Package ‘mcp’

March 17, 2024

Title  Regression with Multiple Change Points
Version 0.3.4
Date  2024-03-14
URL  https://lindeloev.github.io/mcp/
BugReports  https://github.com/lindeloev/mcp/issues

Description  Flexible and informed regression with Multiple Change Points. ‘mcp’ can infer change points in means, variances, autocorrelation structure, and any combination of these, as well as the parameters of the segments in between. All parameters are estimated with uncertainty and prediction intervals are supported - also near the change points. ‘mcp’ supports hypothesis testing via Savage-Dickey density ratio, posterior contrasts, and cross-validation. ‘mcp’ is described in Lindeløv (submitted) <doi:10.31219/osf.io/fzqxv> and generalizes the approach described in Carlin, Gelfand, & Smith (1992) <doi:10.2307/2347570> and Stephens (1994) <doi:10.2307/2986119>.

bernoulli

Bernoulli family for mcp

Description
Bernoulli family for mcp

Usage
bernoulli(link = "logit")

Arguments
  link        Link function.
**Description**

Takes an `mcpfit` as input and computes information criteria using loo or WAIC. Compare models using `loo_compare` and `loo_model_weights`. More in `loo`.

**Usage**

criterion(fit, criterion = "loo", ...)

```r
## S3 method for class 'mcpfit'
loo(x, ...)

## S3 method for class 'mcpfit'
waic(x, ...)
```

**Arguments**

- `fit`: An `mcpfit` object.
- `criterion`: One of "loo" (calls `loo`) or "waic" (calls `waic`).
- `...`: Currently ignored
- `x`: An `mcpfit` object.

**Value**

A `loo` or `psis_loo` object.

**Functions**

- `loo(mcpfit)`: Computes loo on mcpfit objects
- `waic(mcpfit)`: Computes WAIC on mcpfit objects

**Author(s)**

Jonas Kristoffer Lindeløv <jonas@lindeloev.dk>

**See Also**

criterion
criterion
Examples

```r
# Define two models and sample them
# options(mc.cores = 3)  # Speed up sampling
ex = mcp_example("intercepts")  # Get some simulated data.
model1 = list(y ~ 1 + x, ~ 1)
model2 = list(y ~ 1 + x)  # Without a change point
fit1 = mcp(model1, ex$data)
fit2 = mcp(model2, ex$data)

# Compute LOO for each and compare (works for waic(fit) too)
fit1$loo = loo(fit1)
fit2$loo = loo(fit2)
loo::loo_compare(fit1$loo, fit2$loo)
```

demo_fit  

Example mcpfit for examples

Description

This was generated using mcp_examples("demo", sample = TRUE).

Usage

demo_fit

Format

An mcpfit object.

exponential  

Exponential family for mcp

Description

Exponential family for mcp

Usage

exponential(link = "identity")

Arguments

link  
Link function (Character).
Description

Expected Values from the Posterior Predictive Distribution

Usage

```r
## S3 method for class 'mcpfit'
fitted(
  object,
  newdata = NULL,
  summary = TRUE,
  probs = TRUE,
  rate = TRUE,
  prior = FALSE,
  which_y = "ct",
  varying = TRUE,
  arma = TRUE,
  nsamples = NULL,
  samples_format = "tidy",
  scale = "response",
  ...
)
```

Arguments

- `object`: An `mcpfit` object.
- `newdata`: A `tibble` or a `data.frame` containing predictors in the model. If `NULL` (default), the original data is used.
- `summary`: Summarise at each x-value
- `probs`: Vector of quantiles. Only in effect when `summary == TRUE`.
- `rate`: Boolean. For binomial models, plot on raw data (`rate = FALSE`) or response divided by number of trials (`rate = TRUE`). If `FALSE`, linear interpolation on trial number is used to infer trials at a particular x.
- `prior`: TRUE/FALSE. Plot using prior samples? Useful for `mcp(..., sample = "both")`
- `which_y`: What to plot on the y-axis. One of
  - "ct": The central tendency which is often the mean after applying the link function.
  - "sigma": The variance
  - "ar1", "ar2", etc. depending on which order of the autoregressive effects you want to plot.
- `varying`: One of:
fitted.mcpfit

- TRUE All varying effects (fit$pars$varying).
- FALSE No varying effects (c()).
- Character vector: Only include specified varying parameters - see fit$pars$varying.

arma
Whether to include autoregressive effects.
- TRUE Compute autoregressive residuals. Requires the response variable in newdata.
- FALSE Disregard the autoregressive effects. For family = gaussian(), predict() just use sigma for residuals.

nsamples
Integer or NULL. Number of samples to return/summarise. If there are varying effects, this is the number of samples from each varying group. NULL means "all". Ignored if both are FALSE. More samples trade speed for accuracy.

samples_format
One of "tidy" or "matrix". Controls the output format when summary == FALSE. See more under "value"

scale
One of
- "response": return on the observed scale, i.e., after applying the inverse link function.
- "linear": return on the parameter scale (where the linear trends are modelled).

... Currently unused

Value

- If summary = TRUE: A tibble with the posterior mean for each row in newdata. If newdata is NULL, the data in fit$data is used.
- If summary = FALSE and samples_format = "tidy": A tidybayes tibble with all the posterior samples (Ns) evaluated at each row in newdata (Nn), i.e., with Ns x Nn rows. If there are varying effects, the returned data is expanded with the relevant levels for each row.
  The return columns are:
  - Predictors from newdata.
  - Sample descriptors: ".chain", ".iter", ".draw" (see the tidybayes package for more), and "data_row" (newdata rownumber)
  - Sample values: one column for each parameter in the model.
  - The estimate. Either "predict" or "fitted", i.e., the name of the type argument.
- If summary = FALSE and samples_format = "matrix": An N_draws X nrows(newdata) matrix with fitted/predicted values (depending on type). This format is used by brms and it's useful as yrep in bayesplot::ppc_* functions.

hypothesis

Examples

```r
fitted(demo_fit)
fitted(demo_fit, probs = c(0.1, 0.5, 0.9)) # With median and 80% credible interval.
fitted(demo_fit, summary = FALSE) # Samples instead of summary.
fitted(demo_fit,
    newdata = data.frame(time = c(-5, 20, 300)), # New data
    probs = c(0.025, 0.5, 0.975))
```

---

hypothesis

**Test hypotheses on mcp objects.**

Description

Returns posterior probabilities and Bayes Factors for flexible hypotheses involving model parameters. The documentation for the argument `hypotheses` below shows examples of how to specify hypotheses, and read worked examples on the mcp website. For directional hypotheses, `hypothesis` executes the hypothesis string in a `tidybayes` environment and summarises the proportion of samples where the expression evaluates to TRUE. For equals-hypothesis, a Savage-Dickey ratio is computed. Savage-Dickey requires a prior too, so remember `mcp(..., sample = "both")`. This function is heavily inspired by the 'hypothesis' function from the 'brms' package.

Usage

```r
hypothesis(fit, hypotheses, width = 0.95, digits = 3)
```

Arguments

- **fit**: An `mcpfit` object.
- **hypotheses**: String representation of a logical test involving model parameters. Takes R code that evaluates to TRUE or FALSE in a vectorized way. Directional hypotheses are specified using `<`, `>`, `<=`, or `>=`. `hypothesis` returns the posterior probability and odds in favor of the stated hypothesis. The odds can be interpreted as a Bayes Factor. For example:
  - "cp_1 > 30": the first change point is above 30.
  - "int_1 > int_2": the intercept is greater in segment 1 than 2.
  - "x_2 - x_1 <= 3": the difference between slope 1 and 2 is less than or equal to 3.
  - "int_1 > -2 & int_1 < 2": int_1 is between -2 and 2 (an interval hypothesis). This can be useful as a Region Of Practical Equivalence test (ROPE).
  - "cp_1^2 < 30 | (log(x_1) + log(x_2)) > 5": be creative.
  - "\`cp_1_id[1]\` > \`cp_1_id[2]\``": id1 is greater than id2, as estimated through the varying-by-"id" change point in segment 1. Note that `\` required for varying effects.
Hypotheses can also test equality using the equal sign (=). This runs a Savage-Dickey test, i.e., the proportion by which the probability density has increased from the prior to the posterior at a given value. Therefore, it requires mcp(sample = "both"). There are two requirements: First, there can only be one equal sign, so don’t use and (\&) or or (|). Second, the point to test has to be on the right, and the variables on the left.

- "cp_1 = 30": is the first change point at 30? Or to be more precise: by what factor has the credence in cp_1 = 30 risen/fallen when conditioning on the data, relative to the prior credence?
- "int_1 + int_2 = 0": Is the sum of two intercepts zero?
- "cp_1_id[John]/cp_1_id[Erin] = 2": is the varying change point for John (which is relative to 'cp_1") double that of Erin?

width
Float. The width of the highest posterior density interval (between 0 and 1).
digits
A non-null value for digits specifies the minimum number of significant digits to be printed in values. The default, NULL, uses getOption("digits"). (For the interpretation for complex numbers see signif.) Non-integer values will be rounded down, and only values greater than or equal to 1 and no greater than 22 are accepted.

Value
A data.frame with a row per hypothesis and the following columns:
- hypothesis is the hypothesis; often re-arranged to test against zero.
- mean is the posterior mean of the left-hand side of the hypothesis.
- lower is the lower bound of the (two-sided) highest-density interval of width width.
- upper is the upper bound of ditto.
- p Posterior probability. For "=" (Savage-Dickey), it is the BF converted to p. For directional hypotheses, it is the proportion of samples that returns TRUE.
- BF Bayes Factor in favor of the hypothesis. For "=" it is the Savage-Dickey density ratio. For directional hypotheses, it is p converted to odds.

ilogit
Inverse logit function

Description
Inverse logit function

Usage
ilogit(eta)
**is.mcpfit**

**Arguments**
- `eta` A vector of logits

**Value**
A vector with same length as `eta`

---

**is.mcpfit** *Checks if argument is an mcpfit object*

**Description**
Checks if argument is an mcpfit object

**Usage**

```r
is.mcpfit(x)
```

**Arguments**
- `x` An R object.

---

**logit** *Logit function*

**Description**
Logit function

**Usage**

```r
logit(mu)
```

**Arguments**
- `mu` A vector of probabilities (0.0 to 1.0)

**Value**
A vector with same length as `mu`
mcp

**Fit Multiple Linear Segments And Their Change Points**

**Description**

Given a model (a list of segment formulas), mcp infers the posterior distributions of the parameters of each segment as well as the change points between segments. See more details and worked examples on the mcp website. All segments must regress on the same x-variable. Change points are forced to be ordered using truncation of the priors. You can run `fit = mcp(model, sample=FALSE)` to avoid sampling and the need for data if you just want to get the priors (`fit$prior`), the JAGS code `fit$jags_code`, or the R function to simulate data (`fit$simulate`).

**Usage**

```r
mcp(
    model, data = NULL, prior = list(), family = gaussian(), par_x = NULL,
    sample = "post", cores = 1, chains = 3, iter = 3000, adapt = 1500,
    inits = NULL, jags_code = NULL)
```

**Arguments**

- **model**
  A list of formulas - one for each segment. The first formula has the format `response ~ predictors` while the following formulas have the format `response ~ changepoint ~ predictors`. The response and change points can be omitted (`changepoint ~ predictors` assumes same response. ~ predictors assumes an intercept-only change point). The following can be modeled:
  - *Regular formulas*: e.g., `~ 1 + x`). Read more.
  - *Extended formulas*: e.g., `~ I(x^2) + exp(x) + sin(x)`. Read more.
  - *Variance*: e.g., `~sigma(1)` for a simple variance change or `~sigma(re1(1) + I(x^2))` for more advanced variance structures. Read more
  - *Autoregression*: e.g., `~ar(1)` for a simple onset/change in AR(1) or `ar(2, 0 + x)` for an AR(2) increasing by x. Read more

- **data**
  Data.frame or tibble in long format.

- **prior**
  Named list. Names are parameter names (`cp_i`, `int_i`, `xvar_i`, `sigma`) and the values are either
A JAGS distribution (e.g., \( \text{int}_1 = \text{dnorm}(\theta, 1) \text{T}(\theta, ) \)) indicating a conventional prior distribution. Uninformative priors based on data properties are used where priors are not specified. This ensures good parameter estimates, but it is questionable for hypothesis testing. \texttt{mcp} uses SD (not precision) for \texttt{dnorm}, \texttt{dt}, \texttt{dlogis}, etc. See details. Change points are forced to be ordered through the priors using truncation, except for uniform priors where the lower bound should be greater than the previous change point, \texttt{dunif(cp_1, MAXX)}.

A numerical value (e.g., \( \text{int}_1 = -2.1 \)) indicating a fixed value.

A model parameter name (e.g., \( \text{int}_2 = \text{"int}_1\text{"} \)), indicating that this parameter is shared - typically between segments. If two varying effects are shared this way, they will need to have the same grouping variable.

A scaled Dirichlet prior is supported for change points if they are all set to \( \text{cp}_i = \text{"dirichlet}(N) \) where \( N \) is the alpha for this change point and \( N = 1 \) is most often used. This prior is less informative about the location of the change points than the default uniform prior, but it samples less efficiently, so you will often need to set \texttt{iter} higher. It is recommended for hypothesis testing and for the estimation of more than 5 change points. Read more.

**family**

One of \texttt{gaussian()}, \texttt{binomial()}, \texttt{bernoulli()}, or \texttt{poission()}. Only default link functions are currently supported.

**par_x**

String (default: NULL). Only relevant if no segments contain slope (no hint at what \( x \) is). Set this, e.g., \texttt{par_x = "time"}.

**sample**

One of

- "post": Sample the posterior.
- "prior": Sample only the prior. Plots, summaries, etc. will use the prior. This is useful for prior predictive checks.
- "both": Sample both prior and posterior. Plots, summaries, etc. will default to using the posterior. The prior only has effect when doing Savage-Dickey density ratios in \texttt{hypothesis}.
- "none" or \texttt{FALSE}: Do not sample. Returns an \texttt{mcpfit} object without sample. This is useful if you only want to check prior strings (\texttt{fit$sprior}), the JAGS model (\texttt{fit$jags_code}), etc.

**cores**

Positive integer or "all". Number of cores.

- 1: serial sampling. \texttt{options(mc.cores = 3)} will dominate \texttt{cores = 1} but not larger values of cores.
- >1: parallel sampling on this number of cores. Ideally set \texttt{chains} to the same value. Note: \texttt{cores > 1} takes a few extra seconds the first time it's called but subsequent calls will start sampling immediately.
- "all": use all cores but one and sets \texttt{chains} to the same value. This is a convenient way to maximally use your computer's power.

**chains**

Positive integer. Number of chains to run.

**iter**

Positive integer. Number of post-warmup draws from each chain. The total number of draws is \texttt{iter} * \texttt{chains}.

**adapt**

Positive integer. Also sometimes called "burnin", this is the number of samples used to reach convergence. Set lower for greater speed. Set higher if the chains haven’t converged yet or look at \texttt{tips, tricks, and debugging}. 
inits

A list if initial values for the parameters. This can be useful if a model fails to converge. Read more in \texttt{jags.model}. Defaults to \texttt{NULL}, i.e., no inits.

\texttt{jags_code}

String. Pass JAGS code to \texttt{mcp} to use directly. This is useful if you want to tweak the code in \texttt{fit\$jags_code} and run it within the \texttt{mcp} framework.

Details

Notes on priors:

- Order restriction is automatically applied to \texttt{cp\_\*} parameters using truncation (e.g., $\mathcal{T}(cp_1, )$) so that they are in the correct order on the x-axis UNLESS you do it yourself. The one exception is for dunif distributions where you have to do it as above.

- In addition to the model parameters, MINX (minimum x-value), MAXX (maximum x-value), SDX (etc...), MINY, MAXY, and SDY are also available when you set priors. They are used to set uninformative default priors.

- Use SD when you specify priors for dt, dlogis, etc. JAGS uses precision but \texttt{mcp} converts to precision under the hood via the \texttt{sd_to_prec()} function. So you will see SDs in \texttt{fit\$prior} but precision ($1/SD^2$) in \texttt{fit\$jags_code}

Value

An \texttt{mcpfit} object.

**mcpfit-class**

*a class mcpfit of models fitted with the mcp package*

**Description**

Models fitted with the `mcp` function are represented as an `mcpfit` object which contains the user input (model, data, family), derived model characteristics (prior, parameter names, and JAGS code), and the fit (prior and/or posterior mcmc samples).
mcp_example

Details

See methods(class = "mcpfit") for an overview of available methods.

User-provided information (see mcp for more details):

Slots

model A list of formulas, making up the model. Provided by user. See mcp for more details.
data A data frame. Provided by user. See mcp for more details.
family An mcpfamily object. Provided by user. See mcp for more details.
prior A named list. Provided by user. See mcp for more details.
mcmc_post An mcmc.list object with posterior samples.
mcmc_prior An mcmc.list object with prior samples.
mcmc_loglik An mcmc.list object with samples of log-likelihood.
pars A list of character vectors of model parameter names.
jags_code A string with jags code. Use cat(fit$jags_code) to show it.
simulate A method to simulate and predict data.
.other Information that is used internally by mcp.

mcp_example Get example models and data

Description

Get example models and data

Usage

mcp_example(name, sample = FALSE)

Arguments

name Name of the example. One of:

- "demo": Two change points between intercepts and joined/disjoined slopes.
- "ar": One change point in autoregressive residuals.
- "binomial": Binomial with two change points. Much like "demo" on a logit scale.
- "intercepts": An intercept-only change point.
- rel_prior: Relative parameterization and informative priors.
- "quadratic": A change point to a quadratic segment.
- "trigonometric": Trigonometric/seasonal data and model.
- "varying": Varying / hierarchical change points.
- "variance": A change in variance, including a variance slope.

sample TRUE (run fit = mcp(model, data, ...)) or FALSE.
Value

List with

- model: A list of formulas
- data: The simulated data
- simulated: The parameters used for simulating the data.
- fit: an mcpfit if sample = TRUE,
- call: the code to run the above.

Author(s)

Jonas Kristoffer Lindeløv <jonas@lindeloev.dk>

Examples

```r
ex = mcp_example("demo")
plot(ex$data)  # Plot data
print(ex$simulated)  # See true parameters used to simulate
print(ex$call)  # See how the data was simulated

# Fit the model. Either...
fit = mcp(ex$model, ex$data)
plot(fit)

ex_with_fit = mcp_example("demo", sample = TRUE)
plot(ex_with_fit$fit)
```

Description

Parameterized as \( \mu \) (mean; poisson lambda) and size (a shape parameter), so you can do `rnorm(10, mu = 10, size = 1)`. Read more in the doc for `rnorm`.

Usage

```r
negbinomial(link = "log")
```

Arguments

- link Link function (Character).
**phi**

*Inverse probit function*

**Description**

Inverse probit function

**Usage**

\[
\phi(\eta)
\]

**Arguments**

- \( \eta \)  
  A vector of probits

**Value**

A vector with same length as \( \mu \)

---

**plot.mcpfit**

*Plot full fits*

**Description**

Plot prior or posterior model draws on top of data. Use `plot_pars` to plot individual parameter estimates.

**Usage**

```r
## S3 method for class 'mcpfit'
plot(
  x,
  facet_by = NULL,
  lines = 25,
  geom_data = "point",
  cp_dens = TRUE,
  q_fit = FALSE,
  q_predict = FALSE,
  rate = TRUE,
  prior = FALSE,
  which_y = "ct",
  arma = TRUE,
  nsamples = 2000,
  scale = "response",
  ...
)
```
Arguments

**x**
An mcpfit object

**facet_by**
String. Name of a varying group.

**lines**
Positive integer or FALSE. Number of lines (posterior draws). FALSE or lines = 0 plots no lines. Note that lines always plot fitted values - not predicted. For prediction intervals, see the q_predict argument.

**geom_data**
String. One of "point", "line" (good for time-series), or FALSE (don not plot).

**cp_dens**
TRUE/FALSE. Plot posterior densities of the change point(s)? Currently does not respect facet_by. This will be added in the future.

**q_fit**
Whether to plot quantiles of the posterior (fitted value).
  - TRUE Add 2.5% and 97.5% quantiles. Corresponds to q_fit = c(0.025, 0.975).
  - FALSE No quantiles
  - A vector of quantiles. For example, quantiles = 0.5 plots the median and quantiles = c(0.2, 0.8) plots the 20% and 80% quantiles.

**q_predict**
Same as q_fit, but for the prediction interval.

**rate**
Boolean. For binomial models, plot on raw data (rate = FALSE) or response divided by number of trials (rate = TRUE). If FALSE, linear interpolation on trial number is used to infer trials at a particular x.

**prior**
TRUE/FALSE. Plot using prior samples? Useful for mcp(..., sample = "both")

**which_y**
What to plot on the y-axis. One of
  - "ct": The central tendency which is often the mean after applying the link function.
  - "sigma": The variance
  - "ar1", "ar2", etc. depending on which order of the autoregressive effects you want to plot.

**arma**
Whether to include autoregressive effects.
  - TRUE Compute autoregressive residuals. Requires the response variable in newdata.
  - FALSE Disregard the autoregressive effects. For family = gaussian(), predict() just use sigma for residuals.

**nsamples**
Integer or NULL. Number of samples to return/summarise. If there are varying effects, this is the number of samples from each varying group. NULL means "all". Ignored if both are FALSE. More samples trade speed for accuracy.

**scale**
One of
  - "response": return on the observed scale, i.e., after applying the inverse link function.
  - "linear": return on the parameter scale (where the linear trends are modelled).

... Currently ignored.
plot_pars

Plot individual parameters

Description

Plot many types of plots of parameter estimates. See examples for typical use cases.

Usage

```r
plot_pars(
  fit,
  pars = "population",
  regex_pars = character(0),
  type = "combo",
  ncol = 1,
  prior = FALSE
)
```
Arguments

fit An mcpfit object.

pars Character vector. One of:

- Vector of parameter names.
- "population" plots all population parameters.
- "varying" plots all varying effects. To plot a particular varying effect, use regex_pars = "^name".

regex_pars Vector of regular expressions. This will typically just be the beginning of the parameter name(s), i.e., "^cp_" plots all change points, "^my_varying" plots all levels of a particular varying effect, and "^cp_"^my_varying" plots both.

type String or vector of strings. Calls bayesplot::mcmc_type(). Common calls are "combo", "trace", and "dens_overlay". Current options include 'acf', 'acf_bar', 'areas', 'areas_ridges', 'combo', 'dens', 'dens_chains', 'dens_overlay', 'hist', 'intervals', 'rank_hist', 'rank_overlay', 'trace', 'trace_highlight', and 'violin'.

ncol Number of columns in plot. This is useful when you have many parameters and only one plot type.

prior TRUE/FALSE. Plot using prior samples? Useful for mcp(..., sample = "both")

Details

For other type, it calls bayesplot::mcmc_type(). Use these directly on fit$mcmc_post or fit$mcmc_prior if you want finer control of plotting, e.g., bayesplot::mcmc_dens(fit$mcmc_post).

There are also a number of useful plots in the coda package, i.e., coda::gelman.plot(fit$mcmc_post) and coda::crosscorr.plot(fit$mcmc_post).

In any case, if you see a few erratic lines or parameter estimates, this is a sign that you may want to increase argument 'adapt' and 'iter' in mcp.

Value

A ggplot2 object.

Author(s)

Jonas Kristoffer Lindeløv <jonas@lindeloev.dk>

Examples

# Typical usage. demo_fit is an mcpfit object.
plot_pars(demo_fit)

## Not run:
# More options
plot_pars(demo_fit, regex_pars = "^cp_") # Plot only change points
plot_pars(demo_fit, pars = c("int_3", "time_3")) # Plot these parameters
plot_pars(demo_fit, type = c("trace", "violin")) # Combine plots
# Some plots only take pairs. hex is good to assess identifiability

```r
plot_pars(demo_fit, type = "hex", pars = c("cp_1", "time_2"))

# Visualize the priors:
plot_pars(demo_fit, prior = TRUE)

# Useful for varying effects:
# plot_pars(my_fit, pars = "varying", ncol = 3) # plot all varying effects
# plot_pars(my_fit, regex_pars = "my_varying", ncol = 3) # plot all levels of a particular varying

# Customize multi-column ggplots using "x" instead of "+" (patchwork)
library(ggplot2)
plot_pars(demo_fit, type = c("trace", "dens_overlay")) * theme_bw(10)

## End(Not run)
```

### pp_check

**Posterior Predictive Checks For Mcpfit Objects**

**Description**

Plot posterior (default) or prior (prior = TRUE) predictive checks. This is convenience wrapper around the `bayesplot::ppc_*()` methods.

**Usage**

```r
pp_check(
  object, 
  type = "dens_overlay", 
  facet_by = NULL, 
  newdata = NULL, 
  prior = FALSE, 
  varying = TRUE, 
  arma = TRUE, 
  nsamples = 100, 
  ...
)
```

**Arguments**

- `object` An `mcpfit` object.
- `type` One of `bayesplot::available_ppc("grouped", invert = TRUE) %>% stringr::str_remove("ppc_`)
- `facet_by` Name of a column in data modeled as varying effect(s).
- `newdata` A `tibble` or a `data.frame` containing predictors in the model. If NULL (default), the original data is used.
- `prior` TRUE/FALSE. Plot using prior samples? Useful for `mcp(..., sample = "both")`
- `varying` One of:
predict.mcpfit

Description

Samples from the Posterior Predictive Distribution

Examples

pp_check(demo_fit)
pp_check(demo_fit, type = "ecdf_overlay")
# pp_check(some_varying_fit, type = "loo_intervals", facet_by = "id")
Usage

```r
## S3 method for class 'mcpfit'
predict(
  object,
  newdata = NULL,
  summary = TRUE,
  probs = TRUE,
  rate = TRUE,
  prior = FALSE,
  which_y = "ct",
  varying = TRUE,
  arma = TRUE,
  nsamples = NULL,
  samples_format = "tidy",
  ...
)
```

Arguments

- **object**: An `mcpfit` object.
- **newdata**: A `tibble` or a `data.frame` containing predictors in the model. If `NULL` (default), the original data is used.
- **summary**: Summarise at each x-value.
- **probs**: Vector of quantiles. Only in effect when `summary == TRUE`.
- **rate**: Boolean. For binomial models, plot on raw data (`rate = FALSE`) or response divided by number of trials (`rate = TRUE`). If `FALSE`, linear interpolation on trial number is used to infer trials at a particular x.
- **prior**: TRUE/FALSE. Plot using prior samples? Useful for `mcp(..., sample = "both")`.
- **which_y**: What to plot on the y-axis. One of
  - "ct": The central tendency which is often the mean after applying the link function.
  - "sigma": The variance.
  - "ar1", "ar2", etc. depending on which order of the autoregressive effects you want to plot.
- **varying**: One of:
  - TRUE All varying effects (fit$pars$varying).
  - FALSE No varying effects (c()).
  - Character vector: Only include specified varying parameters - see `fit$pars$varying`.
- ** arma**: Whether to include autoregressive effects.
  - TRUE Compute autoregressive residuals. Requires the response variable in `newdata`.
  - FALSE Disregard the autoregressive effects. For `family = gaussian()`, `predict()` just use `sigma` for residuals.
nsamples  Integer or NULL. Number of samples to return/summarise. If there are varying effects, this is the number of samples from each varying group. NULL means "all". Ignored if both are FALSE. More samples trade speed for accuracy.
samples_format One of "tidy" or "matrix". Controls the output format when summary == FALSE. See more under "value"
...

Value

- If summary = TRUE: A tibble with the posterior mean for each row in newdata, If newdata is NULL, the data in fit$data is used.
- If summary = FALSE and samples_format = "tidy": A tidybayes tibble with all the posterior samples (Ns) evaluated at each row in newdata (Nn), i.e., with Ns x Nn rows. If there are varying effects, the returned data is expanded with the relevant levels for each row.

The return columns are:
  - Predictors from newdata.
  - Sample descriptors: ".chain", ".iter", ".draw" (see the tidybayes package for more), and ".data_row" (newdata rownumber)
  - Sample values: one column for each parameter in the model.
  - The estimate. Either "predict" or "fitted", i.e., the name of the type argument.
- If summary = FALSE and samples_format = "matrix": An N_draws X nrows(newdata) matrix with fitted/predicted values (depending on type). This format is used by brms and it's useful as yrep in bayesplot::ppc_* functions.

pp_eval fitted.mcpfit residuals.mcpfit

Examples

```r
predict(demo_fit)  # Evaluate at each demo_fit$data
predict(demo_fit, probs = c(0.1, 0.5, 0.9))  # With median and 80% credible interval.
predict(demo_fit, summary = FALSE)  # Samples instead of summary.
predict(
  demo_fit,
  newdata = data.frame(time = c(-5, 20, 300)),  # Evaluate
  probs = c(0.025, 0.5, 0.975)
)```
print.mcplist  

**Print mcplist**

Description

Shows a list in a more condensed format using `str(list)`.

Usage

```r
## S3 method for class 'mcplist'
print(x, ...)
```

Arguments

- `x` An `mcpfit` object.
- `...` Currently ignored

Author(s)

Jonas Kristoffer Lindeløv <jonas@lindeloev.dk>

print.mcptext  

**Nice printing texts**

Description

Useful for `print(fit$jags_code), print(mcp_demo$call),` etc.

Usage

```r
## S3 method for class 'mcptext'
print(x, ...)
```

Arguments

- `x` Character, often with newlines.
- `...` Currently ignored.

Author(s)

Jonas Kristoffer Lindeløv <jonas@lindeloev.dk>

Examples

```r
mytext = "line1 = 2\n line2 = 'horse'
class(mytext) = "mcptext"
print(mytext)
```
probit

Description
Probit function

Usage
probit(mu)

Arguments
mu A vector of probabilities (0.0 to 1.0)

Value
A vector with same length as mu

residuals.mcpfit Compute Residuals From Mcpfit Objects

Description
Equivalent to fitted(fit, ...) - fit$data[, fit$data$yvar](or fitted(fit, ...) - newdata[, fit$data$yvar]), but with fixed arguments for fitted: rate = FALSE, which_y = 'ct', samples_format = 'tidy'.

Usage
## S3 method for class 'mcpfit'
residuals(
  object,
  newdata = NULL,
  summary = TRUE,
  probs = TRUE,
  prior = FALSE,
  varying = TRUE,
  arma = TRUE,
  nsamples = NULL,
  ...
)
Arguments

object  An mcpfit object.
newdata  A tibble or a data.frame containing predictors in the model. If NULL (default), the original data is used.
summary  Summarise at each x-value
probs  Vector of quantiles. Only in effect when summary == TRUE.
prior  TRUE/FALSE. Plot using prior samples? Useful for mcp(..., sample = "both")
varying  One of:
  • TRUE All varying effects (fit$pars$varying).
  • FALSE No varying effects (c()).
  • Character vector: Only include specified varying parameters - see fit$pars$varying.
arma  Whether to include autoregressive effects.
  • TRUE Compute autoregressive residuals. Requires the response variable in newdata.
  • FALSE Disregard the autoregressive effects. For family = gaussian(), predict() just use sigma for residuals.
nsamples  Integer or NULL. Number of samples to return/summarise. If there are varying effects, this is the number of samples from each varying group. NULL means "all". Ignored if both are FALSE. More samples trade speed for accuracy.

pp_eval fitted.mcpfit predict.mcpfit

Examples

residuals(demo_fit)
residuals(demo_fit, probs = c(0.1, 0.5, 0.9))  # With median and 80% credible interval.
residuals(demo_fit, summary = FALSE)  # Samples instead of summary.
sd_to_prec

Transform a prior from SD to precision.

Description

JAGS uses precision rather than SD. This function converts \( \text{dnorm}(4.2, 1.3) \) into \( \text{dnorm}(4.2, 1/1.3^2) \). It allows users to specify priors using SD and then it’s transformed for the JAGS code. It works for the following distributions: \( \text{dnorm|dt|dcauchy|ddexp|dlogis|dlnorm} \). In all of these, \( \tau/sd \) is the second parameter.

Usage

sd_to_prec(prior_str)

Arguments

prior_str String. A JAGS prior. Can be truncated, e.g. \( \text{dt}(3, 2, 1) \ T(my\_var, ) \).

Value

A string

Author(s)

Jonas Kristoffer Lindeløv <jonas@lindeloev.dk>

summary.mcpfit

Summarise mcpfit objects

Description

Summarise parameter estimates and model diagnostics.

Usage

## S3 method for class 'mcpfit'
summary(object, width = 0.95, digits = 2, prior = FALSE, ...)

dfixef(object, width = 0.95, prior = FALSE, ...)

dranef(object, width = 0.95, prior = FALSE, ...)

## S3 method for class 'mcpfit'
print(x, ...)
Arguments

object
An mcpfit object.

width
Float. The width of the highest posterior density interval (between 0 and 1).

digits
A non-null value for digits specifies the minimum number of significant digits to be printed in values. The default, NULL, uses getOption("digits"). (For the interpretation for complex numbers see signif.) Non-integer values will be rounded down, and only values greater than or equal to 1 and no greater than 22 are accepted.

prior
TRUE/FALSE. Summarise prior instead of posterior?

... Currently ignored

x
An mcpfit object.

Value

A data frame with parameter estimates and MCMC diagnostics. OBS: The change point distributions are often not unimodal and symmetric so the intervals can be deceiving Plot them using plot_pars(fit).

- mean is the posterior mean
- lower is the lower quantile of the highest-density interval (HDI) given in width.
- upper is the upper quantile.
- Rhat is the Gelman-Rubin convergence diagnostic which is often taken to be acceptable if < 1.1. It is computed using gelman.diag.
- n.eff is the effective sample size computed using effectiveSize. Low effective sample sizes are also obvious as poor mixing in trace plots (see plot_pars(fit)). Read how to deal with such problems here
- ts_err is the time-series error, taking autoregressive correlation into account. It is computed using spectrum0.ar.

For simulated data, the summary contains two additional columns so that it is easy to inspect whether the model can recover the parameters. Run simulation and summary multiple times to get a sense of the robustness.

- sim is the value used to generate the data.
- match is "OK" if sim is contained in the HDI interval (lower to upper).

Functions

- fixef(): Get population-level ("fixed") effects of an mcpfit object.
- ranef(): Get varying ("random") effects of an mcpfit object.
- print(mcpfit): Print the posterior summary of an mcpfit object.

Author(s)

Jonas Kristoffer Lindeløv <jonas@lindeloev.dk>
Examples

# Typical usage
summary(demo_fit)
summary(demo_fit, width = 0.8, digits = 4)  # Set HDI width

# Get the results as a data frame
results = summary(demo_fit)

# Varying (random) effects
# ranef(my_fit)

# Summarise prior
summary(demo_fit, prior = TRUE)
