Package ‘meteoland’

March 31, 2020

Type Package
Title Landscape Meteorology Tools
Version 0.9.2
Date 2020-03-29
Description Functions to estimate weather variables at any position of a landscape [De Cáceres et al. (2018) <doi:10.1016/j.envsoft.2018.08.003>].
License GPL (>= 2)
URL https://vegmod.ctfc.cat/software/meteoland/
LazyData TRUE
Depends R (>= 3.4.0), sp
Imports spdep, rgdal, ncdf4, httr, jsonlite, methods, Rcpp (>= 0.12.12)
Suggests knitr, forecast, spacetime, stars
LinkingTo Rcpp
Encoding UTF-8
NeedsCompilation yes
VignetteBuilder utils, knitr
RoxygenNote 6.1.1

**AEMET download**

**Description**

Download data from the Spanish National Meterology Agency (AEMET)

**Usage**

```r

downloadAEMEThistoricalstationlist(api)
downloadAEMEThistorical(api, dates, station_id, export = FALSE, exportDir = getwd(),
                          exportFormat = "meteoland/txt", metadataFile = "MP.txt",
                          verbose = TRUE)
downloadAEMETcurrentday(api, daily = TRUE, verbose = TRUE)
```

**Arguments**

- `api` String with the AEMET API key (see https://opendata.aemet.es/).
- `dates` An object of class `Date`.
- `station_id` A string vector containing station ids (the list of stations for which historical climatic series are available is given by `downloadAEMEThistoricalstationlist`).
- `export` If `export = FALSE` the downloaded data is stored in memory. Otherwise the result is written on the disk (using the format specified in `exportFormat`).
- `exportDir` Output directory for downloaded meteorology.
- `exportFormat` Format of meteorological data. Current accepted formats are "castanea" and "meteoland".
- `metadataFile` The name of the file that will store the meta data describing all written files.
- `verbose` Boolean flag to print process information.
- `daily` Boolean flag. Are data to be returned at a daily or hourly scale?

**Details**

API key needs to be acquired from AEMET (https://opendata.aemet.es/)
Value

Function downloadAEMETHistoricalStationList returns a `SpatialPointsDataFrame-class` object containing the list of AEMET weather stations for which historical climatic series are available and can be retrieved using downloadAEMETHistorical.

Function downloadAEMETHistorical downloads data for the specified AEMET stations and dates. Data are available for dates up to 4 days before current date. If export = FALSE, function downloadAEMETHistorical returns a `SpatialPointsMeteorology-class` object with the downloaded meteorology for each station (point). Otherwise the function writes on the disk at the location specified by exportDir and solely returns a `SpatialPointsDataFrame-class` object containing the files metadata.

Function downloadAEMETCurrentDay downloads recent weather (the last 24h) from all currently available stations and returns data frame if daily = FALSE or a `SpatialPointsDataFrame-class` object with observations aggregated at the daily scale if else.

Note

The list of stations available in downloadAEMETCurrentDay (current observations) is different from the list given by downloadAEMETHistoricalStationList and available in downloadAEMETHistorical (stations with historical climate series).

correctionpoints

Details
Assumes that all points/pixels represent the same area.

Value
An object of class as the input SpatialPointsMeteorology-class with weather series corresponding to the spatial average of the input.

| correctionpoints | Statistical correction of meteorological variables for a set of points |

Description
Functions correctionpoint and correctionpoints perform correction of predicted climatic data by applying statistical correction methods (unbiasing, scaling, or quantile mapping) to meteorological variables. Function correctionpoints.errors allows evaluating, for each point, the bias and mean absolute error (MAE) obtained before and after correcting the climate model for the historical period.
Usage

correctionpoint(obs, mod, proj, dates = NULL, 
params = defaultCorrectionParams(), verbose=TRUE)
correctionpoints(object, points, topodata = NULL, dates = NULL, 
export = FALSE, exportDir = getwd(), exportFile = NULL, 
exportFormat = "meteoland/txt", metadataFile = "MP.txt", 
corrOut = FALSE, verbose = TRUE)
correctionpoints.errors(object, points, topodata = NULL, 
error.type="residuals.cv",keep.data = FALSE, verbose = FALSE)

Arguments

obs A data frame with observed meteorology.
mod, proj Data frame with predicted meteorology for the reference and projection periods, respectively.
params A list with correction params (see defaultCorrectionParams).
object An object of class MeteorologyUncorrectedData-class containing the meteorology of more than one point.
points An object of class SpatialPointsMeteorology-class with the coordinates and historical meteorological data of the locations for which correction of predicted climatic data has to be done. Alternatively, an object of class SpatialPointsDataFrame-class containing the meta data (columns dir, filename and possibly format) of meteorological files that will be read from the disk.
topodata A data frame with topographic data for each point (i.e. three columns named elevation, slope and aspect). If topodata = NULL then Penman’s potential evapotranspiration is not calculated.
dates An object of class Date with a subset of dates of the projection period to be corrected. If dates = NULL then all dates in proj or the projection data of object are processed.
export If export = FALSE the result of correction is stored in memory. Otherwise the result is written in the disk (using the format specified in exportFormat).
exportDir Output directory for corrected meteorology data (txt/rds format).
exportFile Output file for corrected meteorology data (netCDF format).
metadataFile The name of the file that will store the meta data describing all written files.
exportFormat Export format for meteorological data (see writemeteorologypoint). If format is "meteoland/txt","meteoland/rds","castanea/txt" or "castanea/rds" the function tries to write one file per point in exportDir. If format is "netCDF" the function will write data to a single file specified by exportFile.
corrOut Boolean flag to indicate that correction parameters (i.e. calculated biases) should be included with the output. Setting corrOut = TRUE changes the returned value.
verbose Boolean flag to print process information.
error.type String to specify the error to be evaluated, either "before" (before correction), "residual" (after correction) or "residual.cv" (after correction, but using cross-validation).
keep.data Boolean flag to return the uncorrected/corrected data for the historical period.
correctionpoints

Details

Function correctionpoints performs statistical correction of predicted climatic data for all points supplied in points whereas correctionpoint performs statistical correction of one single point. Observed meteorological data for each point typically comes from a nearby meteorological station, but they can be the result of interpolating the meteorology of several stations (see MeteorologyInterpolationData) or they can be extracted from reanalyzed meteorology (e.g. EU-WATCH) (see extractNetCDF).

For each target point, correctionpoints function first determines the predicted cell where the point falls according to the euclidean distance in the geographic space of object. Then it calls correctionpoint. In turn, correctionpoint determines the dates that are shared in observed and predicted data for the historical period. These meteorological data of dates are used to conduct the correction of predicted climatic data for the future period. Corrections biases are calculated and applied for the twelve months separately. The user can control the methods used for correction of each meteorological variable by changing the slot params in object (see class MeteorologyUncorrectedData-class) or the parameter params to correctionpoint. Three options are allowed (see defaultCorrectionParams): (a) 'unbias' for shifting the mean; (b) 'scaling' for multiplication by a factor; and (c) 'quantmap' for empirical quantile mapping between observed and modelled data (Déqué 2007).

A difficulty arises for quantile mapping when the variables bounded by zero, such as precipitation. As the models tend to drizzle (or may have lower frequency of precipitation events), the probability of precipitation in the model may be greater or lower than that observed. To correct this, when model precipitation is zero an observed value is randomly chosen in the interval where the observed cumulative frequency is less than or equal to the probability of no precipitation in the model. This procedure ensures that the probability of precipitation after correction is equal to that observed (Boé 2007).

Value

• Function correctionpoint returns a data frame.

• If export = FALSE, the function correctionpoints returns an object of class SpatialPointsMeteorology-class with the bias-corrected meteorology for each point. If export=TRUE then bias-corrected data is written into the disk. For txt/rds export formats, the function returns an object of class SpatialPointsDataFrame-class containing the meta data of the files written in the disk. For netCDF export format the function returns NULL. If corrOut = TRUE the function returns a list which contains any previous output and an object with the calculated correction factors (biases, mappings) for each point and month.

• Function correctionpoints.errors (keep.data = FALSE) returns a data frame with the mean absolute error (MAE) and bias for each variable and point. If keep.data = TRUE then the function also returns a list of data frames with the uncorrected/corrected series used in the comparisons with observations.

**Low-level correction functions**

## Description

Low-level function to perform bias correction.

## Usage

```r
correction_series(obs, mod, proj = NULL, method = "unbias", isPrec=TRUE, qstep=0.01)
```

## Arguments

- **obs**: Observed series for the reference (historical) period.
- **mod**: Modelled series for the reference (historical) period.
- **proj**: Modelled series for the projected period. If missing, the reference (historical) period is corrected.
- **method**: Correction method, either "unbias"."scaling", "quantmap".
- **isPrec**: A flag to indicate that variable is precipitation (only relevant for quantile mapping).
- **qstep**: Probability step for quantile mapping (see `defaultCorrectionParams`).

## Value

Returns a vector with corrected values.

## Author(s)

Miquel De Cáceres Ainsa, Centre Tecnologic Forestal de Catalunya
defaultCorrectionParams

correctionpoints, defaultCorrectionParams

defaultCorrectionParams

Description

Returns a list with the default parameterization for statistical correction.

Usage

defaultCorrectionParams()

Value

A list with the following items (default values in brackets):

- methods: A list with the correction method for each variable (options are "unbias" (shift of the mean), "scaling" (factor multiplication), "quantmap" (empirical quantile mapping) or "none" (for no correction)). Defaults are:
  - MeanTemperature = "unbias"
  - MinTemperature = "quantmap"
  - MaxTemperature = "quantmap"
  - Precipitation = "quantmap"
  - MeanRelativeHumidity = "unbias"
  - Radiation = "unbias"
  - WindSpeed = "quantmap"
- fill_wind [= TRUE]: A logical flag to fill wind speed values with uncorrected values when reference data is missing.
- allow_saturated [= FALSE]: A logical flag to indicate whether relative humidity values above saturation (>100%) are permitted (bias correction is performed on specific humidity).
- wind_height [= 10]: Wind measurement height (in m).
- qstep [= 0.01]: a numeric value between 0 and 1. Quantile mapping is fitted only for the quantiles defined by quantile(0,1,probs=seq(0,1,by=qstep).

defaultGenerationParams

Default generation parameters

Description

Returns a list with the default parameterization for weather generation.

Usage

defaultGenerationParams()

Value

A list with the following items (default values in brackets):

- **conditional** ["none"]: A string to indicate whether multi-year weather should be conditioned or not. If **conditional** = "arima", annual precipitation is conditioned on a stationary auto-regressive model. If **conditional** = "window", a moving-window is used to sub-set the years used to parametrize the weather generation algorithm for each target year (see parameter **range_size_years**). In this last case, annual precipitation is conditioned to a log-normal variate with parameters fitted from the selected years.

- **dry_wet_threshold** [0.3]: Precipitation threshold (mm) for separating dry from wet days.

- **wet_extreme_quantile_threshold** [0.8]: Quantile for separating wet from extremely wet days.

- **range_size_days** [5]: Minimum half range size to select the subset of dates with DOY similar to the currently simulated.

- **range_size_years** [12]: Half range size to select the subset of years in a moving-window around the current year (if **conditional** = "window").

- **n_knn_annual** [100]: Number of years to be re-sampled using K-nearest neighbour for annual precipitation (if **conditional** = "arima" or **conditional** = "window").

- **adjust_annual_precip** [TRUE]: A logical flag to indicate that annual precipitation generated by the algorithm should be adjusted to fit either overall input annual precipitation or simulated annual precipitation.

- **min_ratio** [0.9]: Minimum adjustment ratio for precipitation.

- **max_ratio** [1.2]: Minimum adjustment ratio for precipitation.
defaultInterpolationParams

Author(s)
Miquel De Cáceres Ainsa, CTFC

References

See Also
weathergeneration

Description
Returns a list with the default parameterization for interpolation. Most parameter values are set according to Thornton et al. (1997).

Usage
defaultInterpolationParams()

Value
A list with the following items (default values in brackets):

- initial_Rp [= 140000]: Initial truncation radius.
- iterations [= 3]: Number of station density iterations.
- alpha_MinTemperature [= 3.0]: Gaussian shape parameter for minimum temperature.
- alpha_MaxTemperature [= 3.0]: Gaussian shape parameter for maximum temperature.
- alpha_DewTemperature [= 3.0]: Gaussian shape parameter for dew-point temperature.
- alpha_PrecipitationEvent [= 5.0]: Gaussian shape parameter for precipitation events.
- alpha_PrecipitationAmount [= 5.0]: Gaussian shape parameter for the regression of precipitation amounts.
- alpha_Wind [= 3.0]: Gaussian shape parameter for wind.
- N_MinTemperature [= 30]: Average number of stations with non-zero weights for minimum temperature.
- **N_MaxTemperature [= 30]**: Average number of stations with non-zero weights for maximum temperature.
- **N_DewTemperature [= 30]**: Average number of stations with non-zero weights for dew-point temperature.
- **N_PrecipitationEvent [= 5]**: Average number of stations with non-zero weights for precipitation events.
- **N_PrecipitationAmount [= 20]**: Average number of stations with non-zero weights for the regression of precipitation amounts.
- **N_Wind [= 2]**: Average number of stations with non-zero weights for wind.
- **St_Precipitation [= 5]**: Number of days for the temporal smoothing of precipitation.
- **St_TemperatureRange [= 15]**: Number of days for the temporal smoothing of temperature range.
- **pop_crit [= 0.50]**: Critical precipitation occurrence parameter.
- **f_max [= 0.6]**: Maximum value for precipitation regression extrapolations (0.6 equals to a maximum of 4 times extrapolation).
- **wind_height [= 10]**: Wind measurement height (in m).

**examplecorrectiondata**  
*Example data set for statistical correction of RCM predictions*

**Description**
Example data set including the predictions of Regional Climate Model (CCLM4-8-17; driving global model CNRM-CERFACS-CNRM-CM5) for 3 model cells in a small area in Catalonia (NE Spain). Meteorological data covers an historical (reference) period (2000-2003) and a future (projection) period (2020-2023), the latter simulated under rcp4.5 scenario.
Usage

data("examplecorrectiondata")

Format

Formal class 'MeteorologyUncorrectedData-class'

Source

ESFG web site (http://esgf.llnl.gov/) that centralizes climate data from GCM and RCM uploaded in the frame of different international consortium, including the EURO-CORDEX regionalisation project.

Examples

data(examplecorrectiondata)

Description

'SpatialGridTopography' object describing topographic features for a grid of 5 km x 5 km and cell size of 100 m in Catalonia (NE Spain).

Usage

data("examplegridtopography")

Format

Formal class 'SpatialGridTopography'

Source

'Institut Cartogràfic de Catalunya' (ICC)

Examples

data(examplegridtopography)
Example data set for interpolation from weather stations

Description

Example data set of spatial location, topography and daily meteorological records from 38 weather stations in Catalonia (NE Spain) corresponding to years 2000-2003.

Usage

data("exampleinterpolationdata")

Format

Formal class \texttt{MeteorologyInterpolationData-class}

Source

'Servei Meteorològic de Catalunya' (SMC) and 'Agencia Española de Meteorología' (AEMET)

Examples

data(exampleinterpolationdata)

extractdates

Extracts meteorological data

Description

Extracts meteorological data from an object.

Usage

extractdates(object, dates = NULL, verbose=FALSE)
extractvars(object, vars, verbose=FALSE)
extractgridindex(grid, index)
extractgridpoints(grid, points, verbose=FALSE)
extractNetCDF

Arguments

- **object**: An object of class `SpatialPointsMeteorology`, `SpatialGridMeteorology` or `SpatialPixelsMeteorology`.
- **dates**: A vector of `Date` with a (subset) of dates to be extracted. If `NULL` all dates will be returned.
- **vars**: A character vector with the set of variables to be extracted.
- **grid**: An object of class `SpatialGridMeteorology-class` or `SpatialPixelsMeteorology-class` with the meteorological data for a full grid or a subset of grid cells, respectively. Alternatively, a string specifying a NetCDF to be read from the disk.
- **index**: An integer with a grid index.
- **points**: An object of class `SpatialPoints`.
- **verbose**: Boolean flag to print process information.

Details

Function `extractpoints` is deprecated, because its functionality can be achieved using subsetting of spatial classes `SpatialGridMeteorology` and `SpatialPixelsMeteorology`.

Value

- Function `extractdates()`, returns a list with the same length as dates. Each element of the list is a spatial object (`SpatialPointsDataFrame`, `SpatialGridDataFrame` or `SpatialPixelsDataFrame`, depending on the input) with the meteorological data for all the spatial elements. If only one date is asked, the function returns directly the spatial object, without embedding it into a list.
- Function `extractvars()`, returns a list with the same length as vars. Each element of the list is a spatial object (`SpatialPointsDataFrame`, `SpatialGridDataFrame` or `SpatialPixelsDataFrame`, depending on the input) with the meteorological data for all the spatial elements. If only one variable is asked, the function returns directly the spatial object, without embedding it into a list.
- Function `extractgridindex()` returns a data frame.
- Function `extractgridpoints()` returns an object of class `SpatialPointsMeteorology`.

Author(s)

Miquel De Cáceres Ainsa, CTFC

---

**extractNetCDF**

`Extraction of climatic data from NetCDF files (deprecated)`

Description

This function reads a set of NetCDF files (one per variable) and extracts data for a set of NetCDF cells that are specified using a boundary box (in lon,lat format) or a set of (x,y) grid indices.
extractNetCDF

Usage

extractNetCDF(ncdf_files, bbox = NULL, offset = 0, cells = NULL, export = TRUE, exportDir = getwd(), exportFormat = "meteoland/txt", mpfilename = "MP.txt")

Arguments

ncdf_files   Character vector containing files to read
bbox         Boundary box (2 x 2 matrix) specifying the limit coordinates of a study area (in lon/lat format).
offset       A buffer to include NetCDF cells that are at a certain distance around the boundary box.
cells        A (n x 2) matrix specifying the x and y indices of n cells in a grid.
export       If export = FALSE the extracted data is stored in memory. Otherwise the result is written in the disk (using the format specified in exportFormat).
exportFormat Export format for meteorological data (see writemeteorologypoint).
exportDir    Output directory for extracted meteorology.
mpfilename   The name of the file that will store the meta data describing all written files.

Details

Function extractNetCDF first identifies which cells in NetCDF data should be extracted according to bbox (or the cells are indicated by the user using cells), and the overall period (days). If neither bbox or cells is supplied, then all NetCDF cells will be processed. For each cell to be processed, the function loops over all files (which can describe different variables and time periods) and extracts the corresponding data. The function transforms units to the units used in meteoland. If specific humidity and mean temperature are available, the function calculates mean relative humidity.

Extracted meteorological data (a data frame with days in rows and meteorological variables in columns) can be stored in an object SpatialPointsMeteorology-class or it can be written in the disk (one file per cell). In the latter case, the output format can be chosen and the function also writes a supplementary file containing the meta data (i.e. the coordinates and filename of each file).

Humidity in climate model files is given as specific humidity. This is converted to relative humidity and the conversion may produce values above saturation (>100%) (see also defaultCorrectionParams for the same issue when performing bias correction).

Value

If export = FALSE, the function returns an object of class SpatialPointsMeteorology-class with the meteorological series for each cell (represented by a spatial point). Otherwise the function returns an object of class SpatialPointsDataFrame-class containing the meta data of the files written in the disk.

humidity

Humidity conversion tools

Description

Functions to transform specific humidity to relative humidity and vice versa.

Usage

humidity_specific2relative(Tc, HS, allowSaturated = FALSE)
humidity_relative2specific(Tc, HR)

Arguments

Tc       A numeric vector of temperature in degrees Celsius.
HS      A numeric vector of specific humidity (unitless).
HR      A numeric vector of relative Humidity (in %).
allowSaturated  Logical flag to allow values over 100%

Value

A numeric vector with specific or relative humidity.

meteocomplete
interpolation.coverage

Spatial and temporal coverage of interpolation data

Description

Function interpolation.coverage calculates, for each meteorological variable, the number of stations with data per date or the number of dates with data per station in an object of class MeteorologyInterpolationData-class.

Usage

interpolation.coverage(object, type = "spatial", percent = FALSE)

Arguments

- object: An object of class MeteorologyInterpolationData-class.
- type: A string with the coverage summary to be produced (either "spatial" or "temporal").
- percent: A boolean flag to indicate that percentages should be returned instead of counts.

Value

If type = "spatial" the function returns an object of class SpatialPointsDataFrame with the number (or percentage) of dates with data per station and meteorological variable. If type = "temporal" the function returns an object of class data.frame with the number (or percentage) of stations with data per day and meteorological variable.

interpolation.cv  
Calibration and validation of interpolation procedures

Description

Function `interpolation.calibration` determines optimal interpolation parameters 'N' and 'alpha' for a given meteorological variable. Optimization is done by minimizing mean absolute error (MAE) (Thornton et al. 1997). Function `interpolation.cv` calculates average mean absolute errors (MAE) for the prediction period of an object of class 'MeteorologyInterpolationData'. Function `summary.interpolation.cv` returns a data.frame with cross-validation summaries and plot.interpolation.cv plots cross-validation results. In both calibration and validation procedures, predictions for each weather station are made using a leave-one-out procedure (i.e. after excluding the station from the predictive set).

Usage

`interpolation.calibration(object, stations = NULL, variable="Tmin",  
N_seq = seq(5,30, by=5), alpha_seq = seq(0.25,10, by=0.25),  
verbose = FALSE)`

`interpolation.calibration.fmax(object, stations = NULL,  
fmax_seq = seq(0.05,0.95, by=0.05),  
verbose = FALSE)`

`interpolation.cv(object, stations = NULL, verbose = FALSE)`

```r
## S3 method for class 'interpolation.cv'
summary(object, ...)
## S3 method for class 'interpolation.cv'
plot(x, type = "stations", ...)
```

Arguments

- **object**: In the case of function `interpolation.cv`, an object of class `MeteorologyInterpolationData-class`. In the case of function `summary`, an object of class `interpolation.cv`

- **stations**: A numeric vector containing the indices of stations to be used to calculate mean absolute errors (MAE) in the calibration or cross-validation analysis. All the stations with data are included in the training set but predictive MAE are calculated for the 'stations' subset only.
variable A string indicating the meteorological variable for which interpolation parameters 'N' and 'alpha' will be calibrated. Accepted values are 'Tmin' (for minimum temperature), 'Tmax' (for maximum temperature), 'Tdew' (for dew-point temperature), 'PrecEvent' (for precipitation events), 'PrecAmount' (for regression of precipitation amounts), 'Prec' (for precipitation with the same values for precipitation events and regression of precipitation amounts).

N_seq Set of average number of points to be tested.

alpha_seq Set of alpha values to be tested.

type A string of the plot type to be produced (either "stations" or "dates").

Value

Function interpolation.calibration returns an object of class 'interpolation.calibration' with the following items:

- MAE: A numeric matrix with the mean absolute error values (averaged across stations) for each combination of parameters 'N' and 'alpha'.
- minMAE: Minimum MAE value.
- N: Value of parameter 'N' corresponding to the minimum MAE.
- alpha: Value of parameter 'alpha' corresponding to the minimum MAE.
- Observed: A matrix with observed values.
- Predicted: A matrix with predicted values for the optimum parameter combination.

Function interpolation.cv returns a list of class 'interpolation.cv' with the following items:

- stations: A data frame with as many rows as weather stations and the following columns:
  - MinTemperature-Bias: Bias (in degrees), calculated over the prediction period, of minimum temperature estimations in weather stations.
  - MinTemperature-MAE: Mean absolute errors (in degrees), averaged over the prediction period, of minimum temperature estimations in weather stations.
  - MaxTemperature-Bias: Bias (in degrees), calculated over the prediction period, of maximum temperature estimations in weather stations.
  - MaxTemperature-MAE: Mean absolute errors (in degrees), averaged over the prediction period, of maximum temperature estimations in weather stations.
  - Precipitation-Total: Difference in the total precipitation of the studied period.
  - Precipitation-OPD: Difference in the proportion of days with precipitation.
  - Precipitation-Bias: Bias (in mm), calculated over the days with precipitation, of precipitation amount estimations in weather stations.
  - Precipitation-MAE: Mean absolute errors (in mm), averaged over the days with precipitation, of precipitation amount estimations in weather stations.
- **RelativeHumidity-Bias**: Bias (in percent), calculated over the prediction period, of relative humidity estimations in weather stations.
- **RelativeHumidity-MAE**: Mean absolute errors (in percent), averaged over the prediction period, of relative humidity estimations in weather stations.
- **Radiation-Bias**: Bias (in MJ/m²), calculated over the prediction period, of incoming radiation estimations in weather stations.
- **Radiation-MAE**: Mean absolute errors (in MJ/m²), averaged over the prediction period, of incoming radiation estimations in weather stations.

- **dates**: A data frame with as many rows as weather stations and the following columns:
  - **MinTemperature-Bias**: Daily bias (in degrees), averaged over the stations, of minimum temperature estimations.
  - **MinTemperature-MAE**: Daily mean absolute error (in degrees), averaged over the stations, of minimum temperature estimations.
  - **MaxTemperature-Bias**: Daily bias (in degrees), averaged over the stations, of maximum temperature estimations.
  - **MaxTemperature-MAE**: Daily mean absolute error (in degrees), averaged over the stations, of maximum temperature estimations.
  - **Precipitation-Bias**: Daily bias (in mm), averaged over the stations, of precipitation amount estimations.
  - **Precipitation-MAE**: Daily mean absolute error (in mm), averaged over the stations, of precipitation amount estimations.
  - **RelativeHumidity-Bias**: Daily bias (in percent), averaged over the stations, of relative humidity estimations.
  - **RelativeHumidity-MAE**: Daily mean absolute error (in percent), averaged over the stations, of relative humidity estimations.
  - **Radiation-Bias**: Daily bias (in MJ/m²), averaged over the stations, of incoming radiation estimations.
  - **Radiation-MAE**: Daily mean absolute errors (in MJ/m²), averaged over the stations, of incoming radiation estimations.

- **MinTemperature**: A data frame with predicted minimum temperature values.
- **MinTemperatureError**: A matrix with predicted minimum temperature errors.
- **MaxTemperature**: A data frame with predicted maximum temperature values.
- **MaxTemperatureError**: A matrix with predicted maximum temperature errors.
- **Precipitation**: A data frame with predicted precipitation values.
- **PrecipitationError**: A matrix with predicted precipitation errors.
- **RelativeHumidity**: A data frame with predicted relative humidity values.
- **RelativeHumidityError**: A matrix with predicted relative humidity errors.
- **Radiation**: A data frame with predicted radiation values.
- **RadiationError**: A matrix with predicted radiation errors.

interpolationpoints  Interpolate daily meteorology over a landscape

Description

Functions to interpolate meteorological data for spatial locations (at points, grid pixels or full grids) using an object of class MeteorologyInterpolationData-class.
Usage

interpolationpoints(object, points, dates = NULL, export = FALSE,
  exportDir = getwd(), exportFile = NULL,
  exportFormat = "meteoland/txt",
  metadataFile = "MP.txt", verbose=TRUE)

interpolationpixels(object, pixels, dates = NULL,
  exportFile = NULL, exportFormat = "netCDF",
  add = FALSE, overwrite = FALSE, verbose=TRUE)

interpolationgrid(object, grid, dates = NULL,
  exportFile = NULL, exportFormat = "netCDF",
  add = FALSE, overwrite = FALSE, verbose=TRUE)

Arguments

object An object of class MeteorologyInterpolationData-class.
points An object of class SpatialPointsTopography-class.
pixels An object of class SpatialPixelsTopography-class representing the target landscape.
grid An object of class SpatialGridTopography-class representing the target landscape.
dates An object of class Date. If this is NULL then all dates in object are processed.
export If export = FALSE the result of interpolation is stored in memory. Otherwise the result is written in the disk (using the format specified in exportFormat).
exportDir Output directory for interpolated meteorology data files (txt/rds format).
exportFile Output file for interpolated meteorology data (netCDF format).
exportFormat Export format for meteorological data (see writemeteorologypoint). If format is "meteoland/txt", "meteoland/rds", "castanea/txt" or "castanea/rds" the function tries to write one file per point in exportDir. If format is "netCDF" the function will write data to a single file specified by exportFile.
metadataFile The name of the ascii text file that will store the meta data describing all written files.
verbose Boolean flag to print process information.
add Boolean flag to indicate that NetCDF exists and data should be added/replaced.
overwrite Boolean flag to force overwriting an existing NetCDF.

Details

If CRS projection is different between object and points/pixels/grid, the function transforms the coordinates of points/pixels/grid to adapt them to the CRS of object.

Value

If export = FALSE, function interpolationpoints returns an object of SpatialPointsMeteorology-class. If export = TRUE files and written in the disk. For text/rds format the function returns an object of class SpatialPointsDataFrame-class containing point meta data.
If export = FALSE, function `interpolationpoints` returns an object of `SpatialPixelsMeteorology-class`, or an object of `SpatialPixelsDataFrame-class` if a single date is interpolated. If export = TRUE, the function writes the results in a NetCDF.

If export = FALSE, function `interpolationgrid` returns an object of `SpatialGridMeteorology-class`, or an object of `SpatialGridDataFrame-class` if a single date is interpolated. If export = TRUE, the function writes the results in files and a data.frame with columns 'dir' and 'filename' is returned.

---

interpolation_lowlevel

**Low-level interpolation functions**

### Description

Low-level functions to interpolate meteorology (one day) on a set of points.

### Usage

- `interpolation_dewtemperature(Xp, Yp, Zp, X, Y, Z, T, 
  iniRp = 140000, alpha = 3.0, N = 30, iterations = 3)`
- `interpolation_temperature(Xp, Yp, Zp, X, Y, Z, T, 
  iniRp = 140000, alpha = 3.0, N = 30, iterations = 3)`
- `interpolation_precipitation(Xp, Yp, Zp, X, Y, Z, P, Psmooth, 
  iniRp = 140000, alpha_event = 6.25, alpha_amount = 6.25, 
  N_event = 20, N_amount = 20, iterations = 3, popcrit = 0.5, 
  fmax = 0.95)`
- `interpolation_wind(Xp, Yp, WS, WD, X, Y, 
  iniRp = 140000, alpha = 2.0, N = 1, iterations = 3, 
  directionsAvailable = TRUE)`

### Arguments

- **Xp, Yp, Zp**: Spatial coordinates and elevation (Zp; in m.a.s.l) of target points.
- **X, Y, Z**: Spatial coordinates and elevation (Zp; in m.a.s.l) of reference locations (e.g. meteorological stations).
- **T**: Temperature (e.g., minimum, maximum or dew temperature) at the reference locations (in degrees).
- **P**: Precipitation at the reference locations (in mm).
- **Psmooth**: Temporally-smoothed precipitation at the reference locations (in mm).
WS, WD
Wind speed (in m/s) and wind direction (in degrees from north clock-wise) at the reference locations.

iniRp
Initial truncation radius.

iterations
Number of station density iterations.

alpha, alpha_amount, alpha_event
Gaussian shape parameter.

N, N_event, N_amount
Average number of stations with non-zero weights.

popcrit
Critical precipitation occurrence parameter.

fmax
Maximum value for precipitation regression extrapolations (0.6 equals to a maximum of 4 times extrapolation).

directionsAvailable
A flag to indicate that wind directions are available (i.e. non-missing) at the reference locations.

Value
All functions return a vector with interpolated values for the target points.

misp = is.na(P100)
Z = exampleinterpolationdata@elevation
X = exampleinterpolationdata@coords[,1]
Y = exampleinterpolationdata@coords[,2]
Zpv = seq(0,1000, by=100)
mergegrids

mergegrids

Merges meteorological data

Description

Merges point or gridded meteorological data into a single object

Usage

mergepoints(..., verbose=TRUE)
mergegrids(..., verbose=TRUE)

Arguments

...      Objects to be merged, either of class SpatialPointsMeteorology, SpatialGridMeteorology or SpatialPixelsMeteorology. All objects of the same class.
verbose  A logical flag to indicate console output.

Details

Function mergepoints requires all coordinate reference systems to the same. The function allows merging data from the same points (i.e. if they have the same coordinates). Function mergegrids pools dates and variables, but spatial structures (i.e. grid topology, pixel indices, reference system, ...) should be the same for all objects to be merged.

Value

Function codemergepoints returns an object SpatialPointsMeteorology-class. Function mergegrids returns an object SpatialGridMeteorology-class or an object SpatialPixelsMeteorology-class, depending on the input.

Miquel De Cáceres Ainsa, CTFC

See Also

SpatialPointsMeteorology-class, SpatialGridMeteorology-class, SpatialPixelsMeteorology-class
Description

Fills missing values of relative humidity, radiation and potential evapotranspiration from a data frame with daily values of minimum/maximum/mean temperature and precipitation.

Usage

```r
meteocomplete(x, latitude, elevation, slope, aspect)
```

Arguments

- `x`: A data frame with dates as row names and columns named 'MeanTemperature', 'MaxTemperature', 'MinTemperature' and 'Precipitation'
- `latitude`: Latitude in degrees North.
- `elevation`: Elevation in m.a.s.l.
- `slope`: Slope in degrees.
- `aspect`: Aspect in degrees from North.

Details

The function fills values for humidity, radiation and PET only if they are missing in the input data frame. If a column 'SpecificHumidity' is present in the input data, relative humidity is calculated from it. Otherwise, relative humidity is calculated assuming that dew point temperature equals the minimum temperature. Potential solar radiation is calculated from latitude, slope and aspect. Incoming solar radiation is then corrected following Thornton & Running (1999) and potential evapotranspiration following Penman (1948).

Value

A data frame copied from `x` but with filled values for variables:

- MeanRelativeHumidity: Mean daily relative humidity (in percent).
- MinRelativeHumidity: Minimum daily relative humidity (in percent).
- MaxRelativeHumidity: Maximum daily relative humidity (in percent).
- Radiation: Incoming solar radiation (MJ/m²).
- PET: Potential evapotranspiration (in mm of water).

Description

Download data from the Galician Meteorology Agency (MeteoGalicia)

Usage

downloadMGstationlist()
downloadMGhistorical(date_from, date_to, station_id = NULL, verbose = TRUE)
downloadMGcurrentday(station_id = NULL, daily = TRUE, verbose = TRUE)

Arguments

date_from, date_to
   Strings or objects of class Date specifying first and last date of the desired period.

station_id
   A string vector containing station ids (the list of stations presently operative is given by downloadMGstationlist). If NULL all stations with available data are returned.

verbose
   Boolean flag to print process information.

daily
   Boolean flag. Are data to be returned at a daily or hourly scale?

Details

See available data services of MeteoGalicia at https://www.meteogalicia.gal/web/RSS/rssIndex.action?request_locale=es.
**Value**

Function `downloadMGstationlist` returns a `SpatialPointsDataFrame-class` object containing the list of MeteoGalicia weather stations currently operative. Function `downloadMGhistorical` downloads data for the specified MG weather stations (or all) and dates and returns a `SpatialPointsMeteorology-class` object with the downloaded meteorology for each station (point).

Function `downloadMGcurrentday` downloads recent weather data (the last 24h) from all currently available stations and returns data frame if daily = FALSE or a `SpatialPointsDataFrame-class` object with observations aggregated at the daily scale otherwise.

**Author(s)**

Miquel De Cáceres Ainsa, CTFC

**References**

MeteoGalicia (from the Conselleria de Medio Ambiente, Territorio e Vivenda of Xunta de Galicia) should be acknowledged as source of information when using this data.

**See Also**

`SpatialPointsMeteorology-class`
freq  A string giving an interval specification for summaries (e.g., "week", "month", "quarter" or "year").

dates  An object of class Date to define the period to be plotted. If dates = NULL then all dates in object are processed.

months  A numeric vector to indicate the subset of months for which plotting is desired (e.g. c(7,8) for July and August). When combined with fun and freq, this parameter allows plotting summaries for particular seasons. For example fun = "sum" freq = "years" and months = 6:8 leads to plotting the sum over summer months of each year.

add  A flag to indicate whether drawing should be done on the current plot (using function lines).

...  Additional parameters for functions plot or lines.

Details

Daily precipitation is plotted using bars (i.e. type = "h" when calling plot). Otherwise the function draws lines (i.e. type = "l" when calling plot). If object is of class SpatialPointsDataFrame-class then the function reads the meteorological data to be plotted from the disk.

MeteorologyInterpolationData

*Description*

Initializes an object for meteorology interpolation over landscapes using weather station data and the methods described in Thornton et al. (1997) and Thornton & Running (1999).

*Usage*

```r
MeteorologyInterpolationData(points, elevation = NULL, slope = NULL, aspect = NULL,
                              MinTemperature = NULL, MaxTemperature = NULL,
                              Precipitation = NULL, RelativeHumidity = NULL,
                              Radiation = NULL, WindSpeed = NULL,
                              WindDirection = NULL, WindFields = NULL,
                              params = defaultInterpolationParams())
```

*Arguments*

- **points**: An object of class `SpatialPointsMeteorology`, an object of `SpatialPointsTopography` or an object of class `SpatialPoints` (see 'Details').
- **elevation**: A numeric vector with elevation values of weather stations (in meters).
- **slope**: A numeric vector with slope values of weather stations (in degrees). Needed for cross-validation of interpolation routines.
- **aspect**: A numeric vector with aspect values of weather stations (in degrees from North). Needed for cross-validation of interpolation routines.
- **MinTemperature**: A matrix with minimum temperature recordings (in degrees Celsius) for all weather stations (in rows) and all days (in columns).
- **MaxTemperature**: A matrix with maximum temperature recordings (in degrees Celsius) for all weather stations (in rows) and all days (in columns).
- **Precipitation**: A matrix with precipitation recordings (in mm of water) for all weather stations (in rows) and all days (in columns).
- **RelativeHumidity**: A matrix with (mean) relative humidity recordings (in percent) for all weather stations (in rows) and all days (in columns).
- **Radiation**: A matrix with relative radiation recordings (in MJ/m2) for all weather stations (in rows) and all days (in columns). Needed for cross-validation only.
- **WindSpeed**: A matrix with wind speed recordings (in m/s) for all weather stations (in rows) and all days (in columns).
- **WindDirection**: A matrix with wind direction recordings (in degrees from North) for all weather stations (in rows) and all days (in columns).
- **WindFields**: Object of class "list". See function `readWindNinjaWindFields`.
- **params**: A list containing interpolation parameters.
Details

There are three ways of building an object of `MeteorologyInterpolationData`:

1. The first way is using an object of `SpatialPointsMeteorology` containing both the coordinates and meteorological series of stations. In this case elevation has to be provided, but aspect and slope may be ommitted. Parameters `MinTemperature` to `WindDirection` can be left as NULL.

2. The second way is using an object of class of `SpatialPointsTopography` containing the coordinates of stations and topographic variables. In this case parameters `MinTemperature`, `MaxTemperature` and `Precipitation` will need to be supplied, each being a matrix with weather stations in rows and days in columns, but `RelativeHumidity` to `WindDirection` may be left as NULL.

3. The third way is using an object of `SpatialPoints` containing the coordinates of stations only. In this case elevation has to be provided, but aspect and slope may be ommitted. As in the second case, parameters `MinTemperature`, `MaxTemperature` and `Precipitation` will need to be supplied, each being a matrix with weather stations in rows and days in columns, but `RelativeHumidity` to `WindDirection` may be left as NULL.

Value

An object of class `MeteorologyInterpolationData`.

Author(s)

Miquel De Cáceres Ainsa, Biodiversity and Landscape Ecology Laboratory, Centre Tecnologic Forestal de Catalunya

MeteorologyInterpolationData-class

Class "MeteorologyInterpolationData"

Description

An S4 class to interpolate meteorology over a landscape.

Objects from the Class

Objects can be created by calls of the form new("MeteorologyInterpolationData",...), or by calls to the function MeteorologyInterpolationData.

Slots

dates: Object of class "Date" describing the time period for which meteorological estimates are possible.
bbox: Object of class "matrix" with the boundary box that sets meteorological estimation boundaries.
proj4string: Object of class "CRS" with the projection string of station spatial coordinates.
coords: Object of class "matrix" containing the coordinates of weather stations (each row is a point).
elevation: A numeric vector with elevation values of weather stations (in meters).
slope: A numeric vector with slope values of weather stations (in degrees). Needed for cross-validation only.
slope: A numeric vector with aspect values of weather stations (in degrees from North). Needed for cross-validation only.
MinTemperature: Object of class "data.frame" with minimum temperature recordings (in degrees Celsius) for all weather stations (in rows) and all days (in columns).
MaxTemperature: Object of class "data.frame" with maximum temperature recordings (in degrees Celsius) for all weather stations (in rows) and all days (in columns).
SmoothedTemperatureRange: Object of class "matrix" with temporally smoothed temperature range recordings (in degrees Celsius) for all weather stations (in rows) and all days (in columns).
Precipitation: Object of class "matrix" with precipitation recordings (in mm of water) for all weather stations (in rows) and all days (in columns).
SmoothedPrecipitation: Object of class "matrix" with temporally smoothed precipitation recordings (in mm of water) for all weather stations (in rows) and all days (in columns).
RelativeHumidity: Object of class matrix with relative humidity recordings (in percent) for all weather stations (in rows) and all days (in columns).
Radiation: Object of class matrix with relative radiation recordings (in MJ/m2) for all weather stations (in rows) and all days (in columns). Needed for cross-validation only.
WindSpeed: Object of class "matrix" with wind speed recordings (in m/s) for all weather stations (in rows) and all days (in columns).
WindDirection: Object of class "matrix" with wind direction recordings (in degrees from North) for all weather stations (in rows) and all days (in columns).

WindFields: Object of class "list". See function `readWindNinjaWindFields`.

WFIndex: Object of class "matrix" with the closest windfield index for each stations in each day.

WFFactor: Object of class "matrix" with the multiplication factor for the wind speed of each stations in each day.

params: A "list" containing interpolation parameters.

Extends

Class "MeteorologyProcedureData", directly. Class "Spatial", by class "MeteorologyProcedureData", distance 2

Methods

**subsample** signature(object = "MeteorologyInterpolationData"): Generates a `MeteorologyInterpolationData` object for a smaller area and a subset of dates.

Author(s)

Miquel De Cáceres Ainsa, Centre Tecnologic Forestal de Catalunya

showClass("MeteorologyInterpolationData")
```

---

Description

A virtual class for estimating meteorology over landscapes

Objects from the Class

A virtual Class: No objects may be created from it.
MeteorologyUncorrectedData

Slots

dates: Object of class "Date" describing the time period for which meteorological estimates are possible.

bbox: Object of class "matrix" with the boundary box that sets meteorological estimation boundaries.

proj4string: Object of class "CRS" with the projection string of accepted coordinates.

Methods

subsample signature(object = "MeteorologyProcedureData"): Generates MeteorologyProcedureData objects for a smaller area and a subset of dates.

Extends

Class "Spatial", directly.

MeteorologyUncorrectedData

Creates an object of class 'MeteorologyUncorrectedData'

Description

Initializes an object for statistical correction of meteorological data over landscapes.

Usage

MeteorologyUncorrectedData(points, reference_data, projection_data, dates, params = defaultCorrectionParams())
MeteorologyUncorrectedData-class

Arguments

points
An object of class SpatialPoints.

reference_data
Reference (historic) meteorological data used to calibrate correction factors when compared with observations. A vector of data frames (one per point) or a single data frame containing the meta data (columns dir and filename) of meteorological files that will be read from the disk.

projection_data
Projected meteorological data to be corrected. A vector of data frames (one per point) or a single data frame containing the meta data (columns dir and filename) of meteorological files that will be read from the disk.

dates
Object of class "Date" describing the time period for which meteorological correction is possible (corresponding to projection_data).

params
A "list" containing correction parameters.

Details

See correction details in vignettes or in correctionpoints.

Value

An object of class MeteorologyUncorrectedData.

Author(s)

Miquel De Cáceres Ainsa, Biodiversity and Landscape Ecology Laboratory, Centre Tecnologic Forestal de Catalunya

See Also

MeteorologyUncorrectedData, examplecorrectiondata, defaultCorrectionParams.

#Structure of the S4 object
showClass("MeteorologyUncorrectedData")
Description

Functions to calculate potential evapotranspiration using Penman or Penman-Monteith.

Usage

```r
penman(latrad, elevation, slorad, asprad, J,
    Tmin, Tmax, RHmin, RHmax, Rs, u,
    z=2.0, z0 = 0.001, alpha = 0.08, windfun="1956")

penmanmonteith(rc, elevation, Tmin, Tmax, RHmin, RHmax, Rn, u = NA)
```

Arguments

- `latrad`: Latitude in radians.
- `elevation`: Elevation (in m).
- `slorad`: Slope (in radians).
- `asprad`: Aspect (in radians from North).
- `J`: Julian day, number of days since January 1, 4713 BCE at noon UTC.
- `Tmax`: Maximum temperature (degrees Celsius).
- `Tmin`: Minimum temperature (degrees Celsius).
- `RHmin`: Minimum relative humidity (percent).
- `RHmax`: Maximum relative humidity (percent).
- `Rs`: Solar radiation (MJ/m^2).
- `u`: With wind speed (m/s).
- `z`: Wind measuring height (m).
- `z0`: Roughness height (m).
- `alpha`: Albedo.
- `windfun`: Wind speed function version, either "1948" or "1956".
- `rc`: Canopy vapour flux (stomatal) resistance (s·m⁻¹).
- `Rn`: Daily net radiation (MJ·m⁻²·day⁻¹).

Details

The code was adapted from package ‘Evapotranspiration’, which follows McMahon et al. (2013). If wind speed is not available, an alternative formulation for potential evapotranspiration is used as an approximation (Valiantzas 2006).
Value

Potential evapotranspiration (in mm of water).

interpolationpoints

Description

Function precipitation_concentration() calculates daily precipitation concentration (Martin-Vide et al. 2004). Function precipitation_rainfallErosivity() calculates a multi-year average of monthly rainfall erosivity using the MedREM model proposed by Diodato and Bellochi (2010) for the Mediterranean area (see also Guerra et al. 2016).

Usage

precipitation_concentration(p)
precipitation_rainfallErosivity(x, long, scale = "month", average = TRUE)

Arguments

p A numeric vector with daily precipitation values.
x A data frame of meteorological variables (dates as row names and variables as columns).
long Longitude in degrees.
scale Either ‘month’ or ‘year’.
average Boolean flag to calculate multi-year averages before applying MedREM’s formula.
Details

MedREM model is: \( R_m = b_0 \cdot P \cdot \sqrt{d} \cdot (\alpha + b_1 \cdot \text{longitude}) \), where \( P \) is cumulated precipitation and \( d \) is maximum daily precipitation. Parameters used for the MedREM model are \( b_0 = 0.117 \), \( b_1 = -0.015 \), \( \alpha = 2 \). Note that there is a mistake in Guerra et al. (2016) regarding parameters \( b_1 \) and \( \alpha \).

Value

Function \( \text{precipitation\_concentration()} \) returns a value between 0 (equal distribution of rainfall) and 1 (one day concentrates all rainfall). Function \( \text{precipitation\_rainfallErosivity()} \) returns a vector of twelve values (one for each month) (in MJ-mm-ha-1-h-1-month-1) or one value (in MJ-mm-ha-1-h-1-yr-1) depending on the scale.

**Solar radiation utility functions**

**Description**

Set of functions used in the calculation of incoming solar radiation and net radiation.

**Usage**

```
radiation_dateStringToJulianDays(dateStrings)
radiation_daylength(latrad, slorad, asprad, delta)
radiation_daylengthseconds(latrad, slorad, asprad, delta)
radiation_directDiffuseInstant(solarConstant, latrad, slorad, asprad, delta, hrad, R_s, clearday)
radiation_directDiffuseDay(solarConstant, latrad, slorad, asprad, delta, R_s, clearday, nsteps = 24)
radiation_potentialRadiation(solarConstant, latrad, slorad, asprad, delta)
radiation_julianDay(year, month, day)
radiation_skyLongwaveRadiation(Tair, vpa, c)
```
radiation

radiation_outgoingLongwaveRadiation(solarConstant, latrad, elevation, slorad, asprad, delta, vpa, tmin, tmax, R_s)
radiation_netRadiation(solarConstant, latrad, elevation, slorad, asprad, delta, vpa, tmin, tmax, R_s, alpha = 0.08)
radiation_solarConstant(J)
radiation_solarDeclination(J)
radiation_solarElevation(latr, delta, hrad)
radiation_solarRadiation(solarConstant, latrad, elevation, slorad, asprad, delta, diffTemp, diffTempMonth, vpa, precipitation)
radiation_sunRiseSet(latr, slorad, asprad, delta)

Arguments

dateStrings A character vector with dates in format "YYYY-MM-DD".
ltrad Latitude (in radians North).
slorad Slope (in radians).
asprad Aspect (in radians from North).
delta Solar declination (in radians).
solarConstant Solar constant (in kW·m-2).
hrad Solar hour (in radians).
R_s Daily incident solar radiation (MJ·m-2).
clearday Boolean flag to indicate a clearsky day (vs. overcast).
nsteps Number of daily substeps.
J Julian day (integer), number of days since January 1, 4713 BCE at noon UTC.
year, month, day Year, month and day as integers.
alpha Surface albedo (from 0 to 1).
Tair Air temperature (in degrees Celsius).
vpa Average daily vapor pressure (kPa).
c Proportion of sky covered by clouds [0-1].
tmin, tmax Minimum and maximum daily temperature (ºC).
elevation Elevation above sea level (in m).
precipitation Precipitation (in mm).
diffTemp Difference between maximum and minimum temperature (ºC).
diffTempMonth Difference between maximum and minimum temperature, averaged over 30 days (ºC).

Value

Values returned for each function are:

- radiation_dateStringToJulianDays: A vector of Julian days (i.e. number of days since January 1, 4713 BCE at noon UTC).
- radiation_daylength: Day length (in hours).
- radiation_daylengthseconds: Day length (in seconds).
- radiation_directDiffuseInstant: A vector with instantaneous direct and diffusive radiation rates (for both SWR and PAR).
- radiation_directDiffuseDay: A data frame with instantaneous direct and diffusive radiation rates (for both SWR and PAR) for each subdaily time step.
- radiation_potentialRadiation: Daily (potential) solar radiation (in MJ·m-2).
- radiation_julianDay: Number of days since January 1, 4713 BCE at noon UTC.
- radiation_skyLongwaveRadiation: Instantaneous incoming (sky) longwave radiation (W·m-2).
- radiation_outgoingLongwaveRadiation: Daily outgoing longwave radiation (MJ·m-2·day-1).
- radiation_netRadiation: Daily net solar radiation (MJ·m-2·day-1).
- radiation_solarConstant: Solar constant (in kW·m-2).
- radiation_solarDeclination: Solar declination (in radians).
- radiation_solarElevation: Angle of elevation of the sun with respect to the horizon (in radians).
- radiation_solarRadiation: Daily incident solar radiation (MJ·m-2·day-1).
- radiation_sunRiseSet: Sunrise and sunset hours in hour angle (radians).

**Note**

Code for radiation_julianDay(), radiation_solarConstant() and radiation_solarDeclination() was translated to C++ from R code in package 'insol' (by J. G. Corripio).

readmeteorologygrid    Reads gridded meteorology from the disk

Description

Functions to read gridded meteorological data from the disk.

Usage

readmeteorologygrid(files, format = "netCDF", varmapping = NULL,     
                      dates = NULL, bbox = NULL, offset = 0, verbose = FALSE)
readmeteorologypixels(files, format = "netCDF", varmapping = NULL,     
                        dates = NULL, bbox = NULL, offset = 0, verbose = FALSE)
readmeteorologygridpoints(files, format = "netCDF", varmapping = NULL,     
                           dates = NULL, bbox = NULL, offset = 0,     
                           relativehumidity = FALSE, verbose = FALSE)

Arguments

files      Character vector with the file names to be read.
format     Format of meteorological data. Currently, the only accepted format is "netCDF".
varmapping Named character vector specifying a mapping of variables in the NetCDF into variables used in meteoland (e.g. c(MinTemperature = "tmn") specifies a map of variable 'tmn' to MinTemperature).
dates      A character or Date vector to specify subset of dates to be read.
bbox       Boundary box (2 x 2 matrix) specifying the minimum and maximum coordinates of a study area.
offset     A buffer to include NetCDF cells that are at a certain distance around the boundary box.
relativehumidity     A logical flag to indicate estimation of relative humidity from specific humidity if possible.
verbose     A logical flag to output process information in the console.

Details

Function readmeteorologygrid reads one or several files containing the meteorology over a grid for a set of days. Function readmeteorologypixels reads one or several file containing the meteorology over a grid for a set of days and filters those pixels with missing data. If more than one file is specified, the functions read all of them and then try to merge the data into a single meteorology object (see function mergegrids).
readmeteorologypoint

Function `readmeteorologygridpoints` is similar to the preceding ones, but is meant to extract specific grid pixels and return them as spatial points. If more than one file is specified, the function reads all of them and then tries to merge the data into a single meteorology object (see function `mergepoints`).

The functions are primarily meant to read NetCDF written by package meteoland, but also to import data written by other software. In this case, a mapping can be supplied to map variable names in the netCDF to variables used in meteoland. Rotated grids should not be read using functions `readmeteorologygrid` or `readmeteorologypixels`.

Value

- Function `readmeteorologygrid` returns an object `SpatialGridMeteorology-class`.
- Function `readmeteorologypixels` returns an object `SpatialPixelsMeteorology-class`.
- Function `readmeteorologygridpoints` returns an object `SpatialPointsMeteorology-class`.

Author(s)

Miquel De Cáceres Ainsa, CTFC

See Also

`writemeteorologygrid`, `writemeteorologypixels`, `SpatialPointsMeteorology-class`, `SpatialGridMeteorology-class`, `SpatialPixelsMeteorology-class`, `mergegrids`, `mergepoints`

---

**readmeteorologypoint**  
Reads point meteorology from the disk

**Description**

Functions to read point meteorological data from the disks in different formats.

**Usage**

```r
readmeteorologypoint(file, dates = NULL, format = "meteoland/txt", sep="\t")
readmeteorologypointfiles(points, files=NULL, dates = NULL, format="meteoland/txt", sep="\t")
readmeteorologypoints(files, dates = NULL, stations = NULL, format = "netCDF", varmapping = NULL, verbose = FALSE)
```

**Arguments**

- `file`  
  A string of the file to be read.

- `points`  
  An object of class `SpatialPoints-class` (in this case files cannot be NULL) or object of class `SpatialPointsDataFrame-class` with two data columns: 'dir' and 'filename' (and possibly 'format').

- `files`  
  A vector of strings to be read (when points is of class `SpatialPoints-class`). Length and order must match points.
dates: Object of class "Date" describing a subset of dates to be extracted from meteorological series. If NULL the whole period read from files is kept.

format: Format of meteorological data. Current accepted formats for readmeteorologypoint and readmeteorologypointfiles are "meteoland/txt", "meteoland/rds", "castanea/txt" and "castanea/rds". The only accepted format for readmeteorologypoints is "netCDF".

sep: The field separator character for ascii text files (see read.table).

stations: An integer vector or string vector identifying point indices or station names in the netCDF.

varmapping: Named character vector specifying a mapping of variables in the NetCDF into variables used in meteoland (e.g. c(MinTemperature = "tmn") specifies a map of variable 'tmn' to MinTemperature).

verbose: A logical flag to output process information in the console.

Details

Function readmeteorologypoint reads data series of a single location from an ascii or rds file and returns a data frame. Function readmeteorologypointfiles can be used to read multiple ascii/rds files and build an object of SpatialPointsMeteorology-class. This is done by supplying an points object of class SpatialPointsDataFrame-class with point meta data. In readmeteorologypointfiles the value of format is used as default but can be overloaded if points includes a column 'format'.

Function readmeteorologypoints is used to read multiple point data from a netCDF. In this case, a mapping can be supplied to map variable names in the netCDF to variables used in meteoland.

Description

Reads WindNinja results

Reads the wind fields generated by 'WindNinja' (http://www.firelab.org/project/windninja) for combinations of domain-level wind speed and wind direction classes.
Usage

```r
readWindNinjaWindFields(filebase, resolution = "100m",
                         directionClasses = c(0, 45, 90, 135, 180, 225, 270, 315),
                         speedClasses = c(5, 15, 25), proj4string = CRS(as.character(NA)))
```

Arguments

- **filebase**: A string to indicate the template for accessing WindNinja files. Resolution, wind directions and wind speed class values are appended to this string to obtain the filename to read.
- **resolution**: Resolution string.
- **directionClasses**: A vector of wind speed directions (in degrees).
- **speedClasses**: A vector of wind class values (in m/s).
- **proj4string**: Object of class "CRS" with the projection string of wind field rasters.

Value

A list with the following items:

- **directionClasses**: The vector of wind direction classes.
- **speedClasses**: The vector of wind speed classes.
- **indexTable**: A numeric matrix indicating the raster index of each combination of domain-level wind directions and wind speed classes.
- **windSpeed**: An object of class `SpatialGridDataFrame` containing wind speed rasters (in m/s) for each combination of domain-level wind direction and wind speed.
- **windDirection**: An object of class `SpatialGridDataFrame` containing wind direction rasters (in degrees from North) for each combination of domain-level wind direction and wind speed.

Note

WindNinja should be run with m/s as wind speed units and for all the combinations of domain-level wind speed and wind direction required.

MeteorologyInterpolationData
Examples

## TO BE DONE ##

### Description ###

Reshapes weather station data acquired using the 'worldmet' or 'weathercan' R packages into formats useful for meteoland

### Usage ###

```r
reshapeworldmet(hourly_data, output = "SpatialPointsMeteorology", proj4string = NULL, complete = TRUE, verbose = TRUE)
```

```r
reshapeweathercan(hourly_data, daily_data = NULL, output = "SpatialPointsMeteorology", proj4string = NULL, complete = TRUE, verbose = TRUE)
```

### Arguments ###

- **hourly_data**: Hourly weather data. In the case of `reshapeworldmet`, a tibble or data frame returned by function `importNOAA`. In the case of `reshapeweathercan`, a tibble or data frame returned by function `weather_dl` with `interval="hour"`.
- **daily_data**: Daily weather data (only for `reshapeweathercan`), a tibble or data frame returned by function `weather_dl` with `interval="day"`.
- **output**: Kind of output desired. Either `'SpatialPointsTopography'`, `'SpatialPointsMeteorology'` or `'MeteorologyInterpolationData'`.
- **proj4string**: A string or CRS to change the coordinate reference system of the output. If NULL the spatial reference will be geographic coordinates (i.e. CRS("+proj=longlat")). When reshaping to `MeteorologyInterpolationData` it is recommended to use a reference system with meters in units, such as UTM.
- **complete**: A flag to indicate that missing variables should be completed using function `meteocomplete`.
- **verbose**: A flag to show information of the reshape process in the console output.

### Details ###

Note that to have precipitation included in downloads from 'worldmet' you should set 'precip = TRUE' when calling function 'importNOAA'. In the case of weathercan, precipitation is only provided for daily data (i.e. setting 'interval="day"' when calling 'weather_dl'), whereas wind speed and relative humidity are only available for hourly data (i.e., setting 'interval="hour"' when calling 'weather_dl'). Hence, in meteoland we recommend downloading both daily and hourly data and then calling function `reshapeweathercan` to merge the two sources.
SMC download

Value

An object of the class indicated in output.

Author(s)

Miquel De Cáceres Ainsa, CTFC

See Also

meteocomplete

Description

Download data from the Catalan automatic weather station network (XEMA from Servei Meteorològic de Catalunya)

Usage

downloadSMCvarmetadata(api, type = "current")
downloadSMCstationlist(api, date = NULL)
downloadSMCcurrentday(api, daily_meteoland = TRUE, variable_code=NULL, station_id=NULL, date = Sys.Date(), verbose=TRUE)
downloadSMChistorical(api, dates, station_id=NULL, variable_code=NULL, export = FALSE, exportDir = getwd(), exportFormat = "meteoland/txt", metadataFile = "MP.txt", verbose=TRUE)

Arguments

api String with the SMC API key (the procedure to apply for an api key is explained in https://apidocs.meteocat.gencat.cat/).
type Either 'current' or 'historical' for current day variable metadata or historical variable metadata, respectively.
daily_meteoland When daily_meteoland = TRUE all the usual variables in meteoland are downloaded and aggregated at the daily scale. When daily_meteoland = FALSE, the user can choose the desired variables using variable_code.
variable_code A character vector with variable codes to be queried. If NULL in downloadSMChistorical all the usual variables for meteoland are downloaded. Otherwise, the results are returned as a data frame.
dates An object of class Date with dates comprised within the last two years.
date An object of class Date. By default the current day in the case of downloadSMCcurrentday(). In the case of downloadSMCstationlist() a date for which operational stations are queried.
station_id A string vector containing station ids (the list of stations for which climatic series are available is given by downloadSMCstationlist()). If NULL, all available stations are queried. Otherwise, only the data corresponding to the specified stations will be returned.

export If export = FALSE the downloaded data is stored in memory. Otherwise the result is written on the disk (using the format specified in exportFormat).

exportDir Output directory for downloaded meteorology.

exportFormat Format of meteorological data. Current accepted formats are “castanea” and “meteoland”.

metadataFile The name of the file that will store the meta data describing all written files.

verbose Boolean flag to print process information.

Details

API key needs to be requested from SMC (https://apidocs.meteocat.gencat.cat/).

Value

Function downloadSMCstationlist returns a SpatialPointsDataFrame-class object containing the list of SMC operational weather stations for the date given.

Function downloadSMCvarmetadata returns a data frame with weather variables, their units and acronym to be used in queries (see parameter variable_code).

Function downloadSMCcurrentday downloads recent weather (the last 24h or the weather for a given date) from all currently available stations and returns data frame if daily_meteoland = FALSE or a SpatialPointsDataFrame-class object with observations aggregated at the daily scale otherwise.

Function downloadSMChistorical downloads historical daily weather corresponding to a given time period from a set (or all currently available) stations. Results are returned (or exported) after formatting data as a SpatialPointsMeteorology-class if variable_code = NULL, or as a data frame otherwise.

SpatialGridMeteorology-class

SpatialGridMeteorology-class

Class "SpatialGridMeteorology"

Description

An S4 class that represents a spatial grid with meteorology daily data.

Objects from the Class

Objects can be created by calls of the form new("SpatialGridMeteorology", ...), or by calls to the function SpatialGridMeteorology.
**SpatialGridTopography**

**Slots**
- **dates**: Object of class "Date" describing the time period for which meteorological estimates are available.
- **data**: A vector of "data.frame" objects, each one containing the grid data for one date.
- **bbox**: Object of class "matrix" with the boundary box.
- **proj4string**: Object of class "CRS" with the projection string.

**Extends**

**Methods**
- [ signature(x = "SpatialGridMeteorology", i = "ANY", j = "ANY", drop = "ANY")]: subsets the grid and associated meteorology; only rows (x values) and columns (y values) can be subsetted.
- **coerce** signature(x = "SpatialGridMeteorology", to = "STFDF"): coerces into a spacetime STFDF object.
- **coerce** signature(x = "SpatialGridMeteorology", to = "stars"): coerces into a stars object.

**Author(s)**
Miquel De Cáceres Ainsa, CTFC

**See Also**
- SpatialGridTopography, SpatialGridDataFrame-class

**Examples**
```r
#Structure of the S4 object
tests <- SpatialGridTopography(grid, elevation, slope = NULL, aspect = NULL)
showClass("SpatialGridMeteorology")
```

**Description**
Function SpatialGridTopography creates an object of class SpatialGridTopography-class containing topographic variables over a landscape.

**Usage**
```r
SpatialGridTopography(grid, elevation, slope = NULL, aspect = NULL, proj4string = CRS(as.character(NA)))
```
Arguments

- **grid**: An object of class `GridTopology-class` or `SpatialGrid-class`.
- **elevation**: A vector of elevation values for all cells of the grid (in m.a.s.l.).
- **slope**: A vector of slope angles for all cells of the grid (in degrees). If `slope=NULL`, slope is calculated as indicated in details.
- **aspect**: A vector of aspect angles for all cells of the grid (in degrees from North clockwise). If `aspect=NULL`, aspect values are calculated as indicated in details.
- **proj4string**: An object of class `CRS-class`.

Details

Slope and aspect calculations were adapted from functions in package 'SDMTools', which used the approach described in Burrough & McDonell (1998).

The rate of change (delta) of the surface in the horizontal \( \frac{dz}{dx} \) and vertical \( \frac{dz}{dy} \) directions from the center cell determines the slope and aspect. The values of the center cell and its eight neighbors determine the horizontal and vertical deltas. The neighbors are identified as letters from 'a' to 'i', with 'e' representing the cell for which the aspect is being calculated. The rate of change in the x direction for cell 'e' is calculated with the algorithm:

\[
\frac{dz}{dx} = \frac{(c + 2f + i) - (a + 2d + g)}{8 \times x_{cell\_size}}
\]

The rate of change in the y direction for cell 'e' is calculated with the following algorithm:

\[
\frac{dz}{dy} = \frac{(g + 2h + i) - (a + 2b + c)}{8 \times y_{cell\_size}}
\]

The algorithm calculates slope as:

\[
\text{slope}\_\text{degrees} = \text{ATAN} \left( \frac{\text{rise}\_\text{run}}{\text{run}} \right) \times 57.29578
\]

The aspect value is then converted to compass direction values (0-360 degrees).

Value

Function `SpatialGridTopography` returns an object `SpatialGridTopography-class`.

SpatialGridTopography-class

Class "SpatialGridTopography"

Description

An S4 class that represents topography over a grid of coordinates.

Objects from the Class

Objects can be created by calls of the form new("SpatialGridTopography",...), or by calls to the function SpatialGridTopography.

Slots

- grid: Object of class GridTopology.
- data: Object of class "data.frame" containing the elevation (in m), slope (in degrees) and aspect (in degrees from North) of every cell.
- bbox: Object of class "matrix" with the boundary box.
- proj4string: Object of class "CRS" with the projection string.

Extends

Methods

[ signature(x = "SpatialGridTopography",i = "ANY",j = "ANY",drop = "ANY")]: subsets the grid and associated topography; only rows (x values) and columns (y values) can be subsetted.

SpatialPixelsTopography-class

Class "SpatialPixelsTopography"

Description

An S4 class that represents topography that has locations on a regular grid.

Objects from the Class

Objects can be created by calls of the form new("SpatialPixelsTopography", ...), or by calls to the function SpatialPixelsTopography.

Slots

data: Object of class "data.frame" containing the elevation (in m), slope (in degrees) and aspect (in degrees from North) of every cell.
coords.nrs: Inherited from SpatialPointsDataFrame but not used.
grid: Object of class GridTopology.
grid.index: Index of points in full grid.
coords: Object of class "matrix" with the spatial coordinates.
bbox: Object of class "matrix" with the boundary box.
proj4string: Object of class "CRS" with the projection string.
SpatialPointsMeteorology

Extends

Methods

[ signature(x = "SpatialGridTopography", i = "ANY", ..., drop = "ANY"): subsets the pixels and associated topography; only one dimension can be subsetted. If drop = TRUE the boundary box is recalculated.

spplot signature(object = "SpatialPixelsTopography"): allows plotting topography maps.

Author(s)

Miquel De Cáceres Ainsa, Biodiversity and Landscape Ecology Laboratory, Centre Tecnologic Forestal de Catalunya

SpatialPointsMeteorology

Creates a 'SpatialPointsMeteorology'

Description

Initializes an object of class SpatialPointsMeteorology-class

Usage

SpatialPointsMeteorology(points, data, dates, dataByDate = FALSE)

Arguments

points An object of class SpatialPoints-class. Row names of point coordinates are used to identify points.
data A list of data frames. If dataByDate = FALSE the elements of data are assumed to correspond to points. If dataByDate = TRUE the elements of data are assumed to correspond to dates (see 'Details').
dates Object of class "Date" describing the time period of meteorological estimates.
dataByDate A flag to indicate that elements of data correspond to dates, as opposed to the default (dataByDate = FALSE) which assumes that elements correspond to points (see 'Details').

Details

There are two ways of building an object of class SpatialPointsMeteorology-class. The first way (dataByDate = FALSE) is to supply as value for data a vector of data frames with one data frame per spatial point, with dates as rows and meteorological variables as columns. In this case all data frames must have the same number of rows (dates) and columns (variables). The second way (if dataByDate = TRUE) is to supply as value for data a vector of data frames with one data frame per date, with points as rows and meteorological variables as columns. In this case, the data frames may have different rows and different columns. Only the information corresponding to points will be taken and some variables may be missing.

Value

An object of class SpatialPointsMeteorology-class

Author(s)

Miquel De Cáceres Ainsa, Centre Tecnologic Forestal de Catalunya

See Also

SpatialPointsMeteorology-class

SpatialPointsMeteorology-class

Class "SpatialPointsMeteorology"

Description

An S4 class that represents a set of points with meteorology data series.

Objects from the Class

Objects can be created by calls of the form new("SpatialPointsMeteorology",...), or by calls to the function SpatialPointsMeteorology.

Slots

dates: Object of class "Date" describing the time period for which meteorological estimates are available.

data: A vector of "data.frame" objects, each one corresponding to one spatial point.
coords: Object of class "matrix" with the spatial coordinates.
bbox: Object of class "matrix" with the boundary box.
proj4string: Object of class "CRS" with the projection string.
SpatialPointsTopography

Extends

Methods

- \texttt{signature(x = "SpatialPointsMeteorology", i = "ANY", j = "ANY", drop = "ANY")}: subsets the spatial points and the corresponding list of meteorological data; only rows (points) can be subsetted.
- \texttt{coerce signature(x = "SpatialPointsMeteorology", to = "STFDF")}: coerces into a spacetime STFDF object.
- \texttt{coerce signature(x = "SpatialPointsMeteorology", to = "stars")}: coerces into a stars object.

Author(s)

Miquel De Cáceres Ainsa, CTFC

SpatialPointsTopography-class, SpatialPoints-class

Examples

```r
# Structure of the S4 object
showClass("SpatialPointsMeteorology")
```

Description

Function \texttt{SpatialPointsTopography} creates an object of class \texttt{SpatialPointsTopography-class} containing topographic variables for a set of points.

Usage

\begin{verbatim}
SpatialPointsTopography(points, elevation, slope = NULL, aspect = NULL,
    proj4string = CRS(as.character(NA)))
\end{verbatim}

Arguments

- \texttt{points}: An object of class \texttt{SpatialPoints-class}.
- \texttt{elevation}: Elevation values (in m) of the points.
- \texttt{slope}: Slope values (in degrees) of the points.
- \texttt{aspect}: Aspect values (in degrees from North) of the points.
- \texttt{proj4string}: Object of class \texttt{CRS} in the first form only used when points does not inherit from \texttt{Spatial}.
SpatialPointsTopography-class

Details

If either slope = NULL or aspect = NULL then when estimating weather on the object locations radiation will be calculated assuming a flat surface.

Value

Function SpatialPointsTopography returns an object ‘SpatialPointsTopography-class’.

SpatialPointsTopography-class

Class "SpatialPointsTopography"

Description

An S4 class that represents topography over a grid of coordinates.

Objects from the Class

Objects can be created by calls of the form new("SpatialPointsTopography",...), or by calls to the function SpatialPointsTopography.
Slots

data: Object of class "data.frame" containing the elevation (in m), slope (in degrees) and aspect (in degrees from North) of every point.

coops: Object of class "matrix" with the spatial coordinates.

cbbox: Object of class "matrix" with the boundary box.

proj4string: Object of class "CRS" with the projection string.

Extends

Methods

[ signature(x = "SpatialPointsTopography", i = "ANY", j = "ANY", drop = "ANY"): subsets the spatial points and associated topography; only rows (points) can be subsetted.

showClass("SpatialPointsTopography")

spplot Spatial grid plots

Description

Function spplot for SpatialGridTopography-class and SpatialPixelsTopography-class objects allows drawing maps of topographic attributes. Function spplot for SpatialGridMeteorology-class and SpatialPixelsMeteorology-class objects allows drawing maps of meteorological variables corresponding to specific dates.
Usage

```r
## S4 method for signature 'SpatialGridTopography'
spplot(obj, variable="elevation", ...)
## S4 method for signature 'SpatialGridMeteorology'
spplot(obj, date, variable="MeanTemperature", ...)
## S4 method for signature 'SpatialPixelsTopography'
spplot(obj, variable="elevation", ...)
## S4 method for signature 'SpatialPixelsMeteorology'
spplot(obj, date, variable="MeanTemperature", ...)
```

Arguments

- `obj`: An object of class `SpatialGridTopography`.
- `variable`: A string of the variable to be plotted (only `type="elevation"`, `type="slope"`, `type="aspect"` are allowed).
- `...`: Additional parameters to function `spplot`.
- `date`: A string or an integer for the date to be plotted.

Author(s)

Miquel De Cáceres Ainsa, Biodiversity and Landscape Ecology Laboratory, Centre Tecnologic Forestal de Catalunya

See Also

`meteoplot`

Examples

```r
data(examplegridtopography)

# Display data
spplot(examplegridtopography, type="elevation", scales=list(draw=TRUE))
spplot(examplegridtopography, type="slope", scales=list(draw=TRUE))
spplot(examplegridtopography, type="aspect", scales=list(draw=TRUE))
```

Subsample

Sub-sampling procedure data

Description

Generates a spatial and/or temporal subset of procedure data
Usage

## S4 method for signature 'MeteorologyUncorrectedData'
subsample(object, bbox = NULL, stations = NULL, dates = NULL, buffer = 0)
## S4 method for signature 'MeteorologyInterpolationData'
subsample(object, bbox = NULL, stations = NULL, dates = NULL, buffer = 0)

Arguments

- **object**: An object of a sub-class `MeteorologyProcedureData-class`.
- **bbox**: A 2x2 numeric matrix with the boundaries of the target area. If NULL, the original boundary box is kept (except if stations is specified).
- **stations**: A numeric, character or logical vector specifying a subset of weather stations. If NULL all original weather stations are kept (except if bbox is specified).
- **dates**: A vector of `Date` with the subset of dates of interest. If NULL, all dates are kept.
- **buffer**: A buffer to put around bbox for the spatial selection of data.

Value

An object of the same class as object.

Methods

- `subsample` signature(object = "MeteorologyUncorrectedData"): Generates a `MeteorologyUncorrectedData` object for a smaller area and a subset of dates.
- `subsample` signature(object = "MeteorologyInterpolationData"): Generates a `MeteorologyInterpolationData` object for a smaller area and a subset of dates.

Examples

```r
data(exampleinterpolationdata)
oridates = exampleinterpolationdata@dates
#Interpolation data using the first ten dates (same boundary box)
subdata = subsample(exampleinterpolationdata, dates = oridates[1:10])
```

summarypoints  

**Summaries of meteorological data**

Description

Summarizes the meteorology of a single location, a set of spatial points, pixels in a grid, or weather stations of interpolation data.
**summarypoints**

**Usage**

```r
summarypoint(x, var, fun = mean, freq = NULL, dates = NULL, months = NULL, ...)  
summarypoints(points, var, fun = mean, freq = NULL, dates = NULL, months = NULL, ...)  
summarygrid(grid, var, fun = mean, freq = NULL, dates = NULL, months = NULL, ...)  
summarypixels(pixels, var, fun = mean, freq = NULL, dates = NULL, months = NULL, ...)  
summaryinterpolationdata(object, var, fun = mean, freq = NULL, dates = NULL, months = NULL, ...)  
```

**Arguments**

- `x`: A data frame with dates in rows and meteorological variables in columns.
- `points`: An object of class `SpatialPointsMeteorology-class` with the coordinates and meteorological data of the locations for which summaries are desired. Alternatively, an object of class `SpatialPointsDataFrame-class` containing the meta data (columns `dir`, `filename` and possibly `format`) of meteorological files that will be sequentially read from the disk. Finally, `points` can also be a string pointing to a netCDF.
- `var`: The name of the meteorological variable to be summarized.
- `fun`: The function to be calculated on values of each point. If `freq` is specified, the function will be calculated by intervals.
- `freq`: A string giving an interval specification (e.g., "week", "month", "quarter" or "year"). If `NULL` then no intervals are defined.
- `dates`: An object of class `Date` to define the period to be summarized. If `dates = NULL` then all dates in `points` are processed.
- `months`: A numeric vector to indicate the subset of months for which summary is desired (e.g., `c(7,8)` for July and August). This parameter allows studying particular seasons, when combined with `freq`. For example `freq = "years"` and `months = 6:8` leads to summarizing summer months of each year.
- `...`: Additional parameters to `fun`.
- `grid`: An object of class `SpatialGridMeteorology-class` with the meteorological data for a grid, or a string pointing to a NetCDF.
- `pixels`: An object of class `SpatialPixelsMeteorology-class` with the meteorological data for grid pixels, or a string pointing to a NetCDF.
- `object`: An object of class `MeteorologyInterpolationData-class`.

**Details**

If `var="ALL"` then function `summarypoints` produces a summary of all variables with default statistics and returns an object of class `SpatialPointsMeteorology`.

**Value**

- Function `summarypoint` returns a named vector of values with dates as names.
- Functions `summarypoints` and `summaryinterpolationdata` return an object of class `SpatialPointsDataFrame` containing summaries (either one variable or several if `freq` is specified).
- Functions `summarygrid` and `summarypixels` return an object of class `SpatialGridDataFrame` and `SpatialPixelsDataFrame`, respectively, containing the summaries analogously to `summarypoints`.

mp.sum = summarypoints(mp, var="PET", freq="months", fun=sum)

mp.sum

utils

Physical utility functions

Description

Set of functions used in the calculation of physical variables.

Usage

utils_airDensity(temperature, Patm)
utils_atmosphericPressure(elevation)
utils_averageDailyVP(Tmin, Tmax, RHmin, RHmax)
utils_averageDaylightTemperature(Tmin, Tmax)
utils_latentHeatVaporisation(temperature)
utils_latentHeatVaporisationMol(temperature)
utils_psychrometricConstant(temperature, Patm)
utils_saturationVP(temperature)
utils_saturationVaporPressureCurveSlope(temperature)
**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>temperature</td>
<td>Air temperature (°C).</td>
</tr>
<tr>
<td>Tmin, Tmax</td>
<td>Minimum and maximum daily temperature (°C).</td>
</tr>
<tr>
<td>RHmin, RHmax</td>
<td>Minimum and maximum relative humidity (%).</td>
</tr>
<tr>
<td>Patm</td>
<td>Atmospheric air pressure (in kPa).</td>
</tr>
<tr>
<td>elevation</td>
<td>Elevation above sea level (in m).</td>
</tr>
</tbody>
</table>

**Value**

Values returned for each function are:

- `utils_airDensity`: air density (in kg·m⁻³).
- `utils_atmosphericPressure`: Air atmospheric pressure (in kPa).
- `utils_averageDailyVP`: average (actual) vapour pressure (in kPa).
- `utils_averageDaylightTemperature`: average daylight air temperature (in °C).
- `utils_latentHeatVaporisation`: Latent heat of vaporisation (MJ·kg⁻¹).
- `utils_latentHeatVaporisationMol`: Latent heat of vaporisation (J·mol⁻¹).
- `utils_psychrometricConstant`: Psychrometric constant (kPa·°C⁻¹).
- `utils_saturationVP`: saturation vapour pressure (in kPa).
- `utils_saturationVaporPressureCurveSlope`: Slope of the saturation vapor pressure curve (kPa·°C⁻¹).

Description

A semiparametric multivariate, multisite weather generator. The algorithm can be interpreted as a way to resample the original data to create synthetic data sets of the same length and similar properties.

Usage

weathergeneration(object, params = defaultGenerationParams(), verbose=TRUE)

Arguments

object An object of class SpatialPointsMeteorology-class, SpatialGridMeteorology-class or SpatialPixelsMeteorology-class.
params A list with parameters for the weather generator (see defaultGenerationParams).
verbose Boolean flag to print process information.

Details

The implemented algorithm is based on Apipattanavis et al. (2007) for the non-conditional version, and is similar to Steinschneider et al. (2013) for the conditional one. Part of the code was adapted from package 'weathergen' by Jeffrey D. Walker, whom we are grateful. Conditioning is controlled via the element conditional of params list, which can be:

- "none" - The non-conditional version is used, which is based on a first order Markov chain (MC) to simulate weather states (dry/wet/extreme wet) and a K-nearest neighbour (KNN) algorithm to select pairs of days with the same transition and similar weather for the initial state (as in Apipattanavis et al. 2007).
- "arima" - Annual precipitation is conditioned using a stationary auto-regressive (ARIMA) model and then a K-nearest neighbour algorithm is used to select a set of years to train the MC-KNN algorithm (similar to Steinschneider et al. 2013). Recommended if low-frequency variation of annual precipitation is to be accounted for in long series.
- "window" - The MC-KNN algorithm is trained with the subset of the input data corresponding to a window around the target year. Annual precipitation is conditioned using a lognormal random trial of the precipitation corresponding to the selected years. Recommended to generate stochastic series from climate change projections.

Value

An object of the same class as the input object. Generated meteorological series are of the same length as the input.
writemeteorologygrid

defaultGenerationParams

Examples

data(examplegridtopography)
data(exampleinterpolationdata)

#Creates spatial topography points from the grid
p = 1:2
spt = as(examplegridtopography, "SpatialPointsTopography")[p]

#Interpolation of two points for the whole time period (2000-2003)
mp = interpolationpoints(exampleinterpolationdata, spt)

#Plot interpolated meteorological series
meteoplot(mp,1, ylab="Mean temperature")

#Generate a stochastic series using interpolated data as template
y = weathergeneration(mp)

#Plot generated meteorological series
meteoplot(y,1, ylab="Mean temperature")
Usage

writemeteorologygrid(object, file, dates = NULL, format = "netCDF",
byPixel = FALSE, chunksizes = NA, add = FALSE, overwrite = FALSE,
verbose = FALSE)

writemeteorologygridpixel(file, index, data, verbose = FALSE)

writeemptymeteorologygrid(file, grid, proj4string, dates, 
byPixel = FALSE, chunksizes = NA, overwrite = FALSE,
verbose = FALSE)

writemeteorologypixels(object, file, dates = NULL, format = "netCDF",
byPixel = FALSE, chunksizes = NA, add = FALSE, overwrite = FALSE,
verbose = FALSE)

Arguments

object An object of class SpatialGridMeteorology-class or class SpatialPixelsMeteorology-class with the meteorological data to be written.
file A string with the file name to be written.
dates A Date vector object or a character string indicating the dates to be written.
format Format of meteorological data. The only accepted format is "netCDF".
byPixel Boolean flag to specify whether file will be written/read by pixels. This forces a different (supposedly) more efficient chunking based on time series data instead of daily grids.
chunksizes Specifies the size of data chunks to be read/written. If set, this must be a vector of three integers corresponding to X/Y/T.
ad Boolean flag to indicate that NetCDF exists and data should be added/replaced.
grid An object of class GridTopology-class
proj4string Object of class CRS.
overwrite Boolean flag to force overwriting an existing NetCDF.
verbose A logical flag to output process information in the console.
index Integer indicating the grid index position to be written.
data A data frame with meteorological data corresponding to a pixel.

details

Functions writemeteorologygrid and writemeteorologypixels writes grided meteorological data (i.e. class SpatialGridMeteorology-class or class SpatialPixelsMeteorology-class, respectively) into a netCDF, with the possibility to overwrite existing data. Function writemeteorologygridpixel is meant to add/replace data in a netCDF corresponding to a specific pixel identified by its grid index. Function writemeteorologygrid creates an empty netCDF with the specified grid dimensions, coordinate reference system and dates.

writemeteorologypoint  Writes point meteorology to the disk

Description
Functions to write point meteorological data to disk files in different formats.

Usage

  writemeteorologypoint(data, file, format = "meteoland/txt")
  writemeteorologypointfiles(object, dir=getwd(), format = "meteoland/txt",
                            metadataFile="MP.txt")
  writemeteorologypoints(object, file, format = "netCDF",
                         add = FALSE, overwrite = FALSE, verbose = FALSE)

Arguments

data  An data frame with meteorological data.
file  A string with the file name to be written.
format  Output format of meteorological data. Current accepted formats are "meteoland/txt",
         "meteoland/rds", "castanea/txt" and "castanea/rds".
object  An object of class SpatialPointsMeteorology-class with the meteorological
data to be written.
dir  Output directory for meteorology data.
metadataFile  The name of the file that will store the meta data describing all written files.
add  Boolean flag to indicate that NetCDF exists and data should be added/replaced
     (see details).
overwrite  Boolean flag to force overwriting an existing NetCDF.
verbose  A logical flag to output process information in the console.

Details
Function writemeteorologypoint writes data series of a single location (i.e. a data frame) to ascii
or rds files. Function writemeteorologypointfiles takes an object of SpatialPointsMeteorology-class
and writes one file for each data point in the same formats as writemeteorologypoint. In addi-
tion, it writes a metadata file (see argument metadataFile) with point coordinates, station names
and file names. Both functions share the same accepted formats, which are "meteoland/txt",
"meteoland/rds", "castanea/txt" and "castanea/rds".

Function writemeteorologypoints takes an object of SpatialPointsMeteorology-class and
writes all its content in a single file (i.e. a netCDF). The same function can be used to replace data
from an existing file or to add new points to the netCDF. This is done by using add=TRUE, and profits
from the fact that some netCDF dimensions (in this case the number of points) can be defined as
unlimited. If data is added to an existing netCDF, the coordinate reference system and the dates of
object must be the same as those in the netCDF.
