Package ‘metamisc’

November 10, 2019

Type Package

Title Diagnostic and Prognostic Meta-Analysis

Version 0.2.2

Date 2019-11-08

Description Meta-analysis of diagnostic and prognostic modeling studies. Summarize estimates of prognostic factors, diagnostic test accuracy and prediction model performance. Validate, update and combine published prediction models. Develop new prediction models with data from multiple studies.

Imports metafor (>= 2.0.0), mvtnorm, lme4, plyr, methods, pROC, ggplot2

Depends R (>= 3.5.0), stats, graphics

Suggests runjags, rjags, logistf (>= 1.23), testthat (>= 1.0.2)

License GPL-3

URL http://r-forge.r-project.org/projects/metamisc/

RoxygenNote 6.1.1

Description

Details

The following functionality is currently implemented: univariate meta-analysis of summary data \texttt{(uvmeta)}, bivariate meta-analysis of correlated outcomes \texttt{(riley)}, meta-analysis of prediction model performance \texttt{(valmeta)}, evaluation of funnel plot asymmetry \texttt{(fat)}.

The \texttt{metamisc} package also provides a comprehensive framework for developing prediction models when patient-level data from multiple studies or settings are available \texttt{(metapred)}.

**ccalc**

*Calculate the concordance statistic*

**Description**

The function calculates (transformed versions of) the concordance (c-) statistic with the corresponding sampling variance.

**Usage**

```r
ccalc(cstat, cstat.se, cstat.cilb, cstat.ciub, cstat.cilv, sd.LP, N, O, Po, data, slab, subset, g = NULL, level = 0.95, approx.se.method = 4, ...)
```

**Arguments**

- `cstat`: vector to specify the estimated c-statistics.
- `cstat.se`: Optional vector to specify the corresponding standard errors.
- `cstat.cilb`: Optional vector to specify the lower limits of the confidence interval.
- `cstat.ciub`: Optional vector to specify the upper limits of the confidence interval.
- `cstat.cilv`: Optional vector to specify the levels of aforementioned confidence interval limits. (default: 0.95, which corresponds to the 95% confidence interval).
- `sd.LP`: Optional vector to specify the standard deviations of the linear predictor (prognostic index).
- `N`: Optional vector to specify the sample/group sizes.
- `O`: Optional vector to specify the total number of observed events.
- `Po`: Optional vector to specify the observed event probabilities.
- `data`: Optional data frame containing the variables given to the arguments above.
- `slab`: Optional vector with labels for the studies.
- `subset`: Optional vector indicating the subset of studies that should be used. This can be a logical vector or a numeric vector indicating the indices of the studies to include.
- `g`: a quoted string that is the function to transform estimates of the c-statistic; see the details below.
- `level`: Optional numeric to specify the level for the confidence interval, default 0.95.
- `approx.se.method`: integer specifying which method should be used for estimating the standard error of the c-statistic (Newcombe, 2006). So far, only method 2 and method 4 (default) have been implemented.
- `...`: Additional arguments.
Details

The c-statistic is a measure of discrimination, and indicates the ability of a prediction model to distinguish between patients developing and not developing the outcome. The c-statistic typically ranges from 0.5 (no discriminative ability) to 1 (perfect discriminative ability).

By default, the function `ccalc` will derive the c-statistic of each study, together with the corresponding standard error and 95% confidence interval. However, it is also possible to calculate transformed versions of the c-statistic. Appropriate standard errors are then derived using the Delta method. For instance, the logit transformation can be applied by specifying `g=log(cstat/(1-cstat))`.

**Restoring the c-statistic:** For studies where the c-statistic is missing, it is estimated from the standard deviation of the linear predictor (`theta.source="std.dev(LP)"`). The corresponding method is described by White et al. (2015).

**Restoring the standard error of the c-statistic:** When missing, the standard error of the c-statistic can be estimated from the confidence interval. Alternatively, the standard error can be approximated from a combination of the reported c-statistic, the total sample size and the total number of events (Newcombe, 2006). This can be achieved by adopting (a modification of) the method proposed by Hanley and McNeil, as specified in `approx.se.method`.

Value

An object of class c("mm_perf","data.frame") with the following columns:

"theta"  The (transformed) c-statistics.
"theta.se" Standard errors of the (transformed) c-statistics.
"theta.cilb" Lower confidence interval of the (transformed) c-statistics. The level is specified in `level`. Intervals are calculated on the same scale as `theta` by assuming a Normal distribution.
"theta.ciub" Upper confidence interval of the (transformed) c-statistics. The level is specified in `level`. Intervals are calculated on the same scale as `theta` by assuming a Normal distribution.
"theta.source" Method used for calculating the (transformed) c-statistic.
"theta.se.source" Method used for calculating the standard error of the (transformed) c-statistic.

est2

# Display the results of all studies in a forest plot
plot(est1)
```

---

**Collins**

**Collins data**

**Description**

A meta-analysis of nine clinical trials investigating the effect of taking diuretics during pregnancy on the risk of pre-eclampsia.

**Usage**

```
data(Collins)
```

**Format**

A data frame with 9 observations on the following 2 variables.

*logOR* a numeric vector with treatment effect sizes (log odds ratio)

*SE* a numeric vector with the standard error of the treatment effect sizes
Daniels

Source

Examples

data(Collins)

<table>
<thead>
<tr>
<th>Daniels</th>
<th>Daniels and Hughes data</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Description

Data frame with treatment differences in CD4 cell count.

Usage

data("Daniels")

Format

A data frame with 15 observations on the following 2 variables.

Y1 Treatment differences for the log hazard ratio for the development of AIDS or death over 2 years.

vars1 Error variances of Y1.

Y2 Difference in mean change in CD4 cell count between baseline and 6 month for studies of the AIDS Clinical Trial Group

vars2 Error variances of Y2.

Details

The Daniels data comprises 15 phase II/III randomized clinical trials of the HIV Disease Section of the Adult AIDS Clinical Trials Group of the National Institutes of Health, which had data available as of May 1996, which had at least six months of follow-up on some patients and in which at least one patient developed AIDS or died. The data were previously used by Daniels and Hughes (1997) to assess whether the change in CD4 cell count is a surrogate for time to either development of AIDS or death in drug trials of patients with HIV.

Source

**Description**

A hypothetical dataset with 500 subjects suspected of having deep vein thrombosis (DVT).

**Usage**

```r
data(DVTtipd)
```

**Format**

A data frame with 500 observations of 16 variables.

- `sex` gender (0=female, 1=male)
- `malign` active malignancy (0=no active malignancy, 1=active malignancy)
- `par` paresis (0=no paresis, 1=paresis)
- `surg` recent surgery or bedridden
- `tend` tenderness venous system
- `oachst` oral contraceptives or hst
- `leg` entire leg swollen
- `notraum` absence of leg trauma
- `calfdif3` calf difference >= 3 cm
- `pit` pitting edema
- `vein` vein distension
- `altdiagn` alternative diagnosis present
- `histdvt` history of previous DVT
- `ddimdich` dichotimized D-dimer value
- `dvt` final diagnosis of DVT
- `study` study indicator

**Details**

Hypothetical dataset derived from the Individual Participant Data Meta-Analysis from Geersing et al (2014). The dataset consists of consecutive outpatients with suspected deep vein thrombosis, with documented information on the presence or absence of proximal deep vein thrombosis (dvt) by an acceptable reference test. Acceptable such tests were either compression ultrasonography or venography at initial presentation, or, if venous imaging was not performed, an uneventful follow-up for at least three months.
Source

Examples

```r
data(DVTipd)
str(DVTipd)
summary(apply(DVTipd,2,as.factor))
```

```r
## Develop a prediction model to predict presence of DVT
model.dvt <- glm("dvt~sex+oachst+malign+surg+notraum+vein+calfdif3+ddimdich",
                 family=binomial, data=DVTipd)
summary(model.dvt)
```

### DVTmodels

*Risk prediction models for diagnosing Deep Venous Thrombosis (DVT)*

Description

Previously published prediction models for predicting the presence of DVT.

Usage

```r
data(DVTmodels)
```

Format

An object of the class litmodels with the following information for each literature model: the study-level descriptives ("descriptives"), the regression coefficient or weight for each predictor ("weights") and the error variance for each regression coefficient or weight ("weights.var").

Details

Previously, several models (Gagne, Oudega) and score charts (Wells, modified Wells, and Hamilton) have been published for evaluating the presence of DVT in suspected patients. These models combine information on multiple predictors into a weighted sum, that can subsequently be used to obtain estimates of absolute risk. See DVTipd for more information on the predictors.

DVTipd

Examples

data(DVTmodels)
c.index  a numeric vector with the estimated concordance statistic of each validation
se.c.index  a numeric vector with the standard error of the concordance statistics

Po  a numeric vector with the overall observed event probability of each validation
Pe  a numeric vector with the overall expected event probability of each validation
SD.Pe  a numeric vector with the standard error of Pe
e.events  a numeric vector with the total number of expected events in each validation
multicentre  a logical vector describing whether the study was a multicentre study
mean.age  a numeric vector describing the mean age of the patients
sd.age  a numeric vector with the spread of the age of the patients
pts.before.2010  a logical vector describing whether studies included patients before 2010 (i.e., before EuroSCORE II was developed)

Details

Published in 2012, EuroSCORE II was developed using logistic regression in a dataset comprising 16,828 adult patients undergoing major cardiac surgery from 154 hospitals in 43 countries over a 12-week period (May-July) in 2010. EuroSCORE II was developed to predict in-hospital mortality for patients undergoing any type of cardiac surgery. In 2014, a systematic review of published evidence on the performance value of the euroSCORE II was undertaken by Guida et al. Twenty-two validations, including more 145,592 patients from 21 external validation articles (one study included two validations) and a split-sample validation contained within original development article were included in the review; 23 validation studies in total.

Regression tests for detecting funnel plot asymmetry

Description

The presence of small-study effects is a common threat to systematic reviews and meta-analyses, especially when it is due to publication bias, which occurs when small primary studies are more likely to be reported (published) if their findings were positive. The presence of small-study effects can be verified by visual inspection of the funnel plot, where for each included study of the meta-analysis, the estimate of the reported effect size is depicted against a measure of precision or sample size. The premise is that the scatter of plots should reflect a funnel shape, if small-study effects do not exist. However, when small studies are predominately in one direction (usually the direction of larger effect sizes), asymmetry will ensue.

The `fat` function implements several tests for detecting funnel plot asymmetry, which can be used when the presence of between-study heterogeneity in treatment effect is relatively low.

Usage

`fat(b, b.se, n.total, d.total, d1, d2, method = "E-FIV")`

Arguments

- `b` Vector with the effect size of each study. Examples are log odds ratio, log hazards ratio, log relative risk.
- `b.se` Optional vector with the standard error of the effect size of each study
- `n.total` Optional vector with the total sample size of each study
- `d.total` Optional vector with the total number of observed events for each study
- `d1` Optional vector with the total number of observed events in the exposed groups
- `d2` Optional vector with the total number of observed events in the unexposed groups
- `method` Method for testing funnel plot asymmetry, defaults to "E-FIV" (Egger’s test with multiplicative dispersion). Other options are E-UW, M-FIV, M-FPV, D-FIV and D-FAV. More info in "Details"

Details

**Egger regression method**: A common method to test the presence of small-study effects is given as the following unweighted regression model (method="E-UW", Egger 1997):

\[
\hat{b}_k = \beta_0 + \beta_1 \text{SE}(\hat{b}_k) + \epsilon_k, \quad \epsilon_k \sim \mathcal{N}(0, \sigma^2)
\]

Whereas $\beta_0$ indicates the size and direction of the treatment effect, $\beta_1$ provides a measure of asymmetry; the larger its deviation from zero the more pronounced the asymmetry. Otherwise, if $\beta_1 = 0$, there is no association between the estimated effect sizes $\hat{b}_k$ and their corresponding...
estimates for the standard error $\hat{SE}(\hat{b}_k)$ among the reported studies, indicating no asymmetry and thus no small-study effects.

It is possible to allow for between-study heterogeneity by adopting a multiplicative overdispersion parameter by which the variance in each study is multiplied (method="E-FIV", Sterne 2000):

$$\hat{\beta}_k = a + b \hat{SE}(\hat{\beta}_k) + \epsilon_k , \epsilon_k \sim \mathcal{N}(0, \phi \; \hat{\text{var}}(\hat{\beta}_k))$$

Unfortunately, both tests are known to be intrinsically biased because: (i) the independent variable is subject to sampling variability; (ii) the standardized treatment effect is correlated with its estimated precision; and (iii) for binary data, the independent regression variable is a biased estimate of the true precision, with larger bias for smaller sample sizes (Macaskill 2001).

**Macaskill regression method:** To overcome the problems with the Egger approach, Macaskill et al. consider fitting a regression directly to the data using the treatment effect as the dependent variable, and study size ($n_k$) as the independent variable. Again, the observations are weighted by the inverse variance of the estimate to allow for possible heteroscedasticity (method="M-FIV", Macaskill 2001):

$$\hat{\beta}_k = a + b n_k + \epsilon_k , \epsilon_k \sim \mathcal{N}(0, \phi \; \hat{\text{var}}(\hat{\beta}_k))$$

Macaskill et al. also proposed an alternative test where a 'pooled' estimate of the outcome proportion is used for the variance $\hat{\text{var}}(\hat{b}_k)$ (method="M-FPV", Macaskill 2001):

$$\hat{\beta}_k = a + b n_k + \epsilon_k , \epsilon_k \sim \mathcal{N}(0, \phi \; \frac{1}{d_k(1 - d_k/n_k)})$$

For studies with zero events, a continuity correction is applied by adding 0.5 to all cell counts.

**Peters regression method:** A modification of Macaskill’s test was proposed by Peters et al. to obtain more balanced type-I error rates in the tail probability areas (method="P-FPV", Peters 2006):

$$\hat{\beta}_k = a + b \frac{1}{n_k} + \epsilon_k , \epsilon_k \sim \mathcal{N}(0, \phi \; \frac{1}{d_k(1 - d_k/n_k)})$$

Again, 0.5 is added to all cells for studies with zero events.

**Debray regression method:** Because the use of aforementioned tests may be less appropriate in the presence of survival data, Debray et al. proposed using the total number of events ($d_k$) as independent variable (method="D-FIV", Debray 2017):

$$\hat{\beta}_k = a + b \frac{1}{d_k} + \epsilon_k , \epsilon_k \sim \mathcal{N}(0, \phi \; \hat{\text{var}}(\hat{\beta}_k))$$

For studies with zero events, the total number of observed events is set to 1. Alternatively, when $\hat{\text{var}}(\hat{\beta}_k)$ is unknown or derived from small samples, Debray at al.proposed to use the following regression model (method="D-FAV", Debray 2017):

$$\hat{\beta}_k = a + b \frac{1}{d_k} + \epsilon_k , \epsilon_k \sim \mathcal{N}(0, \phi \; \left( \frac{1}{d_{k1} + 1/d_{k2}} \right))$$
Value

a list containing the following entries:

"pval" A two-sided P-value indicating statistical significance of the funnel plot asymmetry test. Values below the significance level (usually defined as 10%) support the presence of funnel plot asymmetry, and thus small-study effects.

"model" A fitted glm object, representing the estimated regression model used for testing funnel plot asymmetry.

Fibrinogen

Meta-analysis of the association between plasma fibrinogen concentration and the risk of coronary heart disease

Description

The Fibrinogen data set is a meta-analysis of 31 studies in which the association between plasma fibrinogen concentration and the risk of coronary heart disease (CHD) was estimated.

Usage

data("Fibrinogen")

Format

A data frame with 5 variables:

N.total  a numeric vector describing the total number of patients for each study
N.events  a numeric vector describing the number of observed events within each study
HR  a numeric vector describing the estimated hazard ratio of each study
HR.025  a numeric vector describing the lower boundary of the 95% confidence interval of HR
HR.975  a numeric vector describing the upper boundary of the 95% confidence interval of HR

Source

Examples

data(Fibrinogen)
## maybe str(Fibrinogen) ; plot(Fibrinogen) ...
Description

Extract the fitted values of a `metapred` object. By default returns fitted values of the model in the cross-validation procedure.

Usage

```r
## S3 method for class 'metapred'
fitted(object, select = "cv", step = NULL,
       model = NULL, as.stratified = TRUE, type = "response", ...)
```

Arguments

- `object`: object of class `metapred`
- `select`: character. Select fitted values from "cv" (default) or from "global" model.
- `step`: character or numeric. Name or number of step to select if `select = "cv"`. Defaults to best step.
- `model`: character or numeric. Name or number of model to select if `select = "cv"`. Defaults to best model.
- `as.stratified`: logical. `select = "cv"` determines whether returned predictions are stratified in a list (TRUE, default) or in their original order (FALSE).
- `type`: character. Type of fitted value.
- `...`: For compatibility only.

Details

Function still under development, use with caution.

Only returns `type = "response"`.

Author(s)

Valentijn de Jong
Description

Generate a forest plot by specifying the various effect sizes, confidence intervals and summary estimate.

Usage

forest(...)

Arguments

... Additional arguments, which are currently ignored.

Details

This is a generic function. See forest.default for making forest plots of summary statistics, forest.metapred for plotting metapred objects, and forest.mp.cv.val for plotting mp.cv.val objects.

Author(s)

Thomas Debray <thomas.debray@gmail.com>
Valentijn de Jong <Valentijn.M.T.de.Jong@gmail.com>

---

Description

Generate a forest plot by specifying the various effect sizes, confidence intervals and summary estimate.

Usage

## Default S3 method:
forest(theta, theta.ci.lb, theta.ci.ub, theta.slab, theta.summary, theta.summary.ci.lb, theta.summary.ci.ub, theta.summary.pi.lb, theta.summary.pi.ub, title, sort = "asc", theme = theme_bw(), predint.linetype = 1, xlim, xlab = "", refline = 0, label.summary = "Summary Estimate", label.predint = "Prediction Interval", ...)

---
Arguments

theta Numeric vector with effect size for each study
theta.ci.lb Numeric vector specifying the lower bound of the confidence interval of the effect sizes
theta.ci.ub Numeric vector specifying the upper bound of the confidence interval of the effect sizes
theta.slab Character vector specifying the study labels
theta.summary Meta-analysis summary estimate of the effect sizes
theta.summary.ci.lb Lower bound of the confidence (or credibility) interval of the summary estimate
theta.summary.ci.ub Upper bound of the confidence (or credibility) interval of the summary estimate
theta.summary.pi.lb Lower bound of the (approximate) prediction interval of the summary estimate.
theta.summary.pi.ub Upper bound of the (approximate) prediction interval of the summary estimate.
title Title of the forest plot
sort By default, studies are sorted by ascending effect size (sort="asc"). Set to "desc" for sorting in reverse order, or any other value to ignore sorting.
theme Theme to generate the forest plot. By default, the classic dark-on-light ggplot2 theme is used. See ggtheme for more information.
predint.linetype The linetype of the prediction interval
xlim The x limits (x1,x2) of the forest plot
xlab Optional character string specifying the X label
refline Optional numeric specifying a reference line
label.summary Optional character string specifying the label for the summary estimate
label.predint Optional character string specifying the label for the (approximate) prediction interval
... Additional arguments, which are currently ignored.

Value

An object of class ggplot

Author(s)

Thomas Debray <thomas.debray@gmail.com>
Description

Draw a forest plot of the performance of an internally-externally cross-validated model. By default the final model is shown.

Usage

```r
# S3 method for class 'metapred'
forest(object, perfFUN = 1, step = NULL,
       method = "REML", model = NULL, ...)
```

Arguments

- `object`: A `metapred` fit object.
- `perfFUN`: Numeric or character. Which performance statistic should be plotted? Defaults to the first.
- `step`: Which step should be plotted? Defaults to the best step. numeric is converted to name of the step: 0 for an unchanged model, 1 for the first change...
- `method`: character string specifying whether a fixed- or a random-effects model should be used to summarize the prediction model performance. A fixed-effects model is fitted when using `method="FE"`. Random-effects models are fitted by setting `method` equal to one of the following: "DL", "HE", "SJ", "ML", "REML", "EB", "HS", or "GENQ". Default is "REML".
- `model`: Which model change should be plotted? NULL (default, best change) or character name of variable or (integer) index of model change.
- `...`: Other arguments passed to plotting internals. E.g. `title`. See `forest.default` for details.

Author(s)

Valentijn de Jong <Valentijn.M.T.de.Jong@gmail.com>

Examples

data(DVTipd)

# Internal-external cross-validation of a pre-specified model 'f'
f <- dvt ~ histdvt + ddidich + sex + notraum
fit <- metapred(DVTipd, strata = "study", formula = f, scope = f, family = binomial)

# Display the model's external performance (expressed as mean squared error by default)
# for each study
forest(fit)
Description

Draw a forest plot of the performance of an internally-externally cross-validated model.

Usage

```r
## S3 method for class 'mp.cv.val'
forest(object, perfFUN = 1, method = "REML",
       xlab = NULL, ...)
```

Arguments

- `object`: An `mp.cv.val` or `perf` object.
- `perfFUN`: Numeric or character. Which performance statistic should be plotted? Defaults to the first.
- `method`: character string specifying whether a fixed- or a random-effects model should be used to summarize the prediction model performance. A fixed-effects model is fitted when using `method="FE"`. Random-effects models are fitted by setting `method` equal to one of the following: "DL", "HE", "SJ", "ML", "REML", "EB", "HS", or "GENQ". Default is "REML".
- `xlab`: Label on x-axis. Defaults to the name of the performance function.
- `...`: Other arguments passed to plotting internals. E.g. `title`. See `forest.default` for details.

Framingham

Predictive performance of the Framingham Risk Score in male populations

Description

This data set contains estimates on the performance of the Framingham model for predicting coronary heart disease in male populations (Wilson 1998). Results are based on the original development study and 20 validations identified by Damen et al.

Usage

data("Framingham")
Format

A data frame with 24 observations on the following 19 variables.

- **AuthorYear** a vector describing the study authors
- **n** a numeric vector with the total number of patients on which performance estimates are based
- **n.events** a numeric vector with the total number of observed events
- **c.index** a numeric vector with the estimated concordance statistic of each validation
- **se.c.index** a numeric vector with the standard error of the concordance statistics
- **c.index.95CIl** a numeric vector with the lower bound of the 95% confidence interval of the estimated concordance statistics
- **c.index.95CIu** a numeric vector with the upper bound of the 95% confidence interval of the estimated concordance statistics
- **Po** a numeric vector with the overall observed event probability of each validation
- **Pe** a numeric vector with the overall expected event probability of each validation
- **t.val** a numeric vector describing the time period in which predictive performance was assessed for each validation
- **mean_age** a numeric vector describing the mean age of the patients
- **sd_age** a numeric vector with the spread of the age of the patients
- **mean_SBP** a numeric vector with the mean systolic blood pressure in the validation studies (mm Hg)
- **sd_SBP** a numeric vector with the spread of systolic blood pressure in the validation studies
- **mean_total_cholesterol** a numeric vector with the mean total cholesterol in the validation studies (mg/dL)
- **sd_total_cholesterol** a numeric vector with the spread of total cholesterol in the validation studies
- **mean_hdl_cholesterol** a numeric vector with the mean high-density lipoprotein cholesterol in the validation studies (mg/dL)
- **sd_hdl_cholesterol** a numeric vector with the spread of high-density lipoprotein cholesterol in the validation studies
- **pct_smoker** a numeric vector with the percentage smokers in the validation studies

Details

The Framingham Risk Score allows physicians to predict 10-year coronary heart disease (CHD) risk in patients without overt CHD. It was developed in 1998 from a middle-aged white population sample, and has subsequently been validated across different populations. The current dataset contains the original (internal validation) results, as well as 23 external validations which were identified through a systematic review. In this review, studies were eligible for inclusion if they described the validation of the original Framingham model and assessed its performance for fatal or nonfatal CHD in males from a general population setting.

table

<table>
<thead>
<tr>
<th>gen</th>
<th>Generalizability estimates</th>
</tr>
</thead>
</table>

Description

Obtain generalizability estimates from a model fit.

Usage

gen(object, ...)
generalizability(object, ...)

Arguments

object A model fit object, either a metapred or subset(metapred) object.
... By default, the final model is selected. This parameter allows other arguments to be passed to subset.metapred such that the generalizability estimates of other steps/models may be returned.

Author(s)

Valentijn de Jong

impact

<table>
<thead>
<tr>
<th>impact</th>
<th>IMPACT data</th>
</tr>
</thead>
</table>

Description

The IMPACT dataset comprises 15 studies of patients suffering from traumatic brain injury, including individual patient data from 11 randomized controlled trials and four observational studies.

Usage

data("impact")
Format

A data frame with 11022 observations on the following 11 variables.

name  Name of the study
type  Type of study, RCT: randomized controlled trial, OBS: observational cohort
age  Age of the patient
motor_score  Glasgow Coma Scale motor score
pupil  Pupillary reactivity
tct  Marshall Computerized Tomography classification
hypox  Hypoxia (0=no, 1=yes)
hypots  Hypotension (0=no, 1=yes)
tsah  Traumatic subarachnoid hemorrhage (0=no, 1=yes)
edh  Epidural hematoma (0=no, 1=yes)
mort  6-month mortality (0=alive, 1=dead)

Details

The included studies were part of the IMPACT project, where a total of 25 prognostic factors were considered for prediction of 6-month mortality. Missing values were imputed using the study as a fixed effect in the imputation model (Steyerberg et al, 2008).

inv.logit  

*Apply the inverse logit transformation*

**Description**

Transforms a linear predictor into a probability.

**Usage**

```r
inv.logit(x)
```

**Arguments**

- `x` A vector of numerics (between -Inf and Inf)

**Value**

A vector of numerics between 0 and 1.

**Author(s)**

Thomas Debray <thomas.debray@gmail.com>

**See Also**

**Kertai**  

*Kertai data*

**Description**

Data frame with diagnostic accuracy data from exercise electrocardiography.

**Usage**

```r
data("Kertai")
```

**Format**

One data frame with 4 variables.

- **TP** integer, number of true positives
- **FN** integer, number of false negatives
- **FP** integer, number of false positives
- **TN** integer, number of true negatives
logit

Details
The Kertai data set is a meta-analysis of prognostic test studies and comprises 7 studies where
the diagnostic test accuracy of exercise electrocardiography for predicting cardiac events in patients
undergoing major vascular surgery was measured.

inv.logit
Description

This function provides the (restricted) log-likelihood of a fitted model.

Usage

```r
## S3 method for class 'riley'
logLik(object, ...)
```

Arguments

- `object`: A riley object, representing a fitted alternative model for bivariate random-effects meta-analysis when the within-study correlations are unknown.
- `...`: Additional arguments to be passed on to other functions, currently ignored.

Value

Returns an object of class `logLik`. This is the (restricted) log-likelihood of the model represented by `object` evaluated at the estimated coefficients. It contains at least one attribute, "df" (degrees of freedom), giving the number of (estimated) parameters in the model.

**ma**  
*Random effects meta-analysis*

**Description**

Meta-analysis of the performance or coefficients of a metapred object. Caution: it is still under development.

**Usage**

`ma(object, method, ...)`

**Arguments**

- **object**: A model fit object, such as `metapred` object.
- **method**: Character, method for meta-analysis passed to `valmeta` and `uvmeta`. Defaults to "REML".
- **...**: Other arguments passed to `metapred`, `valmeta` and `uvmeta`.

**Details**

Produces different object types depending on input.

Valentijn de Jong

---

**metapred**  
*Generalized Stepwise Regression for Prediction Models in Clustered Data*

**Description**

Generalized stepwise regression for obtaining a prediction model with adequate performance across data sets. Requires data from individuals in multiple studies.

**Usage**

``` R
metapred(data, strata, formula, estFUN = "glm", scope = NULL, retest = FALSE, max.steps = 1000, center = FALSE, recal.int = FALSE, cvFUN = NULL, cv.k = NULL, metaFUN = NULL, meta.method = NULL, predFUN = NULL, perfFUN = NULL, genFUN = NULL, selFUN = "which.min", ...)
```
Arguments

- **data**: data.frame containing the data. Note that `metapred` removes observations with missing data *listwise* for all variables in `formula` and `scope`, to ensure that the same data is used in each model in each step. The outcome variable should be numeric or coercible to numeric by `as.numeric()`.

- **strata**: Character to specify the name of the strata (e.g. studies or clusters) variable.

- **formula**: formula of the first model to be evaluated. `metapred` will start at `formula` and update it using terms of `scope`. Defaults to full main effects model, where the first column in `data` is assumed to be the outcome and all remaining columns (except `strata`) predictors. See `formula` for formulas in general.

- **estFUN**: Function for estimating the model in the first stage. Currently "lm", "glm" and "logistfirth" are supported.

- **scope**: formula. The difference between `formula` and `scope` defines the range of models examined in the stepwise search. Defaults to NULL, which leads to the intercept-only model. If `scope` is not nested in `formula`, this implies backwards selection will be applied (default). If `scope` is nested in `formula`, this implies forward selection will be applied. If equal, no stepwise selection is applied.

- **retest**: Logical. Should added (removed) terms be retested for removal (addition)? `TRUE` implies bi-directional stepwise search.

- **max.steps**: Integer. Maximum number of steps (additions or removals of terms) to take. Defaults to 1000, which is essentially as many as it takes. 0 implies no stepwise selection.

- **center**: logical. Should numeric predictors be centered around the cluster mean?

- **recal.int**: Logical. Should the intercept be recalibrated in each validation?

- **cvFUN**: Cross-validation method, on the study (i.e. cluster or stratum) level. "l1o" for leave-one-out cross-validation (default). "bootstrap" for bootstrap. Or "fixed", for one or more data sets which are only used for validation. A user written function may be supplied as well.

- **cv.k**: Parameter for `cvFUN`. For `cvFUN="bootstrap"`, this is the number of bootstraps. For `cvFUN="fixed"`, this is a vector of the indices of the (sorted) data sets. Not used for `cvFUN="l1o"`.

- **metaFUN**: Function for computing the meta-analytic coefficient estimates in two-stage MA. By default, `rma.uni`, from the metafor package is used. Default settings are univariate random effects, estimated with "DL". Method can be passed trough the `meta.method` argument.

- **meta.method**: Name of method for meta-analysis. Default is "DL". For more options see `rma.uni`.

- **predFUN**: Function for predicting new values. Defaults to the predicted probability of the outcome, using the link function of `glm()` or `lm()`.

- **perfFUN**: Function for computing the performance of the prediction models. Default: mean squared error (`perfFUN="mse"`). Other options are "var.e" (variance of prediction error), "auc" (area under the curve), "cal.int" (calibration intercept), and "cal.slope" (multiplicative calibration slope) and "cal.add.slope" (additive calibration slope).
metapred

**genFUN**
Function or list of named functions for computing generalizability of the performance. Default: (absolute) mean (genFUN="abs.mean"). Choose coef.var for the coefficient of variation. If a list, only the first is used for model selection.

**selFUN**
Function for selecting the best method. Default: lowest value for genFUN. Should be set to “which.max” if high values for genFUN indicate a good model.

To pass arguments to estFUN (e.g. family = “binomial”), or to other FUNctions.

**Details**
Use `subset.metapred` to obtain an individual prediction model from a `metapred` object.

Note that `formula.changes` is currently unordered; it does not represent the order of changes in the stepwise procedure.

`metapred` is still under development, use with care.

**Value**
A list of class `metapred`, containing the final model in `global.model`, and the stepwise tree of estimates of the coefficients, performance measures, generalizability measures in `stepwise`.

**Author(s)**
Valentijn de Jong <Valentijn.M.T.de.Jong@gmail.com>

oecalc

Usage

oecalc(OE, OE.se, OE.cilb, OE.ciub, OE.cilv, EO, EO.se, citl, citl.se, N, O, E, Po, Po.se, Pe, data, slab, add = 1/2, g = NULL, level = 0.95, ...)

Arguments

OE

OE.se

OE.cilb

OE.ciub

OE.cilv

EO

EO.se

citl

Arguments

vector with the estimated ratio of total observed versus total expected events
Optional vector with the standard errors of the estimated O:E ratios.
Optional vector to specify the lower limits of the confidence interval for OE.
Optional vector to specify the upper limits of the confidence interval for OE.
Optional vector to specify the levels of aforementioned confidence interval limits. (default: 0.95, which corresponds to the 95% confidence interval).
Optional vector with the estimated ratio of total expected versus total observed events
Optional vector with the standard errors of the estimated E:O ratios
Optional vector with the estimated calibration-in-the-large statistics
```
Optional vector with the standard error of the calibration-in-the-large statistics

Optional vector to specify the sample/group sizes.

Optional vector to specify the total number of observed events.

Optional vector to specify the total number of expected events.

Optional vector to specify the (cumulative) observed event probabilities.

Optional vector with the standard errors of \( P_0 \). For time-to-event data, these could also be the SE of the observed survival probabilities (e.g. as obtained from Kaplan-Meier analysis).

Optional vector to specify the (cumulative) expected event probabilities (if specified, during time \( t \).val)

Optional data frame containing the variables given to the arguments above.

Optional vector with labels for the studies.

a non-negative number indicating the amount to add to zero counts. See ‘Details’

a quoted string that is the function to transform estimates of the total O:E ratio; see the details below.

level for confidence interval, default \( 0.95 \).

Additional arguments.

An object of class c("mm_perf","data.frame") with the following columns:

"\( \theta \)" The (transformed) O:E ratio.

"\( \theta \).se" Standard errors of the (transformed) O:E ratio.

"\( \theta \).cilb" Lower confidence interval of the (transformed) O:E ratios. The level is specified in level. Intervals are calculated on the same scale as \( \theta \) by assuming a Normal distribution.

"\( \theta \).ciub" Upper confidence interval of the (transformed) c-statistics. The level is specified in level. Intervals are calculated on the same scale as \( \theta \) by assuming a Normal distribution.

"\( \theta \).source" Method used for calculating the (transformed) O:E ratio.

"\( \theta \).se.source" Method used for calculating the standard error of the (transformed) O:E ratio.

Thomas Debray <thomas.debray@gmail.com>

Examples

data(EuroSCORE)

# Calculate the total O:E ratio and its standard error
est1 <- oecalc(O = n.events, E = e.events, N = n, data = EuroSCORE, slab = Study)
est1

# Calculate the log of the total O:E ratio and its standard error
est2 <- oecalc(O = n.events, E = e.events, N = n, data = EuroSCORE, slab = Study, g = "log(OE)"
est2

# Display the results of all studies in a forest plot
plot(est1)

perf

Performance estimates

Description

Obtain performance estimates from a model fit.

Usage

perf(object, ...)

performance(object, ...)

Arguments

object A model fit object, either a metapred or subset(metapred) object.

... By default, the final model is selected. This parameter allows other arguments
to be passed to subset.metapred such that the performance estimates of other
steps/models may be returned.

Author(s)

Valentijn de Jong
Display results from the funnel plot asymmetry test

Description
Generates a funnel plot for a fitted `fat` object.

Usage
```r
## S3 method for class 'fat'
plot(x, ref, confint = TRUE, confint.level = 0.1,
     confint.col = "skyblue", confint.density = NULL,
     xlab = "Effect size", ...)
```

Arguments
- `x`: An object of class `fat`
- `ref`: A numeric value indicating the fixed or random effects summary estimate. If no value is provided then it will be retrieved from a fixed effects meta-analysis (if possible).
- `confint`: A logical indicator. If `TRUE`, a confidence interval will be displayed for the estimated regression model (based on a Student-T distribution).
- `confint.level`: Significance level for constructing the confidence interval.
- `confint.col`: The color for filling the confidence interval. Choose `NA` to leave polygons unfilled. If `confint.density` is specified with a positive value this gives the color of the shading lines.
- `confint.density`: The density of shading lines, in lines per inch. The default value of `NULL` means that no shading lines are drawn. A zero value of density means no shading nor filling whereas negative values and `NA` suppress shading (and so allow color filling).
- `xlab`: A title for the x axis
- `...`: Additional arguments for `plot`.

Examples
```r
data(Fibrinogen)
b <- log(Fibrinogen$HR)
b.se <- ((log(Fibrinogen$HR.975) - log(Fibrinogen$HR.025))/(2*qnorm(0.975)))
n.total <- Fibrinogen$N.total

# A very simple funnel plot
plot(fat(b=b, b.se=b.se))

# Add custom tickmarks for the X-axis
plot(fat(b=b, b.se=b.se, n.total=n.total, method="M-FIV"), xlab="Hazard ratio", xaxt="n")
```
Description

Function to create forest plots for objects of class "mm_perf".

Usage

## S3 method for class 'mm_perf'
plot(x, ...)

Arguments

x

An object of class "mm_perf"

... Additional arguments which are passed to forest.

Details

The forest plot shows the performance estimates of each study with corresponding confidence intervals.

Value

An object of class ggplot

Author(s)

Thomas Debray <thomas.debray@gmail.com>

**plot.riley**  
*Plot the summary of the bivariate model from Riley et al. (2008)*.

---

**Description**

Generates a forest plot for each outcome of the bivariate meta-analysis.

**Usage**

```r
## S3 method for class 'riley'
plot(x, title, sort = "asc", xlim, refline, ...)
```

**Arguments**

- `x`: An object of class `riley`
- `title`: Title of the forest plot
- `sort`: By default, studies are ordered by ascending effect size (`sort="asc"`). For study ordering by descending effect size, choose `sort="desc"`. For any other value, study ordering is ignored.
- `xlim`: The x limits (`x1, x2`) of the forest plot
- `refline`: Optional numeric specifying a reference line
- `...`: Additional parameters for generating forest plots

**Author(s)**

Thomas Debray <thomas.debray@gmail.com>

**References**

**Examples**

```r
data(Scheidler)

# Perform the analysis
fit <- riley(Scheidler[which(Scheidler$modality==1),])
plot(fit)

require(ggplot2)
plot(fit, sort="none", theme=theme_gray())
```
plot.uvmeta

Description
Function to create forest plots for objects of class "uvmeta".

Usage

```r
## S3 method for class 'uvmeta'
plot(x, sort = "asc", ...)
```

Arguments

- `x`: An object of class "uvmeta"
- `sort`: By default, studies are ordered by ascending effect size (sort="asc"). For study ordering by descending effect size, choose sort="desc". For any other value, study ordering is ignored.
- `...`: Additional arguments which are passed to `forest`.

Details
The forest plot shows the performance estimates of each validation with corresponding confidence intervals. A polygon is added to the bottom of the forest plot, showing the summary estimate based on the model. A 95% prediction interval is added by default for random-effects models, the dotted line indicates its (approximate) bounds.

Note
Full lines indicate confidence intervals or credibility intervals (in case of a Bayesian meta-analysis). Dashed lines indicate prediction intervals. The width of all intervals is defined by the significance level chosen during meta-analysis.

predict.riley  Prediction Interval

Description

Calculates a prediction interval for the summary parameters of Riley’s alternative model for bivariate random-effects meta-analysis. This interval predicts in what range future observations will fall given what has already been observed.

Usage

## S3 method for class 'riley'
predict(object, ...)

Arguments

<table>
<thead>
<tr>
<th>object</th>
<th>A riley object.</th>
</tr>
</thead>
<tbody>
<tr>
<td>...</td>
<td>Additional arguments (currently ignored)</td>
</tr>
</tbody>
</table>

Details

Prediction intervals are based on Student’s t-distribution with (numstudies - 5) degrees of freedom. The width of the interval is specified by the significance level chosen during meta-analysis.

Value

Data frame containing prediction intervals with the summary estimates beta1 and beta2 (for effect size data), or with the mean sensitivity and false positive rate (for diagnostic test accuracy data).

Author(s)

Thomas Debray <thomas.debray@gmail.com>
Recalibrate a Prediction Model

Description

**recalibrate** is used to recalibrate a prediction model of classes `metapred`, `glm` or `lm`.

Usage

```r
recalibrate(object, newdata, f = ~1, estFUN = NULL, ...)
```

Arguments

- **object**: A model fit object to be recalibrated, of class `metapred`, `glm` or `lm`, and more.
- **newdata**: data.frame containing new data set for updating.
- **f**: formula. Which coefficients of the model should be updated? Default: intercept only. Left-hand side may be left out. See `formula` for details.
- **estFUN**: Function for model estimation. If left `NULL`, the function is automatically retrieved for `metapred` objects. For other objects, the function with name corresponding to the first class of the object is taken. E.g. `glm()` for `glm` objects.
- **...**: Optional arguments to pass to `estFUN`.

Details

Currently only the coefficients are updated and the variances and other aspects are left untouched. For updating the entire model and all its statistics, see `update`.

Value

Recalibrated model fit object, of the same class as `object`. Generally, updated coefficients can be retrieved with `coef()`.

Examples

```r
data(DVTipd)
DVTipd$cluster <- 1:4 # Add a fictional clustering to the data set.
# Suppose we estimated the model in three studies:
DVTipd123 <- DVTipd[DVTipd$cluster <= 3, ]
mp <- metamisc:::metapred(DVTipd123, strata = "cluster", f = dvt ~ vein + malign,
family = binomial)
# and now want to recalibrate it for the fourth:
DVTipd4 <- DVTipd[DVTipd$cluster == 4, ]
metamisc:::recalibrate(mp, newdata = DVTipd4)
```
riley  

Fit the alternative model for bivariate random-effects meta-analysis

Description

This function fits the alternative model for bivariate random-effects meta-analysis when the within-study correlations are unknown. This bivariate model was proposed by Riley et al. (2008) and is similar to the general bivariate random-effects model (van Houwelingen et al. 2002), but includes an overall correlation parameter rather than separating the (usually unknown) within- and between-study correlation. As a consequence, the alternative model is not fully hierarchical, and estimates of additional variation beyond sampling error (psi) are not directly equivalent to the between-study variation (tau) from the general model. This model is particularly useful when there is large within-study variability, few primary studies are available or the general model estimates the between-study correlation as 1 or -1.

Usage

riley(X, slab, optimization = "Nelder-Mead", control = list(), pars, ...

Arguments

X  
data frame containing integer variables Y1, vars1, Y2 and vars2, where the columns Y1 and Y2 represent the effect sizes of outcome 1 and, respectively, outcome 2. The columns vars1 and vars2 represent the error variances of Y1 and, respectively, Y2. Alternatively, when considering a meta-analysis of diagnostic test accuracy data, the columns TP, FN, FP and TN may be specified. Corresponding values then represent the number of true positives, the number of false negatives, the number of false positives and, respectively, the number of true negatives.

slab  
Optional vector specifying the label for each study

optimization  
The optimization method that should be used for minimizing the negative (restricted) log-likelihood function. The default method is an implementation of that of Nelder and Mead (1965), that uses only function values and is robust but relatively slow. Other methods are described in optim.

control  
A list of control parameters to pass to optim.

pars  
List with additional arguments. The width of confidence, credibility and prediction intervals is defined by level (defaults to 0.95).

...  
Arguments to be passed on to other functions. See "Details" for more information.

Details

Parameters are estimated by iteratively maximizing the restricted log-likelihood using the Newton-Raphson procedure. The results from a univariate random-effects meta-analysis with a method-of-moments estimator are used as starting values for beta1, beta2, psi1 and psi2 in the optim command. Standard errors for all parameters are obtained from the inverse Hessian matrix.
Meta-analysis of effect sizes: The following parameters are estimated by iteratively maximizing the restricted log-likelihood using the Newton-Raphson procedure: pooled effect size for outcome 1 ($\beta_1$), pooled effect size for outcome 2 ($\beta_2$), additional variation of $\beta_1$ beyond sampling error ($\psi_1$), additional variation of $\beta_2$ beyond sampling error ($\psi_2$) and the correlation $\rho_0$ between $\psi_1$ and $\psi_2$.

Meta-analysis of diagnostic test accuracy: Although the model can also be used for diagnostic test accuracy data when substantial within-study correlations are expected, assuming zero within-study correlations (i.e. applying Reitsma’s approach) is usually justified (Reitsma et al. 2005, Daniels and Hughes 1997, Korn et al. 2005, Thompson et al. 2005, Van Houwelingen et al. 2002).

A logit transformation is applied to the sensitivities ans false positive rates of each study, in order to meet the normality assumptions. When zero cell counts occur, continuity corrections may be required. The correction value can be specified using correction (defaults to 0.5). Further, when the argument correction.control is set to "all" (the default) the continuity correction is added to the whole data if only one cell in one study is zero. If correction.control="single" the correction is only applied to rows of the data which have a zero.

The following parameters are estimated: logit of sensitivity ($\beta_1$), logit of false positive rate ($\beta_2$), additional variation of $\beta_1$ beyond sampling error ($\psi_1$), additional variation of $\beta_2$ beyond sampling error ($\psi_2$) and the correlation ($\rho_0$) between $\psi_1$ and $\psi_2$.

Value
An object of the class riley for which many standard methods are available. A warning message is casted when the Hessian matrix contains negative eigenvalues, which implies that the identified solution is a saddle point and thus not optimal.

Note
The overall correlation parameter $\rho_0$ is transformed during estimation to ensure that corresponding values remain between -1 and 1. The transformed correlation $\rho_{0T}$ is given as $\logit((\rho_0+1)/2)$. During optimization, the starting value for $\rho_{0T}$ is set to 0. The standard error of $\rho_0$ is derived from $\rho_{0T}$ using the Delta method. Similarly, the Delta methods is used to derive the standard error of the sensitivity and false positive rate from $\beta_1$ and, respectively, $\beta_2$.

Algorithms for dealing with missing data are currently not implemented, but Bayesian approaches will become available in later versions.

**Roberts**

**Roberts data**

**Description**

Data frame with summary data from 14 comparative studies.

**Usage**

`data("Roberts")`
Format

One data frame with 2 variables.

**SDM** Effect sizes (standardized differences in means)

**SE** Standard error of the effect sizes

Details

The Roberts data set is a meta-analysis of 14 studies comparing 'set shifting' ability (the ability to move back and forth between different tasks) in people with eating disorders and healthy controls.

Source

---

**Scheidler**

*Diagnostic accuracy data*

Description

Data frame with diagnostic accuracy data from three imaging techniques for the diagnosis of lymph node metastasis in women with cervical cancer.

Usage

`data("Scheidler")`

Format

One data frame with 6 variables.

**author** string . author of article

**modality** integer . type of test (1=CT, 2=LAG, 3=MRI)

**TP** integer. number of true positives

**FN** integer. number of false negatives

**FP** integer. number of false positives

**TN** integer. number of true negatives
Details
The Scheidler data comprises the results from a meta-analysis where three imaging techniques for the diagnosis of lymph node metastasis in women with cervical cancer are compared. Forty-four studies in total were included: 17 studies evaluated lymphangiography, another 17 studies examined computed tomography and the remaining 10 studies focused on magnetic resonance imaging. Diagnosis of metastatic disease by lymphangiography (LAG) is based on the presence of nodal-filling defects, whereas computed tomography (CT) and magnetic resonance imaging (MRI) rely on nodal enlargement.

se  

Standard errors and variances

Description
Obtain standard errors or variances of a model fit

Usage
se(object, ...)
variances(object, ...)
tau(object, ...)
tau2(object, ...)

Arguments
object  A model fit object
...  other arguments

Value
For se the standard errors of object, and for variances the variances. For tau the heterogeneity of the coefficients.

Author(s)
Valentijn de Jong
**stackedglm**  
*Stacked Regression*

**Description**

This function combines one or more existing prediction models into a so-called meta-model.

**Usage**

```r
stackedglm(models, family = binomial, data)
```

**Arguments**

- `models`: a list containing the historical prediction models, which can be defined in several ways. For instance, historical regression models can be specified using a named vector containing the regression coefficients of the individual predictors (no need to include the intercept term). List items may also represent an object for which the function `predict()` exists.

- `family`: a description of the error distribution and link function to be used in the meta-model. This can be a character string naming a family function, a family function or the result of a call to a family function. (See `family` for details of family functions.)

- `data`: an optional data frame, list or environment (or object coercible by `as.data.frame` to a data frame) containing the variables in the model. If not found in `data`, the variables are taken from `environment(formula)`, typically the environment from which `stackedglm` is called.

**subset.metapred**  
*Subsetting metapred fits*

**Description**

Return a model from the cross-validation procedure or the final 'global' model. Caution: This function is still under development.

**Usage**

```r
## S3 method for class 'metapred'
subset(x, select = "cv", step = NULL, model = NULL, stratum = NULL, add = TRUE, ...)
```
Arguments

x

metapred object

select

Which type of model to select: "cv" (default), "global", or (experimental) "stratified", or "stratum".

step

Which step should be selected? Defaults to the best step. numeric is converted to name of the step: 0 for an unchanged model, 1 for the first change...

model

Which model change should be selected? NULL (default, best change) or character name of variable or (integer) index of model change.

stratum

Experimental. Stratum to return if select = "stratum".

add

Logical. Add data, options and functions to the resulting object? Defaults to TRUE. Experimental.

... For compatibility only.

Value

An object of class mp.cv for select = "cv" and an object of class mp.global for select = "global". In both cases, additional data is added to the resulting object, thereby making it suitable for further methods.

Author(s)

Valentijn de Jong

Examples

data(DVTipd)
DVTipd$cluster <- letters[1:4] # Add a fictional clustering to the data.
mp <- metapred(DVTipd, strata = "cluster", formula = dvt ~ histdvt + ddimdich, family = binomial)
subset(mp) # best cross-validated model
subset(mp, select = "global") # Final model fitted on all strata.
subset(mp, step = 1) # The best model of step 1
subset(mp, step = 1, model = "histdvt") # The model in which histdvt was removed, in step 1.

summary.riley

Parameter summaries Provides the summary estimates of the alternative model for bivariate random-effects meta-analysis by Riley et al. (2008) with their corresponding standard errors (derived from the inverse Hessian). For confidence intervals, asymptotic normality is assumed.

Description

Parameter summaries Provides the summary estimates of the alternative model for bivariate random-effects meta-analysis by Riley et al. (2008) with their corresponding standard errors (derived from the inverse Hessian). For confidence intervals, asymptotic normality is assumed.
Summary

Usage

```r
## S3 method for class 'riley'
summary(object, ...)
```

Arguments

- `object`: A `riley` object
- `...`: Arguments to be passed on to other functions (currently ignored)

Details

For meta-analysis of diagnostic test accuracy data, beta1 equals the logit sensitivity (Sens) and beta2 equals the logit false positive rate (FPR).

Value

Array with confidence intervals for the estimated model parameters. For diagnostic test accuracy data, the resulting summary sensitivity and false positive rate are included.

Note

For the overall correlation (rho) confidence intervals are derived using the transformation \( \logit((\rho+1)/2) \). Similarly, the logit transformation is used to derive confidence intervals for the summary sensitivity and false positive rate.

See Also

uvmeta

Description

This function summarizes multiple estimates for a single parameter by assuming a fixed (i.e. common) effect or random effects across studies. The summary estimate is obtained by calculating a weighted mean that accounts for sample size and (in case random effects are assumed) for between-study heterogeneity.

Usage

uvmeta(r, r.se, r.vi, method = "REML", test = "knha", labels, na.action, n.chains = 4, pars, ret.fit = FALSE, verbose = FALSE, ...)

Arguments

r  Vector of numerics containing the effect size of each study
r.se  Vector of numerics containing the standard error of the effect sizes
r.vi  Vector of numerics containing the sampling variance of the effect sizes
method  Character string specifying whether a fixed-effect or a random-effects model should be fitted. A fixed-effect model is fitted when using method="FE". Random-effects models are fitted by setting method equal to one of the following: "REML" (Default), "DL", "HE", "SJ", "ML", "EB", "HS", "GENQ" or "BAYES". See 'Details'.
test

Optional character string when `method!='BAYES'` to specify how test statistics and confidence intervals for the fixed effects should be computed. By default (`test='knha'`), the method by Knapp and Hartung (2003) is used for adjusting test statistics and confidence intervals. Type `rma` for more details.

labels

Optional vector of characters containing the labels for the studies.

na.action

A function which indicates what should happen when the data contain NAs. Defaults to "na.fail", other options are "na.omit", "na.exclude" or "na.pass".

n.chains

Optional numeric specifying the number of chains to use in the Gibbs sampler (`method='BAYES'`). More chains will improve the sensitivity of the convergence diagnostic, but will cause the simulation to run more slowly. The default number of chains is 4.

pars

Optional list with additional arguments. The width of confidence, credibility and prediction intervals is defined by `level` (defaults to 0.95). The following parameters configure the MCMC sampling procedure: `hp.mu.mean` (Hyperparameter: mean of the prior distribution of the fixed/random effects model, defaults to zero), `hp.mu.var` (Hyperparameter: variance of the prior distribution of the fixed/random effects model, defaults to 1000), `hp.tau.min` (Hyperparameter: minimum value for the between-study standard deviation, defaults to 0), `hp.tau.max` (Hyperparameter: maximum value for the between-study standard deviation, defaults to 100).

ret.fit

Logical indicating whether the full results from the fitted model should also be returned.

verbose

If TRUE then messages generated during the fitting process will be displayed.

Details

Unless specified otherwise, all meta-analysis models assume random effects and are fitted using restricted maximum likelihood estimation with the `metafor` package (Viechtbauer 2010). Further, confidence intervals for the average performance are based on the Hartung-Knapp-Sidik-Jonkman method, to better account for the uncertainty in the estimated between-study heterogeneity (Debray 2016). A Bayesian meta-analysis can be performed by specifying `method='BAYES'`. In that case, the R packages `runjags` and `rjags` must be installed.

For random-effects models, a prediction interval for the pooled effect size is displayed. This interval predicts in what range future effect sizes will fall given what has already been observed (Higgins 2009, Riley 2011).

**Bayesian meta-analysis models:** For Bayesian meta-analysis models that involve the Gibbs sampler (`method='BAYES'`), the R packages `runjags` and `rjags` must be installed. The Bayesian approach uses an uninformative Normal prior for the mean and a uniform prior for the between-study variance of the pooled effect size (Higgins 2009). By default, the Normal prior has a mean of 0 and a variance of 1000. These hyperparameters can, however, be altered through the variables `hp.mu.mean` and `hp.mu.var` in the argument `pars`. The prior distribution of the between-study standard deviation is given by a uniform distribution, by default bounded between 0 and 100.
**Value**

An object of the class `uvmeta` for which many standard methods are available.

"data" array with (transformed) data used for meta-analysis, and method(s) used for restoring missing information.

"method" character string specifying the meta-analysis method.

"est" estimated performance statistic of the model. For Bayesian meta-analysis, the posterior median is returned.

"se" standard error (or posterior standard deviation) of the summary estimate.

"tau2" estimated amount of (residual) heterogeneity. Always 0 when method="FE". For Bayesian meta-analysis, the posterior median is returned.

"se.tau2" estimated standard error (or posterior standard deviation) of the between-study variation.

"ci.lb" lower bound of the confidence (or credibility) interval of the summary estimate

"ci.ub" upper bound of the confidence (or credibility) interval of the summary estimate

"pi.lb" lower bound of the (approximate) prediction interval of the summary estimate

"pi.ub" upper bound of the (approximate) prediction interval of the summary estimate

"fit" the full results from the fitted model

"slab" vector specifying the label of each study.

uvmeta-class

Class "uvmeta". Result of a univariate meta-analysis.

Description

This class encapsulates results of a univariate meta-analysis.

Objects from the Class

Objects can be created by calls of the form `uvmeta`.

Slots

call: (language) The call to `uvmeta`.

data: (data frame) The data used for the meta-analysis.

results: (data frame) Contains the pooled effect size (mu), the between-study variability (tausq), Cochran’s Q statistic (Q) and Higgins’ and Thompson’s I square statistic (Isq). For each estimate, error variances are provided with predefined confidence (method="MOM") or credibility (method="bayes") intervals.

model: (character) The meta-analysis model used.

method: (character) The estimator used.

na.action: (character) Information from the action which was applied to object if NAs were handled specially, or NULL.

df: (numeric) Degrees of freedom.

numstudies: (numeric) The amount of studies used in the meta-analysis.

pred.int: (data frame) A prediction interval, predicting in what range future effect sizes will fall given what has already been observed (based on a Student’s t-distribution, cfr. Riley 2011)

formula: (character) If a formula was specified, a character vector giving the formula and parameter specifications.
Methods

- **print** signature(object = "uvmeta"): Print object summary.
- **forest** signature(object = "uvmeta"): Plot a forest plot with the summary estimate.
- **summary** signature(object = "uvmeta"): Generate object summary.

Examples

```r
data(Collins)

#Extract effect size and error variance
r <- Collins$logOR
vars <- Collins$SE**2

#Frequentist random-effects meta-analysis
fit1 <- uvmeta(r,vars)

#Extract results
fit1$results
```

### Description

This function provides summary estimates for the concordance statistic, the total observed-expected ratio or the calibration slope. Where appropriate, data transformations are applied and missing information is derived from available quantities. Unless specified otherwise, all meta-analysis models assume random effects and are fitted using restricted maximum likelihood estimation with the `metafor` package (Viechtbauer 2010). Further, confidence intervals for the average performance are based on the Hartung-Knapp-Sidik-Jonkman method. When conducting a Bayesian meta-analysis, the R packages `runjags` and `rjags` must be installed.

### Usage

```r
valmeta(measure = "cstat", cstat, cstat.se, cstat.cilb, cstat.ciub,
cstat.cilv, sd.LP, OE, OE.se, OE.cilb, OE.ciub, OE.cilv, citl, citl.se,
N, O, E, Po, Po.se, Pe, data, method = "REML", test = "knha",
ret.fit = FALSE, verbose = FALSE, slab, n.chains = 4, pars, ...)
```

### Arguments

- **measure** A character string indicating which summary performance measure should be calculated. Options are "cstat" (meta-analysis of the concordance statistic) and "OE" (meta-analysis of the total observed-expected ratio). See ‘Details’ for more information.
- **cstat** Optional vector with the estimated c-statistic for each validation
- **cstat.se** Optional vector with the standard error of the estimated c-statistics
cstat.cilb  Optional vector to specify the lower limits of the confidence interval.
cstat.ciub  Optional vector to specify the upper limits of the confidence interval.
cstat.cilv  Optional vector to specify the levels of aforementioned confidence interval limits. (default: 0.95, which corresponds to the 95% confidence interval).

sd.LP     Optional vector with the standard deviation of the linear predictor (prognostic index)

OE       Optional vector with the estimated ratio of total observed versus total expected events
OE.se    Optional vector with the standard errors of the estimated O:E ratios
OE.cilb  Optional vector to specify the lower limits of the confidence interval for OE.
OE.ciub  Optional vector to specify the upper limits of the confidence interval for OE.
OE.cilv  Optional vector to specify the levels of aforementioned confidence interval limits. (default: 0.95, which corresponds to the 95% confidence interval).

citl     Optional vector with the estimated calibration-in-the-large for each validation
citl.se  Optional vector with the standard error of the estimated calibration-in-the-large statistics

N       Optional vector with the total number of participants for each validation
O       Optional vector with the total number of observed events for each validation (if specified, during time t.val)
E       Optional vector with the total number of expected events for each validation (if specified, during time t.val)
Po      Optional vector with the (cumulative) observed event probability for each validation (if specified, during time t.val)
Po.se   Optional vector with the standard errors of Po.
Pe      Optional vector with the (cumulative) expected event probability for each validation (if specified, during time t.val)
data    optional data frame containing the variables given to the arguments above.
method  Character string specifying whether a fixed- or a random-effects model should be fitted. A fixed-effects model is fitted when using method="FE". Random-effects models are fitted by setting method equal to one of the following: "REML" (Default), "DL", "HE", "SJ", "ML", "EB", "HS", "GENQ" or "BAYES". See 'Details'.
test    Optional character string specifying how test statistics and confidence intervals for the fixed effects should be computed. By default (test="knha"), the method by Knapp and Hartung (2003) is used for adjusting test statistics and confidence intervals. Type '?rma' for more details.
ret.fit  logical indicating whether the full results from the fitted model should also be returned.
verbose If TRUE then messages generated during the fitting process will be displayed.
slab    Optional vector specifying the label for each study
Optional numeric specifying the number of chains to use in the Gibbs sampler (if method=\"BAYES\").. More chains will improve the sensitivity of the convergence diagnostic, but will cause the simulation to run more slowly. The default number of chains is 4.

A list with additional arguments. See 'Details' for more information. The following parameters configure the MCMC sampling procedure: hp.mu.mean (mean of the prior distribution of the random effects model, defaults to 0), hp.mu.var (variance of the prior distribution of the random effects model, defaults to 1E6), hp.tau.min (minimum value for the between-study standard deviation, defaults to 0), hp.tau.max (maximum value for the between-study standard deviation, defaults to 2), hp.tau.sigma (standard deviation of the prior distribution for the between-study standard-deviation), hp.tau.dist (prior distribution for the between-study standard-deviation. Defaults to \"dunif\"), hp.tau.df (degrees of freedom for the prior distribution for the between-study standard-deviation. Defaults to 3). Other arguments are method.restore.c.se (method for restoring missing estimates for the standard error of the c-statistic. See ccalc for more information), model.cstat (The likelihood/link for modeling the c-statistic; see \"Details\"), model.oe (The likelihood/link for modeling the O:E ratio; see \"Details\") Additional arguments that are passed to rma or runjags (if method=\"BAYES\").

Details

Meta-analysis of the concordance statistic: A summary estimate for the concordance (c-) statistic can be obtained by specifying measure=\"cstat\". The c-statistic is a measure of discrimination, and indicates the ability of a prediction model to distinguish between patients developing and not developing the outcome. The c-statistic typically ranges from 0.5 (no discriminative ability) to 1 (perfect discriminative ability). When missing, the c-statistic and/or its standard error are derived from other reported information. See ccalc for more information.

By default, it is assumed that the logit of the c-statistic is Normally distributed within and across studies (pars$model.cstat = \"normal/logit\") Alternatively, it is possible to assume that the raw c-statistic is Normally distributed across studies pars$model.cstat = \"normal/identity\".

Meta-analysis of the total observed versus expected ratio: A summary estimate for the total observed versus expected (O:E) ratio can be obtained by specifying \"OE\". The total O:E ratio provides a rough indication of the overall model calibration (across the entire range of predicted risks). When missing, the total O:E ratio and/or its standard error are derived from other reported information. See oecalc for more information.

For frequentist meta-analysis, within-study variation can either be modeled using a Normal (model.oe = \"normal/log\" or model.oe = \"normal/identity\") or a Poisson distribution (model.oe = \"normal/log\").. When performing a Bayesian meta-analysis, all data are modeled using a one-stage random effects (hierarchical related regression) model. In particular, a binomial distribution (if 0, E and N is known), a Poisson distribution (if only 0 and E are known) or a Normal distribution (if OE and OE.se or OE.95CI are known) is selected separately for each study.

Bayesian meta-analysis: All Bayesian meta-analysis models assume random effects by default. Results are based on the posterior median. Credibility and prediction intervals are directly obtained from the corresponding posterior quantiles.
The prior distribution for the (transformed) summary estimate is always modeled using a Normal distribution, with mean \( \text{hp.mu.mean} \) (defaults to 0) and variance \( \text{hp.mu.var} \) (defaults to 1E6). For meta-analysis of the total O:E ratio, the maximum value for \( \text{hp.mu.var} \) is 100.

By default, the prior distribution for the between-study standard deviation is modeled using a uniform distribution (\( \text{hp.tau.dist} = \text{"dunif"} \)), with boundaries \( \text{hp.tau.min} \) and \( \text{hp.tau.max} \). Alternatively, it is possible to specify a truncated Student-t distribution (\( \text{hp.tau.dist} = \text{"dhalft"} \)) with a mean of \( \text{hp.tau.mean} \), a standard deviation of \( \text{hp.tau.sigma} \) and \( \text{hp.tau.df} \) degrees of freedom. This distribution is again restricted to the range \( \text{hp.tau.min} \) to \( \text{hp.tau.max} \).

Value

An object of class \text{valmeta} with the following elements:

"data" array with (transformed) data used for meta-analysis, and method(s) used for restoring missing information.

"measure" character string specifying the performance measure that has been meta-analysed.

"method" character string specifying the meta-analysis method.

"model" character string specifying the meta-analysis model (link function).

"est" summary estimate for the performance statistic. For Bayesian meta-analysis, the posterior median is returned.

"ci.lb" lower bound of the confidence (or credibility) interval of the summary performance estimate.

"ci.ub" upper bound of the confidence (or credibility) interval of the summary performance estimate.

"pi.lb" lower bound of the (approximate) prediction interval of the summary performance estimate.

"pi.ub" upper bound of the (approximate) prediction interval of the summary performance estimate.

"fit" the full results from the fitted model. Only defined if \text{ret.fit} = \text{TRUE}.

"slab" vector specifying the label of each study.

Note

The width of calculated confidence, credibility and prediction intervals can be specified using \text{level} in the \text{pars} argument (defaults to 0.95).

**vcov.riley**

_Calculate Variance-Covariance Matrix for a Fitted Riley Model Object_

**Description**

Returns the variance-covariance matrix of the main parameters of a fitted model object.

**Usage**

```r
# S3 method for class 'riley'
vcov(object, ...)
```

**Arguments**

- `object` a `riley` object.
- `...` arguments to be passed on to other functions

**Details**

The variance-covariance matrix is obtained from the inverse Hessian as provided by `optim`.

**Value**

A matrix of the estimated covariances between the parameter estimates in the Riley model: logit of sensitivity (mu1), logit of false positive rate (mu2), additional variation of mu1 beyond sampling error (psi1), additional variation of mu2 beyond sampling error (psi2) and a transformation of the correlation between psi1 and psi2 (rhoT). The original correlation is given as `inv.logit(rhoT) * 2 - 1`.

**Note**

A warning message is casted when the Hessian matrix contains negative eigenvalues. This implies that the identified minimum for the (restricted) negative log-likelihood is a saddle point, and that the solution is therefore not optimal.

Zhang

Meta-analysis of the prognostic role of hormone receptors in endometrial cancer

Description

This dataset comprises the results from 16 studies assessing the prognostic role of human epidermal growth factor receptor 2 (HER2) in endometrial cancer. These studies were previously identified in a systematic review by Zhang et al. to evaluate the overall risk of several hormone receptors for endometrial cancer survival.

Usage

data("Zhang")

Format

A data frame with 20 observations on the following 10 variables.

Study a factor with 16 levels to indicate the study
PrimaryAuthor a factor indicating the first author’s last name
year a numeric vector indicating the publication year
Country a factor indicating the source country of the study data
Disease a factor indicating the studied disease. Possible levels are EC (endometrial cancer), EEC (endometrioid endometrial cancer) and UPSC (uterine papillary serous carcinoma)
N a numeric vector describing the total sample size of each study
HR a numeric vector describing the estimated hazard ratio of each study
HR.025 a numeric vector describing the lower boundary of the 95% confidence interval of HR
HR.975 a numeric vector describing the upper boundary of the 95% confidence interval of HR
outcome a factor indicating the studied outcome. Possible levels are OS (overall survival) and PFS (progression-free survival)

Details

Eligible studies were identified by searching the PubMed and EMBASE databases for publications from 1979 to May 2014. Data were collected from studies comparing overall survival or progression-free survival in patients with elevated levels of human epidermal growth factor receptor 2 with those in patients with lower levels.
