Package ‘matsindf’

Type Package
Title Matrices in Data Frames
Version 0.4.7
Date 2023-12-20
Maintainer Matthew Heun <matthew.heun@me.com>
Description Provides functions to collapse a tidy data frame into matrices in a data frame
and expand a data frame of matrices into a tidy data frame.

add_UKEnergy2000_matnames

Add a column of matrix names to tidy data frame

Description

Add a column of matrix names to tidy data frame

Usage

add_UKEnergy2000_matnames(
  .DF,  
  ledger_side_colname = "Ledger.side",  
  energy_colname = "E.ktoe",  
  supply_side = "Supply",  
  consumption_side = "Consumption",  
  matname_colname = "matname",  
  U_name = "U",  
  V_name = "V",  
  Y_name = "Y"
)
Arguments

- `.DF` a data frame with `ledger_side_colname` and `energy_colname`.
- `ledger_side_colname` the name of the column in `.DF` that contains ledger side (a string). Default is "Ledger.side".
- `energy_colname` the name of the column in `.DF` that contains energy values (a string). Default is "E.ktoe".
- `supply_side` the identifier for items on the supply side of the ledger (a string). Default is "Supply".
- `consumption_side` the identifier for items on the consumption side of the ledger (a string). Default is "Consumption".
- `matname_colname` the name of the output column containing the name of the matrix in which this row belongs (a string). Default is "UVY".
- `U_name` the name for the use matrix (a string). Default is "U".
- `V_name` the name for the make matrix (a string). Default is "V".
- `Y_name` the name for the final demand matrix (a string). Default is "Y".

Value

`.DF` with an added column, `UVY_colname`.

Examples

```r
matsindf::add_UKEnergy2000_matnames(UKEnergy2000)
```

Description

Add row, column, row type, and column type metadata

Usage

```r
add_UKEnergy2000_row_col_meta(
  .DF,
  matname_colname = "matname",
  U_name = "U",
  V_name = "V",
  Y_name = "Y",
  product_colname = "Product",
  flow_colname = "Flow",
)```
industry_type = "Industry",
product_type = "Product",
sector_type = "Sector",
rowname_colname = "rowname",
colname_colname = "colname",
rowtype_colname = "rowtype",
coltype_colname = "coltype"
)

Arguments

 DF a data frame containing matname_colname.
matname_colname the name of the column in .DF that contains names of matrices (a string). Default is "matname".
U_name the name for use matrices (a string). Default is "U".
V_name the name for make matrices (a string). Default is "V".
Y_name the name for final demand matrices (a string). Default is "Y".
product_colname the name of the column in .DF where Product names is found (a string). Default is "Product".
flow_colname the name of the column in .DF where Flow information is found (a string). The Flow column usually contains the industries involved in this flow. Default is "Flow".
industry_type the name that identifies production industries and and transformation processes (a string). Default is "Industry".
product_type the name that identifies energy carriers (a string). Default is "Product".
sector_type the name that identifies final demand sectors (a string). Default is "Sector".
rowname_colname the name of the output column that contains row names for matrices (a string). Default is "rowname".
colname_colname the name of the output column that contains column names for matrices (a string). Default is "colname".
rowtype_colname the name of the output column that contains row types for matrices (a string). Default is "rowtype".
coltype_colname the name of the output column that contains column types for matrices (a string). Default is "coltype".

Value

.DF with additional columns named rowname_colname, colname_colname, rowtype_colname, and coltype_colname.
**build_keep_args**

**Examples**

```r
UKEnergy2000 %>%
matsindf:::add_UKEnergy2000_matnames(.) %>%
matsindf:::add_UKEnergy2000_row_col_meta(.)
```

---

**Description**

In the process of building data frames of arguments to FUN, we need to decide which arguments to keep from each source, ..., .dat, and defaults to FUN. This function does that work in one place.

**Usage**

```r
build_keep_args(where_to_find_args)
```

**Arguments**

- `where_to_find_args`
  
  A list created by `where_to_get_args()`.

**Value**

A list with names .dat, dots, and FUN which gives items to keep from each source.

---

**build_matsindf_apply_data_frame**

Create a data frame consisting of the input data for matsindf_apply()

---

**Description**

This is an internal helper function that takes the types list and creates a data frame from which calculations can proceed.

**Usage**

```r
build_matsindf_apply_data_frame(
  .dat = NULL,
  FUN,
  ..., 
  types = matsindf_apply_types(.dat, FUN = FUN, ... = ...)
)
```
collapse_to_matrices

Description

A "tidy" data frame contains information that can be collapsed into matrices, including columns for matrix names, row names, column names, row types, column types, and values (entries in matrices). These column names are specified as strings by the matnames, rownames, colnames, rowtypes, coltypes, and values arguments to collapse_to_matrices(), respectively. A matsindf-style matrix has named rows and columns. In addition, matsindf-style matrices have "types" for row and column information, such as "Commodities", "Industries", "Products", or "Machines". The row and column types for the matsindf-style matrices are stored as attributes on the matrix (rowtype and coltype), which can be accessed with the functions matsbyname::rowtype() and matsbyname::coltype(). Row and column types are both respected and propagated by the various *_byname functions of the matsbyname package. Use the *_byname functions when you do operations on the matsindf-style matrices. The matsindf-style matrices will be stored in a column with same name as the incoming values column. This function is similar to tidyr::nest(), which stores data frames into a cell of a data frame. With collapse_to_matrices(), matrices are created. This function respects groups, like dplyr::summarise(). (In fact, calls to this function may not work properly unless grouping is provided. Errors of the form "Error: Duplicate identifiers for rows ..." are usually fixed by grouping .DF prior to calling this function.) The usual approach is to dplyr::group_by() the matnames column and any other columns to be preserved in the output. Note that execution is halted if any of rownames, colnames, rowtypes, coltypes, or values is a grouping variable in .DF. rowtypes and coltypes should be the same for all rows of the same matrix in .DF; execution is halted if that is not the case. tidyr::pivot_wider()ing the output by matnames may be necessary before calculations are done on the collapsed matrices. See the example.
collapse_to_matrices

Usage

collapse_to_matrices(
  .DF,
  matnames = "matnames",
  matvals = "matvals",
  rownames = "rownames",
  colnames = "colnames",
  rowtypes = if ("rowtypes" %in% names(.DF)) "rowtypes" else NULL,
  coltypes = if ("coltypes" %in% names(.DF)) "coltypes" else NULL,
  matrix.class = lifecycle::deprecated(),
  matrix_class = c("matrix", "Matrix")
)

Arguments

  .DF       the "tidy" data frame
  matnames  A string identifying the column in .DF containing matrix names for matrices to
             be created. Default is "matnames".
  matvals   A string identifying the column in .DF containing values to be inserted into the
             matrices to be created. This will also be the name of the column in the output
             containing matrices formed from the data in the matvals column. Default is
             "matvals".
  rownames  A string identifying the column in .DF containing row names for matrices to
             be created. Default is "rownames".
  colnames  A string identifying the column in .DF containing column names for matrices to
             be created. Default is "colnames".
  rowtypes  An optional string identifying the column in .DF containing the type of values
             in rows of the matrices to be created. Default is if ("rowtypes" %in%
             names(.DF)) "rowtypes" else NULL, so that failure to set the rowtypes argument
             will give NULL, as appropriate.
  coltypes  An optional string identifying the column in .DF containing the type of values
             in columns of the matrices to be created Default is if ("coltypes" %in%
             names(.DF)) "rowtypes" else NULL, so that failure to set the coltypes argument
             will give NULL, as appropriate.
  matrix.class  [Deprecated] Use matrix_class instead.
  matrix_class  One of "matrix" or "Matrix". "matrix" creates a base::matrix object with
                 the matrix() function. "Matrix" creates a Matrix::Matrix object using the
                 matsbyname::Matrix() function. This could be a sparse matrix. Default is
                 "matrix".

Details

Groups are not preserved on output.

Note that two types of matrices can be created, a matrix or a Matrix. Matrix has the advantage
of representing sparse matrices with less memory (and disk space). Matrix objects are created by
matsbyname::Matrix().
df_to_msg

Create a message from a data frame

Description

This function is especially helpful for cases when a data frame of missing or unset values is at hand. Trim unneeded columns, then call this function to create a string with rows separated by semicolons and entries separated by commas.

Usage

df_to_msg(df)
everything_except

Arguments

df
The data frame to be converted to a message

Value

A string with rows separated by semicolons and entries separated by commas.

Examples

```r
data.frame(a = c(1, 2, 3), b = c("a", "b", "c")) |> df_to_msg()
```

```
everything_except(DF, "a", "b")
everything_except(DF, "a", "b", symbols = FALSE)
everything_except(DF, c("a", "b"))
everything_except(DF, list("a", "b"))
```

Description

This convenience function performs a set difference between the columns of .DF and the variable names (or symbols) given in .

Usage

```
everything_except(.DF, ..., .symbols = TRUE)
```

Arguments

.DF
A data frame whose variable names are to be differedenced.

... A string, strings, vector of strings, or list of strings representing column names to be subtracted from the names of .DF/

.symbols A boolean that defines the return type: TRUE for symbols, FALSE for strings.

Value

A vector of symbols (when .symbols = TRUE) or strings (when symbol = FALSE) containing all variables names except those given in .

Examples

```r
DF <- data.frame(a = c(1, 2, 3), b = c(3, 4), c = c(5, 6))
everything_except(DF, "a", "b")
everything_except(DF, "a", "b", symbols = FALSE)
everything_except(DF, c("a", "b"))
everything_except(DF, list("a", "b"))
```
**expand_to_tidy**

**Expand a matsindf data frame**

**Description**

Any tidy data frame of matrices (in which each row represents one matrix observation) can also be represented as a tidy data frame with each non-zero matrix entry as an observation on its own row. This function (and `collapse_to_matrices()`) convert between the two representations.

**Usage**

```r
expand_to_tidy(
  .DF,
  matnames = "matnames",
  matvals = "matvals",
  rownames = "rownames",
  colnames = "colnames",
  rowtypes = "rowtypes",
  coltypes = "coltypes",
  drop = NA
)
```

**Arguments**

- `.DF`  
  The data frame containing `matsindf`-style matrices. (.DF may also be a named list of matrices, in which case names of the matrices are taken from the names of items in the list and list items are expected to be matrices.)

- `matnames`  
  The name of the column in `.DF` containing matrix names (a string). Default is "matnames".

- `matvals`  
  The name of the column in `.DF` containing IO-style matrices or constants (a string). This will also be the name of the column containing matrix entries in the output data frame. Default is "matvals".

- `rownames`  
  The name for the output column of row names (a string). Default is "rownames".

- `colnames`  
  The name for the output column of column names (a string). Default is "colnames".

- `rowtypes`  
  An optional name for the output column of row types (a string). Default is "rowtypes".

- `coltypes`  
  The optional name for the output column of column types (a string) Default is "coltypes".

- `drop`  
  If specified, the value to be dropped from output. For example, `drop = 0` will cause 0 entries in the matrices to be deleted from output. If `NA`, no values are dropped from output. Default is `NA`.

Details

Names for output columns are specified in the rownames, colnames, rowtypes, and coltypes arguments. The entries of the matsindf-style matrices are stored in an output column named values.

Value

A tidy data frame containing expanded matsindf-style matrices

Examples

```r
library(dplyr)
library(matsbyname)
ptype <- "Products"
itype <- "Industries"
                   row = c( "c1", "c2", "c1", "c2", "c2", "i1", "i2", "c1", "c1", "c1", "c2", NA, NA),
                   col = c( "i1", "i2", "i1", "i2", "i3", "c1", "c2", "i1", "i2", "i1", "i2", NA, NA),
                   rowtypes = c( ptype, ptype, ptype, ptype, ptype, itype, itype, ptype, ptype, ptype, ptype, itype, itype),
                   coltypes = c(itype, itype, itype, itype, itype, ptype, ptype, itype, ptype, itype, ptype, itype, itype),
                   vals = c(11 , 22, 11 , 22 , 23 , 11 , 22 , 11 , 12 , 11 , 22 , 0.2, 0.3)) %>%
group_by(Country, Year, matrix)
mats <- collapse_to_matrices(tidy, matnames = "matrix", rownames = "row", colnames = "col",
                             rowtypes = "rowtypes", coltypes = "coltypes",
                             matvals = "vals") %>%
ungroup()
expand_to_tidy(mats, matnames = "matrix", matvals = "vals",
               rownames = "rows", colnames = "cols",
               rowtypes = "rt", coltypes = "ct")
expand_to_tidy(mats, matnames = "matrix", matvals = "vals",
               rownames = "rows", colnames = "cols",
               rowtypes = "rt", coltypes = "ct", drop = 0)
```

get_useable_default_args

Create a usable list of default arguments to a function
**Description**

`formals(FUN)` does not handle arguments without a default well, returning a name vector of length 1, which when converted to character is "". This function detects that condition and replaces the no-default argument with the value of `.no_default`, by default NULL.

**Usage**

```r
get_useable_default_args(FUN, which = c("values", "names"), no_default = NULL)
```

**Arguments**

- **FUN**: A function from which values of default arguments are to be extracted.
- **which**: Tells whether to get "names" of arguments or "values" of arguments. Default is "values".
- **no_default**: The placeholder value for arguments with no default.

**Value**

A named list of default arguments to FUN. Names are the argument names. Values are the default argument values.

**Examples**

```r
f <- function(a = 42, b) {
  return(a + b)
}
matsindf:::get_useable_default_args(f)
matsindf:::get_useable_default_args(f, no_default = logical())
```

---

**group_by_everything_except**

*Group by all variables except some*

---

**Description**

This is a convenience function that allows grouping of a data frame by all variables (columns) except those variables specified in . . . .

**Usage**

```r
group_by_everything_except(.DF, ..., .add = FALSE, .drop = FALSE)
```
handle_empty_data

Arguments

.DO.F
A data frame to be grouped.

... A string, strings, vector of strings, or list of strings representing column names
to be excluded from grouping.

.add When .add = FALSE, the default, dplyr::group_by() will override existing
groups. To add to the existing groups, use .add = TRUE.

.drop When .drop = TRUE, empty groups are dropped. Default is FALSE.

Value

A grouped version of .DO.F.

Examples

library(dplyr)
DF <- data.frame(a = c(1, 2), b = c(3, 4), c = c(5, 6))
group_by_everything_except(DF) %>% group_vars()
group_by_everything_except(DF, NULL) %>% group_vars()
group_by_everything_except(DF, c()) %>% group_vars()
group_by_everything_except(DF, list()) %>% group_vars()
group_by_everything_except(DF, c) %>% group_vars()
group_by_everything_except(DF, "a") %>% group_vars()
group_by_everything_except(DF, "c") %>% group_vars()
group_by_everything_except(DF, c("a", "c")) %>% group_vars()
group_by_everything_except(DF, c("a")) %>% group_vars()
group_by_everything_except(DF, list("a")) %>% group_vars()

Description

When empty data are provided to matsindf_apply(), care must be take with the return value. This
function assembles the correct zero-row data frame or zero-length lists.

Usage

handle_empty_data(.dat = NULL, FUN, DF, types)

Arguments

.dat The .dat argument to matsindf_apply().
FUN The FUN argument to matsindf_apply().
DF The assembled DF inside matsindf_apply().
types The types object assembled inside matsindf_apply().
Value

The appropriate return value from `matsindf_apply()`, either a zero-length list or a zero-row data frame.

---

**handle_null_args**

Gracefully handle NULL arguments

---

Description

When NULL is passed as an element of the .dat or ... arguments to `matsindf_apply()`, special care must be taken. This function helps in those situations.

Usage

```r
handle_null_args(.arg)
```

Arguments

- `.arg` One of .dat or ... (as a list) arguments to `matsindf_apply()`.

Value

A list representation of .arg with NULL values handled appropriately.

---

**index_column**

Index a column in a data frame by groups relative to an initial year

---

Description

This function indexes (by ratio) variables in `vars_to_index` to the first time in `time_var` or to `index_time` (if specified). Groups in .DF are both respected and required. Neither `var_to_index` nor `time_var` can be in the grouping variables.

Usage

```r
index_column(
  .DF,
  var_to_index,
  time_var = "Year",
  index_time = NULL,
  indexed_var = paste0(var_to_index, suffix),
  suffix = "_indexed"
)
```
**index_column**  

**Arguments**

- `.DF` the data frame in which the variables are contained
- `var_to_index` the column name representing the variable to be indexed (a string)
- `time_var` the name of the column containing time information. Default is "Year".
- `index_time` the time to which data in `var_to_index` are indexed. If NULL (the default), index_time is set to the first time of each group.
- `indexed_var` the name of the indexed variable. Default is "<<var_to_index>>_<suffix>>".
- `suffix` the suffix to be appended to the indexed variable. Default is "_indexed".

**Details**

Note that this function works when the variable to index is a column of numbers or a column of matrices.

**Value**

a data frame with same number of rows as `.DF` and the following columns: grouping variables of `.DF`, `var_to_index`, `time_var`, and one additional column containing indexed `var_to_index` named with the value of `indexed_var`.

**Examples**

```r
columns(data.frame(Year = c(2000, 2005, 2010), a = c(10, 15, 20), b = c(5, 5.5, 6)) %>%  
gather(key = name, value = var, a, b) %>%  
group_by(name)  
index_column(.DF, var_to_index = "var", time_var = "Year", suffix = "_ratioed")  
index_column(.DF, var_to_index = "var", time_var = "Year", indexed_var = "now.indexed")  
index_column(.DF, var_to_index = "var", time_var = "Year", index_time = 2005,  
  indexed_var = "now.indexed")
```

---

## Not run:

```r
library(dplyr)
library(tidyr)
DF <- data.frame(Year = c(2000, 2005, 2010), a = c(10, 15, 20), b = c(5, 5.5, 6)) %>%  
gather(key = name, value = var, a, b) %>%  
group_by(name)  
index_column(.DF, var_to_index = "var", time_var = "Year", suffix = "_ratioed")  
index_column(.DF, var_to_index = "var", time_var = "Year", indexed_var = "now.indexed")  
index_column(.DF, var_to_index = "var", time_var = "Year", index_time = 2005,  
  indexed_var = "now.indexed")
```

## End(Not run)

---
matrix_cols

Find columns that contain matrices

Description

It is often helpful to find the columns of a matsinfd data frame that contain exclusively or some matrices. This function helps with that task.

Usage

```
matrix_cols(.df, .drop_names = FALSE, .any = FALSE)
```

Arguments

- `.df` The data frame to be queried for matrix columns.
- `.drop_names` A boolean that tells whether to remove the names from the returned integer vector. Default is `FALSE`.
- `.any` A boolean that tells whether a column is reported when `any()` of the rows contain matrices (instead of `all()` rows contain matrices). Default is `FALSE`, in which case all entries in a column must be a matrix for the column to be reported.

Details

By default, a column is considered a matrix column if `all()` of the rows contain matrices. Use the `.test_any` argument to modify this behavior.

By default, the vector of integers returned from this function is named by the columns. Use the `.drop_names` function to modify this behavior.

Value

A vector of integers saying which columns contain matrices.

Examples

```
tidy <- tibble::tibble(matrix = c("V1", "V1", "V1", "V2", "V2"),
  row = c("i1", "i1", "i2", "i1", "i2"),
  col = c("p1", "p2", "p2", "p1", "p2"),
  vals = c(1, 2, 3, 4, 5)) %>%
dplyr::mutate(
  rowtypes = "Industries",
  coltypes = "Products"
) %>%
dplyr::group_by(matrix)
matsdf <- tidy %>%
collapse_to_matrices(matnames = "matrix", matvals = "vals",
  rownames = "row", colnames = "col",
  rowtypes = "rowtypes", coltypes = "coltypes")
```
matsindf_apply

matsdf
matrix_cols(matsdf)
matrix_cols(matsdf, .drop_names = TRUE)

matsindf_apply Apply a function to a matsindf data frame (and more)

Description
Applies FUN to .dat or performs the calculation specified by FUN on numbers or matrices. FUN must return a named list. The values of the list returned FUN become entries in columns in a returned data frame or entries in the sub-lists of a returned list. The names of the items in the list returned by FUN become names of the columns in a returned data frame or names of the list items in the returned list.

Usage
matsindf_apply(.dat = NULL, FUN, ..., .warn_missing_FUN_args = TRUE)

Arguments
.dat A list of named items or a data frame.
FUN The function to be applied to .dat.
... Named arguments to be passed by name to FUN.
.warn_missing_FUN_args A boolean that tells whether to warn of missing arguments to FUN. Default is TRUE.

Details
If is.null(.dat) and ... are all named numbers or matrices of the form argname = m, ms are passed to FUN by argnames. The return value is a named list provided by FUN. The arguments in ... are not included in the output.

If is.null(.dat) and ... are all lists of numbers or matrices of the form argname = l, FUN is Mapped across the various ls to obtain a list of named lists returned from FUN. The return value is a list whose top-level names are the names of the returned items from FUN .dat is not included in the return value.

If !is.null(.dat) and ... are all named, length == 1 character strings of the form argname = string, argnames are expected to be names of arguments to FUN, and strings are expected to be column names in .dat. The return value is .dat with additional columns (at right) whose names are the names of list items returned from FUN. When .dat contains columns whose names are same as columns added at the right, a warning is emitted.

.dat can be a list of named items in which case a list will be returned instead of a data frame.

If items in .dat have same names as arguments to FUN, it is not necessary to specify any arguments in .... matsindf_apply assumes that the appropriately-named items in .dat are intended to be arguments to FUN. When an item name appears in both ... and .dat, ... takes precedence.
if .dat is a data frame, the items in its columns (possibly matrices) are \texttt{unname()}d before calling \texttt{FUN}.

NULL arguments in ... are ignored for the purposes of deciding whether all arguments are numbers, matrices, lists of numbers of matrices, or named character strings. However, all NULL arguments are passed to \texttt{FUN}, so \texttt{FUN} should be able to deal with NULL arguments appropriately.

If .dat is present, ... contains \texttt{length == 1} strings, and one of the ... strings is not the name of a column in .dat, \texttt{FUN} is called WITHOUT the argument whose column is missing. I.e., that argument is treated as missing. If \texttt{FUN} works despite the missing argument, execution proceeds. If \texttt{FUN} cannot handle the missing argument, an error will occur in \texttt{FUN}.

It is suggested that \texttt{FUN} is able to handle empty data gracefully, returning an empty result with the same names as when non-empty data are fed to \texttt{FUN}. Attempts are made to handle zero-row data (in .dat or ...) gracefully. First, \texttt{FUN} is called with the empty (but named) data. If \texttt{FUN} can handle empty data without error, the result is returned. If \texttt{FUN} errors when fed empty data, \texttt{FUN} is called with an empty argument list in the hopes that \texttt{FUN} has reasonable default values. If that fails, .dat is returned unmodified (if not \texttt{NULL}) or the data in ... is returned.

Value

A named list or a data frame. (See details.)

Examples

\begin{verbatim}
library(matsbyname)
example_fun <- function(a, b){
  return(list(c = sum_byname(a, b),
             d = difference_byname(a, b)))
}
# Single values for arguments
matsindf_apply(FUN = example_fun, a = 2, b = 2)
# Matrices for arguments
a <- 2 * matrix(c(1,2,3,4), nrow = 2, ncol = 2, byrow = TRUE,
                dimnames = list(c("r1", "r2"), c("c1", "c2")))
b <- 0.5 * a
matsindf_apply(FUN = example_fun, a = a, b = b)
# Single values in lists are treated like columns of a data frame
matsindf_apply(FUN = example_fun, a = list(2, 2), b = list(1, 2))
# Matrices in lists are treated like columns of a data frame
matsindf_apply(FUN = example_fun, a = list(a, a), b = list(b, b))
# Single numbers in a data frame
DF <- data.frame(a = c(4, 4, 5), b = c(4, 4, 4))
matsindf_apply(DF, FUN = example_fun, a = "a", b = "b")
# By default, arguments to \texttt{FUN} come from \texttt{DF}
matsindf_apply(DF, FUN = example_fun)
# Now put some matrices in a data frame.
DF2 <- data.frame(a = I(list(a, a)), b = I(list(b,b)))
matsindf_apply(DF2, FUN = example_fun, a = "a", b = "b")
# All arguments to \texttt{FUN} are supplied by named items in .dat
matsindf_apply(list(a = 1, b = 2), FUN = example_fun)
# All arguments are supplied by named arguments in ..., but mix them up.
# Note that the named arguments override the items in .dat
\end{verbatim}
The various FUN_arg_* components give information about the arguments to FUN. FUN_arg_all_names gives the names of all arguments to FUN, regardless of whether they have default values. FUN_arg_default_names gives the names of only those arguments with default values. FUN_arg_default_values gives the
values of the default arguments, already eval()ed in the global environment. When there are no
default arguments, already eval()ed in the global environment. When there are no
values in a category, NULL is returned. thus, if FUN has no arguments with default values assigned
values in a category, NULL is returned. thus, if FUN has no arguments with default values assigned
in the signature of the function, both FUN_arg_default_names and FUN_arg_default_values
in the signature of the function, both FUN_arg_default_names and FUN_arg_default_values
will be NULL. If FUN has no arguments, all of FUN_arg_all_names, FUN_arg_default_names and
will be NULL. If FUN has no arguments, all of FUN_arg_all_names, FUN_arg_default_names and
FUN_arg_default_values will be NULL.

keep_args is a named list() of arguments, which indicates which arguments to keep from which
source (..., .dat, or default args to FUN) by order of preference, ... over .dat over default
arguments to FUN. Arguments not used by FUN are kept, again according to the rules of preference.

Value

A logical list with components named .dat_null, .dat_df, .dat_list, .dat_names, FUN_arg_all_names,
FUN_arg_default_names, FUN_arg_default_values, dots_present, all_dots_num, all_dots_mats,
all_dots_list, all_dots_vect, all_dots_char, all_dots_longer_than_1, dots_names, and
keep_args.

Examples

identity_fun <- function(a, b) {list(a = a, b = b)}
matsindf_apply_types(.dat = NULL, FUN = identity_fun, a = 1, b = 2)
matsindf_apply_types(.dat = data.frame(), FUN = identity_fun,
am = matrix(c(1, 2)), b = matrix(c(2, 3)))
matsindf_apply_types(.dat = list(), FUN = identity_fun,
a = c(1, 2), b = c(3, 4))
matsindf_apply_types(.dat = NULL, FUN = identity_fun,
a = list(1, 2), b = list(3, 4))
Arguments

.matrix The IO-style matrix to be converted to a data frame with rows, columns, and values.

.matvals A string for the name of the output column containing values. Default is "matvals".

.rownames A string for the name of the output column containing row names. Default is "rownames".

colnames A string for the name of the output column containing column names. Default is "colnames".

.rowtypes A string for the name of the output column containing row types. Default is "rowtypes".

coltypes A string for the name of the output column containing column types. Default is "coltypes".

drop If specified, the value to be dropped from output. Default is NA. For example, drop = 0 will cause 0 entries in the matrices to be deleted from output. If NA, no values are dropped from output.

Value

A data frame with rows, columns, and values.

Examples

library(matsbyname)

data <- data.frame(Country = c("GH", "GH", "GH"),
                    rows = c("c1", "c1", "c2"),
                    cols = c("i1", "i2", "i2"),
                    rt = c("Commodities", "Commodities", "Commodities"),
                    ct = c("Industries", "Industries", "Industries"),
                    vals = c( 11 , 12, 22 ))

data

A <- data %>%
  rowcolval_to_mat(rownames = "rows", colnames = "cols",
                  rowtypes = "rt", coltypes = "ct", matvals = "vals")

A

mat_to_rowcolval(A, rownames = "rows", colnames = "cols",
                 rowtypes = "rt", coltypes = "ct", matvals = "vals")

mat_to_rowcolval(A, rownames = "rows", colnames = "cols",
                 rowtypes = "rt", coltypes = "ct", matvals = "vals", drop = 0)

# This also works for single values

mat_to_rowcolval(2, matvals = "vals",
                 rownames = "rows", colnames = "cols",
                 rowtypes = "rt", coltypes = "ct")

mat_to_rowcolval(0, matvals = "vals",
                 rownames = "rows", colnames = "cols",
                 rowtypes = "rt", coltypes = "ct", drop = 0)
rowcolval_to_mat  
Collapse a tidy data frame into a matrix with named rows and columns

Description

Columns not specified in one of rownames, colnames, rowtype, coltype, or values are silently dropped. rowtypes and coltypes are added as attributes to the resulting matrix (via matsbyname::setrowtype() and matsbyname::setcoltype()). The resulting matrix is a (under the hood) a data frame. If both rownames and colnames columns of .DF contain NA, it is assumed that this is a single value, not a matrix, in which case the value in the values column is returned.

Usage

```r
rowcolval_to_mat(
  .DF,
  matvals = "matvals",
  rownames = "rownames",
  colnames = "colnames",
  rowtypes = "rowtypes",
  coltypes = "coltypes",
  fill = 0,
  matrix.class = lifecycle::deprecated(),
  matrix_class = c("matrix", "Matrix")
)
```

Arguments

- `.DF` [A tidy data frame containing columns for row names, column names, and values.]
- `matvals` The name of the column in `.DF` containing values with which to fill the matrix (a string). Default is "matvals".
- `rownames` The name of the column in `.DF` containing row names (a string). Default is "rownames".
- `colnames` The name of the column in `.DF` containing column names (a string). Default is "colnames".
- `rowtypes` An optional string identifying the types of information found in rows of the matrix to be constructed. Default is "rowtypes".
- `coltypes` An optional string identifying the types of information found in columns of the matrix to be constructed. Default is "coltypes".
- `fill` The value for missing entries in the resulting matrix. default is 0.
- `matrix.class` [Deprecated] Use `matrix_class` instead.
- `matrix_class` One of "matrix" or "Matrix". "matrix" creates a base::matrix object with the matrix() function. "Matrix" creates a Matrix::Matrix object using the matsbyname::Matrix() function. This could be a sparse matrix. Default is "matrix".
should_unlist

Tell whether a column can be unlisted

Description

When evaluating each row of a data frame in matsindf_apply(), the result will be a tibble with list columns. This function tells whether a column can be unlisted. This is internal helper function and should not be called externally.
should_unlist(this_col)

Arguments

this_col The column to be checked. Or a data.frame, in which case every column is checked.

Value

A boolean. TRUE if the column can be unlisted, FALSE otherwise. When this_col is a data.frame,
a named boolean vector, one entry for each column.

Description

Usage

UKEnergy2000

Format

A data frame with 36 rows and 7 variables:

Country country, GB (Great Britain, only one country)
Year year, 2000 (only one year)
Ledger.side Supply or Consumption
Flow.aggregation.point tells where each row should be aggregated
Flow the Industry or Sector involved in this flow
Product the energy product involved in this flow
E.ktoe magnitude of the energy flow in ktoe

Source

doi:10.1016/j.apenergy.2018.05.109
verify_cols_missing

Verify that column names in a data frame are not already present

Description

In the Recca package, many functions add columns to an existing data frame. If the incoming data frame already contains columns with the names of new columns to be added, a name collision could occur, deleting the existing column of data. This function provides a way to quickly check whether newcols are already present in .DF.

Usage

verify_cols_missing(.DF, newcols)

Arguments

.DF the data frame to which newcols are to be added
newcols a single string, a single name, a vector of strings representing the names of new columns to be added to .DF, or a vector of names of new columns to be added to .DF

Details

This function terminates execution if a column of .DF will be overwritten by one of the newcols.

Value

NULL. This function should be called for its side effect of checking the validity of the names of newcols to be added to .DF.

Examples

df <- data.frame(a = c(1,2), b = c(3,4))
verify_cols_missing(df, "d") # Silent. There will be no problem adding column "d".
newcols <- c("c", "d", "a", "b")
## Not run: verify_cols_missing(df, newcols) # Error: a and b are already in df.
where_to_get_args  Decide where to get each argument to FUN

Description

The precedence rules for where to obtain values for the FUN argument to matsindf_apply() are codified here. The rules are:

- Precedence order: ..., .dat, defaults arguments to FUN (highest priority to lowest priority).
- If an element of ... is a character string of length 1, the element of ... provides a mapping between an item in .dat (with same name as the value of the character string of length 1) to an argument of FUN (with the same name as the name of the character string of length 1).
- If the value of the character string of length 1 is not a name in .dat, the default arguments to FUN are checked in this order.
  - If the name of a default argument to FUN is the same as the value of the string of length 1 argument in ..., a mapping occurs.
  - If a mapping is not possible, the default arg to FUN is used directly.

Usage

where_to_get_args(.dat = NULL, FUN, ...)

Arguments

- .dat  The .dat argument to matsindf_apply().
- FUN  The FUN argument to matsindf_apply().
- ...  The ... argument to matsindf_apply().

Value

A named list wherein the names are the argument names to FUN. Values are character vectors with 2 elements. The first element is named source and provides the argument to matsindf_apply() from which the named argument should be found, one of ".dat", "FUN", or "...". The second element is named arg_name and provides the variable name or argument name in the source that contains the input data for the argument to FUN.

Examples

example_fun <- function(a = 1, b) {
  list(c = a + b, d = a - b)
}
# b is not available anywhere, likely causing an error later
matsindf:::where_to_get_args(FUN = example_fun)
# b is now available in ...
matsindf:::where_to_get_args(FUN = example_fun, b = 2)
# b is now available in .dat
matsindf:::where_to_get_args(list(b = 2), FUN = example_fun)
# b now comes from ..., because ... takes precedence over .dat
matsindf:::where_to_get_args(list(b = 2), FUN = example_fun, b = 3)

# Mapping from c in .dat to b in FUN
matsindf:::where_to_get_args(list(c = 2),
    FUN = example_fun, b = "c")

# Redirect from an arg in ... to a different default to FUN
matsindf:::where_to_get_args(FUN = example_fun, b = "a")

# b is found in FUN, not in .dat, because the mapping (b = "a")
# is not available in .dat
matsindf:::where_to_get_args(list(b = 2), FUN = example_fun, b = "a")
