>% setcoltype("col")
cumsum_byname(list(m1, m2, m3))
# Groups are respected in the context of mutate.
data.frame(grp = c("A", "A", "B"), m = I(list(m1, m2, m3))) %>% group_by(grp) %>%
  mutate(m2 = cumsum_byname(m))
```
difference_byname

Name-wise subtraction of matrices

Description

Name-wise subtraction of matrices

Usage

difference_byname(minuend, subtrahend)

Arguments

- **minuend**: matrix or constant
- **subtrahend**: matrix or constant

Performs a union and sorting of row and column names prior to differencing. Zeroes are inserted for missing matrix elements.

Value

A matrix representing the name-wise difference between minuend and subtrahend

Examples

```r
library(dplyr)
difference_byname(100, 50)
commoditynames <- c("c1", "c2")
industrynames <- c("i1", "i2")
U <- matrix(1:4, ncol = 2, dimnames = list(commoditynames, industrynames)) %>%
  setrowtype("Commodities") %>% setcoltype("Industries")
G <- matrix(rev(1:4), ncol = 2, dimnames = list(rev(commoditynames), rev(industrynames))) %>%
  setrowtype("Commodities") %>% setcoltype("Industries")
U - G # Non-sensical. Row and column names not respected.
difference_byname(U, G) # Row and column names respected! Should be all zeroes.
difference_byname(100, U)
difference_byname(10, G)
difference_byname(G) # When subtrahend is missing, return minuend (in this case, G).
difference_byname(subtrahend = G) # When minuend is missing, return - subtrahend (in this case, -G)
# This also works with lists
difference_byname(list(100, 100), list(50, 50))
difference_byname(list(U,U), list(G,G))
df <- data.frame(U = I(list()), G = I(list()))
DF[1,"U"] <- U
DF[2,"U"] <- U
DF[1,"G"] <- G
DF[2,"G"] <- G
difference_byname(DF$U, DF$G)
DF %>% mutate(diffs = difference_byname(U, G))
```
elementapplybyname

**Apply a function to an element of a matrix specified by rows and columns**

**Description**

Fun is applied to the element of a that is

**Usage**

\[
\text{elementapplybyname}(\text{FUN, } a, \text{ row, } \text{ col, } .\text{FUNdots} = \text{NULL})
\]

**Arguments**

- **FUN**: A unary function to be applied to specified rows and columns of a.
- **a**: The argument to FUN.
- **row**: The row name of the element to which FUN will be applied.
- **col**: The column name of the element to which FUN will be applied.
- **.FUNdots**: A list of additional arguments to FUN. (Default is NULL.)

**Details**

Row and col can be any of row or column names or integer indices or a mix of both.

**Value**

a, after FUN has been applied to the element at row and col

**Examples**

\[
\text{divide} <- \text{function}(x, \text{divisor})\{
  x/\text{divisor}
\}
\]

\[
\text{m} \leftarrow \text{matrix}(\text{c}(1:4), \text{nrow} = 2, \text{ncol} = 2, \text{dimnames} = \text{list}(\text{c}("r1", "r2"), \text{c}("c1", "c2"))) \text{%% setrowtype}(\text{"row"}) \text{%% setcoltype}(\text{"col"})
\]

\[
\text{elementapplybyname}(\text{divide}, a = \text{m}, \text{row} = 1, \text{col} = 1, .\text{FUNdots} = \text{list}(\text{divisor} = 2))
\]

\[
\text{elementapplybyname}(\text{divide}, a = \text{m}, \text{row} = 1, \text{col} = 2, .\text{FUNdots} = \text{list}(\text{divisor} = 10))
\]

\[
\text{elementapplybyname}(\text{divide}, a = \text{m}, \text{row} = \text{"r2"}, \text{col} = \text{"c2"}, .\text{FUNdots} = \text{list}(\text{divisor} = 100))
\]
equal_byname

Compare two matrices "by name" for equality

Description

If operands are matrices, they are completed and sorted relative to one another prior to comparison.

Usage

```r
equal_byname(...)```

Arguments

```r
...
operands to be compared
```

Details

Comparisons are made by `isTRUE(all.equal(a, b))` so that variations among numbers within the computational precision will still return `TRUE`.

If EXACT comparison is needed, use `identical_byname`, which compares using `identical(a, b)`.

Value

`TRUE` iff all information is equal, including row and column types and row and column names and entries in the matrices.

Examples

```r
a <- matrix(1:4, nrow = 2)
b <- matrix(1:4, nrow = 2)
equal_byname(a, b)
equal_byname(a, b + 1e-100)
identical_byname(a, b + 1e-100)
a <- a %>% setrowtype("Industries") %>% setcoltype("Commodities")
equal_byname(a, b) # FALSE because a has row and column types, but b does not.
b <- b %>% setrowtype("Industries") %>% setcoltype("Commodities")
equal_byname(a, b)
dimnames(a) <- list(c("i1", "i2"), c("c1", "c2"))
dimnames(b) <- list(c("c1", "c2"), c("i1", "i2"))
equal_byname(a, b) # FALSE, because row and column names are not equal
dimnames(b) <- dimnames(a)
equal_byname(a, b)```
exp_byname

Description
Gives the exponential of all elements of a matrix or list of matrices

Usage
exp_byname(a)

Arguments
a a matrix of list of matrices

Value
M with each element replaced by its exponential

Examples
exp_byname(1)
m <- matrix(c(log(10),log(1),log(1),log(100)),
nrow = 2, dimnames = list(paste0("i", 1:2),paste0("c", 1:2)))
setrowtype("Industry") %>% setcoltype("Commodity")
exp_byname(m)

fractionize_byname

Description
This function divides all entries in a by the specified sum, thereby "fractionizing" the matrix.

Usage
fractionize_byname(a, margin)

Arguments
a the matrix to be fractionized
margin If 1 (rows), each entry in a is divided by its row’s sum. If 2 (columns), each entry in a is divided by its column’s sum. If c(1,2) (both rows and columns), each entry in a is divided by the sum of all entries in a.
Value

a fractionized matrix of same dimensions and same row and column types as a.

Examples

```r
M <- matrix(c(1, 5, 4, 5),
nrow = 2, ncol = 2, byrow = TRUE,
 dimnames = list(c("p1", "p2"), c("i1", "i2"))) %>%
setcoltype("Products") %>% setrowtype("Industries")
fractionize_byname(M, margin = c(1,2))
fractionize_byname(M, margin = 1)
fractionize_byname(M, margin = 2)
```

description

Gives the geometric mean of corresponding entries of a and b.

Usage

`geometricmean_byname(...)`

Arguments

... operands; constants, matrices, or lists of matrices

Details

This function performs a union and sorting of row and column names prior to performing geometric mean. Zeroes are inserted for missing matrix elements.

Value

name-wise geometric mean of operands

Examples

```r
library(dplyr)
geometricmean_byname(10, 1000)
geometricmean_byname(10, 1000, 100000)
commoditynames <- c("c1", "c2")
industrynames <- "i1"
U <- matrix(c(10, 1000), ncol = 1, nrow = 2, 
dimnames = list(commoditynames, industrynames)) %>%
setrowtype("Commodities") %>% setcoltype("Industries")
G <- matrix(c(1e3, 1e5), ncol = 1, nrow = 2,
dimnames = list(rev(commoditynames), rev(industrynames))) %>%
```

geometricmean_byname  Name- and element-wise geometric mean of two matrices.
setrowtype("Commodities") %>% setcoltype("Industries")
# Non-sensical. Row and column names not respected.
sqrt(U*G)
# Row and column names respected!
geometricmean_byname(U, G)
geometricmean_byname(1000, U)
geometricmean_byname(10, G)
# This also works with lists
geometricmean_byname(list(10, 1000), list(1000, 10))
geometricmean_byname(list(U, U), list(G, G))
DF <- data.frame(U = I(list()), G = I(list()))
DF[[1, "U"]]<- U
DF[[2, "U"]]<- U
DF[[1, "G"]]<- G
DF[[2, "G"]]<- G
geometricmean_byname(DF$U, DF$G)
DF %>% mutate(geomeans = geometricmean_byname(U, G))

getcolnames_byname

Gets column names

Description

Gets column names in a way that is amenable to use in chaining operations in a functional programming way

Usage

getcognames_byname(a)

Arguments

a

The matrix or data frame from which column names are to be retrieved

Value

column names of m

Examples

m <- matrix(c(1:6), nrow = 2, dimnames = list(paste0("i", 1:2), paste0("c", 1:3))) %>%
setrowtype("Industries") %>% setcoltype("Commodities")
getcognames_byname(m)
# This also works for lists
getcognames_byname(list(m,m))
DF <- data.frame(m = I(list()))
DF[[1, "m"]]<- m
DF[[2, "m"]]<- m
getcognames_byname(DF$m)
**getrownames_byname** \(\bar{\text{Gets row names}}\)

**Description**

Gets row names in a way that is amenable to use in chaining operations in a functional programming way.

**Usage**

\[
\text{getrownames_byname}(a)
\]

**Arguments**

- \(a\) The matrix or data frame on which row names are to be retrieved

**Value**

row names of \(a\)

**Examples**

```r
m <- matrix(c(1:6), nrow = 2, dimnames = list(paste0("i", 1:2), paste0("c", 1:3))) %>%
  setrowtype("Industries") %>%
  setcoltype("Commodities")
getrownames_byname(m)
```

```r
# This also works for lists
getrownames_byname(list(m,m))
```

```r
DF <- data.frame(m = I(list()))
DF[[1,"m"]]
```

```r
# This also works for lists
getrownames_byname(DF$m)
```

**hadamardproduct_byname** \(\bar{\text{Name-wise matrix Hadamard multiplication}}\)

**Description**

Performs a union and sorting of names of rows and columns for both multiplicand and multiplier for each sequential multiplication step. Zeros are inserted for missing matrix elements. Doing so ensures that the dimensions of the multiplicand and multiplier are be conformable for each sequential multiplication.

**Usage**

\[
\text{hadamardproduct_byname}(\ldots)
\]
hatinv_byname

Arguments

... operands; constants, matrices, or lists of matrices

Details

The Hadamard product is also known as the entrywise product.

Value

name-wise element product of operands

Examples

library(dplyr)
hadamardproduct_byname(2, 2)
commoditynames <- c("c1", "c2")
industrynames <- c("i1", "i2")
U <- matrix(1:4, ncol = 2, dimnames = list(commoditynames, industrynames)) %>%
  setrowtype("Commodities") %>% setcoltype("Industries")
G <- matrix(1:4, ncol = 2, dimnames = list(rev(commoditynames), rev(industrynames))) %>%
  setrowtype("Commodities") %>% setcoltype("Industries")
U * G # Not what is desired, because names aren't aligned
hadamardproduct_byname(U, G)
hadamardproduct_byname(U, G, G)
hadamardproduct_byname(U, 0)
hadamardproduct_byname(0, G)
# This also works with lists
hadamardproduct_byname(list(U, U), list(G, G))
DF <- data.frame(U = I(list()), G = I(list()))
DF[1,"U"] <- U
DF[2,"U"] <- U
DF[1,"G"] <- G
DF[2,"G"] <- G
hadamardproduct_byname(DF$U, DF$G)
DF %>% mutate(entrywiseprods = hadamardproduct_byname(U, G))

hatinv_byname

Hatize and invert a vector

Description

When dividing rows or columns of a matrix by elements of a vector, the vector elements are placed on the diagonal of a new matrix, the diagonal matrix is inverted, and the result is pre- or post-multiplied into the matrix. This function performs the hatizing and inverting of vector v in one step and takes advantage of computational efficiencies to achieve the desired result. The computational shortcut is apparent when one observes that the matrix produced by hatizing and inverting a vector is a diagonal matrix whose non-zero elements are the numerical inverses of the individual elements of v. So this function first inverts each element of v then places the inverted elements on the diagonal of a diagonal matrix.
hatinv_byname

Usage

hatinv_byname(v, inf_becomes = .Machine$double.xmax)

Arguments

v the vector to be hatized and inverted
inf_becomes a value to be substitute for any Inf produced by the inversion process. Default is .Machine$double.xmax. If FALSE (the default), Inf is not handled differently. If TRUE, Inf values in the resulting matrix are converted to zeroes.

Details

Note that this function gives the same result as invert_byname(hatize_byname(v)), except that invert_byname(hatize_byname(v)) fails due to a singular matrix error when any of the elements of v are zero. This function will give inf_becomes on the diagonal of the result for each zero element of v, arguably a better answer. The sign of Inf is preserved in the substitution. The default value of inf_becomes is .Machine$double.xmax. Set inf_becomes to NULL to disable this behavior.

The default behavior is helpful for cases when the result of hatinv_byname is later multiplied by 0 to obtain 0. Multiplying Inf by 0 gives NaN which would effectively end the stream of calculations.

Value

a square diagonal matrix with inverted elements of v on the diagonal

Examples

v <- matrix(1:10, ncol = 1, dimnames = list(c(paste0("i", 1:10)), c("c1"))) %>% setrowtype("Industries") %>% setcoltype(NA)

r <- matrix(1:5, nrow = 1, dimnames = list(c("r1"), c(paste0("c", 1:5)))) %>% setrowtype(NA) %>% setcoltype("Commodities")

hatinv_byname(v)
hatinv_byname(r)
# This function also works with lists.
hatinv_byname(list(v, v))
# Watch out for 0 values
v2 <- matrix(0:1, ncol = 1, dimnames = list(c(paste0("i", 0:1)), c("p1"))) %>% setrowtype("Industries") %>% setcoltype(NA)
# Produces singular matrix error
## Not run: v2 %>% hatize_byname() %>% invert_byname
# Handles 0 values well
hatinv_byname(v2)
hatinv_byname(v2, inf_becomes = 42)
hatinv_byname(v2, inf_becomes = NULL)
hatize_byname

Creates a diagonal "hat" matrix from a vector

Description

A "hat" matrix is one in which the only non-zero elements are stored on the diagonal. To "hatize" a vector is to place its elements on the diagonal of an otherwise-zero square matrix. \( v \) must be a matrix object with one of its two dimensions of length 1 (i.e., a vector). The names of both dimensions of the hatized matrix are the same and taken from \( v \). Note that the vector names are sorted prior to forming the "hat" matrix.

Usage

\[
\text{hatize_byname}(v)
\]

Arguments

- \( v \): The vector from which a "hat" matrix is to be created.

Value

A square "hat" matrix with size equal to the length of \( v \).

Examples

\[
\begin{align*}
\text{v} & \leftarrow \text{matrix}(1:10, \text{ncol} = 1, \text{dimnames} = \text{list}(\text{c(paste0("i", 1:10)), c("c1"))), \%\% \\
& \quad \text{setrowtype("Industries")) \%\% setcoltype(NA)} \\
\text{r} & \leftarrow \text{matrix}(1:5, \text{nrow} = 1, \text{dimnames} = \text{list}(\text{c("r1")), c(paste0("c", 1:5)))), \%\% \\
& \quad \text{setrowtype(NA)) \%\% setcoltype("Commodities")} \\
\text{hatize_byname(v)} \\
\text{hatize_byname(r)} \\
& \text{# This also works with lists.} \\
& \text{hatize_byname(list(v, v))}
\end{align*}
\]

identical_byname

Compare two matrices "by name" for exact equality

Description

If operands are matrices, they are completed and sorted relative to one another prior to comparison.

Usage

\[
\text{identical_byname}(...)
\]
Arguments

... operands to be compared

Details

Comparisons are made by identical(a, b) so that variations among numbers within the computational precision will return FALSE.

If fuzzy comparison is needed, use equal_byname, which compares using isTRUE(all.equal(a, b)).

Value

TRUE iff all information is identical, including row and column types and row and column names and entries in the matrices.

Examples

```r
a <- matrix(1:4, nrow = 2)
b <- matrix(1:4, nrow = 2)
identical_byname(a, b)
identical_byname(a, b + 1e-100)
a <- a %>% setrowtype("Industries") %>% setcoltype("Commodities")
identical_byname(a, b) # FALSE because a has row and column types, but b does not.
b <- b %>% setrowtype("Industries") %>% setcoltype("Commodities")
identical_byname(a, b)
dimnames(a) <- list(c("i1", "i2"), c("c1", "c2"))
dimnames(b) <- list(c("c1", "c2"), c("i1", "i2"))
identical_byname(a, b) # FALSE, because row and column names are not equal
dimnames(b) <- dimnames(a)
identical_byname(a, b)
```

identize_byname

Named identity matrix or vector

Description

Creates an identity matrix (I) or vector (i) of same size and with same names and same row and column types as a. If margin = 1, makes a column matrix filled with 1s. Row names and type are taken from row names and type of a. Column name and type are same as column type of a. If margin = 2, make a row matrix filled with 1s. Column names and type are taken from column name and type of a. Row name and type are same as row type of a. If c(1, 2) (the default), make an identity matrix with 1s on the diagonal. Row and column names are sorted on output.

Usage

```r
identize_byname(a, margin = c(1, 2))
```
Arguments

a the matrix whose names and dimensions are to be preserved in an identity matrix or vector

margin determines whether an identity vector or matrix is returned. See details.

Value

An identity matrix or vector.

Examples

```r
M <- matrix(1:16, ncol = 4, dimnames=list(c(paste0("i", 1:4)), paste0("c", 1:4))) %>%
  setrowtype("Industries") %>% setcoltype("Commodities")
identify_byname(M)
identify_byname(M, margin = c(1,2))
identify_byname(M, margin = 1)
identify_byname(M, margin = 2)
N <- matrix(c(-21, -12, -21, -10), ncol = 2, dimnames = list(c("b", "a"), c("b", "a"))) %>%
  setrowtype("Industries") %>% setcoltype("Commodities")
identify_byname(N)
N <- matrix(c(-21, -12, -21, -10), ncol = 2, dimnames = list(c("b", "a"), c("b", "a"))) %>%
  setrowtype("Industries") %>% setcoltype("Commodities")
identify_byname(N)
# This also works with lists
identify_byname(list(M, M))
```

---

Iminus_byname

Subtract a matrix with named rows and columns from a suitably named and sized identity matrix (I)

Description

The order of rows and columns of m may change before subtracting from I, because the rows and columns are sorted by name prior to subtracting from I. Furthermore, if m is not square, it will be made square before subtracting from I by calling complete_and_sort.

Usage

Iminus_byname(a)

Arguments

a the matrix to be subtracted from I

Value

The difference between an identity matrix (I) and m (whose rows and columns have been completed and sorted)
Examples

```r
m <- matrix(c(-21, -12, -21, -10), ncol = 2, dimnames = list(c("b", "a"), c("b", "a"))) %>%
  setrowtype("Industries") %>% setcoltype("Commodities")
# Rows and columns are unsorted
diag(1, nrow = 2) - m
# Rows and columns are sorted prior to subtracting from the identity matrix
Iminus_byname(m)
# This also works with lists
Iminus_byname(list(m, m))
# If the m is not square before subtracting from I,
# it will be made square by the function complete_and_sort.
m2 <- matrix(c(1,2,3,4,5,6), ncol = 2, dimnames = list(c("a", "b", "c"), c("a", "b"))) %>%
  setrowtype("Industries") %>% setcoltype("Commodities")
Iminus_byname(m2)
```

invert_byname

Invert a matrix

Description

This function transposes row and column names as well as row and column types. Rows and columns of `a` are sorted prior to inverting.

Usage

```r
invert_byname(a)
```

Arguments

- `a` the matrix to be inverted. `a` must be square.

Value

the inversion of `a`

Examples

```r
m <- matrix(c(10,0,0,100), nrow = 2, dimnames = list(paste0("i", 1:2), paste0("c", 1:2))) %>%
  setrowtype("Industry") %>% setcoltype("Commodity")
invert_byname(m)
matrixproduct_byname(m, invert_byname(m))
matrixproduct_byname(invert_byname(m), m)
invert_byname(list(m, m))
```
iszerobyname

Test whether this is the zero matrix

Description

Note that this function tests whether the elements of $\text{abs}(a)$ are $\leq \text{tol}$. So, you can set $\text{tol} = 0$ to discover if $a$ is EXACTLY the zero matrix.

Usage

```r
iszerobyname(a, tol = 1e-06)
```

Arguments

- `a`  a matrix of list of matrices
- `tol`  the allowable deviation from 0 for any element

Value

`TRUE` iff this is the zero matrix within `tol`.

Examples

```r
zero <- matrix(0, nrow = 50, ncol = 50)
iszerobyname(zero)
nonzero <- matrix(1:4, nrow = 2)
iszerobyname(nonzero)
# Also works for lists
iszerobyname(list(zero, nonzero))
# And it works for data frames
DF <- data.frame(A = I(list()), B = I(list()))
DF[[1,"A"]] <- zero
DF[[2,"A"]] <- nonzero
DF[[1,"B"]] <- nonzero
DF[[2,"B"]] <- zero
iszerobyname(DF$A)
iszerobyname(DF$B)
iszerobyname(matrix(1e-10, nrow = 2))
iszerobyname(matrix(1e-10, nrow = 2), tol = 1e-11)
```
list_of_rows_or_cols  Named list of rows or columns of matrices

Description

This function takes matrix $m$ and converts it to a list of single-row (if $\text{margin} == 1$) or single-column (if $\text{margin} == 2$) matrices. Each item in the list is named for its row (if $\text{margin} == 1$) or column (if $\text{margin} == 2$).

Usage

```r
list_of_rows_or_cols(a, margin)
```

Arguments

- **a**: a matrix or list of matrices (say, from a column of a data frame)
- **margin**: the margin of the matrices to be extracted (1 for rows, 2 for columns)

Details

Note that the result provides column vectors, regardless of the value of $\text{margin}$.

Value

a named list of rows or columns extracted from $m$

Examples

```r
m <- matrix(data = c(1:6),
    nrow = 2, ncol = 3,
    dimnames = list(c("p1", "p2"), c("i1", "i2", "i3")))
setrowtype(rowtype = "Products")
setcoltype(coltype = "Industries")
list_of_rows_or_cols(m, margin = 1)
list_of_rows_or_cols(m, margin = 2)
```

logarithmicmean_byname  Name- and element-wise logarithmic mean of matrices

Description

The logarithmic mean of corresponding entries of $a$ and $b$ is $0$ if $a = 0$ or $b = 0$, $a$ if $a = b$, or $(b - a) / (\log(b) - \log(a))$ otherwise.

Usage

```r
logarithmicmean_byname(a, b, base = \exp(1))
```
logmean

Arguments

- **a**: first operand (a matrix or constant value or lists of same).
- **b**: second operand (a matrix or constant value or lists of same).
- **base**: the base of the logarithm used when computing the logarithmic mean. (Default is base = \(\exp(1)\).)

Details

This function performs a union and sorting of row and column names prior to performing logarithmic mean. Zeroes are inserted for missing matrix elements.

Internally, the third condition is implemented as \((b - a) / \log(b/a)\).

Note that \((b - a) / \log(b/a) = (a - b) / \log(a/b)\), so logarithmic mean is commutative; the order of arguments \(a\) and \(b\) does not change the result.

Value

A matrix representing the name-wise logarithmic mean of \(a\) and \(b\).

Examples

```r
library(dplyr)
m1 <- matrix(c(1:6), nrow = 3, ncol = 2) %>%
setrownames_byname(c("r1", "r2", "r3")) %>%
setcolnames_byname(c("c1", "c2")) %>%
setrowtype("row") %>%
setcoltype("col")
m2 <- matrix(c(7:12), nrow = 3, ncol = 2) %>%
setrownames_byname(c("r2", "r3", "r4")) %>%
setcolnames_byname(c("c2", "c3")) %>%
setrowtype("row") %>%
setcoltype("col")
logarithmicmean_byname(m1, m2)
# This also works with lists
logarithmicmean_byname(list(m1, m1), list(m2, m2))
DF <- data.frame(m1 = I(list()), m2 = I(list()))
DF[[1,"m1"]]<- m1
DF[[2,"m1"]]<- m1
DF[[1,"m2"]]<- m2
DF[[2,"m2"]]<- m2
logarithmicmean_byname(DF$m1, DF$m2)
DF %>% mutate(logmeans = logarithmicmean_byname(m1, m2))
```

logmean

Logarithmic mean of two numbers

Description

Calculates the logarithmic mean of two numbers.

Usage

```r
logmean(a, b, base = exp(1))
```
Arguments

a: the first operand (must be non-negative)
b: the second operand (must be non-negative)
base: the base of the logarithm used in this calculation. (Default is \( \exp(1) \).)

Details

This is an internal helper function for logarithmicmean_byname.

Value

0 if \( a = 0 \) or \( b = 0 \); \( \times 1 \) if \( a == b \); and \( (a - b) / \log(a/b, \text{base} = \text{base}) \) for all other values of \( a \) and \( b \)

Examples

- \( \text{matsbyname:::logmean}(0, 0) \) # 0
- \( \text{matsbyname:::logmean}(0, 1) \) # 0
- \( \text{matsbyname:::logmean}(1, 0) \) # 0
- \( \text{matsbyname:::logmean}(1, 1) \) # 1
- \( \text{matsbyname:::logmean}(2, 1) \)
- \( \text{matsbyname:::logmean}(1, 2) \) # commutative
- \( \text{matsbyname:::logmean}(1, 10) \) # base = \( \exp(1) \), the default
- \( \text{matsbyname:::logmean}(1, 10, \text{base} = 10) \)

Description

Specify the base of the log with base argument.

Usage

\[
\text{log_byname}(a, \text{base} = \exp(1))
\]

Arguments

- a: a matrix or list of matrices
- base: the base of the logarithm (default is \( \exp(1) \), giving the natural logarithm)

Value

M with each element replaced by its base base logarithm
Examples

logbyname(exp(1))

m <- matrix(c(10,1,1,100), nrow = 2, dimnames = list(paste0("i", 1:2), paste0("c", 1:2))) %>%
  setrownames("Industry") %>% setcolnames("Commodity")
logbyname(m)
logbyname(m, base = 10)

---

make_list

Makes a list of items in x, regardless of x's type

Description

Repeats x as necessary to make n of them. Does not try to simplify x.

Usage

make_list(x, n, lenx = ifelse(is.vector(x), length(x), 1))

Arguments

x the object to be duplicated
n the number of times to be duplicated
lenx the length of item x. Normally lenx is taken to be length(x), but if x is itself a list, you may wish for the list to be duplicated several times. In that case, set lenx = 1.

Value

a list of x duplicated n times

Examples

m <- matrix(c(1:6), nrow=3, dimnames = list(c("r1", "r2", "r3"), c("c2", "c1")))
make_list(m, n = 1)
make_list(m, n = 2)
make_list(m, n = 5)
make_list(list(c(1,2), c(1,2)), n = 4)
m <- matrix(1:4, nrow = 2)
l <- list(m, m+100)
make_list(l, n = 4)
make_list(l, n = 1) # Warning because l is trimmed.
make_list(l, n = 5) # Warning because length(l) (i.e., 2) not evenly divisible by 5
make_list(list(c("r10", "r11"), c("c10", "c11")), n = 2) # Confused by x being a list
make_list(list(c("r10", "r11"), c("c10", "c11")), n = 2, lenx = 1) # Fix by setting lenx = 1
make_pattern  
Create regex patterns for row and column selection by name

Description

This function is intended for use with the select_rows_byname and select_cols_byname functions. make_pattern correctly escapes special characters in row_col_names, such as ( and ), as needed. Thus, it is highly recommended that make_pattern be used when constructing patterns for row and column selections with select_rows_byname and select_cols_byname.

Usage

make_pattern(  
row_col_names,  
pattern_type = c("exact", "leading", "trailing", "anywhere")  
)

Arguments

row_col_names   a vector of row and column names
pattern_type    one of exact, leading, trailing, or anywhere.

Details

pattern_type controls the type of pattern created:

• exact produces a pattern that selects row or column names by exact match.
• leading produces a pattern that selects row or column names if the item in row_col_names matches the beginnings of row or column names.
• trailing produces a pattern that selects row or column names if the item in row_col_names matches the ends of row or column names.
• anywhere produces a pattern that selects row or column names if the item in row_col_names matches any substring of row or column names.

Value

an extended regex pattern suitable for use with select_rows_byname or select_cols_byname.

Examples

make_pattern(row_col_names = c("a", "b"), pattern_type = "exact")
**Description**

Name-wise matrix multiplication

**Usage**

```r
matrixproduct_byname(...)```

**Arguments**

... operands; constants, matrices, or lists of matrices

Multiples operands from left to right. Performs a union and sorting of multiplicand rows and multiplier columns by name prior to multiplication. Zeroes are inserted for missing matrix elements. Doing so ensures that the dimensions of multiplicand and multiplier matrices will be conformable. I.e., the number of columns in multiplicand will equal the number of rows in multiplier, so long as the column names of multiplicand are unique and the row names of multiplier are unique. If column type of the multiplicand is not same as row type of the multiplier on any step of the multiplication, the function will fail. The result is matrix product with row names from the first multiplicand and column names from the last multiplier.

**Value**

A matrix representing the name-wise product of operands

**Examples**

```r
library(dplyr)
V <- matrix(1:6, ncol = 3, dimnames = list(c("i1", "i2"), c("c1", "c2", "c3"))) %>%
  setrowtype("Industries") %>% setcoltype("Commodities")
G <- matrix(1:4, ncol = 2, dimnames = list(c("c2", "c1"), c("i2", "i1"))) %>%
  setrowtype("Commodities") %>% setcoltype("Industries")
Z <- matrix(11:14, ncol = 2, dimnames = list(c("i1", "i2"), c("s1", "s2"))) %>%
  setrowtype("Industries") %>% setcoltype("Sectors")
# Succeeds because G is completed to include a row named c3 (that contains zeroes).
matrixproduct_byname(V, G)
## Not run: V %*% G # Fails because E lacks a row named c3.
matrixproduct_byname(V, G, Z)
# This also works with lists
matrixproduct_byname(list(V, V), list(G, G))
DF <- data.frame(V = I(list()), G = I(list()))
DF[1,"V"] <- V
DF[2,"V"] <- V
DF[1,"G"] <- G
DF[2,"G"] <- G```
### mean_byname

**Name- and element-wise arithmetic mean of matrices**

**Description**

Gives the arithmetic mean of operands in . . .

**Usage**

```r
mean_byname(...)  
```

**Arguments**

- `...`: operands: constants, matrices, or lists of matrices

**Details**

This function performs a union and sorting of row and column names prior to performing arithmetic mean. Zeroes are inserted for missing matrix elements.

**Value**

name-wise arithmetic mean of operands.

**Examples**

```r
library(dplyr)
mean_byname(100, 50)
mean_byname(10, 20, 30)
commoditynames <- c("c1", "c2")
industrynames <- c("i1", "i2")
U <- matrix(1:4, ncol = 2, dimnames = list(commoditynames, industrynames)) %>%
  setrowtype("Commodities") %>% setcoltype("Industries")
G <- matrix(rev(1:4), ncol = 2, dimnames = list(rev(commoditynames), rev(industrynames))) %>%
  setrowtype("Commodities") %>% setcoltype("Industries")
(U + G) / 2 # Non-sensical. Row and column names not respected.
mean_byname(U, G) # Row and column names respected! Should be 1, 2, 3, and 4.
mean_byname(U, 100)
mean_byname(100, G)
mean_byname(100, 50, U)
mean_byname(10, G)
# This also works with lists
mean_byname(list(100, 100), list(50, 50))
mean_byname(list(U, U), list(G, G))
DF <- data.frame(U = I(list()), G = I(list()))
DF[, "U"] <- U
DF[, "G"] <- U
```

```r
matrixproduct_byname(DF$V, DF$G)
DF %>% mutate(matprods = matrixproduct_byname(V, G))
```
naryapplylogical_byname

\[ DF[[1,"G"]]<-G \]
\[ DF[[2,"G"]]<-G \]
\[ \text{mean\_byname}(DF\$U, \ DF\$G) \]
\[ \text{DF} \ %>% \ \text{mutate(means = mean\_byname(U, G))} \]

---

**naryapplylogical_byname**

*Apply a function logically to numbers, matrices, or lists of numbers or matrices*

---

**Description**

Operands should be logical, although numerical operands are accepted. Numerical operands are interpreted as 0 is FALSE, and any other number is TRUE.

**Usage**

```r
naryapplylogical_byname(
  FUN,
  ...,  # additional named arguments passed to FUN.
  .FUNdots = NULL,
  match_type = c("all", "matmult", "none"),
  set_rowcoltypes = TRUE,
  .organize = TRUE
)
```

**Arguments**

- **FUN**: a binary function (that returns logical values) to be applied over operands
- **...**: operands; constants, matrices, or lists of matrices
- **.FUNdots**: a list of additional named arguments passed to FUN.
- **match_type**: one of "all", "matmult", or "none". When ... are matrices, "all" (the default) indicates that rowtypes of all ... matrices must match and coltypes of all ... matrices must match. If "matmult", the coltype of the first operand must match the rowtype of the second operand for every sequential invocation of FUN. If "none", neither coltypes nor rowtypes are checked by naryapply_byname.
- **set_rowcoltypes**: tells whether to apply row and column types from operands in ... to the output of each sequential invocation of FUN. Set TRUE (the default) to apply row and column types. Set FALSE, to not apply row and column types to the output.
- **.organize**: a boolean that tells whether or not to automatically complete operands in ... relative to each other and sort the rows and columns of the completed matrices. This organizing is done on each sequential invocation of FUN. Normally, this should be TRUE (the default). However, if FUN takes over this responsibility, set to FALSE.
naryapply_byname

Details

This function is not exported, thereby retaining the right to future changes.

Value

the result of FUN applied logically to ...

Examples

matsbyname:::naryapplylogical_byname("&", TRUE, TRUE, TRUE)
matsbyname:::naryapplylogical_byname("&", TRUE, TRUE, FALSE)

naryapply_byname Apply a function "by name" to any number of operands

Description

Applies FUN to all operands in .... Other arguments have similar meaning as binaryapply_byname. See details for more information.

Usage

naryapply_byname(
  FUN,
  ..., .FUNdots = NULL,
  match_type = c("all", "matmult", "none"),
  set_rowcoltypes = TRUE,
  .organize = TRUE
)

Arguments

FUN a binary function to be applied "by name" to all operands in ....
...
the operands for FUN.
.FUNdots a list of additional named arguments passed to FUN.
match_type one of "all", "matmult", or "none". When ... are matrices, "all" (the default) indicates that rowtypes of all ... matrices must match and coltypes of all ... matrices must match. If "matmult", the coltype of the first operand must match the rowtype of the second operand for every sequential invocation of FUN. If "none", neither coltypes nor rowtypes are checked by naryapply_byname.
set_rowcoltypes tells whether to apply row and column types from operands in ... to the output of each sequential invocation of FUN. Set TRUE (the default) to apply row and column types. Set FALSE, to not apply row and column types to the output.
organize_args

.organize

a boolean that tells whether or not to automatically complete operands in ... relative to each other and sort the rows and columns of the completed matrices. This organizing is done on each sequential invocation of FUN. Normally, this should be TRUE (the default). However, if FUN takes over this responsibility, set to FALSE.

Details

If only one ... argument is supplied, FUN must be capable of handling one argument, and the call is routed to `unaryapplybyname`. When `set_rowcoltypes` is TRUE, the `rowcoltypes` argument of `unaryapplybyname` is set to "all", but when `set_rowcoltypes` is FALSE, the `rowcoltypes` argument of `unaryapplybyname` is set to "none". If finer control is desired, the caller should use `unaryapplybyname` directly. If more than one argument is passed in ..., FUN must be a binary function, but its use in by `naryapplybyname` is "n-ary." Arguments `match_type`, `set_rowcoltypes`, and `.organize` have same meaning as for `binaryapplybyname`. Thus, all of the operands in ... must obey the rules of type matching when `match_type` is TRUE.

`naryapplybyname` and `cumapplybyname` are similar. Their differences can be described by considering a data frame. `naryapplybyname` applies FUN to several columns (variables) of the data frame. For example, `sumbyname` applied to several variables gives another column containing the sums across each row of the data frame. `cumapplybyname` applies FUN to successive entries in a single column. For example `sumbyname` applied to a single column gives the sum of all numbers in that column.

Value

the result of applying FUN to all operands in ...

Examples

```r
naryapplybyname(FUN = sumbyname, 2, 3)
naryapplybyname(FUN = sumbyname, 2, 3, 4, -4, -3, -2)
# Routes to unaryapplybyname
naryapplybyname(FUN = `^`, list(1, 2, 3), .FUNdots = 2)
```

---

<table>
<thead>
<tr>
<th>organize_args</th>
<th>Organize binary arguments</th>
</tr>
</thead>
</table>

Description

Organizes arguments of binary (2 arguments) _byname functions. Actions performed are:

- if only one argument is a list, make the other argument also a list of equal length.
- if both arguments are lists, ensure that they are same length.
- if one argument is a matrix and the other is a constant, make the constant into a matrix.
- ensures that row and column types match for `typematch_margins`.
- ensures that list item names match if both `a` and `b` are lists; no complaints are made if neither `a` nor `b` has names.
- completes and sorts the matrices.
Usage

organize_args(a, b, match_type = "all", fill)

Arguments

a  the first argument to be organized
b  the second argument to be organized
match_type  one of "all", "matmult", "none". When both a and b are matrices, "all" (the default) indicates that rowtypes of a must match rowtypes of b and coltypes of a must match coltypes of b. If "matmult", coltypes of a must match rowtypes of b.
fill  a replacement value for a or b if either is missing or NULL.

Value

a list with two elements (named a and b) containing organized versions of the arguments

---

pow_byname  Powers of matrix elements

Description

Gives the result of raising all elements of a matrix or list of matrices to a power.

Usage

pow_byname(a, pow)

Arguments

a  a matrix of list of matrices
pow  the power to which elements of a will be raised

Value

a with each element raised to pow

Examples

library(dplyr)
pow_byname(2, 3)
m <- matrix(2, nrow = 2, ncol = 3, dimnames = list(paste0("r", 1:2), paste0("c", 1:3))) %>%
  setrowtype("rows") %>% setcoltype("cols")
pow_byname(m, 2)
DF <- data.frame(m = I(list()), pow = I(list()))
DF[1, "m"] <- m
DF[2, "m"] <- m
prodall_byname

DF[1, "pow"] <- 0.5
DF[2, "pow"] <- -1
DF %>% mutate(
    sqrtm = pow_byname(m, 0.5),
    mtopow = pow_byname(m, pow)
)

prodall_byname  Product of all elements in a matrix

Description

This function is equivalent to a %>% rowprods_byname() %>% colprods_byname(), but returns a single numeric value instead of a 1x1 matrix.

Usage

prodall_byname(a)

Arguments

a  the matrix whose elements are to be multiplied

Value

the product of all elements in a as a numeric.

Examples

library(dplyr)
M <- matrix(2, nrow=2, ncol=2, dimnames = list(paste0("i", 1:2), paste0("c", 1:2))) %>%
    setrowtype("Industry") %>% setcoltype("Product")
prodall_byname(M)
rowprods_byname(M) %>% colprods_byname
# Also works for lists
prodall_byname(list(M,M))
DF <- data.frame(M = I(list(1l)))
DF[1,"M"] <- M
DF[2,"M"] <- M
prodall_byname(DF$M[1])
prodall_byname(DF$M)
res <- DF %>% mutate(
    prods = prodall_byname(M)
)
res$prods
Description

Element-wise division of two matrices.

Usage

\texttt{quotientbyname(dividend, divisor)}

Arguments

\begin{itemize}
  \item \texttt{dividend} \hspace{1cm} Dividend matrix or constant
  \item \texttt{divisor} \hspace{1cm} Divisor matrix or constant
\end{itemize}

Details

 Performs a union and sorting of names of rows and columns for both \texttt{dividend} and \texttt{divisor} prior to element division. Zeroes are inserted for missing matrix elements. Doing so ensures that the dimensions of the \texttt{dividend} and \texttt{divisor} will be conformable.

Value

A matrix representing the name-wise element quotient of \texttt{dividend} and \texttt{divisor}

Examples

\begin{verbatim}
library(dplyr)
commoditynames <- c("c1", "c2")
industrynames <- c("i1", "i2")
U <- matrix(1:4, ncol = 2, dimnames = list(commoditynames, industrynames)) %>%
  setrowtype("Commodities") %>% setcoltype("Industries")
G <- matrix(rev(1:4), ncol = 2, dimnames = list(rev(commoditynames), rev(industrynames))) %>%
  setrowtype("Commodities") %>% setcoltype("Industries")
U / G # Non-sensical. Names aren't aligned
quotientbyname(U, G)
quotientbyname(U, 10)
quotientbyname(10, G)
# This also works with lists
quotientbyname(10, list(G,G))
quotientbyname(list(G,G), 10)
quotientbyname(list(U, U), list(G, G))
DF <- data.frame(U = I(list()), G = I(list()))
DF[1,"U"] <- U
DF[2,"U"] <- U
DF[1,"G"] <- G
DF[2,"G"] <- G
\end{verbatim}
replaceNaN_byname

replaceNaN_byname(DF$U, DF$G)
DF %>% mutate(elementquotients = quotient_byname(U, G))

replaceNaN_byname Replace NaN values with a value

Description

In a matrix or within matrices in a list, replace all NaN matrix values with val.

Usage

replaceNaN_byname(a, val = 0)

Arguments

a a matrix of list of matrices in which NaN will be replaced by val

val NaNs are replaced by val

Value

a matrix or list of matrices in which all NaN are replaced by val

Examples

suppressWarnings(a <- matrix(c(1, sqrt(-1))))
replaceNaN_byname(a)
replaceNaN_byname(a, 42)

rowprods_byname Row products, sorted by name

Description

Calculates row products (the product of all elements in a row) for a matrix. An optional colname for the resulting column vector can be supplied. If colname is NULL or NA (the default), the column name is set to the column type as given by coltype(a).

Usage

rowprods_byname(a, colname = NA)

Arguments

a a matrix or list of matrices from which row products are desired.

colname name of the output column containing row products
rowsums_byname

Value

a column vector of type matrix containing the row products of \( a \)

Examples

```r
library(dplyr)
M <- matrix(c(1:6), ncol = 2, dimnames = list(paste0("i", 3:1), paste0("c", 1:2))) %>%
  setrowtype("Industries") %>% setcoltype("Products")
rowprods_byname(M)
rowprods_byname(M, "E.ktoe")
# This also works with lists
rowprods_byname(list(M, M))
rowprods_byname(list(M, M), "E.ktoe")
rowprods_byname(list(M, M), NA)
rowprods_byname(list(M, M), NULL)
DF <- data.frame(M = I(list()))
DF[[1,"M"]]<- M
DF[[2,"M"]]<- M
rowprods_byname(DF$M[[1]])
rowprods_byname(DF$M)
ans <- DF %>% mutate(rs = rowprods_byname(M))
ans
ans$rs[[1]]
# Nonsensical
## Not run: rowprods_byname(NULL)
```

rowsums_byname

Row sums, sorted by name

Description

Calculates row sums for a matrix by post-multiplying by an identity vector (containing all 1's). In contrast to `rowSums` (which returns a numeric result), the return value from `rowsums_byname` is a matrix. An optional `colname` for the resulting column vector can be supplied. If `colname` is `NULL` or `NA` (the default), the column name is set to the column type as given by `coltype(a)`.

Usage

`rowsums_byname(a, colname = NA)`

Arguments

- `a`: a matrix or list of matrices from which row sums are desired.
- `colname`: name of the output column containing row sums

Value

a column vector of type matrix containing the row sums of \( m \)
Examples

```r
library(dplyr)
m <- matrix(c(1:6), ncol = 2, dimnames = list(paste0("i", 3:1), paste0("c", 1:2))) %>%
setrowtype("Industries") %>% setcoltype("Commodities")
rowsumsbyname(m)
rowsumsbyname(m, "E.ktoe")
# This also works with lists
rowsumsbyname(list(m, m))
rowsumsbyname(list(m, m), "E.ktoe")
rowsumsbyname(list(m, m), NA)
rowsumsbyname(list(m, m), NULL)
DF <- data.frame(m = I(list()))
DF[[1,"m"]]<- m
DF[[2,"m"]]<- m
rowsumsbyname(DF$m[[1]])
rowsumsbyname(DF$m)
ans <- DF %>% mutate(rs = rowsumsbyname(m))
an
ans$rs[[1]]
# Nonsensical
## Not run: rowsumsbyname(NULL)
```

Description

Extracts row type of a.

Usage

```r
rowtype(a)
```

Arguments

- `a` the object from which you want to extract row types

Value

the row type of a

Examples

```r
library(dplyr)
commoditynames <- c("c1", "c2")
industrynames <- c("i1", "i2")
U <- matrix(1:4, ncol = 2, dimnames = list(commoditynames, industrynames)) %>%
setrowtype(rowtype = "Commodities") %>% setcoltype("Industries")
rowtype(U)
# This also works for lists
rowtype(list(U,U))
```
samestructure_byname  Test whether matrices or lists of matrices have same structure

Description
Matrices are said to have the same structure if row and column types are identical and if row and column names are identical. Values can be different.

Usage
samestructure_byname(...)  

Arguments
...  operands to be compared

Value
TRUE if all operands have the same structure, FALSE otherwise.

Examples
samestructure_byname(2, 2)
productnames <- c("p1", "p2")
industrynames <- c("i1", "i2")
U <- matrix(1:4, ncol = 2, dimnames = list(productnames, industrynames)) %>%
  setrowtype("Products") %>% setcoltype("Industries")
samestructure_byname(U, U)
samestructure_byname(U, U %>% setrowtype("row"))
samestructure_byname(U %>% setcoltype("col"), U)
# Also works with lists
samestructure_byname(list(U, U), list(U, U))

select_cols_byname  Select columns of a matrix (or list of matrices) by name

Description
Arguments indicate which columns are to be retained and which are to be removed. For maximum flexibility, arguments are extended regex patterns that are matched against column names.

Usage
select_cols_byname(a, retain_pattern = "$^", remove_pattern = "$^")
select_cols_byname

Arguments

- a: a matrix or a list of matrices
- retain_pattern: an extended regex or list of extended regular expressions that specifies which columns of \( m \) to retain. Default pattern (\$^\) retains nothing.
- remove_pattern: an extended regex or list of extended regular expressions that specifies which columns of \( m \) to remove. Default pattern (\$^\) removes nothing.

Details

If \( a \) is NULL, NULL is returned.

Patterns are compared against column names using extended regex. If no column names of \( a \) match the retain_pattern, NULL is returned. If no column names of \( a \) match the remove_pattern, \( a \) is returned.

Retaining columns takes precedence over removing columns, always.

Some typical patterns are:

- \(^Electricity\|^Oil\): column names that are EXACTLY Electricity or Oil.
- \(^Electricity|^Oil\): column names that START WITH Electricity or Oil.
- \(Electricity|Oil\): column names that CONTAIN Electricity or Oil anywhere within them.

Given a list of column names, a pattern can be constructed easily using the make_pattern function.

make_pattern escapes regex strings using escapeRegex. This function assumes that retain_pattern and remove_pattern have already been suitably escaped.

Note that the default retain_pattern and remove_pattern (\$^\) retain nothing and remove nothing.

Value

a matrix that is a subset of \( a \) with columns selected by retain_pattern and remove_pattern.

Examples

```r
m <- matrix(1:16, ncol = 4, dimnames=list(c(paste0("i", 1:4)), paste0("p", 1:4))) %>%
  setrowtype("Industries") %>%
  setcoltype("Commodities")
select_cols_byname(m, retain_pattern = make_pattern(c("p1", "p4"), pattern_type = "exact"))
select_cols_byname(m, remove_pattern = make_pattern(c("p1", "p3"), pattern_type = "exact"))
# Also works for lists and data frames
select_cols_byname(list(m,m), retain_pattern = "^p1|\^p4$\)
```
select_rows_byname

Select rows of a matrix (or list of matrices) by name

Description
Arguments indicate which rows are to be retained and which are to be removed. For maximum flexibility, arguments are extended regex patterns that are matched against row names.

Usage

select_rows_byname(a, retain_pattern = "^\^", remove_pattern = "^\^")

Arguments

- a: a matrix or a list of matrices
- retain_pattern: an extended regex or list of extended regular expressions that specifies which rows of \( m \) to retain. Default pattern (\(^*\)) retains nothing.
- remove_pattern: an extended regex or list of extended regular expressions that specifies which rows of \( m \) to remove. Default pattern (\(^*\)) removes nothing.

Details

- If \( a \) is NULL, NULL is returned.
- Patterns are compared against row names using extended regex. If no row names of \( m \) match the retain_pattern, NULL is returned. If no row names of \( m \) match the remove_pattern, \( m \) is returned.
- Note that the default retain_pattern and remove_pattern (\(^*\)) retain nothing and remove nothing.
- Retaining rows takes precedence over removing rows, always.
- Some typical patterns are:
  - \(^Electricity\|^Oil\): row names that are EXACTLY Electricity or EXACTLY Oil.
  - \(^Electricity|^Oil\): row names that START WITH Electricity or START WITH Oil.
  - Electricity|Oil: row names that CONTAIN Electricity or CONTAIN Oil anywhere within them.

- Given a list of row names, a pattern can be constructed easily using the make_pattern function. make_pattern escapes regex strings using escapeRegex. This function assumes that retain_pattern and remove_pattern have already been suitably escaped.

Value

- a matrix that is a subset of \( m \) with rows selected by retain_pattern and remove_pattern.
Examples

```r
m <- matrix(1:16, ncol = 4, dimnames=list(c(paste0("i", 1:4)), paste0("p", 1:4))) %>%
  setrowtype("Industries") %>% setcoltype("Commodities")
select_rows_byname(m, retain_pattern = make_pattern(c("i1", "i4"), pattern_type = "exact"))
select_rows_byname(m, remove_pattern = make_pattern(c("i1", "i3"), pattern_type = "exact"))
# Also works for lists and data frames
select_rows_byname(list(m,m), retain_pattern = "^i1|^i4$")
```

---

### setcolnamesbyname

**Sets column names**

Sets column names in a way that is amenable to use in piping operations in a functional programming way. If `a` is `NULL`, `NULL` is returned. If `a` is a constant, it is converted to a matrix and `colnames` are applied. If `a` is a matrix, `colnames` should be a vector of new column names that is as long as the number of columns in `a`. If `a` is a list of matrices, `colnames` can also be a list, and it should be as long as `a`. Or `colnames` can be a vector of column names which will be applied to every matrix in the list of `a`. Each item in the list should be a vector containing column names for the corresponding matrix in `a`.

**Description**

Sets column names in a way that is amenable to use in piping operations in a functional programming way. If `a` is `NULL`, `NULL` is returned. If `a` is a constant, it is converted to a matrix and `colnames` are applied. If `a` is a matrix, `colnames` should be a vector of new column names that is as long as the number of columns in `a`. If `a` is a list of matrices, `colnames` can also be a list, and it should be as long as `a`. Or `colnames` can be a vector of column names which will be applied to every matrix in the list of `a`. Each item in the list should be a vector containing column names for the corresponding matrix in `a`.

**Usage**

```r
setcolnamesbyname(a, colnames)
```

**Arguments**

- `a`: A matrix or a list of matrices in which column names are to be set
- `colnames`: A vector of new column names or a list of vectors of new column names

**Value**

A copy of `a` with new column names

**Examples**

```r
m <- matrix(c(1:6), nrow = 2, dimnames = list(paste0("i", 1:2), paste0("c", 1:3))) %>%
  setrowtype("Industries") %>% setcoltype("Commodities")
setcolnamesbyname(m, c("a", "b", "c"))
```
setcoltype

Sets column type for a matrix or a list of matrices

Description
This function is a wrapper for attr so that setting can be accomplished by the pipe operator (%>%). Column types are strings stored in the coltype attribute.

Usage
setcoltype(a, coltype)

Arguments
a the matrix on which column type is to be set
coltype the type of item stored in columns

Details
#' If is.null(coltype), the coltype attribute is deleted and subsequent calls to coltype will return NULL.

Value
a with coltype attribute set.

Examples
library(dplyr)
commoditynames <- c("c1", "c2")
industrynames <- c("i1", "i2")
U <- matrix(1:4, ncol = 2, dimnames = list(commoditynames, industrynames))
U %>% setcoltype("Industries")
# This also works for lists
setcoltype(list(U,U), coltype = "Industries")
setcoltype(list(U,U), coltype = list("Industries", "Industries"))
DF <- data.frame(U = I(list()))
DF[1,"U"] <- U
DF[2,"U"] <- U
setcoltype(DF$U, "Industries")
DF <- DF %>% mutate(newcol = setcoltype(U, "Industries"))
DF$newcol[[1]]
DF$newcol[[2]]
Description

Sets row names in a way that is amenable to use in piping operations in a functional programming way. If \(a\) is NULL, NULL is returned. If \(a\) is a constant, it is converted to a matrix and rownames are applied. If \(a\) is a matrix, rownames should be a vector of new row names that is as long as the number of rows in \(a\). If \(a\) is a list of matrices, rownames can also be a list, and it should be as long as \(a\). Or rownames can be a vector of row names which will be applied to every matrix in the list of \(a\). Each item in the list should be a vector containing row names for the corresponding matrix in \(a\).

Usage

\[
\text{setrownames\_byname}(a, \text{rownames})
\]

Arguments

- \(a\): A matrix or a list of matrices in which row names are to be set
- \(rownames\): A vector of new row names or a list of vectors of new row names

Value

A copy of \(m\) with new row names

Examples

```r
library(dplyr)
m <- matrix(c(1:6), nrow = 2, dimnames = list(paste0("i", 1:2), paste0("c", 1:3))) %>%
  setrowtype("Industries") %>% setcoltype("Commodities")
setrownames\_byname(m, c("a", "b"))
setrownames\_byname(m %>% setrowtype("Industries") %>% setcoltype("Commodities"), c("c", "d"))
m %>% setrownames\_byname(NULL)
m %>% setrownames\_byname(c(NA, NA))
2 %>% setrownames\_byname("row")
# This also works for lists
setrownames\_byname(list(m, m), c("a", "b"))
DF <- data.frame(m = I(list()))
DF[[1,"m"]] <- m
DF[[2,"m"]] <- m
setrownames\_byname(DF$m, c("r1", "r2"))
setrownames\_byname(DF$m, c("c", "d"))
DF <- DF %>% mutate(m = setrownames\_byname(m, c("r1", "r2")))
DF$m[[1]]
```
setrowtype

Sets row type for a matrix or a list of matrices

Description

This function is a wrapper for attr so that setting can be accomplished by the pipe operator (%>%). Row types are strings stored in the rowtype attribute.

Usage

setrowtype(a, rowtype)

Arguments

a
the matrix on which row type is to be set

rowtype
the type of item stored in rows

Details

If is.null(rowtype), the rowtype attribute is deleted and subsequent calls to rowtype will return NULL.

Value

a with rowtype attribute set to rowtype.

Examples

library(dplyr)
commoditynames <- c("c1", "c2")
industrynames <- c("i1", "i2")
U <- matrix(1:4, ncol = 2, dimnames = list(commoditynames, industrynames))
U %>% setrowtype("Commodities")
# This also works for lists
setrowtype(list(U,U), rowtype = "Commodities")
setrowtype(list(U,U), rowtype = list("Commodities", "Commodities"))
DF <- data.frame(U = I(list()))
DF[1,"U"] <- U
DF[2,"U"] <- U
setrowtype(DF$U, "Commodities")
DF <- DF %>% mutate(newcol = setrowtype(U, "Commodities"))
DF$newcol[[1]]
DF$newcol[[2]]
sort_rows_cols

Sorts rows and columns of a matrix

Description

Checks that row names are unique and that column names are unique. Then, sorts the rows and columns in a way that ensures any other matrix with the same row and column names will have the same order.

Usage

sort_rows_cols(a, margin = c(1, 2), roworder = NA, colorder = NA)

Arguments

- **a**: a matrix or data frame whose rows and columns are to be sorted
- **margin**: specifies the subscript(s) in a over which sorting will occur. margin has nearly the same semantic meaning as in apply. For rows only, give 1; for columns only, give 2; for both rows and columns, give c(1, 2), the default value.
- **roworder**: specifies the order for rows with default sort(rownames(a)). If NA (the default), default sort order is used. Unspecified rows are removed from the output, thus providing a way to delete rows from a. Extraneous row names (row names in roworder that do not appear in a) are ignored.
- **colorder**: specifies the order for columns with default sort(colnames(a)). If NA (the default), default sort order is used. Unspecified columns are removed from the output, thus providing a way to delete columns from a. Extraneous column names (column names in colorder that do not appear in a) are ignored.

Details

Default sort order is given by base::sort() with decreasing = FALSE.

Value

A modified version of a with sorted rows and columns

Examples

```r
m <- matrix(c(1:6), nrow=3, dimnames = list(c("r3", "r5", "r1"), c("c4", "c2")))
sort_rows_cols(m)
sort_rows_cols(t(m))
sort_rows_cols(m, margin=1) # Sorts rows
sort_rows_cols(m, margin=2) # Sorts columns
v <- matrix(c(1:5), ncol=1, dimnames=list(rev(paste0("r", 1:5)), "c1")) # Column vector
sort_rows_cols(v)
sort_rows_cols(v, margin = 1) # Sorts rows
sort_rows_cols(v, margin = 2) # No effect: only one column
```
r <- matrix(c(1:4), nrow=1, dimnames=list("r1", rev(paste0("c", 1:4)))) # Row vector
sort_rows_cols(r) # Sorts columns
n <- matrix(c(1,2), nrow = 1, dimnames = list(NULL, c("c2", "c1"))) # No row name
sort_rows_cols(n) # Sorts columns, because only one row.
# Also works with lists
sort_rows_cols(list(m,m)) # Sorts rows and columns for both m's.
# Sort rows only for first one, sort rows and columns for second one.
# Row order is applied to all m's. Column order is natural.
sort_rows_cols(a = list(m,m), margin = 1, roworder = c("r5", "r3", "r1"))
# Columns are sorted as default, because no colorder is given.
# roworder is ignored.
sort_rows_cols(a = list(m,m), margin = 2, roworder = c("r5", "r3", "r1"))
# Both columns and rows sorted, rows by the list, columns in natural order.
sort_rows_cols(a = list(m,m), margin = c(1,2), roworder = c("r5", "r3", "r1"))

sumall_byname

**sumall_byname**

*Sum of all elements in a matrix*

**Description**

This function is equivalent to a `%%rowsums_byname() %>% colsums_byname()`, but returns a single numeric value instead of a 1x1 matrix.

**Usage**

`sumall_byname(a)`

**Arguments**

- `a` the matrix whose elements are to be summed

**Value**

the sum of all elements in a as a numeric

**Examples**

library(dplyr)
m <- matrix(2, nrow=2, ncol=2, dimnames = list(paste0("i", 1:2), paste0("c", 1:2))) %>%
  setrowtype("Industry") %>%
  setcoltype("Commodity")
sumall_byname(m)
rowsums_byname(m) %>%
  colsums_byname
# Also works for lists
sumall_byname(list(m,m))
DF <- data.frame(m = 1(list()))
DF[['m']] <- m
DF[['m']] <- m
sumall_byname(DF$m[[1]])
sumall_byname(DF$m)
res <- DF %>%
  mutate(
sum_byname

    sums = sumall_byname(m)
)
res$sums

---

**sum_byname**

*Name-wise addition of matrices*

**Description**

Performs a union and sorting of addend and augend row and column names prior to summation. Zeroes are inserted for missing matrix elements. Treats missing or NULL operands as 0.

**Usage**

```r
sum_byname(...)```

**Arguments**

...  

operands: constants, matrices, or lists of matrices

**Details**

«Stuff here about cores.»

**Value**

A matrix representing the name-wise sum of addend and augend

**Examples**

```r
library(dplyr)
sum_byname(2, 2)
sum_byname(2, 2, 2)
sum_byname(2, 2, -2, -2)
productnames <- c("p1", "p2")
industrynames <- c("i1", "i2")
U <- matrix(1:4, ncol = 2, dimnames = list(productnames, industrynames)) %>% setrowtype("Products") %>% setcoltype("Industries")
Y <- matrix(1:4, ncol = 2, dimnames = list(rev(productnames), rev(industrynames))) %>% setrowtype("Products") %>% setcoltype("Industries")
sum_byname(U, 100)
sum_byname(200, Y)
U + Y # Non-sensical. Row and column names not respected.
sum_byname(U, U)
sum_byname(U, Y)
sum_byname(U, U, Y)
V <- matrix(1:4, ncol = 2, dimnames = list(industrynames, productnames)) %>% setrowtype("Industries") %>% setcoltype("Products")
U + V # row and column names are non-sensical and blindly taken from first argument (U)
## Not run: sum_byname(U, V) # Fails, because row and column types are different
# This also works with lists
sum_byname(list(U, U), list(Y, Y))
sum_byname(list(U, U), list(100, 100))
sum_byname(list(U, U), as.list(rep_len(100, 2)))
DF <- data.frame(U = I(list()), Y = I(list()))
DF[[1,"U"]]<-U
DF[[2,"U"]]<-U
DF[[1,"Y"]]<-Y
DF[[2,"Y"]]<-Y
sum_byname(DF$U, DF$Y)
DF %>% mutate(sums = sum_byname(U, Y))

# If only one argument, return it.
sum_byname(2, NULL) # Gives 2
sum_byname(2, NA) # Gives NA
sum_byname(NULL, 1) # Gives 1
sum_byname(list(NULL, 1), list(1, 1))

DF2 <- data.frame(U = I(list()), Y = I(list()))
DF2[[1,"U"]]<-NULL
DF2[[2,"U"]]<-U
DF2[[1,"Y"]]<-Y
DF2[[2,"Y"]]<-Y
sum_byname(DF2$U, DF2$Y)
DF3 <- DF2 %>% mutate(sums = sum_byname(U, Y))

value
sum_byname(2, NULL) # Gives 2
sum_byname(2, NA) # Gives NA
sum_byname(NULL, 1) # Gives 1
sum_byname(list(NULL, 1), list(1, 1))

Description
Gives the transpose of a matrix or list of matrices

Usage
transpose_byname(a)

Arguments
a the matrix to be transposed

Value
the transposed matrix
Examples

```r
m <- matrix(c(11,21,31,12,22,32), ncol = 2, dimnames = list(paste0("i", 1:3), paste0("c", 1:2))) %>%
  setrowtype("Industry") %>%
  setcoltype("Commodity")
transpose_byname(m)
transpose_byname(list(m, m))
```

Description

Note that if `a` is a list, the names of `a` are applied to the output.

Usage

```r
unaryapply_byname(
  FUN, 
  a, 
  .FUNdots = NULL,
  rowcoltypes = c("all", "transpose", "row", "col", "none")
)
```

Arguments

- **FUN**: a unary function to be applied "by name" to `a`.
- **a**: the argument to `FUN`.
- **.FUNdots**: a list of additional named arguments passed to `FUN`.
- **rowcoltypes**: a string that tells how to transfer row and column types of `a` to output. Options are:
  - **all**: transfer both row and column types of `a` directly to output.
  - **transpose**: rowtype of `a` becomes coltype of output; coltype of `a` becomes rowtype of output. "transpose" is helpful for FUNs that transpose a upon output.
  - **row**: rowtype of `a` becomes both rowtype and coltype of output.
  - **col**: coltype of `a` becomes both rowtype and coltype of output.
  - **none**: rowtype and coltype not set by unaryapply_byname. Rather, FUN will set rowtype and coltype.

Value

the result of applying FUN "by name" to `a`. 
Examples

productnames <- c("p1", "p2")
industrynames <- c("i1", "i2")
U <- matrix(1:4, ncol = 2, dimnames = list(productnames, industrynames)) %>%
  setrowtype("Products") %>% setcoltype("Industries")
difference_byname(0, U)
unaryapply_byname("-", U)
