Package ‘mirt’

September 15, 2019

Version 1.31
Type Package
Title Multidimensional Item Response Theory
Description Analysis of dichotomous and polytomous response data using unidimensional and multidimensional latent trait models under the Item Response Theory paradigm (Chalmers (2012) <doi:10.18637/jss.v048.i06>). Exploratory and confirmatory models can be estimated with quadrature (EM) or stochastic (MHRM) methods. Confirmatory bi-factor and two-tier analyses are available for modeling item testlets. Multiple group analysis and mixed effects designs also are available for detecting differential item and test functioning as well as modeling item and person covariates. Finally, latent class models such as the DINA, DINO, multidimensional latent class, and several other discrete latent variable models, including mixture and zero-inflated response models, are supported.

*Full information maximum likelihood estimation of IRT models.*

**Description**

Full information maximum likelihood estimation of multidimensional IRT models

**Details**

Analysis of dichotomous and polytomous response data using unidimensional and multidimensional latent trait models under the Item Response Theory paradigm. Exploratory and confirmatory models can be estimated with quadrature (EM) or stochastic (MHRM) methods. Confirmatory bi-factor and two-tier analyses are available for modeling item testlets. Multiple group analysis and mixed effects designs also are available for detecting differential item and test functioning as well as modeling item and person covariates. Finally, latent class models such as the DINA, DINO, multidimensional latent class, and several other discrete variable models are supported.

Users interested in the most recent version of this package can visit [https://github.com/philchalmers/mirt](https://github.com/philchalmers/mirt) and follow the instructions for installing the package from source. Questions regarding the package can be sent to the mirt-package Google Group, located at [https://groups.google.com/forum/#!forum/mirt-package](https://groups.google.com/forum/#!forum/mirt-package). User contributed files, workshop files, and evaluated help files are also available on the package wiki ([https://github.com/philchalmers/mirt/wiki](https://github.com/philchalmers/mirt/wiki)).

**anova-method**

Compare nested models with likelihood-based statistics

**Description**

Compare nested models using likelihood ratio test (X2), Akaike Information Criterion (AIC), sample size adjusted AIC (AICc), Bayesian Information Criterion (BIC), Sample-Size Adjusted BIC (SABIC), and Hannan-Quinn (HQ) Criterion.
Usage

```r
## S4 method for signature 'SingleGroupClass'
anova(object, object2, bounded = FALSE,
      mix = 0.5, verbose = TRUE)
```

Arguments

- `object`: an object of class `SingleGroupClass`, `MultipleGroupClass`, or `MixedClass`
- `object2`: a second model estimated from any of the mirt package estimation methods
- `bounded`: logical; are the two models comparing a bounded parameter (e.g., comparing a single 2PL and 3PL model with 1 df)? If `TRUE` then a 50:50 mix of chi-squared distributions is used to obtain the p-value
- `mix`: proportion of chi-squared mixtures. Default is 0.5
- `verbose`: logical; print additional information to console?

Value

A `data.frame/mirt_df` object

References

Examples

```r
## Not run:
x <- mirt(Science, 1)
x2 <- mirt(Science, 2)
anova(x, x2)

# in isolation
anova(x)

# bounded parameter
dat <- expand.table(LSAT7)
mod <- mirt(dat, 1)
mod2 <- mirt(dat, 1, itemtype = c(rep('2PL', 4), '3PL'))
anova(mod, mod2) #unbounded test
anova(mod, mod2, bounded = TRUE) #bounded

# priors
model <- 'F = 1-5
      PRIOR = (5, g, norm, -1, 1)'
mod1b <- mirt(dat, model, itemtype = c(rep('2PL', 4), '3PL'))
anova(mod1b)

model2 <- 'F = 1-5
      PRIOR = (1-5, g, norm, -1, 1)'
```
mod2b <- mirt(dat, model2, itemtype = '3PL')
anova(mod1b, mod2b)

## End(Not run)

### areainfo  

**Function to calculate the area under a selection of information curves**

**Description**

Compute the area within test or item information over a definite integral range.

**Usage**

```r
areainfo(x, theta_lim, which.items = 1:extract.mirt(x, "nitems"),
          group = NULL, ...)
```

**Arguments**

- `x` an object of class `SingleGroupClass`, or an object of class `MultipleGroup-Class` if a suitable group input were supplied
- `theta_lim` range of integration to be computed
- `which.items` an integer vector indicating which items to include in the expected information function. Default uses all possible items
- `group` group argument to pass to `extract.group` function. Required when the input object is a multiple-group model
- `...` additional arguments passed to `integrate`

**Value**

A `data.frame` with the lower and upper integration range, the information area within the range (Info), the information area over the range -10 to 10 (Total.Info), proportion of total information given the integration range (Info.Proportion), and the number of items included (nitems)

averageMI

Examples

dat <- expand.table(LSAT7)
mod <- mirt(dat, 1)

areainfo(mod, c(-2,0), which.items = 1) # item 1
## Not run:
areainfo(mod, c(-2,0), which.items = 1:3) # items 1 to 3
areainfo(mod, c(-2,0)) # all items (total test information)

# plot the area
area <- areainfo(mod, c(-2,0))
Theta <- matrix(seq(-3,3, length.out=1000))
info <- testinfo(mod, Theta)
plot(info ~ Theta, type = 'l')

pick <- Theta >= -2 & Theta <=0
polygon(c(-2, Theta[pick], 0), c(0, info[pick], 0), col='lightblue')
text(x = 2, y = 0.5, labels = paste("Total Information: ", round(area$TotalInfo, 3),
\n\nInformation in (-2, 0):", round(area$Info, 3),
paste("(", round(100 * area$Proportion, 2), ")", sep = ",")), cex = 1.2)

## End(Not run)

averageMI

Collapse values from multiple imputation draws

Description

This function computes updated parameter and standard error estimates using multiple imputation methodology. Given a set of parameter estimates and their associated standard errors the function returns the weighted average of the overall between and within variability due to the multiple imputations according to Rubin’s (1987) methodology.

Usage

averageMI(par, SEpar, as.data.frame = TRUE)

Arguments

par a list containing parameter estimates which were computed the imputed datasets
SEpar a list containing standard errors associated with par
as.data.frame logical; return a data.frame instead of a list? Default is TRUE

Value

returns a list or data.frame containing the updated averaged parameter estimates, standard errors, and t-values with the associated degrees of freedom and two tailed p-values
Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

Examples

```r
## Not run:

#simulate data
set.seed(1234)
N <- 1000

# covariates
X1 <- rnorm(N); X2 <- rnorm(N)
covdata <- data.frame(X1, X2)
Theta <- matrix(0.5 * X1 + -1 * X2 + rnorm(N, sd = 0.5))

#items and response data
a <- matrix(1, 20); d <- matrix(rnorm(20))
dat <- simdata(a, d, 1000, itemtype = '2PL', Theta=Theta)
mod1 <- mirt(dat, 1, 'Rasch', covdata=covdata, formula = ~ X1 + X2)
coef(mod1, simplify=TRUE)

#draw plausible values for secondary analyses
pv <- fscores(mod1, plausible.draws = 10)
pvmods <- lapply(pv, function(x, covdata) lm(x ~ covdata$X1 + covdata$X2), covdata=covdata)

# compute Rubin's multiple imputation average
so <- lapply(pvmods, summary)
par <- lapply(so, function(x) x$coefficients[, 'Estimate'])
SEpar <- lapply(so, function(x) x$coefficients[, 'Std. Error'])
averageMI(par, SEpar)

## End(Not run)
```
Description

bfactor fits a confirmatory maximum likelihood two-tier/bifactor/testlet model to dichotomous and polytomous data under the item response theory paradigm. The IRT models are fit using a dimensional reduction EM algorithm so that regardless of the number of specific factors estimated the model only uses the number of factors in the second-tier structure plus 1. For the bifactor model the maximum number of dimensions is only 2 since the second-tier only consists of a ubiquitous unidimensional factor. See mirt for appropriate methods to be used on the objects returned from the estimation.

Usage

bfactor(data, model, model2 = paste0("G = 1-", ncol(data)),
         group = NULL, quadpts = NULL, invariant = "", ...)

Arguments

data: a matrix or data.frame that consists of numerically ordered data, with missing data coded as NA

model: a numeric vector specifying which factor loads on which item. For example, if for a 4 item test with two specific factors, the first specific factor loads on the first two items and the second specific factor on the last two, then the vector is c(1,1,2,2). For items that should only load on the second-tier factors (have no specific component) NA values may be used as place-holders. These numbers will be translated into a format suitable for mirt.model(), combined with the definition in model2, with the letter ‘S’ added to the respective factor number

model2: a two-tier model specification object defined by mirt.model() or a string to be passed to mirt.model. By default the model will fit a unidimensional model in the second-tier, and therefore be equivalent to the bifactor model

group: a factor variable indicating group membership used for multiple group analyses

quadpts: number of quadrature nodes to use after accounting for the reduced number of dimensions. Scheme is the same as the one used in mirt, however it is in regards to the reduced dimensions (e.g., a bifactor model has 2 dimensions to be integrated)

invariance: see multipleGroup for details, however, the specific factor variances and means will be constrained according to the dimensional reduction algorithm

...: additional arguments to be passed to the estimation engine. See mirt for more details and examples

Details

bfactor follows the item factor analysis strategy explicated by Gibbons and Hedeker (1992), Gibbons et al. (2007), and Cai (2010). Nested models may be compared via an approximate chi-squared difference test or by a reduction in AIC or BIC (accessible via anova). See mirt for more details regarding the IRT estimation approach used in this package.

The two-tier model has a specific block diagonal covariance structure between the primary and secondary latent traits. Namely, the secondary latent traits are assumed to be orthogonal to all traits
and have a fixed variance of 1, while the primary traits can be organized to vary and covary with other primary traits in the model.

\[
\Sigma_{\text{two-tier}} = \begin{pmatrix} G & 0 \\ 0 & \text{diag}(S) \end{pmatrix}
\]

The bifactor model is a special case of the two-tier model when \( G \) above is a 1x1 matrix, and therefore only 1 primary factor is being modeled. Evaluation of the numerical integrals for the two-tier model requires only \( \text{ncol}(G) + 1 \) dimensions for integration since the \( S \) second order (or 'specific') factors require only 1 integration grid due to the dimension reduction technique. Note: for multiple group two-tier analyses only the second-tier means and variances should be freed since the specific factors are not treated independently due to the dimension reduction technique.

**Value**

function returns an object of class `SingleGroupClass` (`SingleGroupClass-class`) or `MultipleGroupClass` (`MultipleGroupClass-class`).

### Description of Bock 1997 data

**Description**

A 3-item tabulated data set extracted from Table 3 in Chapter Two.

**Author(s)**

Phil Chalmers <rphilip.chalmers@gmail.com>
References

Examples

```r
## Not run:
dat <- expand.table(Bock1997)
head(dat)
mod <- mirt(dat, 1, 'nominal')

# reproduce table 3 in Bock (1997)
fs <- round(fscores(mod, verbose = FALSE, full.scores = FALSE)[,c('F1', 'SE_F1')], 2)
fttd <- residuals(mod, type = 'exp')
table <- data.frame(fttd[,-ncol(fttd)], fs)
table

mod <- mirt(dat, 1, 'nominal')
coef(mod)

## End(Not run)
```

---

**boot.LR**

*Parametric bootstrap likelihood-ratio test*

**Description**

Given two fitted models, compute a parametric bootstrap test to determine whether the less restrictive models fits significantly better than the more restricted model. Note that this hypothesis test also works when prior parameter distributions are included for either model. Function can be run in parallel after using a suitable *mirtCluster* definition.

**Usage**

```r
boot.LR(mod, mod2, R = 1000)
```

**Arguments**

- `mod`: an estimated model object
- `mod2`: an estimated model object
- `R`: number of parametric bootstraps to use.
**boot.mirt**

*Calculate bootstrapped standard errors for estimated models*

**Value**

A p-value evaluating whether the more restrictive model fits significantly worse than the less restrictive model.

**Author(s)**

Phil Chalmers <rphilip.chalmers@gmail.com>

**References**

**Examples**

```r
## Not run:
#standard
dat <- expand.table(LSAT7)
mod1 <- mirt(dat, 1)
mod2 <- mirt(dat, 1, '3PL')

# standard LR test
anova(mod1, mod2)

# bootstrap LR test (run in parallel to save time)
mirtCluster()
boot.LR(mod1, mod2, R=200)

## End(Not run)
```

**Description**

Given an internal mirt object estimate the bootstrapped standard errors. It may be beneficial to run the computations using multi-core architecture (e.g., the parallel package). Parameters are organized from the freely estimated values in `mod2values(x)` (equality constraints will also be returned in the bootstrapped estimates).

**Usage**

```r
boot.mirt(x, R = 100, technical = NULL, ...)
```
Arguments

x an estimated model object
R number of draws to use (passed to the boot() function)
technical technical arguments passed to estimation engine. See mirt for details
... additional arguments to be passed on to boot(...) and estimation engine

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

References

Examples

```r
## Not run:

#standard
mod <- mirt(Science, 1)
booted <- boot.mirt(mod, R=20)
plot(booted)
booted

#run in parallel using snow back-end using all available cores
mod <- mirt(Science, 1)
booted <- boot.mirt(mod, parallel = 'snow', ncpus = parallel::detectCores())
booted

## End(Not run)
```

describe_coef_method

Description

Return a list (or data.frame) of raw item and group level coefficients. Note that while the output to the console is rounded to three digits, the returned list of objects is not. Hence, elements from cfs <- coef(mod); cfs[[1]] will contain the unrounded results (useful for simulations).
Usage

```
## S4 method for signature 'SingleGroupClass'
coef(object, CI = 0.95, printSE = FALSE,
      rotate = "none", Target = NULL, IRTpars = FALSE, rawug = FALSE,
      as.data.frame = FALSE, simplify = FALSE, unique = FALSE,
      verbose = TRUE, ...)
```

Arguments

- **object**: an object of class `SingleGroupClass`, `MultipleGroupClass`, or `MixedClass`
- **CI**: the amount of converged used to compute confidence intervals; default is 95 percent confidence intervals
- **printSE**: logical; print the standard errors instead of the confidence intervals? When `IRTpars = TRUE` then the delta method will be used to compute the associated standard errors from mirt’s default slope-intercept form
- **rotate**: see `summary` method for details. The default rotation is 'none'
- **Target**: a dummy variable matrix indicating a target rotation pattern
- **IRTpars**: logical; convert slope intercept parameters into traditional IRT parameters? Only applicable to unidimensional models. If a suitable ACOV estimate was computed in the fitted model, and `printSE = FALSE`, then suitable CIs will be included based on the delta method (where applicable)
- **rawug**: logical; return the untransformed internal g and u parameters? If FALSE, g and u’s are converted with the original format along with delta standard errors
- **as.data.frame**: logical; convert list output to a data.frame instead?
- **simplify**: logical; if all items have the same parameter names (indicating they are of the same class) then they are collapsed to a matrix, and a list of length 2 is returned containing a matrix of item parameters and group-level estimates
- **unique**: return the vector of uniquely estimated parameters
- **verbose**: logical; allow information to be printed to the console?
- **...**: additional arguments to be passed

Examples

```
## Not run:
dat <- expand.table(LSAT7)
x <- mirt(dat, 1)
```
createGroup

Create a user defined group-level object with correct generic functions

Description

Initializes the proper S4 class and methods necessary for mirt functions to use in estimation for defining customized group-level functions. To use the defined objects pass to the mirt(...,customGroup = OBJECT) command, and ensure that the class parameters are properly labeled.

Usage

createGroup(par, est, den, nfact, gr = NULL, hss = NULL, gen = NULL, lbound = NULL, ubound = NULL, derivType = "Richardson")

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>par</td>
<td>a named vector of the starting values for the parameters</td>
</tr>
<tr>
<td>est</td>
<td>a logical vector indicating which parameters should be freely estimated by default</td>
</tr>
<tr>
<td>den</td>
<td>the probability density function given the Theta/ability values. First input contains a vector of all the defined parameters and the second input must be a matrix called Theta. Function also must return a numeric vector object corresponding to the associated densities for each row in the Theta input</td>
</tr>
<tr>
<td>nfact</td>
<td>number of factors required for the model. E.g., for unidimensional models with only one dimension of integration nfact = 1</td>
</tr>
<tr>
<td>gr</td>
<td>gradient function (vector of first derivatives) of the log-likelihood used in estimation. The function must be of the form gr(x,Theta), where x is the object defined by createGroup() and Theta is a matrix of latent trait parameters</td>
</tr>
</tbody>
</table>
createItem

**hss**
Hessian function (matrix of second derivatives) of the log-likelihood used in estimation. If not specified a numeric approximation will be used. The input is identical to the **gr** argument.

**gen**
a function used when GenRandomPars = TRUE is passed to the estimation function to generate random starting values. Function must be of the form function(object) ... and must return a vector with properties equivalent to the par object. If NULL, parameters will remain at the defined starting values by default.

**lbound**
optional vector indicating the lower bounds of the parameters. If not specified then the bounds will be set to -Inf

**ubound**
optional vector indicating the lower bounds of the parameters. If not specified then the bounds will be set to Inf

**derivType**
if the gr or hss terms are not specified this type will be used to obtain them numerically. Default is 'Richardson'

**Author(s)**
Phil Chalmers <rphilip.chalmers@gmail.com>

**References**

**Examples**

```r
# normal density example, N(mu, sigma^2)
den <- function(obj, Theta) dnorm(Theta, obj@par[1], sqrt(obj@par[2]))
par <- c(mu = 0, sigma2 = .5)
est <- c(FALSE, TRUE)
lbound <- c(-Inf, 0)
grp <- createGroup(par, est, den, nfact = 1, lbound=lbound)

dat <- expand.table(LSAT6)
mod <- mirt(dat, 1, 'Rasch')
modcustom <- mirt(dat, 1, 'Rasch', customGroup=grp)
coef(mod)
coef(modcustom)
```

createItem  
Create a user defined item with correct generic functions
createItem

Description

Initializes the proper S4 class and methods necessary for mirt functions to use in estimation. To use the defined objects pass to the mirt(...,customItems = list()) command, and ensure that the classes are properly labeled and unique in the list. Additionally, the input mirt(...,customItemsData = list()) can also be included to specify additional item-level information to better recycle custom-item definitions (e.g., for supplying varying Q-matricies), where the list input must have the same length as the number of items. For further examples regarding how this function can be used for fitting unfolding-type models see Liu and Chalmers (2018).

Usage

createItem(name, par, est, P, gr = NULL, hss = NULL, gen = NULL, lbound = NULL, ubound = NULL, derivType = "Richardson", derivType.hss = "Richardson", bytecompile = TRUE)

Arguments

name  
a character indicating the item class name to be defined

par  
a named vector of the starting values for the parameters

est  
a logical vector indicating which parameters should be freely estimated by default

P  
the probability trace function for all categories (first column is category 1, second category two, etc). First input contains a vector of all the item parameters, the second input must be a matrix called Theta, the third input must be the number of categories called ncat, and (optionally) a fourth argument termed itemdata may be included containing further users specification information. The last optional input is to be utilized within the estimation functions such as mirt via the list input customItemsData to more naturally recycle custom-item definitions. Therefore, these inputs must be of the form

function(par,Theta,ncat){...}

or

function(par,Theta,ncat,itemdata){...}

to be valid; however, the names of the arguments is not relevant.

Finally, this function must return a matrix object of category probabilities, where the columns represent each respective category

gr  
gradient function (vector of first derivatives) of the log-likelihood used in estimation. The function must be of the form gr(x,Theta), where x is the object defined by createItem() and Theta is a matrix of latent trait parameters. Tabulated (EM) or raw (MHRM) data are located in the x@dat slot, and are used to form the complete data log-likelihood. If not specified a numeric approximation will be used

hss  
Hessian function (matrix of second derivatives) of the log-likelihood used in estimation. If not specified a numeric approximation will be used (required for the MH-RM algorithm only). The input is identical to the gr argument

gen  
a function used when GenRandomPars = TRUE is passed to the estimation function to generate random starting values. Function must be of the form function(object)
... and must return a vector with properties equivalent to the par object. If NULL, parameters will remain at the defined starting values by default.

- **lbound**: optional vector indicating the lower bounds of the parameters. If not specified then the bounds will be set to -Inf.
- **ubound**: optional vector indicating the lower bounds of the parameters. If not specified then the bounds will be set to Inf.
- **derivType**: if the gr term is not specified this type will be used to obtain the gradient numerically or symbolically. Default is the 'Richardson' extrapolation method; see `numerical_deriv` for details and other options. If 'symbolic' is supplied then the gradient will be computed using a symbolical approach (potentially the most accurate method, though may fail depending on how the P function was defined).
- **derivType.hss**: if the hss term is not specified this type will be used to obtain the Hessian numerically. Default is the 'Richardson' extrapolation method; see `numerical_deriv` for details and other options. If 'symbolic' is supplied then the Hessian will be computed using a symbolical approach (potentially the most accurate method, though may fail depending on how the P function was defined).
- **bytecompile**: logical; where applicable, byte compile the functions provided? Default is TRUE to provide.

**Details**

The `summary()` function will not return proper standardized loadings since the function is not sure how to handle them (no slopes could be defined at all!). Instead loadings of .001 are filled in as place-holders.

---

**Description of deAyala data**

**Description**

Mathematics data from de Ayala (2009; pg. 14); 5 item dataset in table format.
Author(s)
Phil Chalmers <rphilip.chalmers@gmail.com>

References

Examples
```r
## Not run:
dat <- expand.table(deAyala)
head(dat)
## End(Not run)
```

**DIF**

Differential item functioning statistics

Description
This function runs the Wald and likelihood-ratio approaches for testing differential item functioning (DIF). This is primarily a convenience wrapper to the `multipleGroup` function for performing standard DIF procedures. Independent models can be estimated in parallel by defining a parallel object with `mirtCluster`, which will help to decrease the runtime. For best results, the baseline model should contain a set of 'anchor' items and have freely estimated hyper-parameters in the focal groups.

Usage
```r
DIF(MGmodel, which.par, scheme = "add",
items2test = 1:extract.mirt(MGmodel, "nitems"), seq_stat = "SABIC",
Wald = FALSE, p.adjust = "none", return_models = FALSE,
return_seq_model = FALSE, max_run = Inf, plotdif = FALSE,
type = "trace", simplify = TRUE, verbose = TRUE, ...)
```

Arguments
- **MGmodel**: an object returned from `multipleGroup` to be used as the reference model
- **which.par**: a character vector containing the parameter names which will be inspected for DIF
- **scheme**: type of DIF analysis to perform, either by adding or dropping constraints across groups. These can be:
'add' parameters in which `par` will be constrained each item one at a time for items that are specified in `items2test`. This is beneficial when examining DIF from a model with parameters freely estimated across groups, and when inspecting differences via the Wald test.

'drop' parameters in which `par` will be freely estimated for items that are specified in `items2test`. This is useful when supplying an overly restrictive model and attempting to detect DIF with a slightly less restrictive model.

'add_sequential' sequentially loop over the items being tested, and at the end of the loop treat DIF tests that satisfy the seq_stat criteria as invariant. The loop is then re-run on the remaining invariant items to determine if they are now displaying DIF in the less constrained model, and when no new invariant item is found the algorithm stops and returns the items that displayed DIF. Note that the DIF statistics are relative to this final, less constrained model which includes the DIF effects.

'drop_sequential' sequentially loop over the items being tested, and at the end of the loop treat items that violate the seq_stat criteria as demonstrating DIF. The loop is then re-run, leaving the items that previously demonstrated DIF as variable across groups, and the remaining test items that previously showed invariance are re-tested. The algorithm stops when no more items showing DIF are found and returns the items that displayed DIF. Note that the DIF statistics are relative to this final, less constrained model which includes the DIF effects.

`items2test` a numeric vector, or character vector containing the item names, indicating which items will be tested for DIF. In models where anchor items are known, omit them from this vector. For example, if items 1 and 2 are anchors in a 10 item test, then `items2test = 3:10` would work for testing the remaining items (important to remember when using sequential schemes).

`seq_stat` select a statistic to test for in the sequential schemes. Potential values are (in descending order of power) 'AIC', 'AICC', 'SABIC', 'HQ', and 'BIC'. If a numeric value is input that ranges between 0 and 1, the 'p' value will be tested (e.g., `seq_stat = .05` will test for the difference of `p < .05` in the add scheme, or `p > .05` in the drop scheme), along with the specified `p.adjust` input. For models fitted with prior distributions 'DIC' is also supported, though for these models the p-value approach is not.

`Wald` logical; perform Wald tests for DIF instead of likelihood ratio test?

`p.adjust` string to be passed to the `p.adjust` function to adjust p-values. Adjustments are located in the `adj_pvals` element in the returned list.

`return_models` logical; return estimated model objects for further analysis? Default is FALSE.

`return_seq_model` logical; on the last iteration of the sequential schemes, return the fitted multiple-group model containing the freely estimated parameters indicative of DIF? This is generally only useful when scheme = 'add_sequential'. Default is FALSE.

`max_run` a number indicating the maximum number of cycles to perform in sequential searches. The default is to perform search until no further DIF is found.

`plotdif` logical; create item plots for items that are displaying DIF according to the seq_stat criteria? Only available for 'add' type schemes.
the type of plot argument passed to `plot()`. Default is 'trace', though another
good option is 'intrace'. For ease of viewing, the `facet_item` argument to
mirt's `plot()` function is set to TRUE

simplify logical; simplify the output by returning a data.frame object with the differences
between AIC, BIC, etc, as well as the chi-squared test (X2) and associated df
and p-values

verbose logical print extra information to the console?

... additional arguments to be passed to `multipleGroup` and `plot`

Details

Generally, the precomputed baseline model should have been configured with two estimation prop-
erties: 1) a set of 'anchor' items, where the anchor items have various parameters that have been
constrained to be equal across the groups, and 2) contain freely estimated latent mean and variance
terms in all but one group (the so-called 'reference' group). These two properties help to fix the
metric of the groups so that item parameter estimates do not contain latent distribution characteris-
tics.

## DiscreteClass-class

### Class "DiscreteClass"

#### Description

Defines the object returned from mdirt.

#### Slots

- **Call**: function call
- **Data**: list of data, sometimes in different forms
- **Options**: list of estimation options
- **Fit**: a list of fit information
- **Model**: a list of model-based information
- **ParObjects**: a list of the S4 objects used during estimation
- **OptimInfo**: a list of arguments from the optimization process
- **Internals**: a list of internal arguments for secondary computations (inspecting this object is generally not required)
- **vcov**: a matrix represented the asymptotic covariance matrix of the parameter estimates
- **time**: a data.frame indicating the breakdown of computation times in seconds

#### Methods

- **print** signature(x = "DiscreteClass")
- **show** signature(object = "DiscreteClass")
- **anova** signature(object = "DiscreteClass")
- **coef** signature(x = "DiscreteClass")
- **summary** signature(object = "DiscreteClass")
- **residuals** signature(object = "DiscreteClass")

draw_parameters

Draw plausible parameter instantiations from a given model

Description

Draws plausible parameters from a model using parametric sampling (if the information matrix was computed) or via bootstrap sampling. Primarily for use with the DRF function.

Usage

draw_parameters(mod, draws, method = c("parametric", "bootstrap"), redraws = 20, ...)

Arguments

mod estimated single or multiple-group model
draws number of draws to obtain
method type of plausible values to obtain. Can be 'parametric', for the parametric sampling scheme which uses the estimated information matrix, or 'bootstrap' to obtain values from the boot function. Default is 'parametric'
redraws number of redraws to perform when the given parameteric sample does not satisfy the upper and lower parameter bounds. If a valid set cannot be found within this number of draws then an error will be thrown
...
additional arguments to be passed

Value

returns a draws x p matrix of plausible parameters, where each row corresponds to a single set

Examples

## Not run:
set.seed(1234)
n <- 40
N <- 500

# only first 5 items as anchors
model <- 'F = 1:40
   CONSTRAINTB = (1-5, a1), (1-5, d)'

a <- matrix(1, n)
d <- matrix(rnorm(n), n)
group <- c(rep('Group_1', N), rep('Group_2', N))

## --------------
# groups completely equal
dat1 <- simdata(a, d, N, itemtype = 'dich')
dat2 <- simdata(a, d, N, itemtype = 'dich')
dat <- rbind(dat1, dat2)
mod <- multipleGroup(dat, model, group=group, SE=TRUE, invariance=c('free_means', 'free_var'))

param_set <- draw_parameters(mod, 100)
head(param_set)

## End(Not run)

**DRF**

*Differential Response Functioning statistics*

**Description**

Function performs various omnibus differential item (DIF), bundle (DBF), and test (DTF) functioning procedures on an object estimated with `multipleGroup()`. The compensatory and non-compensatory statistics provided are described in Chalmers (accepted), which generally can be interpreted as IRT generalizations of the SIBTEST and CSIBTEST statistics. These require the ACOV matrix to be computed in the fitted multiple-group model (otherwise, sets of plausible draws from the posterior are explicitly required).

**Usage**

```r
DRF(mod, draws = NULL, focal_items = 1L:extract.mirt(mod, "nitems"), param_set = NULL, CI = 0.95, npts = 1000, quadpts = NULL, theta_lim = c(-6, 6), Theta_nodes = NULL, plot = FALSE, DIF = FALSE, par.strip.text = list(cex = 0.7), par.settings = list(strip.background = list(col = "#9ECAE1"), strip.border = list(col = "black")), auto.key = list(space = "right", points = FALSE, lines = TRUE), ...)```

**Arguments**

- `mod` a `multipleGroup` object which estimated only 2 groups
- `draws` a number indicating how many draws to take to form a suitable multiple imputation or bootstrap estimate of the expected test scores (100 or more). If `boot=FALSE`, requires an estimated parameter information matrix. Returns a list containing the bootstrap/imputation distribution and null hypothesis test for the sDRF statistics
- `focal_items` a numeric vector indicating which items to include in the DRF tests. The default uses all of the items (note that including anchors in the focal items has no effect because they are exactly equal across groups). Selecting fewer items will result in tests of 'differential bundle functioning'
param_set: an N x p matrix of parameter values drawn from the posterior (e.g., using the parametric sampling approach, bootstrap, of MCMC). If supplied, then these will be used to compute the DRF measures. Can be much more efficient to pre-compute these values if DIF, DBF, or DTF are being evaluated within the same model (especially when using the bootstrap method). See `draw_parameters`.

CI: range of confidence interval when using draws input.

npts: number of points to use for plotting. Default is 1000.

quadpts: number of quadrature nodes to use when constructing DRF statistics. Default is extracted from the input model object.

theta_lim: lower and upper limits of the latent trait (theta) to be evaluated, and is used in conjunction with quadpts and npts.

Theta_nodes: an optional matrix of Theta values to be evaluated in the draws for the sDRF statistics. However, these values are not averaged across, and instead give the bootstrap confidence intervals at the respective Theta nodes. Useful when following up a large sDRF or uDRF statistic, for example, to determine where the difference between the test curves are large (while still accounting for sampling variability). Returns a matrix with observed variability.

plot: logical; plot the 'sDRF' functions for the evaluated sDBF or sDTF values across the integration grid or, if DIF = TRUE, the selected items as a faceted plot of individual items? If plausible parameter sets were obtained/supplied then imputed confidence intervals will be included.

DIF: logical; return a list of item-level imputation properties using the DRF statistics? These can generally be used as a DIF detection method and as a graphical display for understanding DIF within each item.

par.strip.text: plotting argument passed to lattice.

par.settings: plotting argument passed to lattice.

auto.key: plotting argument passed to lattice.

... additional arguments to be passed to lattice.

### Differential test functioning statistics

**Description**

Function performs various omnibus differential test functioning procedures on an object estimated with `multipleGroup()`. If the latent means/covariances are suspected to differ then the input object should contain a set of 'anchor' items to ensure that only differential test features are being detected rather than group differences. Returns signed (average area above and below) and unsigned (total area) statistics, with descriptives such as the percent average bias between group total scores for each statistic. If a grid of Theta values is passed, these can be evaluated as well to determine specific DTF location effects. For best results, the baseline model should contain a set of 'anchor' items and have freely estimated hyper-parameters in the focal groups. See **DIF** for details.

**Usage**

```r
DTF(mod, draws = NULL, CI = 0.95, npts = 1000, theta_lim = c(-6, 6), 
    Theta_nodes = NULL, plot = "none", auto.key = list(space = 
    "right", points = FALSE, lines = TRUE), ...)```

**Arguments**

- **mod**: a multipleGroup object which estimated only 2 groups
- **draws**: a number indicating how many draws to take to form a suitable multiple imputation estimate of the expected test scores (usually 100 or more). Returns a list containing the imputation distribution and null hypothesis test for the sDTF statistic
- **CI**: range of confidence interval when using draws input
- **npts**: number of points to use in the integration. Default is 1000
- **theta_lim**: lower and upper limits of the latent trait (theta) to be evaluated, and is used in conjunction with npts
Theta_nodes

an optional matrix of Theta values to be evaluated in the draws for the sDTF statistic. However, these values are not averaged across, and instead give the bootstrap confidence intervals at the respective Theta nodes. Useful when following up a large uDTF/sDTF statistic to determine where the difference between the test curves are large (while still accounting for sampling variability). Returns a matrix with observed variability

plot

a character vector indicating which plot to draw. Possible values are 'none', 'func' for the test score functions, and 'sDTF' for the evaluated sDTF values across the integration grid. Each plot is drawn with imputed confidence envelopes

auto.key

logical; automatically generate key in lattice plot?

additional arguments to be passed to lattice and boot

Empirical effect sizes based on latent trait estimates

Description
Computes effect size measures of differential item functioning and differential test/bundle functioning based on expected scores from Meade (2010). Item parameters from both reference and focal group are used in conjunction with focal group empirical theta estimates (and an assumed normally distributed theta) to compute expected scores.

Usage
empirical_ES(mod, Theta.focal = NULL, focal_items = 1L:extract.mirt(mod, "nitems"), DIF = TRUE, npts = 61, theta_lim = c(-6, 6), ref.group = 1, plot = FALSE, par.strip.text = list(cex = 0.7), par.settings = list(strip.background = list(col = "#9ECAE1"), strip.border = list(col = "black")), ...)

Arguments
mod a multipleGroup object which estimated only 2 groups
Theta.focal an optional matrix of Theta values from the focal group to be evaluated. If not supplied the default values to fscores will be used in conjunction with the ...
arguments passed
focal_items a numeric vector indicating which items to include the tests. The default uses all of the items. Selecting fewer items will result in tests of 'differential bundle functioning' when DIF = FALSE
DIF logical; return a data.frame of item-level imputation properties? If FALSE, only DBF and DTF statistics will be reported
npts number of points to use in the integration. Default is 61
theta_lim lower and upper limits of the latent trait (theta) to be evaluated, and is used in conjunction with npts
ref.group either 1 or 2 to indicate which group is considered the 'reference' group. Default is 1
plot logical; plot expected scores of items/test where expected scores are computed using focal group thetas and both focal and reference group item parameters
par.strip.text plotting argument passed to lattice
par.settings plotting argument passed to lattice
... additional arguments to be passed to fscores and xyplot
DIF
The default `DIF = TRUE` produces several effect sizes indices at the item level. Signed indices allow DIF favoring the focal group at one point on the theta distribution to cancel DIF favoring the reference group at another point on the theta distribution. Unsigned indices take the absolute value before summing or averaging, thus not allowing cancellation of DIF across theta.

**SIDS** Signed Item Difference in the Sample. The average difference in expected scores across the focal sample using both focal and reference group item parameters.

**UIDS** Unsigned Item Difference in the Sample. Same as SIDS except absolute value of expected scores is taken prior to averaging across the sample.

**D-Max** The maximum difference in expected scores in the sample.

**ESSD** Expected Score Standardized Difference. Cohen’s D for difference in expected scores.

**SIDN** Signed Item Difference in a Normal distribution. Identical to SIDS but averaged across a normal distribution rather than the sample.

**UIDN** Unsigned Item Difference in a Normal distribution. Identical to UIDS but averaged across a normal distribution rather than the sample.

DBF/DTF

`DIF = FALSE` produces a series of test/bundle-level indices that are based on item-level indices.

**STDS** Signed Test Differences in the Sample. The sum of the SIDS across items.

**UTDS** Unsigned Test Differences in the Sample. The sum of the UIDS across items.

**Stark’s DTFR** Stark’s version of STDS using a normal distribution rather than sample estimated thetas.

**UDTFR** Unsigned Expected Test Scores Differences in the Sample. The difference in observed summed scale scores expected, on average, across a hypothetical focal group with a normally distributed theta, had DF been uniform in nature for all items

**UETSDS** Unsigned Expected Test Score Differences in the Sample. The hypothetical difference expected scale scores that would have been present if scale-level DF had been uniform across respondents (i.e., always favoring the focal group).

**UETSDN** Identical to UETSDS but computed using a normal distribution.

**Test D-Max** Maximum expected test score differences in the sample.

**ETSSD** Expected Test Score Standardized Difference. Cohen’s D for expected test scores.

### End (Not run)
empirical_plot  Function to generate empirical unidimensional item and test plots

Description

Given a dataset containing item responses this function will construct empirical graphics using the observed responses to each item conditioned on the total score. When individual item plots are requested then the total score will be formed without the item of interest (i.e., the total score without that item).

Usage

```r
empirical_plot(data, which.items = NULL, smooth = FALSE,
               formula = resp ~ s(TS, k = 5), main = NULL,
               par.strip.text = list(cex = 0.7), boxplot = FALSE,
               par.settings = list(strip.background = list(col = "#9ECAE1"),
                                   strip.border = list(col = "black"),
                                   auto.key = list(space = "right",
                                                  points = FALSE, lines = TRUE), ...)
```

Arguments

- `data`: a data.frame or matrix of item responses (see `mirt` for typical input)
- `which.items`: a numeric vector indicating which items to plot in a faceted image plot. If NULL then an empirical test plot will be constructed instead
- `smooth`: logical; include a GAM smoother instead of the raw proportions? Default is FALSE
- `formula`: formula used for the GAM smoother
- `main`: the main title for the plot. If NULL an internal default will be used
- `par.strip.text`: plotting argument passed to `lattice`
- `boxplot`: logical; use a boxplot to display the marginal total score differences instead of scatter plots of proportions? Default is FALSE
- `par.settings`: plotting argument passed to `lattice`
- `auto.key`: plotting argument passed to `lattice`
- `...`: additional arguments to be passed to `lattice` and `coef()`

Details

Note that these types of plots should only be used for unidimensional tests with monotonically increasing item response functions. If monotonicity should be true for all items, however, then these plots may serve as a visual diagnostic tool so long as the majority of items are indeed monotonic.

References

empirical_rxx

Function to calculate the empirical (marginal) reliability

description

Given secondary latent trait estimates and their associated standard errors returned from fscores, compute the empirical reliability.

Usage

empirical_rxx(Theta_SE)

Arguments

Theta_SE a matrix of latent trait estimates returned from fscores with the options full.scores = TRUE and full.scores.SE = TRUE

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>
estfun.AllModelClass

estfun.AllModelClass  Extract Empirical Estimating Functions

Description

A function for extracting the empirical estimating functions of a fitted mirt, multipleGroup or bfactor model. This is the derivative of the log-likelihood with respect to the parameter vector, evaluated at the observed (case-wise) data. In other words, this function returns the case-wise scores, evaluated at the fitted model parameters. Currently, models fitted via the EM or BL method are supported. For the computations, the internal Theta grid of the model is being used which was already used during the estimation of the model itself along with its matching normalized density.

Usage

estfun.AllModelClass(x, weights = extract.mirt(x, "survey.weights"),
                 centering = FALSE)

Arguments

x  a fitted model object of class SingleGroupClass or MultipleGroupClass
weights by default, the `survey.weights` which were (optionally) specified when fitting
the model are included to calculate the scores. If specified by the user, this
should be a numeric vector of length equal to the total sample size. Note that
if not all cases were weighted equally when fitting the model, the weights must
be corrected by taking their square root if the scores are being used to compute
the outer product of gradients (OPG) estimate of the variance-covariance matrix
(see examples below).

centering a boolean variable that allows the centering of the case-wise scores (i.e., setting
their expected values to 0). If the case-wise scores were obtained from maxi-
mum likelihood estimates, this setting does not affect the result.

Value
An n x k matrix corresponding to n observations and k parameters

Author(s)
Lennart Schneider <lennart.sch@web.de>; centering argument contributed by Rudolf Debelak
(<rudolf.debelak@psychologie.uzh.ch>)

**expand.table**  
*Expand summary table of patterns and frequencies*

**Description**

The `expand.table` function expands a summary table of unique response patterns to a full sized data-set. The response frequencies must be on the rightmost column of the input data.

**Usage**

```r
expand.table(tabdata, sample = FALSE)
```

**Arguments**

- `tabdata`  
  An object of class `data.frame` or `matrix` with the unique response patterns and the number of frequencies in the rightmost column

- `sample`  
  logical; randomly switch the rows in the expanded table? This does not change the expanded data, only the row locations

**Value**

Returns a numeric matrix with all the response patterns.

**Author(s)**

Phil Chalmers <rphilip.chalmers@gmail.com>
References

Examples

data(LSAT7)
head(LSAT7)
LSAT7full <- expand.table(LSAT7)
head(LSAT7full)

LSAT7full <- expand.table(LSAT7, sample = TRUE)
head(LSAT7full)

expected.item

*Function to calculate expected value of item*

Description

Given an internal mirt object extracted from an estimated model compute the expected value for an item given the ability parameter(s).

Usage

```r
expected.item(x, Theta, min = 0)
```

Arguments

- **x**: an extracted internal mirt object containing item information (see `extract.item`)
- **Theta**: a vector (unidimensional) or matrix (multidimensional) of latent trait values
- **min**: a constant value added to the expected values indicating the lowest theoretical category. Default is 0

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

References

`extract.item`, `expected.test`
expected.test

Examples

```r
mod <- mirt(Science, 1)
extr.2 <- extract.item(mod, 2)
Theta <- matrix(seq(-6, 6, length.out=200))
expected <- expected.item(extr.2, Theta, min(Science[,1])) #min() of first item
head(data.frame(expected, Theta=Theta))
```

---

**expected.test**

*Function to calculate expected test score*

---

**Description**

Given an estimated model compute the expected test score. Returns the expected values in the same form as the data used to estimate the model.

**Usage**

```r
expected.test(x, Theta, group = NULL, mins = TRUE,
    individual = FALSE, which.items = NULL)
```

**Arguments**

- `x` an estimated mirt object
- `Theta` a matrix of latent trait values
- `group` a number signifying which group the item should be extracted from (applies to `MultipleGroupClass` objects only)
- `mins` logical; include the minimum value constants in the dataset. If FALSE, the expected values for each item are determined from the scoring 0:(ncat-1)
- `individual` logical; return tracelines for individual items?
- `which.items` an integer vector indicating which items to include in the expected test score. Default uses all possible items

**References**

expected.item
Examples

## Not run:
```
dat <- expand.table(deAyala)
model <- 'F = 1-5
  CONSTRAIN = (1-5, a1)'
mod <- mirt(dat, model)

Theta <- matrix(seq(-6,6,.01))
tscore <- expected.test(mod, Theta)
tail(cbind(Theta, tscore))

# use only first two items (i.e., a bundle)
bscore <- expected.test(mod, Theta, which.items = 1:2)
tail(cbind(Theta, bscore))
```
## End(Not run)

extract.group 

*Extract a group from a multiple group mirt object*

Description

Extract a single group from an object defined by `multipleGroup`.

Usage

```
extract.group(x, group)
```

Arguments

- `x` : mirt model of class 'MultipleGroupClass'
- `group` : a number signifying which group should be extracted

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

## Not run:
set.seed(12345)
a <- matrix(abs(rnorm(15,1,.3)), ncol=1)
d <- matrix(rnorm(15,0,.7),ncol=1)
itemtype <- rep('2PL', nrow(a))
N <- 1000
dataset1 <- simdata(a, d, N, itemtype)
dataset2 <- simdata(a, d, N, itemtype, mu = .1, sigma = matrix(1.5))
dat <- rbind(dataset1, dataset2)
group <- c(rep('D1', N), rep('D2', N))
models <- 'F1 = 1-15'
mod_configural <- multipleGroup(dat, models, group = group)
grph1 <- extract.group(mod_configural, 1) #extract first group
summary(grph1)
plot(grph1)
## End(Not run)
```

### extract.item

**Extract an item object from mirt objects**

**Description**

Extract the internal mirt objects from any estimated model.

**Usage**

```r
extract.item(x, item, group = NULL, drop.zeros = FALSE)
```

**Arguments**

- `x`: mirt model of class 'SingleGroupClass' or 'MultipleGroupClass'
- `item`: a number or character signifying which item to extract
- `group`: a number signifying which group the item should be extracted from (applies to 'MultipleGroupClass' only)
- `drop.zeros`: logical; drop slope values that are numerically close to zero to reduce dimensionality? Useful in objects returned from `bfactor` or other confirmatory models that contain several zero slopes

extract.mirt Extract various elements from estimated model objects

Description

A generic function to extract the internal objects from estimated models.

Usage

extract.mirt(x, what)

Arguments

x mirt model of class 'SingleGroupClass', 'MultipleGroupClass', 'MixedClass' or 'DiscreteGroupClass'
what a string indicating what to extract

Details

Objects which can be extracted from mirt objects include:

logLik observed log-likelihood
logPrior log term contributed by prior parameter distributions
G2 goodness of fit statistic
df degrees of freedom
p p-value for G2 statistic
RMSEA root mean-square error of approximation based on G2
CFI CFI fit statistic
TLI TLI fit statistic
AIC AIC
AICc corrected AIC
BIC BIC
SABIC  sample size adjusted BIC
DIC  DIC
HQ  HQ
F  unrotated standardized loadings matrix
h2  factor communality estimates
LLHistory  EM log-likelihood history
tabdata  a tabular version of the raw response data input. Frequencies are stored in freq
freq  frequencies associated with tabdata
K  an integer vector indicating the number of unique elements for each item
mins  an integer vector indicating the lowest category found in the input data
model  input model syntax
method  estimation method used
itemtype  a vector of item types for each respective item (e.g., 'graded', '2PL', etc)
itemnames  a vector of item names from the input data
data  raw input data of item responses
covdata  raw input data of data used as covariates
tabdatalong  similar to tabdata, however the responses have been transformed into dummy coded variables
fulldatalong  analogous to tabdatafull, but for the raw input data instead of the tabulated frequencies
exp_resp  expected probability of the unique response patterns
survey.weights  if supplied, the vector of survey weights used during estimation (NULL if missing)
converged  a logical value indicating whether the model terminated within the convergence criteria
iterations  number of iterations it took to reach the convergence criteria
nest  number of freely estimated parameters
parvec  vector containing uniquely estimated parameters
vcov  parameter covariance matrix (associated with parvec)
condnum  the condition number of the Hessian (if computed). Otherwise NA
constrain  a list of item parameter constraints to indicate which item parameters were equal during estimation
Prior  prior density distribution for the latent traits
key  if supplied, the data scoring key
nfact  number of latent traits/factors
nitems  number of items
ngroups  number of groups
groupNames  character vector of unique group names
group  a character vector indicating the group membership
secondordertest  a logical indicating whether the model passed the second-order test based on the Hessian matrix. Indicates whether model is a potential local maximum solution
SEMconv  logical; check whether the supplemented EM information matrix converged. Will be NA if not applicable
time  estimation time, broken into different sections

---

**fixef**  
*Compute latent regression fixed effect expected values*

Description
Create expected values for fixed effects parameters in latent regression models.

Usage

```r
fixef(x)
```

Arguments

- `x` an estimated model object from the `mixedmirt` or `mirt` function

Author(s)
Phil Chalmers <rphilip.chalmers@gmail.com>
fscores

fscores  
Compute factor score estimates (a.k.a, ability estimates, latent trait estimates, etc)
Description

Computes MAP, EAP, ML (Embretson & Reise, 2000), EAP for sum-scores (Thissen et al., 1995), or WLE (Warm, 1989) factor scores with a multivariate normal prior distribution using equally spaced quadrature. EAP scores for models with more than three factors are generally not recommended since the integration grid becomes very large, resulting in slower estimation and less precision if the quadpts are too low. Therefore, MAP scores should be used instead of EAP scores for higher dimensional models. Multiple imputation variants are possible for each estimator if a parameter information matrix was computed, which are useful if the sample size/number of items were small. As well, if the model contained latent regression predictors this information will be used in computing MAP and EAP estimates (for these models, full.scores=TRUE will always be used). Finally, plausible value imputation is also available, and will also account for latent regression predictor effects.

Usage

fscores(object, method = "EAP", full.scores = TRUE,
        rotate = "oblimin", Target = NULL, response.pattern = NULL,
        append_response.pattern = TRUE, na.rm = FALSE, plausible.draws = 0,
        plausible.type = "normal", quadpts = NULL, returnER = FALSE,
        return.acov = FALSE, mean = NULL, cov = NULL, verbose = TRUE,
        full.scores.SE = FALSE, theta_lim = c(-6, 6), MI = 0,
        use_dentype_estimate = FALSE, QMC = FALSE, custom_den = NULL,
        custom_theta = NULL, min_expected = 1, converge_info = FALSE,
        max_theta = 20, start = NULL, ...)

Arguments

object a computed model object of class SingleGroupClass, MultipleGroupClass, or DiscreteClass
method type of factor score estimation method. Can be:
        • "EAP" for the expected a-posteriori (default)
        • "MAP" for the maximum a-posteriori (i.e, Bayes modal)
        • "ML" for maximum likelihood
        • "WLE" for weighted likelihood estimation
        • "EAPsum" for the expected a-posteriori for each sum score
        • "plausible" for a single plausible value imputation for each case. This is equivalent to setting plausible.draws = 1
        • "classify" for the posteriori classification probabilities (only applicable when the input model was of class MixtureClass)
full.scores if FALSE then a summary table with factor scores for each unique pattern is displayed. Otherwise, a matrix of factor scores for each response pattern in the data is returned (default)
rotate prior rotation to be used when estimating the factor scores. See summary-method for details. If the object is not an exploratory model then this argument is ignored
Target target rotation; see summary-method for details
fscores

response.pattern
an optional argument used to calculate the factor scores and standard errors for a given response vector or matrix/data.frame

append_response.pattern
logical; should the inputs from response.pattern also be appended to the factor score output?

na.rm
logical; remove rows with any missing values? This is generally not required due to the nature of computing factors scores, however for the "EAPsum" method this may be necessary to ensure that the sum-scores correspond to the same composite score

plausible.draws
number of plausible values to draw for future researchers to perform secondary analyses of the latent trait scores. Typically used in conjunction with latent regression predictors (see mirt for details), but can also be generated when no predictor variables were modeled. If plausible.draws is greater than 0 a list of plausible values will be returned

plausible.type
type of plausible values to obtain. Can be either 'normal' (default) to use a normal approximation based on the ACOV matrix, or 'MH' to obtain Metropolis-Hastings samples from the posterior (silently passes object to mirt, therefore arguments like technical can be supplied to increase the number of burn-in draws and discarded samples)

quadpts
number of quadratures to use per dimension. If not specified, a suitable one will be created which decreases as the number of dimensions increases (and therefore for estimates such as EAP, will be less accurate). This is determined from the switch statement quadpts <- switch(as.character(nfact), '1'=61, '2'=31, '3'=15, '4'=9, '5'=7, 3)

returnER
logical; return empirical reliability (also known as marginal reliability) estimates as a numeric values?

return.acov
logical; return a list containing covariance matrices instead of factors scores? impute = TRUE not supported with this option

mean
a vector for custom latent variable means. If NULL, the default for 'group' values from the computed mirt object will be used

cov
a custom matrix of the latent variable covariance matrix. If NULL, the default for 'group' values from the computed mirt object will be used

verbose
logical; print verbose output messages?

full.scores.SE
logical; when full.scores == TRUE, also return the standard errors associated with each respondent? Default is FALSE

theta_lim
lower and upper range to evaluate latent trait integral for each dimension. If omitted, a range will be generated automatically based on the number of dimensions

MI
a number indicating how many multiple imputation draws to perform. Default is 0, indicating that no MI draws will be performed

use_dentype_estimate
logical; if the density of the latent trait was estimated in the model (e.g., via Davidian curves or empirical histograms), should this information be used to compute the latent trait estimates? Only applicable for EAP-based estimates (EAP, EAPsum, and plausible)
QMC logical; use quasi-Monte Carlo integration? If quadpts is omitted the default number of nodes is 5000

custom_den a function used to define the integration density (if required). The NULL default assumes that the multivariate normal distribution with the 'GroupPars' hyperparameters are used. At the minimum must be of the form:

function(Theta,...)

where Theta is a matrix of latent trait values (will be a grid of values if method == 'EAPsum' or method == 'EAP', otherwise Theta will have only 1 row). Additional arguments may included and are caught through the fscores(...) input. The function must return a numeric vector of density weights (one for each row in Theta)

custom_theta a matrix of custom integration nodes to use instead of the default, where each column corresponds to the respective dimension in the model

min_expected when computing goodness of fit tests when method = 'EAPsum', this value is used to collapse across the conditioned total scores until the expected values are greater than this value. Note that this only affect the goodness of fit tests and not the returned EAP for sum scores table

converge_info logical; include a column in the return objects containing a logical for each response pattern indicating whether a maximum value was found (not relevant for non-iterative methods, such as EAP and EAPsum). Value is a reflection of the code element from nlm (e.g., 1 indicates convergence)

max_theta the maximum/minimum value any given factor score estimate will achieve using any modal estimator method (e.g., MAP, WLE, ML)

start a matrix of starting values to use for iterative estimation methods. Default will start at a vector of 0's for each response pattern, or will start at the EAP estimates (unidimensional models only). Must be in the form that matches full.scores = FALSE (mostly used in the mirtCAT package)

... additional arguments to be passed to nlm

Details

The function will return either a table with the computed scores and standard errors, the original data matrix with scores appended to the rightmost column, or the scores only. By default the latent means and covariances are determined from the estimated object, though these can be overwritten. Iterative estimation methods can be estimated in parallel to decrease estimation times if a mirtCluster object is available.

If the input object is a discrete latent class object estimated from mdirt then the returned results will be with respect to the posterior classification for each individual. The method inputs for 'DiscreteClass' objects may only be 'EAP', for posterior classification of each response pattern, or 'EAPsum' for posterior classification based on the raw sum-score. For more information on these algorithms refer to the mirtCAT package and the associated JSS paper (Chalmers, 2016).

**imputeMissing**

**Imputing plausible data for missing values**

**Description**

Given an estimated model from any of mirt’s model fitting functions and an estimate of the latent trait, impute plausible missing data values. Returns the original data in a data.frame without any NA values. If a list of Theta values is supplied then a list of complete datasets is returned instead.

**Usage**

```r
imputeMissing(x, Theta, warn = TRUE, ...)
```

**Arguments**

- `x` : an estimated model x from the mirt package
- `Theta` : a matrix containing the estimates of the latent trait scores (e.g., via `fscores`
- `warn` : logical; print warning messages?
- `...` : additional arguments to pass

**Author(s)**

fulldata2 <- imputeMissing(mod2, fs)

## End(Not run)
```

**itemfit**

**Item fit statistics**

**Description**

Computes item-fit statistics for a variety of unidimensional and multidimensional models. Poorly fitting items should be inspected with the empirical plots/tables for unidimensional models, otherwise *itemGAM* can be used to diagnose where the functional form of the IRT model was misspecified, or models can be refit using more flexible semi-parametric response models (e.g., *itemtype* = 'spline'). If the latent trait density was approximated (e.g., Davidian curves, Empirical histograms, etc) then passing *use_dentype_estimate = TRUE* will use the internally saved quadrature and density components (where applicable). Currently, only S-X2 statistic supported for mixture IRT models. Finally, where applicable the root mean-square error of approximation (RMSEA) is reported to help guage the magnitude of item misfit.

**Usage**

```r
itemfit(x, fit_stats = "S_X2", which.items = 1:extract.mirt(x, "nitems"), na.rm = FALSE, group.bins = 10, group.size = NA,
```
group.fun = mean, mincell = 1, mincell.X2 = 2, 
S_X2.tables = FALSE, pv_draws = 30, boot = 1000, 
boot_dfapprox = 200, ERange = c(-2, 2), EPoints = 11, 
empirical.plot = NULL, empirical.CI = 0.95, empirical.table = NULL, 
empirical.poly.collapse = FALSE, method = "EAP", Theta = NULL, 
par.strip.text = list(cex = 0.7), 
par.settings = list(strip.background = list(col = "#9ECAE1")), 
strip.border = list(col = "black"), ...)

Arguments

x

a computed model object of class SingleGroupClass, MultipleGroupClass, or DiscreteClass

fit.stats

a character vector indicating which fit statistics should be computed. Supported inputs are:

- 'Zh' : Drasgow, Levine, & Williams (1985) Zh
- 'X2' : Bock's (1972) chi-squared method. The default inputs compute Yen's (1981) Q1 variant of the X2 statistic (i.e., uses a fixed group.bins = 10). However, Bock's group-size variable median-based method can be computed by passing group.fun = median and modifying the group.size input to the desired number of bins
- 'G2' : McKinley & Mills (1985) G2 statistic (similar method to Q1, but with the likelihood-ratio test).
- 'PV_Q1' : Chalmers and Ng's (2017) plausible-value variant of the Q1 statistic.
- 'PV_Q1*' : Chalmers and Ng's (2017) plausible-value variant of the Q1 statistic that uses parametric bootstrapping to obtain a suitable empirical distribution.
- 'X2*' : Stone's (2000) fit statistics that require parametric bootstrapping
- 'X2*_df' : Stone's (2000) fit statistics that require parametric bootstrapping to obtain scaled versions of the X2* and degrees of freedom
- 'infit' : (Unidimensional Rasch model only) compute the infit and outfit statistics. Ignored if models are not from the Rasch family

Note that 'infit', 'S_X2', and 'Zh' cannot be computed when there are missing response data (i.e., will require multiple-imputation/row-removal techniques).

which.items

an integer vector indicating which items to test for fit. Default tests all possible items

na.rm

logical; remove rows with any missing values? This is required for methods such as S-X2 because they require the "EAPsum" method from fscores

group.bins

the number of bins to use for X2 and G2. For example, setting group.bins = 10 will will compute Yen's (1981) Q1 statistic when 'X2' is requested

group.size

approximate size of each group to be used in calculating the $\chi^2$ statistic. The default NA disables this command and instead uses the group.bins input to try and construct equally sized bins
group.fun: function used when 'X2' or 'G2' are computed. Determines the central tendency measure within each partitioned group. E.g., setting group.fun = median will obtain the median of each respective ability estimate in each subgroup (this is what was used by Bock, 1972).

mincell: the minimum expected cell size to be used in the S-X2 computations. Tables will be collapsed across items first if polytomous, and then across scores if necessary.

mincell.X2: the minimum expected cell size to be used in the X2 computations. Tables will be collapsed if polytomous, however if this condition can not be met then the group block will be omitted in the computations.

S_X2.tables: logical; return the tables in a list format used to compute the S-X2 stats?

pv.draws: number of plausible-value draws to obtain for PV_Q1 and PV_Q1*

boot: number of parametric bootstrap samples to create for PV_Q1* and X2*

boot_dfapprox: number of parametric bootstrap samples to create for the X2*_df statistic to approximate the scaling factor for X2* as well as the scaled degrees of freedom estimates.

ETRange: range of integration nodes for Stone’s X2* statistic.

ETPoints: number of integration nodes to use for Stone’s X2* statistic.

empirical.plot: a single numeric value or character of the item name indicating which item to plot (via itemplot) and overlay with the empirical $\theta$ groupings (see empirical.CI). Useful for plotting the expected bins based on the 'X2' or 'G2' method.

empirical.CI: a numeric value indicating the width of the empirical confidence interval ranging between 0 and 1 (default of 0 plots not interval). For example, a 95 interval would be plotted when empirical.CI = .95. Only applicable to dichotomous items.

empirical.table: a single numeric value or character of the item name indicating which item table of expected values should be returned. Useful for visualizing the expected bins based on the 'X2' or 'G2' method.

empirical.poly.collapse: logical; collapse polytomous item categories to for expected scoring functions for empirical plots? Default is FALSE.

method: type of factor score estimation method. See fscores for more detail.

Theta: a matrix of factor scores for each person used for statistics that require empirical estimates. If supplied, arguments typically passed to fscores() will be ignored and these values will be used instead. Also required when estimating statistics with missing data via imputation.

par.strip.text: plotting argument passed to lattice.

par.settings: plotting argument passed to lattice.

...: additional arguments to be passed to fscores() and lattice.

itemGAM

Parametric smoothed regression lines for item response probability functions

Description

This function uses a generalized additive model (GAM) to estimate response curves for items that do not seem to fit well in a given model. Using a stable axillary model, traceline functions for poorly fitting dichotomous or polytomous items can be inspected using point estimates (or plausible values) of the latent trait. Plots of the tracelines and their associated standard errors are available to help interpret the misfit. This function may also be useful when adding new items to an existing, well established set of items, especially when the parametric form of the items under investigation are unknown.

Usage

itemGAM(item, Theta, formula = resp ~ s(Theta, k = 10), CI = 0.95, theta_lim = c(-3, 3), return.models = FALSE, ...)

# collapsed tables (see mincell.X2) for X2 and G2
itemfit(mod, empirical.table = 1)
mod2 <- mirt(dat, 1, 'Rasch')
itemfit(mod2, 'infit', method = 'ML')

#massive list of tables for S-X2
tables <- itemfit(mod, S_X2.tables = TRUE)

#observed and expected total score patterns for item 1 (post collapsing)
tables$O[[1]]
tables$E[[1]]

# fit stats with missing data (run in parallel using all cores)
dat[sample(1:prod(dim(dat)), 100)] <- NA
raschfit <- mirt(dat, 1, itemtype='Rasch')

#use only valid data by removing rows with missing terms
itemfit(raschfit, c('S_X2', 'infit'), na.rm = TRUE)

# note that X2, G2, PV-Q1, and X2* do not require complete datasets
thetas <- fscores(raschfit, method = 'ML') # save scores for faster computations
itemfit(raschfit, c('X2', 'G2'), Theta=thetas)
itemfit(raschfit, empirical.plot=1, Theta=thetas)
itemfit(raschfit, empirical.table=1, Theta=thetas)

## End(Not run)
## S3 method for class 'itemGAM'

```r
plot(x, y = NULL, par.strip.text = list(cex = 0.7),
     par.settings = list(strip.background = list(col = "#9ECAE1"),
                      strip.border = list(col = "black"),
                      auto.key = list(space = "right",
                          points = FALSE, lines = TRUE), ...)
```

### Arguments

- **item**: a single poorly fitting item to be investigated. Can be a vector or matrix.
- **Theta**: a list or matrix of latent trait estimates typically returned from `fscores`.
- **formula**: an R formula to be passed to the `gam` function. Default fits a spline model with 10 nodes. For multidimensional models, the traits are assigned the names 'Theta1', 'Theta2', ..., 'ThetaN'.
- **CI**: a number ranging from 0 to 1 indicating the confidence interval range. Default provides the 95 percent interval.
- **theta_lim**: range of latent trait scores to be evaluated.
- **return.models**: logical; return a list of GAM models for each category? Useful when the GAMs should be inspected directly, but also when fitting multidimensional models (this is set to TRUE automatically for multidimensional models).
- **...**: additional arguments to be passed to `gam` or `lattice`.
- **x**: an object of class 'itemGAM'.
- **y**: a NULL value ignored by the plotting function.
- **par.strip.text**: plotting argument passed to `lattice`.
- **par.settings**: plotting argument passed to `lattice`.
- **auto.key**: plotting argument passed to `lattice`.

names(IG4)
plot(IG4[[1]], main = 'Category 1')
plot(IG4[[2]], main = 'Category 2')
plot(IG4[[3]], main = 'Category 3')

## End(Not run)
```

---

**iteminfo**

*Function to calculate item information*

**Description**

Given an internal mirt item object extracted by using `extract.item`, compute the item information.
### Usage

```r
iteminfo(x, Theta, degrees = NULL, total.info = TRUE, multidim_matrix = FALSE)
```

### Arguments

- **x**: an extracted internal mirt object containing item information (see `extract.item`)
- **Theta**: a vector (unidimensional) or matrix (multidimensional) of latent trait values
- **degrees**: a vector of angles in degrees that are between 0 and 90. Only applicable when the input object is multidimensional
- **total.info**: logical; return the total information curve for the item? If FALSE, information curves for each category are returned as a matrix
- **multidim_matrix**: logical; compute the information matrix for each row in Theta? If Theta contains more than 1 row then a list of matrices will be returned, otherwise if Theta has exactly one row then a matrix will be returned

### Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

### Examples

```r
mod <- mirt(Science, 1)
extr.2 <- extract.item(mod, 2)
Theta <- matrix(seq(-4,4, by = .1))
info.2 <- iteminfo(extr.2, Theta)

#do something with the info?
plot(Theta, info.2[,1], type = 'l', main = 'Item information')

## Not run:

#category information curves
cat.info <- iteminfo(extr.2, Theta, total.info = FALSE)
plot(Theta, cat.info[,1], type = 'l', ylim = c(0, max(cat.info)), ylab = 'info', main = 'Category information')
for(i in 2:ncol(cat.info))
  lines(Theta, cat.info[,i], col = i)
```
## Customized test information plot

T1 <- T2 <- 0
dat <- expand.table(LSAT7)
mod1 <- mirt(dat, 1)
mod2 <- mirt(dat, 1, 'Rasch')
for(i in 1:5){
  T1 <- T1 + iteminfo(extract.item(mod1, i), Theta)
  T2 <- T2 + iteminfo(extract.item(mod2, i), Theta)
}
plot(Theta, T2/T1, type = 'l', ylab = 'Relative Test Information', las = 1)
lines(Theta, T1/T1, col = 'red')

# multidimensional
mod <- mirt(dat, 2, TOL=1e-2)
ii <- extract.item(mod, 1)
Theta <- as.matrix(expand.grid(-4:4, -4:4))

iteminfo(ii, Theta, degrees=c(45,45)) # equal angle
iteminfo(ii, Theta, degrees=c(90,0)) # first dimension only

# information matrices
iteminfo(ii, Theta, multidim_matrix = TRUE)
iteminfo(ii, Theta[1, , drop=FALSE], multidim_matrix = TRUE)

## End(Not run)

---

### Description

itemplot displays various item based IRT plots, with special options for plotting items that contain several 0 slope parameters. Supports up to three dimensional models.

### Usage

```r
itemplot(object, item, type = "trace", degrees = 45, CE = FALSE,
  CAlpha = 0.05, CEdraws = 1000, drop.zeros = FALSE,
  theta_lim = c(-6, 6), shiny = FALSE, rot = list(xaxis = -70, yaxis = 30, zaxis = 10),
  par.strip.text = list(cex = 0.7), npts = 200,
  par.settings = list(strip.background = list(col = "#9ECAE1"),
    strip.border = list(col = "black"), auto.key = list(space = "right",
    points = FALSE, lines = TRUE), ...)
```

### Arguments

- **object**
  - a computed model object of class SingleGroupClass or MultipleGroupClass.
  - Input may also be a list for comparing similar item types (e.g., 1PL vs 2PL)
itemplot

item  a single numeric value, or the item name, indicating which item to plot

type plot type to use, information ('info'), standard errors ('SE'), item trace lines ('trace'), information and standard errors ('infoSE') or information and trace lines ('infotrace'), relative efficiency lines ('RE'), expected score 'score', or information and trace line contours ('infocontour' and 'tracecontour'); not supported for MultipleGroupClass objects

degrees the degrees argument to be used if there are two or three factors. See iteminfo for more detail. A new vector will be required for three dimensional models to override the default

CE logical; plot confidence envelope?

CEalpha area remaining in the tail for confidence envelope. Default gives 95% confidence region

CEDraws draws number of draws to use for confidence envelope

drop.zeros logical; drop slope values that are numerically close to zero to reduce dimensionality? Useful in objects returned from bfactor or other confirmatory models that contain several zero slopes

theta_lim lower and upper limits of the latent trait (theta) to be evaluated, and is used in conjunction with npts

shiny logical; run interactive display for item plots using the shiny interface. This primarily is an instructive tool for demonstrating how item response curves behave when adjusting their parameters

rot a list of rotation coordinates to be used for 3 dimensional plots

par.strip.text plotting argument passed to lattice

npts number of quadrature points to be used for plotting features. Larger values make plots look smoother

par.settings plotting argument passed to lattice

auto.key plotting argument passed to lattice

... additional arguments to be passed to lattice and coef()

## Not run:
data(LSAT7)
fulldata <- expand.table(LSAT7)
mod1 <- mirt(fulldata,1,SE=TRUE)
key2binary

Score a test by converting response patterns to binary data

Description

The `key2binary` function will convert response pattern data to a dichotomous format, given a response key.
key2binary

Usage

key2binary(fulldata, key, score_missing = FALSE)

Arguments

fulldata an object of class data.frame, matrix, or table with the response patterns
key a vector or matrix consisting of the 'correct' response to the items. Each value/row corresponds to each column in fulldata. If the input is a matrix, multiple scoring keys can be supplied for each item. NA values are used to indicate no scoring key (or in the case of a matrix input, no additional scoring keys)
score_missing logical; should missing data elements be returned as incorrect (i.e., 0)? If FALSE, all missing data terms will be kept as missing

Value

Returns a numeric matrix with all the response patterns in dichotomous format

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

### likert2int

`likert2int` is a function to convert ordered Likert-scale responses (character or factors) to integers.

#### Description

Given a matrix or data.frame object consisting of Likert responses return an object of the same dimensions with integer values.

#### Usage

`likert2int(x, levels = NULL)`
Arguments

x  a matrix of character values or data.frame of character/factor vectors
levels  a named character vector indicating which integer values should be assigned to
which elements. If omitted, the order of the elements will be determined after
converting each column in x to a factor variable

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

logLik-method  

**Extract log-likelihood**

**Description**

Extract the observed-data log-likelihood.

**Usage**

```r
## S4 method for signature 'SingleGroupClass'
logLik(object)
```

**Arguments**

- `object` an object of class `SingleGroupClass`, `MultipleGroupClass`, or `MixedClass`
References

Examples

```r
## Not run:
x <- mirt(Science, 1)
logLik(x)

## End(Not run)
```

Description

Data from Thissen (1982): contains 5 dichotomously scored items obtained from the Law School Admissions Test, section 6.

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

References

Examples

```r
## Not run:
dat <- expand.table(LSAT6)
head(dat)
model <- 'F = 1-5
    CONSTRAIN = (1-5, a1)'
(mod <- mirt(dat, model))
M2(mod)
itemfit(mod)
coef(mod, simplify=TRUE)

# equivalently, but with a different parameterization
mod2 <- mirt(dat, 1, itemtype = 'Rasch')
```
LSAT7

Description of LSAT7 data

Description

Data from Bock & Lieberman (1970); contains 5 dichotomously scored items obtained from the Law School Admissions Test, section 7.

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

References

Examples

```r
## Not run:
dat <- expand.table(LSAT7)
head(dat)
(mod <- mirt(dat, 1))
coef(mod)
## End(Not run)
```
Description

Computes the M2 (Maydeu-Olivares & Joe, 2006) statistic when all data are dichotomous, the collapsed M2* statistic (collapsing over univariate and bivariate response categories; see Cai and Hansen, 2013), and the hybrid C2 statistic which only collapses only the bivariate moments (Cai and Monro, 2014). The C2 variant is mainly useful when polytomous response models do not have sufficient degrees of freedom to compute M2*. This function also computes associated fit indices that are based on fitting the null model. Supports single and multiple-group models. If the latent trait density was approximated (e.g., Davidian curves, Empirical histograms, etc) then passing use_dentype_estimate = TRUE will use the internally saved quadrature and density components (where applicable).

Usage

```r
M2(obj, type = "M2*", calcNull = TRUE, na.rm = FALSE,
    quadpts = NULL, theta_lim = c(-6, 6), CI = 0.9, residmat = FALSE,
    QMC = FALSE, suppress = 1, ...)
```

Arguments

- **obj**: an estimated model object from the mirt package
- **type**: type of fit statistic to compute. Options are "M2", "M2*" for the univariate and bivariate collapsed version of the M2 statistic ("M2" currently limited to dichotomous response data only), and "C2" for a hybrid between M2 and M2* where only the bivariate moments are collapsed
- **calcNull**: logical; calculate statistics for the null model as well? Allows for statistics such as the limited information TLI and CFI. Only valid when items all have a suitable null model (e.g., those created via createItem will not)
- **na.rm**: logical; remove rows with any missing values? The M2 family of statistics requires a complete dataset in order to be well defined
- **quadpts**: number of quadrature points to use during estimation. If NULL, a suitable value will be chosen based on the rubric found in fscores
- **theta_lim**: lower and upper range to evaluate latent trait integral for each dimension
- **CI**: numeric value from 0 to 1 indicating the range of the confidence interval for RMSEA. Default returns the 90% interval
- **residmat**: logical; return the residual matrix used to compute the SRMSR statistic? Only the lower triangle of the residual correlation matrix will be returned (the upper triangle is filled with NA’s)
- **QMC**: logical; use quasi-Monte Carlo integration? Useful for higher dimensional models. If quadpts not specified, 5000 nodes are used by default
suppress a numeric value indicating which parameter residual dependency combinations to flag as being too high. Absolute values for the standardized residuals greater than this value will be returned, while all values less than this value will be set to NA. Must be used in conjunction with the argument residmat = TRUE

... additional arguments to pass

Value
Returns a data.frame object with the M2-type statistic, along with the degrees of freedom, p-value, RMSEA (with 90% confidence interval), SRMSR for each group (if all items were ordinal), and optionally the TLI and CFI model fit statistics if calcNull = TRUE.

Examples

```r
## Not run:
dat <- as.matrix(expand.table(LSAT7))
(mod1 <- mirt(dat, 1))
M2(mod1)
M2(mod1, residmat=TRUE) # lower triangle of residual correlation matrix

# M2 with missing data present
dat[sample(1:prod(dim(dat)), 250)] <- NA
mod2 <- mirt(dat, 1)
# Compute stats by removing missing data row-wise
M2(mod2, na.rm = TRUE)

# C2 statistic (useful when polytomous IRT models have too few df)
pmod <- mirt(Science, 1)
# This fails with too few df:
# M2(pmod)
# This, however, works:
M2(pmod, type = 'C2')

## End(Not run)
```
marginal_rxx

Function to calculate the marginal reliability

Description

Given an estimated model and a prior density function, compute the marginal reliability (Thissen and Wainer, 2001). This is only available for unidimensional tests.

Usage

marginal_rxx(mod, density = dnorm, ...)

Arguments

mod
an object of class 'SingleGroupClass'
density
a density function to use for integration. Default assumes the latent traits are from a normal (Gaussian) distribution
...additional arguments passed to the density function

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

table

Examples

dat <- expand.table(deAyala)
mod <- mirt(dat, 1)

# marginal estimate
marginal_rxx(mod)

## Not run:

# empirical estimate (assuming the same prior)
fscores(mod, returnER = TRUE)
MDIFF

Compute multidimensional difficulty index

Description

Returns a matrix containing the MDIFF values (Reckase, 2009). Only supported for items of class 'dich' and 'graded'.

Usage

MDIFF(x, which.items = NULL, group = NULL)

Arguments

x an object of class 'SingleGroupClass', or an object of class 'MultipleGroupClass' if a suitable group input were supplied
which.items a vector indicating which items to select. If NULL is used (the default) then MDISC will be computed for all items

Arguments

x an object of class 'SingleGroupClass', or an object of class 'MultipleGroupClass' if a suitable group input were supplied
which.items a vector indicating which items to select. If NULL is used (the default) then MDISC will be computed for all items

Arguments

x

which.items

group

MDIFF(mod)

## End(Not run)
```

### Description

`mdirt` fits a variety of item response models with discrete latent variables. These include, but are not limited to, latent class analysis, multidimensional latent class models, multidimensional discrete latent class models, DINA/DINO models, grade of measurement models, C-RUM, and so on. If response models are not defined explicitly then customized models can be defined using the `createItem` function.

### Usage

```r
mdirt(data, model, customTheta = NULL, structure = NULL, 
      item.Q = NULL, nruns = 1, method = "EM", covdata = NULL, 
      formula = NULL, itemtype = "lca", optimizer = "nlminb", 
      return_max = TRUE, group = NULL, GenRandomPars = FALSE, 
      verbose = TRUE, pars = NULL, technical = list(), ...)
```

### Arguments

- `data`: a matrix or data.frame that consists of numerically ordered data, with missing data coded as NA
- `model`: number of mutually exclusive classes to fit, or alternatively a more specific `mirt.model` definition (which reflects the so-called Q-matrix). Note that when using a `mirt.model`, the order with which the syntax factors/attributes are defined are associated with the columns in the `customTheta` input
- `customTheta`: input passed to `technical = list(customTheta = ...)`, but is included directly in this function for convenience. This input is most interesting for discrete latent models because it allows customized patterns of latent classes (i.e., defines the possible combinations of the latent attribute profile). The default builds the pattern `customTheta = diag(model)`, which is the typical pattern for the traditional latent class analysis whereby class membership mutually distinct and exhaustive. See `thetaComb` for a quick method to generate a matrix with all possible combinations
structure

an R formula allowing the profile probability patterns (i.e., the structural component of the model) to be fitted according to a log-linear model. When `NULL`, all profile probabilities (except one) will be estimated. Use of this input requires that the `customTheta` input is supplied, and that the column names in this matrix match the names found within this formula.

`item.Q`

a list of item-level Q-matrices indicating how the respective categories should be modeled by the underlying attributes. Each matrix must represent a $K_i \times A$ matrix, where $K_i$ represents the number of categories for the $i$th item, and $A$ is the number of attributes included in the $\Theta$ matrix; otherwise, a value of `NULL` will default to a matrix consisting of 1’s for each $K_i \times A$ element except for the first row, which contains only 0’s for proper identification. Incidentally, the first row of each matrix must contain only 0’s so that the first category represents the reference category for identification.

`nruns`

a numeric value indicating how many times the model should be fit to the data when using random starting values. If greater than 1, `GenRandomPars` is set to true by default.

`method`

estimation method. Can be 'EM' or 'BL' (see `mirt` for more details).

`covdata`

a data.frame of data used for latent regression models.

`formula`

an R formula (or list of formulas) indicating how the latent traits can be regressed using external covariates in `covdata`. If a named list of formulas is supplied (where the names correspond to the latent trait/attribute names in `model`) then specific regression effects can be estimated for each factor. Supplying a single formula will estimate the regression parameters for all latent variables by default.

`itemtype`

a vector indicating the itemtype associated with each item. For discrete models this is limited to only 'lca' or items defined using a `createItem` definition.

`optimizer`

optimizer used for the M-step, set to 'nlminb' by default. See `mirt` for more details.

`return_max`

logical; when `nruns > 1`, return the model that has the most optimal maximum likelihood criteria? If FALSE, returns a list of all the estimated objects.

`group`

a factor variable indicating group membership used for multiple group analyses.

`GenRandomPars`

logical; use random starting values.

`verbose`

logical; turn on messages to the R console.

`pars`

used for modifying starting values; see `mirt` for details.

`technical`

list of lower-level inputs. See `mirt` for details.

... additional arguments to be passed to the estimation engine. See `mirt` for more details and examples.

**Details**

Posterior classification accuracy for each response pattern may be obtained via the `fscores` function. The `summary()` function will display the category probability values given the class membership, which can also be displayed graphically with `plot()`, while `coef()` displays the raw coefficient values (and their standard errors, if estimated). Finally, `anova()` is used to compare nested models, while `M2` and `itemfit` may be used for model fitting purposes.
'Ica' model definition

The latent class IRT model with two latent classes has the form

\[ P(x = k|\theta_1, \theta_2, a_1, a_2) = \frac{\exp(a_1\theta_1 + a_2\theta_2)}{\sum_{j}^{K} \exp(a_1\theta_1 + a_2\theta_2)} \]

where the \( \theta \) values generally take on discrete points (such as 0 or 1). For proper identification, the first category slope parameters (\( a_1 \) and \( a_2 \)) are never freely estimated. Alternatively, supplying a different grid of \( \theta \) values will allow the estimation of similar models (multidimensional discrete models, grade of membership, etc.). See the examples below.

When the \( \text{item.Q} \) for is utilized, the above equation can be understood as

\[ P(x = k|\theta_1, \theta_2, a_1, a_2) = \frac{\exp(a_1\theta_1 Q_{j1} + a_2\theta_2 Q_{j2})}{\sum_{j}^{K} \exp(a_1\theta_1 Q_{j1} + a_2\theta_2 Q_{j2})} \]

where by construction \( Q \) is a \( K \times A \) matrix indicating whether the category should be modeled according to the latent class structure. For the standard latent class model, the Q-matrix has as many rows as categories, as many columns as the number of classes/attributes modeled, and consist of 0’s in the first row and 1’s elsewhere. This of course can be over-written by passing an alternative \( \text{item.Q} \) definition for each respective item.

**MDISC**

*Compute multidimensional discrimination index*

**Description**

Returns a vector containing the MDISC values for each item in the model input object (Reckase, 2009).
Usage

MDISC(x, group = NULL)

Arguments

x
an object of class 'SingleGroupClass', or an object of class 'MultipleGroupClass' if a suitable group input were supplied

group
group argument to pass to \texttt{extract.group} function. Required when the input object is a multiple-group model

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

\textbf{mirt} \hspace{1cm} \textit{Full-Information Item Factor Analysis (Multidimensional Item Response Theory)}

Description

\texttt{mirt} fits a maximum likelihood (or maximum a posteriori) factor analysis model to any mixture of dichotomous and polychotomous data under the item response theory paradigm using either Cai's (2010) Metropolis-Hastings Robbins-Monro (MHRM) algorithm, with an EM algorithm approach outlined by Bock and Aiken (1981) using rectangular or quasi-Monte Carlo integration grids, or with the stochastic EM (i.e., the first two stages of the MH-RM algorithm). Models containing 'explanatory' person or item level predictors can only be included by using the \texttt{mixedmirt} function, though latent regression models can be fit using the \texttt{formula} input in this function. Tests that
form a two-tier or bi-factor structure should be estimated with the bfactor function, which uses a
dimension reduction EM algorithm for modeling item parcels. Multiple group analyses (useful for
DIF and DTF testing) are also available using the multipleGroup function.

Usage

mirt(data, model, itemtype = NULL, guess = 0, upper = 1,
SE = FALSE, covdata = NULL, formula = NULL, SE.type = "Oakes",
method = "EM", optimizer = NULL, dentype = "Gaussian",
pars = NULL, constrain = NULL, parprior = NULL, calcNull = FALSE,
draws = 5000, survey.weights = NULL, quadpts = NULL, TOL = NULL,
gpcm_mats = list(), grsm.block = NULL, rsm.block = NULL,
monopoly.k = 1L, key = NULL, large = FALSE,
GenRandomPars = FALSE, accelerate = "Ramsay", verbose = TRUE,
solnp_args = list(), nloptr_args = list(), spline_args = list(),
control = list(), technical = list(), ...)

Arguments

data a matrix or data.frame that consists of numerically ordered data, with missing
data coded as NA (to convert from an ordered factor data.frame see data.matrix)
model a string to be passed (or an object returned from) mirt.model, declaring how the
IRT model is to be estimated (loadings, constraints, priors, etc). For exploratory
IRT models, a single numeric value indicating the number of factors to extract
is also supported
itemtype type of items to be modeled, declared as a vector for each item or a single value
which will be recycled for each item. The NULL default assumes that the items
follow a graded or 2PL structure, however they may be changed to the following:

- 'Rasch' - Rasch/partial credit model by constraining slopes to 1 and freely
  estimating the variance parameters (alternatively, can be specified by
  applying equality constraints to the slope parameters in 'gpcm'; Rasch, 1960)
- '2PL', '3PL', '3PLu', and '4PL' - 2-4 parameter logistic model, where
  3PL estimates the lower asymptote only while 3PLu estimates the upper
  asymptote only (Lord and Novick, 1968; Lord, 1980)
- 'graded' - graded response model (Samejima, 1969)
- 'grsm' and 'grsmIRT' - graded ratings scale model in the slope-intercept
  and classical IRT parameterization. 'grsmIRT' is restricted to unidimen-
  sional models (Muraki, 1992)
- 'gpcm' and 'gpcmIRT' - generalized partial credit model in the slope-
  intercept and classical parameterization. 'gpcmIRT' is restricted to uni-
  dimensional models. Note that optional scoring matrices for 'gpcm' are
  available with the gpcm_mats input (Muraki, 1992)
- 'rsm' - Rasch rating scale model using the 'gpcmIRT' structure (unidi-
  mensional only; Andrich, 1978)
- 'nominal' - nominal response model (Bock, 1972)
- 'ideal' - dichotomous ideal point model (Maydeu-Olivares, 2006)
• 'ggum' - generalized graded unfolding model (Roberts, Donoghue, & Laughlin, 2000) and its multidimensional extension
• 'sequential' - multidimensional sequential response model (Tutz, 1990) in slope-intercept form
• 'Tutz' - same as the 'sequential' itemtype, except the slopes are fixed to 1 and the latent variance terms are freely estimated (similar to the 'Rasch' itemtype input)
• 'PC2PL' and 'PC3PL' - 2-3 parameter partially compensatory model. Note that constraining the slopes to be equal across items will reduce the model to Embretson’s (a.k.a. Whitemy’s) multicomponent model (1980).
• '2PLNRM', '3PLNRM', '3PLuNRM', and '4PLNRM' - 2-4 parameter nested logistic model, where 3PLNRM estimates the lower asymptote only while 3PLuNRM estimates the upper asymptote only (Suh and Bolt, 2010)
• 'spline' - spline response model with the bs (default) or the ns function (Winsberg, Thissen, and Wainer, 1984)
• 'monopoly' - monotonic polynomial model for unidimensional tests for dichotomous and polytomous response data (Falk and Cai, 2016)

Additionally, user defined item classes can also be defined using the createItem function

guess fixed pseudo-guessing parameters. Can be entered as a single value to assign a global guessing parameter or may be entered as a numeric vector corresponding to each item
upper fixed upper bound parameters for 4-PL model. Can be entered as a single value to assign a global guessing parameter or may be entered as a numeric vector corresponding to each item
SE logical; estimate the standard errors by computing the parameter information matrix? See SE.type for the type of estimates available
covdata a data.frame of data used for latent regression models
formula an R formula (or list of formulas) indicating how the latent traits can be regressed using external covariates in covdata. If a named list of formulas is supplied (where the names correspond to the latent trait names in model) then specific regression effects can be estimated for each factor. Supplying a single formula will estimate the regression parameters for all latent traits by default
SE.type type of estimation method to use for calculating the parameter information matrix for computing standard errors and wald tests. Can be:
  • 'Richardson', 'forward', or 'central' for the numerical Richardson, forward difference, and central difference evaluation of observed Hessian matrix
  • 'crossprod' and 'Louis' for standard error computations based on the variance of the Fisher scores as well as Louis' (1982) exact computation of the observed information matrix. Note that Louis' estimates can take a long time to obtain for large sample sizes and long tests
  • 'sandwich' for the sandwich covariance estimate based on the 'crossprod' and 'Oakes' estimates (see Chalmers, in press, for details)
- 'sandwich.Louis' for the sandwich covariance estimate based on the 'crossprod' and 'Louis' estimates
- 'Oakes' for Oakes' (1999) method using a central difference approximation (see Chalmers, in press, for details)
- 'SEM' for the supplemented EM (disables the accelerate option automatically; EM only)
- 'Fisher' for the expected information, 'complete' for information based on the complete-data Hessian used in EM algorithm
- 'FMHRM' and 'FMHRM' for stochastic approximations of observed information matrix based on the Robbins-Monro filter or a fixed number of MHRM draws without the RM filter. These are the only options supported when method = 'MHRM'
- 'numerical' to obtain the numerical estimate from a call to optim when method = 'BL'

Note that both the 'SEM' method becomes very sensitive if the ML solution has has not been reached with sufficient precision, and may be further sensitive if the history of the EM cycles is not stable/sufficient for convergence of the respective estimates. Increasing the number of iterations (increasing NCYCLES and decreasing TOL, see below) will help to improve the accuracy, and can be run in parallel if a mirtCluster object has been defined (this will be used for Oakes’ method as well). Additionally, inspecting the symmetry of the ACOV matrix for convergence issues by passing technical = list(symmetric = FALSE) can be helpful to determine if a sufficient solution has been reached

method

a character object specifying the estimation algorithm to be used. The default is 'EM', for the standard EM algorithm with fixed quadrature, 'QMCEM' for quasi-Monte Carlo EM estimation, or 'MCEM' for Monte Carlo EM estimation. The option 'MHRM' may also be passed to use the MH-RM algorithm, 'SEM' for the Stochastic EM algorithm (first two stages of the MH-RM stage using an optimizer other than a single Newton-Raphson iteration), and 'BL' for the Bock and Lieberman approach (generally not recommended for longer tests).

The 'EM' is generally effective with 1-3 factors, but methods such as the 'QMCEM', 'MCEM', 'SEM', or 'MHRM' should be used when the dimensions are 3 or more. Note that when the optimizer is stochastic the associated SE.type is automatically changed to SE.type = 'MHRM' by default to avoid the use of quadrature

optimizer

a character indicating which numerical optimizer to use. By default, the EM algorithm will use the 'BFGS' when there are no upper and lower bounds box-constraints and 'nlminb' when there are.

Other options include the Newton-Raphson ('NR'), which can be more efficient than the 'BFGS' but not as stable for more complex IRT models (such as the nominal or nested logit models) and the related 'NR1' which is also the Newton-Raphson but consists of only 1 update that has been coupled with RM Hessian (only applicable when the MH-RM algorithm is used). The MH-RM algorithm uses the 'NR1' by default, though currently the 'BFGS', 'L-BFGS-B', and 'NR' are also supported with this method (with fewer iterations by default) to emulate stochastic EM updates. As well, the 'Nelder-Mead' and 'SANN' estimators are available, but their routine use generally is not required or recommended.
Additionally, estimation subroutines from the Rsolnp and nloptr packages are available by passing the arguments 'solnp' and 'nloptr', respectively. This should be used in conjunction with the solnp_args and nloptr_args specified below. If equality constraints were specified in the model definition only the parameter with the lowest parnum in the pars = 'values' data.frame is used in the estimation vector passed to the objective function, and group hyperparameters are omitted. Equality an inequality functions should be of the form function(p,optim_args), where optim_args is a list of internally parameters that largely can be ignored when defining constraints (though use of browser() here may be helpful).

dentype

type of density form to use for the latent trait parameters. Current options include

- 'Gaussian' (default) assumes a multivariate Gaussian distribution with an associated mean vector and variance-covariance matrix
- 'empiricalhist' or 'EH' estimates latent distribution using an empirical histogram described by Bock and Aitkin (1981). Only applicable for unidimensional models estimated with the EM algorithm. For this option, the number of cycles, TOL, and quadpts are adjusted accommodate for less precision during estimation (namely: TOL = 3e-5, NCYCLES = 2000, quadpts = 121)
- 'empiricalhist_Woods' or 'EHW' estimates latent distribution using an empirical histogram described by Bock and Aitkin (1981), with the same specifications as in dentype = 'empiricalhist', but with the extrapolation-interpolation method described by Woods (2007). NOTE: to improve stability in the presence of extreme response styles (i.e., all highest or lowest in each item) the technical option zeroExtreme = TRUE may be required to down-weight the contribution of these problematic patterns
- 'Davidian-#' estimates semi-parametric Davidian curves described by Woods and Lin (2009), where the # placeholder represents the number of Davidian parameters to estimate (e.g., 'Davidian-6' will estimate 6 smoothing parameters). By default, the number of quadpts is increased to 121, and this method is only applicable for unidimensional models estimated with the EM algorithm

pars

a data.frame with the structure of how the starting values, parameter numbers, estimation logical values, etc, are defined. The user may observe how the model defines the values by using pars = 'values', and this object can in turn be modified and input back into the estimation with pars = mymodifiedpars

constrain

a list of user declared equality constraints. To see how to define the parameters correctly use pars = 'values' initially to see how the parameters are labeled. To constrain parameters to be equal create a list with separate concatenated vectors signifying which parameters to constrain. For example, to set parameters 1 and 5 equal, and also set parameters 2, 6, and 10 equal use constrain = list(c(1,5),c(2,6,10)). Constraints can also be specified using the mirt.model syntax (recommended)

parprior

a list of user declared prior item probabilities. To see how to define the parameters correctly use pars = 'values' initially to see how the parameters are labeled. Can define either normal (e.g., intercepts, lower/guessing and upper
bounds), log-normal (e.g., for univariate slopes), or beta prior probabilities. To specify a prior the form is `c('priortype', ...), where normal priors are `parprior = list(c(parnumbers, 'norm', mean, sd)), parprior = list(c(parnumbers, 'lnorm', log_mean, log_sd)) for log-normal, and `parprior = list(c(parnumbers, 'beta', alpha, beta)) for beta, and `parprior = list(c(parnumbers, 'expbeta', alpha, beta)) for the beta distribution after applying the function `plogis` to the input value (note, this is specifically for applying a beta prior to the lower/upper-bound parameters in 3/4PL models). Priors can also be specified using `mirt.model` syntax (recommended).

calcNull logical; calculate the Null model for additional fit statistics (e.g., TLI)? Only applicable if the data contains no NA's and the data is not overly sparse.
draws the number of Monte Carlo draws to estimate the log-likelihood for the MH-RM algorithm. Default is 5000.
survey.weights a optional numeric vector of survey weights to apply for each case in the data (EM estimation only). If not specified, all cases are weighted equally (the standard IRT approach). The sum of the survey.weights must equal the total sample size for proper weighting to be applied.
quadpts number of quadrature points per dimension (must be larger than 2). By default the number of quadrature uses the following scheme: `switch(as.character(nfact), '1' = 61, '2' = 31, '3' = 15, '4' = 9, '5' = 7,3)`. However, if the method input is set to 'QMCEM' and this argument is left blank then the default number of quasi-Monte Carlo integration nodes will be set to 5000 in total.
TOL convergence threshold for EM or MH-RM; defaults are .0001 and .001. If SE.type = 'SEM' and this value is not specified, the default is set to 1e-5. If dentype = 'empiricalhist' (i.e., 'EH') or 'empiricalhist_Woods' (i.e., 'EHW') and TOL is not specified then the default 3e-5 will be used. To evaluate the model using only the starting values pass `TOL = NaN`, and to evaluate the starting values without the log-likelihood pass `TOL = NA`.
gpcm_mats a list of matrices specifying how the scoring coefficients in the (generalized) partial credit model should be constructed. If omitted, the standard gpcm format will be used (i.e., `seq(0,k,by = 1)` for each trait). This input should be used if traits should be scored different for each category (e.g., `matrix(c(0:3,1,0,0,0),4,2)` for a two-dimensional model where the first trait is scored like a gpcm, but the second trait is only positively indicated when the first category is selected). Can be used when itemtypes are 'gpcm' or 'Rasch', but only when the respective element in gpcm_mats is not NULL.
grsm.block an optional numeric vector indicating where the blocking should occur when using the grsm. NA represents items that do not belong to the grsm block (other items that may be estimated in the test data). For example, to specify two blocks of 3 with a 2PL item for the last item: `grsm.block = c(rep(1,3), rep(2,3), NA)`. If NULL, the all items are assumed to be within the same group and therefore have the same number of item categories.
rsm.block same as grsm.block, but for 'rsm' blocks.
monopoly.k a vector of values (or a single value to repeated for each item) which indicate the degree of the monotone polynomial fitted, where the monotone polynomial corresponds to `monopoly.k * 2 + 1` (e.g., `monopoly.k = 2` fits a 5th degree polynomial). Default is `monopoly.k = 1`, which fits a 3rd degree polynomial.
key a numeric vector of the response scoring key. Required when using nested logit
item types, and must be the same length as the number of items used. Items that
are not nested logit will ignore this vector, so use NA in item locations that are
not applicable

large either a logical, indicating whether the internal collapsed data should be re-
turned, or a list of internally computed data tables. If TRUE is passed, a list
containing the organized tables is returned. This list object can then be passed
back into large to avoid reorganizing the data again (useful when the dataset is
very large and computing the tabulated data is computationally burdensome).
The best strategy for large data is to always pass the internal data to the estima-
tion function, shown below:

Compute organized data e.g., internaldat <-mirt(Science,1,large = TRUE)
Pass the organized data to all estimation functions e.g., mod <-mirt(Science,1,large
 = internaldat)

GenRandomPars logical; generate random starting values prior to optimization instead of using
the fixed internal starting values?

accelerate a character vector indicating the type of acceleration to use. Default is 'Ramsay',
but may also be 'squarem' for the SQUAREM procedure (specifically, the
gSqS3 approach) described in Varadhan and Roldand (2008). To disable the
acceleration, pass 'none'

verbose logical; print observed- (EM) or complete-data (MHRM) log-likelihood after
each iteration cycle? Default is TRUE

solnp_args a list of arguments to be passed to the solnp::solnp() function for equality
constraints, inequality constraints, etc

nloptr_args a list of arguments to be passed to the nloptr::nloptr() function for equality
constraints, inequality constraints, etc

spline_args a named list of lists containing information to be passed to the bs (default) and
ns for each spline itemtype. Each element must refer to the name of the itemtype
with the spline, while the internal list names refer to the arguments which are
passed. For example, if item 2 were called 'read2', and item 5 were called
'read5', both of which were of itemtype 'spline' but item 5 should use the ns
form, then a modified list for each input might be of the form:
spline_args = list(read2 = list(degree = 4), read5 = list(fun = 'ns', knots
 = c(-2,2)))
This code input changes the bs() splines function to have a degree = 4 input,
while the second element changes to the ns() function with knots set a c(-2,2)

control a list passed to the respective optimizers (i.e., optim(), nlminb(), etc). Ad-
ditional arguments have been included for the 'NR' optimizer: 'tol' for the
convergence tolerance in the M-step (default is TOL/1000), while the default
number of iterations for the Newton-Raphson optimizer is 50 (modified with the
'maxit' control input)

technical a list containing lower level technical parameters for estimation. May be:

NCYCLES maximum number of EM or MH-RM cycles; defaults are 500 and 2000
**MAXQUAD** maximum number of quadratures, which you can increase if you have more than 4GB or RAM on your PC; default 20000

**theta_lim** range of integration grid for each dimension; default is \(c(-6,6)\)

**set.seed** seed number used during estimation. Default is 12345

**SEtol** standard error tolerance criteria for the S-EM and MHRM computation of the information matrix. Default is 1e-3

**symmetric** logical; force S-EM/Oakes information matrix estimates to be symmetric? Default is TRUE so that computation of standard errors are more stable. Setting this to FALSE can help to detect solutions that have not reached the ML estimate

**SEM_window** ratio of values used to define the S-EM window based on the observed likelihood differences across EM iterations. The default is \(c(0,1-SEtol)\), which provides nearly the very full S-EM window (i.e., nearly all EM cycles used). To use the a smaller SEM window change the window to something like \(c(.9,.999)\) to start at a point farther into the EM history

**warn** logical; include warning messages during estimation? Default is TRUE

**message** logical; include general messages during estimation? Default is TRUE

**customK** a numeric vector used to explicitly declare the number of response categories for each item. This should only be used when constructing mirt model for reasons other than parameter estimation (such as to obtain factor scores), and requires that the input data all have 0 as the lowest category. The format is the same as the `extract.mirt(mod,'K')` slot in all converged models

**customPriorFun** a custom function used to determine the normalized density for integration in the EM algorithm. Must be of the form `function(Theta,Etable){...}`, and return a numeric vector with the same length as number of rows in `Theta`. The `Etable` input contains the aggregated table generated from the current E-step computations. For proper integration, the returned vector should sum to 1 (i.e., normalized). Note that if using the `Etable` it will be NULL on the first call, therefore the prior will have to deal with this issue accordingly

**zeroExtreme** logical; assign extreme response patterns a survey.weight of 0 (formally equivalent to removing these data vectors during estimation)? When dentity = 'EHW', where Woods’ extrapolation is utilized, this option may be required if the extrapolation causes expected densities to tend towards positive or negative infinity. The default is FALSE

**customTheta** a custom `Theta` grid, in matrix form, used for integration. If not defined, the grid is determined internally based on the number of quadpts

**delta** the deviation term used in numerical estimates when computing the ACOV matrix with the ‘forward’ or ‘central’ numerical approaches, as well as Oakes’ method with the Richardson extrapolation. Default is 1e-5

**parallel** logical; use the parallel cluster defined by `mirtCluster`? Default is TRUE

**removeEmptyRows** logical; remove response vectors that only contain NA’s? Default is FALSE

**internal_constraints** logical; include the internal constraints when using certain IRT models (e.g., ‘grsm’ itemtype). Disable this if you want to use
special optimizers such as the solnp. Default is `TRUE`.

- **gain** a vector of two values specifying the numerator and exponent values for the RM gain function \((val_1/cycle)^{val_2}\). Default is \(c(0.10, 0.75)\)

- **BURNIN** number of burn in cycles (stage 1) in MH-RM; default is 150

- **SEMCYCLES** number of SEM cycles (stage 2) in MH-RM; default is 100

- **MHDRAWS** number of Metropolis-Hasting draws to use in the MH-RM at each iteration; default is 5

- **MHcand** a vector of values used to tune the MH sampler. Larger values will cause the acceptance ratio to decrease. One value is required for each group in unconditional item factor analysis (mixedmirt() requires additional values for random effect). If null, these values are determined internally, attempting to tune the acceptance of the draws to be between .1 and .4

- **MHRM_SE_draws** number of fixed draws to use when \(SE=TRUE\) and \(SE.type = 'FMHRM'\) and the maximum number of draws when \(SE.type = 'MHHRM'\). Default is 2000

- **MCEM_draws** a function used to determine the number of quadrature points to draw for the 'MCEM' method. Must include one argument which indicates the iteration number of the EM cycle. Default is \(function(cycles) 500 + (cycles -1)*2\), which starts the number of draws at 500 and increases by 2 after each full EM iteration

- **info_if_converged** logical; compute the information matrix when using the MH-RM algorithm only if the model converged within a suitable number of iterations? Default is `TRUE`

- **loglik_if_converged** logical; compute the observed log-likelihood when using the MH-RM algorithm only if the model converged within a suitable number of iterations? Default is `TRUE`

- **keep_vcov_PD** logical; attempt to keep the variance-covariance matrix of the latent traits positive definite during estimation in the EM algorithm? This generally improves the convergence properties when the traits are highly correlated. Default is `TRUE`

... additional arguments to be passed

### Value

Function returns an object of class `SingleGroupClass` (**SingleGroupClass-class**)

### Confirmatory and Exploratory IRT

Specification of the confirmatory item factor analysis model follows many of the rules in the structural equation modeling framework for confirmatory factor analysis. The variances of the latent factors are automatically fixed to 1 to help facilitate model identification. All parameters may be fixed to constant values or set equal to other parameters using the appropriate declarations. Confirmatory models may also contain ‘explanatory’ person or item level predictors, though including predictors is currently limited to the `mixedmirt` function.

When specifying a single number greater than 1 as the model input to `mirt` an exploratory IRT model will be estimated. Rotation and target matrix options are available if they are passed to
generic functions such as `summary-method` and `fscores`. Factor means and variances are fixed to ensure proper identification.

If the model is an exploratory item factor analysis estimation will begin by computing a matrix of quasi-polychoric correlations. A factor analysis with `nfact` is then extracted and item parameters are estimated by \( a_{ij} = \frac{f_{ij}}{u_j} \), where \( f_{ij} \) is the factor loading for the \( j \)th item on the \( i \)th factor, and \( u_j \) is the square root of the factor uniqueness, \( \sqrt{1 - h_j^2} \). The initial intercept parameters are determined by calculating the inverse normal of the item facility (i.e., item easiness), \( q_j \), to obtain \( d_j = q_j/u_j \). A similar implementation is also used for obtaining initial values for polytomous items.

**A note on upper and lower bound parameters**

Internally the \( g \) and \( u \) parameters are transformed using a logit transformation \( \log(x/(1-x)) \), and can be reversed by using \( 1/(1 + \exp(-x)) \) following convergence. This also applies when computing confidence intervals for these parameters, and is done so automatically if `coef(mod, rawug = FALSE)`.

As such, when applying prior distributions to these parameters it is recommended to use a prior that ranges from negative infinity to positive infinity, such as the normally distributed prior via the 'norm' input (see `mirt.model`).

**Convergence for quadrature methods**

Unrestricted full-information factor analysis is known to have problems with convergence, and some items may need to be constrained or removed entirely to allow for an acceptable solution. As a general rule dichotomous items with means greater than .95, or items that are only .05 greater than the guessing parameter, should be considered for removal from the analysis or treated with prior parameter distributions. The same type of reasoning is applicable when including upper bound parameters as well. For polytomous items, if categories are rarely endorsed then this will cause similar issues. Also, increasing the number of quadrature points per dimension, or using the quasi-Monte Carlo integration method, may help to stabilize the estimation process in higher dimensions. Finally, solutions that are not well defined also will have difficulty converging, and can indicate that the model has been misspecified (e.g., extracting too many dimensions).

**Convergence for MH-RM method**

For the MH-RM algorithm, when the number of iterations grows very high (e.g., greater than 1500) or when `Max Change = .2500` values are repeatedly printed to the console too often (indicating that the parameters were being constrained since they are naturally moving in steps greater than 0.25) then the model may either be ill defined or have a very flat likelihood surface, and genuine maximum-likelihood parameter estimates may be difficult to find. Standard errors are computed following the model convergence by passing `SE = TRUE`, to perform an addition MH-RM stage but treating the maximum-likelihood estimates as fixed points.

**Additional helper functions**

Additional functions are available in the package which can be useful pre- and post-estimation. These are:
**mirt.model** Define the IRT model specification use special syntax. Useful for defining between and within group parameter constraints, prior parameter distributions, and specifying the slope coefficients for each factor

**coef-method** Extract raw coefficients from the model, along with their standard errors and confidence intervals

**summary-method** Extract standardized loadings from model. Accepts a rotate argument for exploratory item response model

**anova-method** Compare nested models using likelihood ratio statistics as well as information criteria such as the AIC and BIC

**residuals-method** Compute pairwise residuals between each item using methods such as the LD statistic (Chen & Thissen, 1997), as well as as response pattern residuals

**plot-method** Plot various types of test level plots including the test score and information functions and more

**itemplot** Plot various types of item level plots, including the score, standard error, and information functions, and more

**createItem** Create a customized itemtype that does not currently exist in the package

**imputeMissing** Impute missing data given some computed Theta matrix

**fscores** Find predicted scores for the latent traits using estimation methods such as EAP, MAP, ML, WLE, and EAPsum

**wald** Compute Wald statistics follow the convergence of a model with a suitable information matrix

**M2** Limited information goodness of fit test statistic based to determine how well the model fits the data

**itemfit** and **personfit** Goodness of fit statistics at the item and person levels, such as the S-X2, infit, outfit, and more

**boot.mirt** Compute estimated parameter confidence intervals via the bootstrap methods

**mirtCluster** Define a cluster for the package functions to use for capitalizing on multi-core architecture to utilize available CPUs when possible. Will help to decrease estimation times for tasks that can be run in parallel

**IRT Models**

The parameter labels use the follow convention, here using two factors and $k$ as the number of categories.

**Rasch** Only one intercept estimated, and the latent variance of $\theta$ is freely estimated. If the data have more than two categories then a partial credit model is used instead (see ’gpcm’ below).

$$P(x = 1|\theta, d) = \frac{1}{1 + exp(-(\theta + d))}$$

**2-4PL** Depending on the model $u$ may be equal to 1 and $g$ may be equal to 0.

$$P(x = 1|\theta, \psi) = g + \frac{(u - g)}{1 + exp(-(a_1 \theta_1 + a_2 \theta_2 + d))}$$
The graded model consists of sequential 2PL models, and here \( k \) is the predicted category.

\[
P(x = k | \theta, \psi) = P(x \geq k | \theta, \phi) - P(x \geq k + 1 | \theta, \phi)
\]

**grsm and grsmIRT** A more constrained version of the graded model where graded spacing is equal across item blocks and only adjusted by a single ‘difficulty’ parameter (c) while the latent variance of \( \theta \) is freely estimated. Again,

\[
P(x = k | \theta, \psi) = P(x \geq k | \theta, \phi) - P(x \geq k + 1 | \theta, \phi)
\]

but now

\[
P = \frac{1}{1 + \exp(-(a_1 \theta_1 + a_2 \theta_2 + d_k + c))}
\]

The grsmIRT model is similar to the grsm item type, but uses the IRT parameterization instead (see Muraki, 1990 for this exact form). This is restricted to unidimensional models only, whereas grsm may be used for unidimensional or multidimensional models and is more consistent with the form of other IRT models in mirt.

**gpcm/nominal** For the gpcm the \( d \) values are treated as fixed and ordered values from 0:(k-1) (in the nominal model \( d_0 \) is also set to 0). Additionally, for identification in the nominal model \( a_k = 0, a_k(k-1) = (k-1) \).

\[
P(x = k | \theta, \psi) = \frac{\exp(a_k \theta_1 + a_2 \theta_2 + d_{k-1})}{\sum_k \exp(a_k \theta_1 + a_2 \theta_2 + d_{k-1})}
\]

For the partial credit model (when `itemtype` = ‘Rasch’; unidimensional only) the above model is further constrained so that \( a_k = (0, 1, \ldots, k-1) \), \( a_1 = 1 \), and the latent variance of \( \theta_1 \) is freely estimated. Alternatively, the partial credit model can be obtained by containing all the slope parameters in the gpcm to be equal. More specific scoring function may be included by passing a suitable list or matrices to the `gpcm_mats` input argument. In the nominal model this parametrization helps to identify the empirical ordering of the categories by inspecting the \( ak \) values. Larger values indicate that the item category is more positively related to the latent trait(s) being measured. For instance, if an item was truly ordinal (such as a Likert scale), and had 4 response categories, we would expect to see \( a_{k0} < a_{k1} < a_{k2} < a_{k3} \) following estimation. If on the other hand \( a_{k0} > a_{k3} \) then it would appear that the second category is less related to the trait than the first, and therefore the second category should be understood as the ‘lowest score’. NOTE: The nominal model can become numerical unstable if poor choices for the high and low values are chosen, resulting in \( ak \) values greater than abs(10) or more. It is recommended to choose high and low anchors that cause the estimated parameters to fall between 0 and the number of categories - 1 either by theoretical means or by re-estimating the model with better values following convergence.

**gpcmIRT and rsm** The gpcmIRT model is the classical generalized partial credit model for unidimensional response data. It will obtain the same fit as the gpcm presented above, however the parameterization allows for the Rasch/generalized rating scale model as a special case.

E.g., for a 4 category response model,

\[
P(x = 0 | \theta, \psi) = \exp(1)/G
\]

\[
P(x = 1 | \theta, \psi) = \exp(1 + a(\theta - b1) + c)/G
\]
The multidimensional sequential response model has the form

\[ P(x = 2|\theta, \psi) = \exp(1 + a(2\theta - b_1 - b_2) + 2c)/G \]
\[ P(x = 3|\theta, \psi) = \exp(1 + a(3\theta - b_1 - b_2 - b_3) + 3c)/G \]

where

\[ G = \exp(1) + \exp(1 + a(\theta - b_1) + c) + \exp(1 + a(2\theta - b_1 - b_2) + 2c) + a(3\theta - b_1 - b_2 - b_3) + 3c \]

Here \( a \) is the slope parameter, the \( b \) parameters are the threshold values for each adjacent category, and \( c \) is the so-called difficulty parameter when a rating scale model is fitted (otherwise, \( c = 0 \) and it drops out of the computations).

The gpcmIRT can be constrained to the partial credit IRT model by either constraining all the slopes to be equal, or setting the slopes to 1 and freeing the latent variance parameter.

Finally, the rsm is a more constrained version of the (generalized) partial credit model where the spacing is equal across item blocks and only adjusted by a single 'difficulty' parameter \( c \). Note that this is analogous to the relationship between the graded model and the grsm (with an additional constraint regarding the fixed discrimination parameters).

**sequential/Tutz** The multidimensional sequential response model has the form

\[ P(x = k|\theta, \psi) = \prod (1 - F(a_1\theta_1 + a_2\theta_2 + d_{ik})) F(a_1\theta_1 + a_2\theta_2 + d_{jk}) \]

where \( F(\cdot) \) is the cumulative logistic function. The Tutz variant of this model (Tutz, 1990) (via `itemtype = 'Tutz'`) assumes that the slope terms are all equal to 1 and the latent variance terms are estimated (i.e., is a Rasch variant).

**ideal** The ideal point model has the form, with the upper bound constraint on \( d \) set to 0:

\[ P(x = 1|\theta, \psi) = \exp(-0.5 * (a_1 * \theta_1 + a_2 * \theta_2 + d))^2 \]

**partcomp** Partially compensatory models consist of the product of 2PL probability curves.

\[ P(x = 1|\theta, \psi) = g + (1 - g)(\frac{1}{1 + \exp(-(a_1 * \theta_1 + d_{1}^i))} * \frac{1}{1 + \exp(-(a_2 * \theta_2 + d_{2}^j))}) \]

Note that constraining the slopes to be equal across items will reduce the model to Embretson’s (a.k.a. Whitely’s) multicomponent model (1980).

**2-4PLNRM** Nested logistic curves for modeling distractor items. Requires a scoring key. The model is broken into two components for the probability of endorsement. For successful endorsement the probability trace is the 1-4PL model, while for unsuccessful endorsement:

\[ P(x = 0|\theta, \psi) = (1 - P_{1-4PL}(x = 1|\theta, \psi)) * P_{nominal}(x = k|\theta, \psi) \]

which is the product of the complement of the dichotomous trace line with the nominal response model. In the nominal model, the slope parameters defined above are constrained to be 1’s, while the last value of the \( a_k \) is freely estimated.

**ggum** The (multidimensional) generalized graded unfolding model is a class of ideal point models useful for ordinal response data. The form is

\[ P(z = k|\theta, \psi) = \frac{\exp \left[ \sum_{d=1}^{D} a_{id}^2(\theta_{jd} - b_{id})^2 + \sum_{k=0}^{z} \psi_{ik} \right] + \exp \left[ (M - z) \sqrt{\sum_{d=1}^{D} a_{id}^2(\theta_{jd} - b_{id})^2} \right]}{\sum_{w=0}^{C} \exp \left[ w \sqrt{\sum_{d=1}^{D} a_{id}^2(\theta_{jd} - b_{id})^2} + \sum_{k=0}^{z} \psi_{ik} \right] + \exp \left[ (M - w) \sqrt{\sum_{d=1}^{D} a_{id}^2(\theta_{jd} - b_{id})^2} \right]} \]
where $\theta_{jd}$ is the location of the $j$th individual on the $d$th dimension, $b_{id}$ is the difficulty location of the $i$th item on the $d$th dimension, $a_{id}$ is the discrimination of the $j$th individual on the $d$th dimension (where the discrimination values are constrained to be positive), $\psi_{ik}$ is the $k$th subjective response category threshold for the $i$th item, assumed to be symmetric about the item and constant across dimensions, where $\psi_{ik} = \sum_{d=1}^{D} a_{id} t_{ik} z = 1, 2, \ldots, C$ (where $C$ is the number of categories minus 1), and $M = 2C + 1$.

**spline**  Spline response models attempt to model the response curves using non-linear and potentially non-monotonic patterns. The form is

$$P(x = 1|\theta, \eta) = \frac{1}{1 + exp(-\eta_1 X_1 + \eta_2 X_2 + \cdots + \eta_n X_n)}$$

where the $X_n$ are from the spline design matrix $X$ organized from the grid of $\theta$ values. B-splines with a natural or polynomial basis are supported, and the intercept input is set to TRUE by default.

**monopoly**  Monotone polynomial model for polytomous response data of the form

$$P(x = k|\theta, \psi) = \frac{\exp(\sum_{c=1}^{k-1} (m^*(\psi) + \xi_{c-1}))}{\sum_{c=1}^{C} \exp(\sum_{c}^{k-1} (m^*(\psi) + \xi_{c-1}))}$$

where $m^*(\psi)$ is the monotone polynomial function without the intercept.

## End(Not run)
Arguments

input  input for writing out the model syntax. Can either be a string declaration of class character or the so-called Q-matrix or class matrix that specifies the model either with integer or logical values. If the Q-matrix method is chosen covariances terms can be specified with the COV input.

itemnames  a character vector or factor indicating the item names. If a data.frame or matrix object is supplied the names will be extracted using colnames(itemnames). Supplying this input allows the syntax to be specified with the raw item names rather than item locations.

file  a input specifying an external file that declares the input.

COV  a symmetric, logical matrix used to declare which covariance terms are estimated.

quiet  logical argument passed to scan() to suppress console read message.

...  additional arguments for scan() 

Details

Factors are first named and then specify which numerical items they affect (i.e., where the slope is not equal to 0), separated either by commas or by - to indicate a range of items. Products between factors may be specified by enclosing the left hand term within brackets. To finish the declaration of a model simply enter a blank line with only a carriage return (i.e., the ‘enter’ or ‘return’ key), or instead read in an input version of the model syntax. The associated slopes throughout the package label these coefficients as a1, a2, . . . , ak, where the associated number is assigned according to the respective order of the defined factors.

For example, if the syntax were

"G = 1-10 F = 1-5 A = 6-10"

then the G factor would be assigned the slopes a1 for each item, F assigned the slopes a2, and A assigned the slopes a3. The same principle applies to the bfactor function whereby the slopes are automatically included for the specific factors after the general factor structure has been assigned.

There is an optional keyword for specifying the correlation between relationships between factors called COV, and non-linear factor products can be included by enclosing the product combination on the left hand side of the declaration (e.g., (F1*F1) would create a quadratic factor for F1).

The keywords CONSTRAIN, CONSTRAINB, PRIOR, FIXED, FREE, START, UBOUND, LBOUND can be applied to specific sub-groups in multiple-group models by included square brackets before the = sign, where groups are separated by commas. For example, to apply within-group equality constraints to a group called "male", then specifying:

CONSTRAIN [male] = (1-5,a1)

is appropriate, while specifying the same constraints to the sub-groups "male" and "female" would appear as

CONSTRAIN [male,female] = (1-5,a1)

For all other groups in the multi-group model, these within-group equality constraints would not appear. Therefore, these bracketed group specifications are useful when modifying priors, starting values, between/within group equality constraints, and so on when the specifications for each subgroup may differ.
Finally, the keyword GROUP can be used to specify the group-level hyper-parameter terms, such as the means and variance of the default Gaussian distribution. For example, to set the starting value of the variance parameter (COV_11) to 1.5:

\[
\text{START} = (\text{GROUP, COV}_11, 1.5)
\]

COV Specify the relationship between the latent factors. Estimating a correlation between factors is declared by joining the two factors with an asterisk (e.g., F1*F2), or with an asterisk between three or more factors to estimate all the possible correlations (e.g., F1*F2*F3)

MEAN A comma separated list specifying which latent factor means to freely estimate. E.g., MEAN = F1, F2 will free the latent means for factors F1 and F2

CONSTRAIN A bracketed, comma separated list specifying equality constrains between items. The input format is CONSTRAIN = (items,...,parameterName(s)),(items,...,parameterName). For example, in a single group 10-item dichotomous tests, using the default 2PL model, the first and last 5 item slopes (a1) can be constrained to be equal by using CONSTRAIN = (1-5,a1),(6-10,a1), or some combination such as CONSTRAIN = (1-3,4,5,a1),(6,7,8-10,a1).

When constraining parameters to be equal across items with different parameter names, a balanced bracketed vector must be supplied. E.g., setting the first slope for item 1 equal to the second slope in item 3 would be CONSTRAIN = (1,3,a1,a2)

CONSTRAINB A bracketed, comma separate list specifying equality constrains between groups. The input format is CONSTRAINB = (items,...,parameterName),(items,...,parameterName). For example, in a two group 10-item dichotomous tests, using the default 2PL model, the first 5 item slopes (a1) can be constrained to be equal across both groups by using CONSTRAINB = (1-5,a1), or some combination such as CONSTRAINB = (1-3,4,5,a1)

PRIOR A bracketed, comma separate list specifying prior parameter distributions. The input format is PRIOR = (items,...,parameterName,priorType,val1,val2),(items,...,parameterName,priorType,val1,val2). For example, in a single group 10-item dichotomous tests, using the default 2PL model, defining a normal prior of N(0,2) for the first 5 item intercepts (d) can be defined by PRIOR = (1-5,d,norm,0,2)

Currently supported priors are of the form: (items,norm,mean,sd) for the normal/Gaussian, (items,lnorm,log_mean,log_sd) for log-normal, (items,beta,alpha,beta) for beta, and (items,expbeta,alpha,beta) for the beta distribution after applying the function plogis to the input value (note, this is specifically for applying a beta prior to the lower-bound parameters in 3/4PL models)

LBOUND A bracketed, comma separate list specifying lower bounds for estimated parameters (used in optimizers such as L-BFGS-B and nlminb). The input format is LBOUND = (items,...,parameterName,value). For example, in a single group 10-item dichotomous tests, using the 3PL model and setting lower bounds for the 'g' parameters for the first 5 items to 0.2 is accomplished with LBOUND = (1-5,g,0.2)

UBOUND same as LBOUND, but specifying upper bounds in estimated parameters

START A bracketed, comma separate list specifying the starting values for individual parameters. The input is of the form (items,...,parameterName,value). For instance, setting the 10th and 12th to 15th item slope parameters (a1) to 1.0 is specified with START = (10,12-15,a1,1.0)

For more hands on control of the starting values pass the argument pars = 'values' through whatever estimation function is being used
**mirt.model**

**FIXED** A bracketed, comma separate list specifying which parameters should be fixed at their starting values (i.e., not freely estimated). The input is of the form \(\text{items}, \ldots, \text{parameterName}\). For instance, fixing the 10th and 12th to 15th item slope parameters \((a1)\) is accomplished with \(\text{FIXED} = (10,12-15,a1)\).

For more hands on control of the estimated values pass the argument `pars = 'values'` through whatever estimation function is being used.

**FREE** Equivalent to the **FIXED** input, except that parameters are freely estimated instead of fixed at their starting value.

**NEXPLORE** Number of exploratory factors to extract. Usually this is not required because passing a numeric value to the `model` argument in the estimation function will generate an exploratory factor analysis model, however if different start values, priors, lower and upper bounds, etc, are desired then this input can be used.

**Value**

Returns a model specification object to be used in `mirt`, `bfactor`, `multipleGroup`, or `mixedmirt`.

**Author(s)**

Phil Chalmers <rphilip.chalmers@gmail.com> and Alexander Robitzsch.

**References**

**Examples**

```r
## Not run:
# interactively through the console (not run)
#model <- mirt.model()
# F1 = 1,2,3,4-10
# F2 = 10-20
# (F1*F2) = 1,2,3,4-10
# COV = F1*F2

#Or alternatively with a string input
s <- 'F1 = 1,2,3,4-10
     F2 = 10-20
     (F1*F2) = 1,2,3,4-10
     COV = F1*F2'
model <- mirt.model(s)

# strings can also be passed to the estimation functions directly,
# which silently calls mirt.model(). E.g., using the string above:
# mod <- mirt(data, s)
```
### Q-matrix specification

```r
Q <- matrix(c(1,1,1,0,0,0,0,0,0,1,1,1), ncol=2, dimnames = list(NULL, c('Factor1', 'Factor2'))) 
COV <- matrix(c(FALSE, TRUE, TRUE, FALSE), 2) 
model <- mirt.model(Q, COV=COV)
```

## constrain various items slopes and all intercepts in single group model to be equal, 
# and use a log-normal prior for all the slopes

```r
s <- 'F = 1-10
  CONSTRAIN = (1-3, 5, 6, a1), (1-10, d)
  PRIOR = (1-10, a1, lnorm, .2, .2)'
model <- mirt.model(s)
```

## constrain various items slopes and intercepts across groups for use in multipleGroup(), 
# and constrain first two slopes within 'group1' to be equal

```r
s <- 'F = 1-10
  CONSTRAIN = (1-2, a1)
  CONSTRAINB = (1-3, 5, 6, a1), (1-10, d)
model <- mirt.model(s)
```

## specify model using raw item names

```r
data(data.read, package = 'sirt')
dat <- data.read

# syntax with variable names
mirtsyn2 <- "
  F1 = A1,B2,B3,C4
  F2 = A1-A4,C2,C4
  MEAN = F1
  COV = F1xF1, F1xF2
  CONSTRAIN=(A2-A4,a2), (A3,C2,d)
  PRIOR = (C3,A2-A4, a2, lnorm, .2, .2), (B3,d, norm, 0, .0001)"
# create a mirt model
mirtmodel <- mirt.model(mirtsyn2, itemnames=dat)
# or equivalently:
# mirtmodel <- mirt.model(mirtsyn2, itemnames=colnames(dat))

# mod <- mirt(dat, mirtmodel)
```

## End(Not run)

---

### mirtCluster

**Define a parallel cluster object to be used in internal functions**

**Description**

This function defines an object that is placed in a relevant internal environment defined in mirt. Internal functions such as calcLogLik, fscores, etc, will utilize this object automatically to capitalize...
on parallel processing architecture. The object defined is a call from `parallel::makeCluster()`. Note that if you are defining other parallel objects (for simulation designs, for example) it is not recommended to define a mirtCluster.

Usage

```r
mirtCluster(spec, ..., remove = FALSE)
```

Arguments

- `spec`: input that is passed to `parallel::makeCluster()`. If no input is given the maximum number of available local cores will be used.
- `...`: additional arguments to pass to `parallel::makeCluster`.
- `remove`: logical; remove previously defined mirtCluster()?

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

References

Examples

```r
## Not run:
#make 4 cores available for parallel computing
mirtCluster(4)

#' #stop and remove cores
mirtCluster(remove = TRUE)

## End(Not run)
```

MixedClass-class

Class "MixedClass"

Description

Defines the object returned from `mixedmirt`.
Slots

Call: function call
Data: list of data, sometimes in different forms
Options: list of estimation options
Fit: a list of fit information
Model: a list of model-based information
ParObjects: a list of the S4 objects used during estimation
OptimInfo: a list of arguments from the optimization process
Internals: a list of internal arguments for secondary computations (inspecting this object is generally not required)
vcov: a matrix represented the asymptotic covariance matrix of the parameter estimates
time: a data.frame indicating the breakdown of computation times in seconds

Methods

coef signature(object = "MixedClass")
print signature(x = "MixedClass")
residuals signature(object = "MixedClass")
show signature(object = "MixedClass")
summary signature(object = "MixedClass")
logLik signature(object = "MixedClass")
anova signature(object = "MixedClass")

mixedmirt Mixed effects modeling for MIRT models

Description

mixedmirt fits MIRT models using FIML estimation to dichotomous and polytomous IRT models conditional on fixed and random effect of person and item level covariates. This can also be understood as 'explanatory IRT' if only fixed effects are modeled, or multilevel/mixed IRT if random and fixed effects are included. The method uses the MH-RM algorithm exclusively. Additionally, computation of the log-likelihood can be sped up by using parallel estimation via mirtCluster.
Usage

mixedmirt(data, covdata = NULL, model, fixed = ~1, random = NULL,
  itemtype = "Rasch", lr.fixed = ~1, lr.random = NULL,
  itemdesign = NULL, constrain = NULL, pars = NULL,
  return.design = FALSE, SE = TRUE, internal_constraints = TRUE,
  technical = list(SEtol = 1e-04), ...)

Arguments

data a matrix or data.frame that consists of numerically ordered data, with missing data coded as NA

covdata a data.frame that consists of the nrow(data) by K 'person level' fixed and random predictors

model an object returned from, or a string to be passed to, mirt.model() to declare how the IRT model is to be estimated. See mirt.model for more details

fixed a right sided R formula for specifying the fixed effect (aka 'explanatory') predictors from covdata and itemdesign. To estimate the intercepts for each item the keyword items is reserved and automatically added to the itemdesign input. If any polytomous items are being model the items argument is not valid since all intercept parameters are freely estimated and identified with the parameterizations found in mirt, and the first column in the fixed design matrix (commonly the intercept or a reference group) is omitted

random a right sided formula or list of formulas containing crossed random effects of the form v1 + ... v_n | G, where G is the grouping variable and v_n are random numeric predictors within each group. If no intercept value is specified then by default the correlations between the v's and G are estimated, but can be suppressed by including the ~ -1 + ... or 0 constant. G may contain interaction terms, such as group:items to include cross or person-level interactions effects

itemtype same as itemtype in mirt, except when the fixed or random inputs are used does not support the following item types: c('PC2PL', 'PC3PL', '2PLNRM', '3PLNRM', '3PLuNRM', '4PLNRM',

lr.fixed an R formula (or list of formulas) to specify regression effects in the latent variables from the variables in covdata. This is used to construct models such as the so-called 'latent regression model' to explain person-level ability/trait differences. If a named list of formulas is supplied (where the names correspond to the latent trait names in model) then specific regression effects can be estimated for each factor. Supplying a single formula will estimate the regression parameters for all latent traits by default.

lr.random a list of random effect terms for modeling variability in the latent trait scores, where the syntax uses the same style as in the random argument. Useful for building so-called 'multilevel IRT' models which are non-Rasch (multilevel Rasch models do not technically require these because they can be built using the fixed and random inputs alone)

itemdesign a data.frame object used to create a design matrix for the items, where each nrow(itemdesign) == nitems and the number of columns is equal to the number of fixed effect predictors (i.e., item intercepts). By default an items variable is reserved for modeling the item intercept parameters
mixedmirt

constrain a list indicating parameter equality constraints. See mirt for more detail
pars used for parameter starting values. See mirt for more detail
return.design logical; return the design matrices before they have (potentially) been reassigned?
SE logical; compute the standard errors by approximating the information matrix using the MHRM algorithm? Default is TRUE
internal_constraints logical; use the internally defined constraints for constraining effects across persons and items? Default is TRUE. Setting this to FALSE runs the risk of under-identification
technical the technical list passed to the MH-RM estimation engine, with the SEtol default increased to .0001. Additionally, the argument RANDSTART is available to indicate at which iteration (during the burn-in stage) the additional random effect variables should begin to be approximated (i.e., elements in lr.random and random). The default for RANDSTART is to start at iteration 100, and when random effects are included the default number of burn-in iterations is increased from 150 to 200. See mirt for further details
... additional arguments to be passed to the MH-RM estimation engine. See mirt for more details and examples

Details

For dichotomous response models, mixedmirt follows the general form

\[ P(x = 1|\theta, \psi) = g + \frac{(u - g)}{1 + exp(-1 * [\theta a + X \beta + Z \delta])} \]

where X is a design matrix with associated \( \beta \) fixed effect intercept coefficients, and Z is a design matrix with associated \( \delta \) random effects for the intercepts. For simplicity and easier interpretation, the unique item intercept values typically found in \( X \beta \) are extracted and reassigned within mirt’s ‘intercept’ parameters (e.g., ‘d’). To observe how the design matrices are structured prior to reassignment and estimation pass the argument return.design = TRUE.

Polytomous IRT models follow a similar format except the item intercepts are automatically estimated internally, rendering the items argument in the fixed formula redundant and therefore must be omitted from the specification. If there are a mixture of dichotomous and polytomous items the intercepts for the dichotomous models are also estimated for consistency.

The decomposition of the \( \theta \) parameters is also possible to form latent regression and multilevel IRT models by using the lr.fixed and lr.random inputs. These effects decompose \( \theta \) such that

\[ \theta = VT + W\zeta + \epsilon \]

where V and W are fixed and random effects design matrices for the associated coefficients.

To simulate maximum a posteriori estimates for the random effect terms use the randef function.

Value

function returns an object of class MixedClass (MixedClass-class).

mod2values: Convert an estimated mirt model to a data.frame

Description

Given an estimated model from any of mirt’s model fitting functions this function will convert the model parameters into the design data frame of starting values and other parameter characteristics (similar to using the pars = 'values' for obtaining starting values).

Usage

mod2values(x)

Arguments

x an estimated model x from the mirt package

Author(s)
Phil Chalmers <rphilip.chalmers@gmail.com>
multipleGroup

References

See Also

extract.mirt

Examples

```r
## Not run:
dat <- expand.table(LSAT7)
mod <- mirt(dat, 1)
values <- mod2values(mod)
values

#use the converted values as starting values in a new model, and reduce TOL
mod2 <- mirt(dat, 1, pars = values, TOL=1e-5)

## End(Not run)
```

**multipleGroup**

**Multiple Group Estimation**

Description

`multipleGroup` performs a full-information maximum-likelihood multiple group analysis for any combination of dichotomous and polytomous data under the item response theory paradigm using either Cai’s (2010) Metropolis-Hastings Robbins-Monro (MHRM) algorithm or with an EM algorithm approach. This function may be used for detecting differential item functioning (DIF), though the `DIF` function may provide a more convenient approach. If the grouping variable is not specified then the `dentine` input can be modified to fit mixture models to estimate any latent group components.

Usage

```r
multipleGroup(data, model, group, invariance = "", method = "EM", rotate = "oblimin", dentype = "Gaussian", ...)
```

Arguments

- **data**: a matrix or data.frame that consists of numerically ordered data, with missing data coded as NA
- **model**: string to be passed to, or a model object returned from, `mirt.model` declaring how the global model is to be estimated (useful to apply constraints here)
- **group**: a character or factor vector indicating group membership
**invariance**

a character vector containing the following possible options:

'free_means’ for freely estimating all latent means (reference group constrained to 0)

'free_var’ for freely estimating all latent variances (reference group constrained to 1’s)

'slopes’ to constrain all the slopes to be equal across all groups

'intercepts’ to constrain all the intercepts to be equal across all groups, note for nominal models this also includes the category specific slope parameters

Additionally, specifying specific item name bundles (from colnames(data)) will constrain all freely estimated parameters in each item to be equal across groups. This is useful for selecting 'anchor' items for vertical and horizontal scaling, and for detecting differential item functioning (DIF) across groups

**method**

a character object that is either 'EM', 'QMCEM', or 'MHRM' (default is 'EM'). See mirt for details

**rotate**

rotation if models are exploratory (see mirt for details)

**dентype**

type of density form to use for the latent trait parameters. Current options include all of the methods described in mirt, as well as

• 'mixture-#' estimates mixtures of Gaussian distributions, where the # placeholder represents the number of potential grouping variables (e.g., 'mixture-3' will estimate 3 underlying classes). Each class is assigned the group name MIXTURE_#, where # is the class number. Note that internally the mixture coefficients are stored as log values where the first mixture group coefficient is fixed at 0

... additional arguments to be passed to the estimation engine. See mirt for details and examples

**Details**

By default the estimation in multipleGroup assumes that the models are maximally independent, and therefore could initially be performed by sub-setting the data and running identical models with mirt and aggregating the results (e.g., log-likelihood). However, constrains may be automatically imposed across groups by invoking various invariance keywords. Users may also supply a list of parameter equality constraints to by constrain argument, of define equality constraints using the mirt.model syntax (recommended).

**Value**

function returns an object of class MultipleGroupClass (MultipleGroupClass-class).

### MultipleGroupClass-class

**Class** "MultipleGroupClass"

#### Description

Defines the object returned from `multipleGroup`.

#### Slots

- **Call**: function call
- **Data**: list of data, sometimes in different forms
- **Options**: list of estimation options
- **Fit**: a list of fit information
- **Model**: a list of model-based information
- **ParObjects**: a list of the S4 objects used during estimation
- **OptimInfo**: a list of arguments from the optimization process
- **Internals**: a list of internal arguments for secondary computations (inspecting this object is generally not required)
- **vcov**: a matrix represented the asymptotic covariance matrix of the parameter estimates
- **time**: a data.frame indicating the breakdown of computation times in seconds

#### Methods

- **`coef`** signature(object = "MultipleGroupClass")
- **`print`** signature(x = "MultipleGroupClass")
- **`show`** signature(object = "MultipleGroupClass")
- **`anova`** signature(object = "MultipleGroupClass")

numerical_deriv  Compute numerical derivatives

Description

Compute numerical derivatives using forward/backward difference, central difference, or Richardson extrapolation.

Usage

numerical_deriv(f, par, ..., delta = 1e-05, gradient = TRUE,
                   type = "Richardson")

Arguments

f  the objective function being evaluated
par a vector of parameters
... additional arguments to be passed to f
delta the term used to perturb the f function. Default is 1e-5
gradient logical; compute the gradient terms? If FALSE then the Hessian is computed instead
type type of difference to compute. Can be either 'forward' for the forward difference, 'central' for the central difference, or 'Richardson' for the Richardson extrapolation (default). Backward difference is achieved by supplying a negative delta value with 'forward'. When type = 'Richardson', the default value of delta is increased to delta * 1000 for the Hessian and delta * 10 for the gradient to provide a reasonable perturbation starting location (each delta is halved at each iteration).

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

Examples

## Not run:
f <- function(x) 3*x[1]^3 - 4*x[2]^2
par <- c(3,8)

# grad = 9 x*2 , -8 * y
(actual <- c(9 * par[1]^2, -8 * par[2]))
numerical_deriv(f, par, type = 'forward')
numerical_deriv(f, par, type = 'central')
numerical_deriv(f, par, type = 'Richardson') # default

# Hessian = h11 -> 18 * x, h22 -> -8, h12 -> h21 -> 0
personfit <- matrix(c(18 * par[1], 0, 0, -8), 2, 2)
numerical_deriv(f, par, type = 'forward', gradient = FALSE)
numerical_deriv(f, par, type = 'central', gradient = FALSE)
numerical_deriv(f, par, type = 'Richardson', gradient = FALSE) # default

## End(Not run)

personfit  Person fit statistics

Description

personfit calculates the Zh values from Drasgow, Levine and Williams (1985) for unidimensional and multidimensional models. For Rasch models infit and outfit statistics are also produced. The returned object is a data.frame consisting either of the tabulated data or full data with the statistics appended to the rightmost columns.

Usage

personfit(x, method = "EAP", Theta = NULL, stats.only = TRUE, ...)

Arguments

x  a computed model object of class SingleGroupClass or MultipleGroupClass
method type of factor score estimation method. See fscores for more detail
Theta a matrix of factor scores used for statistics that require empirical estimates. If supplied, arguments typically passed to fscores() will be ignored and these values will be used instead
stats.only logical; return only the person fit statistics without their associated response pattern?
... additional arguments to be passed to fscores()

head(pf)

## End(Not run)
```

PLCI.mirt

Compute profiled-likelihood (or posterior) confidence intervals

Description

Computes profiled-likelihood based confidence intervals. Supports the inclusion of equality constraints. Object returns the confidence intervals and whether the respective interval could be found.
Usage

PLCI.mirt(mod, parnum = NULL, alpha = 0.05, search_bound = TRUE,
step = 0.5, lower = TRUE, upper = TRUE, inf2val = 30,
NealeMiller = FALSE, ...)

Arguments

mod a converged mirt model
parnum a numeric vector indicating which parameters to estimate. Use mod2values to
determine parameter numbers. If NULL, all possible parameters are used
alpha two-tailed alpha critical level
search_bound logical; use a fixed grid of values around the ML estimate to determine more
suitable optimization bounds? Using this has much better behaviour than setting
fixed upper/lower bound values and searching from more extreme ends
step magnitude of steps used when search_bound is TRUE. Smaller values create
more points to search a suitable bound for (up to the lower bound value visible
with mod2values). When upper/lower bounds are detected this value will be
adjusted accordingly
lower logical; search for the lower CI?
upper logical; search for the upper CI?
inf2val a numeric used to change parameter bounds which are infinity to a finite number.
Decreasing this too much may not allow a suitable bound to be located. Default
is 30
NealeMiller logical; use the Neale and Miller 1997 approximation? Default is FALSE
... additional arguments to pass to the estimation functions

result3 <- PLCI.mirt(mod2, parnum)
result3

## End(Not run)
```

---

**plot-method**

*Plot various test-implied functions from models*

**Description**

Plot various test implied response functions from models estimated in the mirt package.

**Usage**

```r
## S4 method for signature 'SingleGroupClass,missing'
plot(x, y, type = "score",
npts = 200, degrees = 45, theta_lim = c(-6, 6),
which.items = 1:extract.mirt(x, "nitems"), MI = 0, CI = 0.95,
rot = list(xaxis = -70, yaxis = 30, zaxis = 10), facet_items = TRUE,
main = NULL, drape = TRUE, colorkey = TRUE, ehist.cut = 1e-10,
add.ylab2 = TRUE, par.strip.text = list(cex = 0.7),
par.settings = list(strip.background = list(col = "#9ECAE1"),
strip.border = list(col = "black"), auto.key = list(space = "right",
points = FALSE, lines = TRUE), profile = FALSE, ...)```
Arguments

- **x**: an object of class `SingleGroupClass`, `MultipleGroupClass`, or `DiscreteClass`
- **y**: an arbitrary missing argument required for R CMD check
- **type**: type of plot to view. Can be
  - `'info'` test information function
  - `'rxx'` for the reliability function
  - `'infocontour'` for the test information contours
  - `'SE'` for the test standard error function
  - `'infotrace'` item information traceline plots
  - `'infoSE'` a combined test information and standard error plot
  - `'trace'` item probability traceline plots
  - `'itemscore'` item scoring traceline plots
  - `'score'` expected total score surface
  - `'scorecontour'` expected total score contour plot

Note that if `dentype = ' empiricalhist'` was used in estimation then the type ` ' empiricalhist'` also will be available to generate the empirical histogram plot, and if `dentype = 'Davidian-#'` was used then the type ` 'Davidian'` will also be available to generate the curve estimates at the quadrature nodes used during estimation.

- **npts**: number of quadrature points to be used for plotting features. Larger values make plots look smoother
- **degrees**: numeric value ranging from 0 to 90 used in `plot` to compute angle for information-based plots with respect to the first dimension. If a vector is used then a bubble plot is created with the summed information across the angles specified (e.g., `degrees = seq(0, 90, by=10)`)
- **theta_lim**: lower and upper limits of the latent trait (theta) to be evaluated, and is used in conjunction with `npts`
- **which.items**: numeric vector indicating which items to be used when plotting. Default is to use all available items
- **MI**: a single number indicating how many imputations to draw to form bootstrapped confidence intervals for the selected test statistic. If greater than 0 a plot will be drawn with a shaded region for the interval
- **CI**: a number from 0 to 1 indicating the confidence interval to select when MI input is used. Default uses the 95% confidence (CI = .95)
- **rot**: allows rotation of the 3D graphics
- **facet_items**: logical; apply grid of plots across items? If FALSE, items will be placed in one plot for each group
- **main**: argument passed to lattice. Default generated automatically
- **drape**: logical argument passed to lattice. Default generated automatically
- **colorkey**: logical argument passed to lattice. Default generated automatically
ehist.cut: a probability value indicating a threshold for excluding cases in empirical histogram plots. Values larger than the default will include more points in the tails of the plot, potentially squishing the 'meat' of the plot to take up less area than visually desired.

add.ylab2: logical argument passed to lattice. Default generated automatically.

par.strip.text: plotting argument passed to lattice.

par.settings: plotting argument passed to lattice.

auto.key: plotting argument passed to lattice.

profile: logical; provide a profile plot of response probabilities (objects returned from mirt only).

... additional arguments to be passed to lattice.

plot(x2, type = 'itemscore', which.items = 1:2)
plot(x2, type = 'trace', which.items = 1, facet_items = FALSE) #facet by group
plot(x2, type = 'info')
```
poly2dich

Description
Transforms a matrix of items into a new matrix where the select polytomous items have been converted into comparable dichotomous items with the same information.

Usage
poly2dich(data, which.items = 1:ncol(data))

Arguments
data: an object of class data.frame or matrix
which.items: a vector indicating which items should be transformed into the dichotomous form. Default uses all input items

Value
Returns an integer matrix

Author(s)
Phil Chalmers <rphilip.chalmers@gmail.com>

References

Examples

head(newScience2)

## End(Not run)

---

**print-method**

*Print the model objects*

---

**Description**

Print model object summaries to the console.

**Usage**

```r
## S4 method for signature 'SingleGroupClass'
print(x)
```

**Arguments**

- `x`: an object of class SingleGroupClass, MultipleGroupClass, or MixedClass

**References**

**Examples**

```r
## Not run:
x <- mirt(Science, 1)
print(x)
## End(Not run)
```

---

**print.mirt_df**

*Print generic for customized data.frame console output*

---

**Description**

Provides a nicer output for most printed data.frame objects defined by functions in mirt.

**Usage**

```r
## S3 method for class 'mirt_df'
print(x, digits = 3, ...)
```
print.mirt_list

Arguments

- x: object of class 'mirt_df'
- digits: number of digits to round
- ...: additional arguments passed to print(...)

Description

Provides a nicer output for most printed list objects defined by functions in mirt.

Usage

```r
## S3 method for class 'mirt_list'
print(x, digits = 3, ...)
```

Arguments

- x: object of class 'mirt_list'
- digits: number of digits to round
- ...: additional arguments passed to print(...)

print.mirt_matrix

Print generic for customized matrix console output

Description

Provides a nicer output for most printed matrix objects defined by functions in mirt.

Usage

```r
## S3 method for class 'mirt_matrix'
print(x, digits = 3, ...)
```

Arguments

- x: object of class 'mirt_matrix'
- digits: number of digits to round
- ...: additional arguments passed to print(...)
probtrace

Function to calculate probability trace lines

Description

Given an internal mirt object extracted from an estimated model, or the single-group estimated model itself, compute the probability trace lines for all categories.

Usage

probtrace(x, Theta)

Arguments

x either an extracted internal mirt object containing item information (see extract.item) or a model of class SingleGroupClass typically returned by the function mirt or bfactor

Theta a vector (unidimensional) or matrix (unidimensional/multidimensional) of latent trait values

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

References

See Also

extract.item, extract.group

Examples

mod <- mirt(Science, 1)

# single item probability tracelines for Item 2
extr.2 <- extract.item(mod, 2)
Theta <- matrix(seq(-4, 4, by = .1))
traceline <- probtrace(extr.2, Theta)
head(data.frame(traceline, Theta=Theta))

# probability tracelines for all items in test
tracelines <- probtrace(mod, Theta)
head(tracelines)
**randef**

**Compute posterior estimates of random effect**

**Description**

Stochastically compute random effects for `MixedClass` objects with Metropolis-Hastings samplers and averaging over the draws. Returns a list of the estimated effects.

**Usage**

```r
randef(x, ndraws = 1000, thin = 10, return.draws = FALSE)
```

**Arguments**

- `x`: an estimated model object from the `mixedmirt` function
- `ndraws`: total number of draws to perform. Default is 1000
- `thin`: amount of thinning to apply. Default is to use every 10th draw
- `return.draws`: logical; return a list containing the thinned draws of the posterior?

**Author(s)**

Phil Chalmers `<rphilip.chalmers@gmail.com>`

**References**

**Examples**

```r
## Not run:
# make an arbitrary groups
covdat <- data.frame(group = rep(paste0('group', 1:49), each=nrow(Science)/49))

# partial credit model
mod <- mixedmirt(Science, covdat, model=1, random = ~ 1|group)
summary(mod)

effects <- randef(mod, ndraws = 2000, thin = 20)
head(effects$Theta)
head(effects$group)

## End(Not run)
```
residuals-method

Description

Return model implied residuals for linear dependencies between items or at the person level. If the latent trait density was approximated (e.g., Davian curves, Empirical histograms, etc) then passing use_dentype_estimate = TRUE will use the internally saved quadrature and density components (where applicable).

Usage

```r
## S4 method for signature 'SingleGroupClass'
residuals(object, type = "LD",
  df.p = FALSE, full.scores = FALSE, QMC = FALSE,
  printvalue = NULL, tables = FALSE, verbose = TRUE, Theta = NULL,
  suppress = 1, theta_lim = c(-6, 6), quadpts = NULL, fold = TRUE,
  ...)
```

Arguments

- **object**: an object of class SingleGroupClass or MultipleGroupClass. Bifactor models are automatically detected and utilized for better accuracy.
- **type**: type of residuals to be displayed. Can be either 'LD' or 'LDG2' for a local dependence matrix based on the X2 or G2 statistics (Chen & Thissen, 1997), 'Q3' for the statistic proposed by Yen (1984), 'JSI' for the jack-knife statistic proposed Edwards et al. (2018), 'exp' for the expected values for the frequencies of every response pattern, and 'expfull' for the expected values for every theoretically observable response pattern. For the 'LD' and 'LDG2' types, the upper diagonal elements represent the standardized residuals in the form of signed Cramers V coefficients.
- **df.p**: logical; print the degrees of freedom and p-values?
- **full.scores**: logical; compute relevant statistics for each subject in the original data?
- **QMC**: logical; use quasi-Monte Carlo integration? If quadpts is omitted the default number of nodes is 5000.
- **printvalue**: a numeric value to be specified when using the res='exp' option. Only prints patterns that have standardized residuals greater than abs(printvalue). The default (NULL) prints all response patterns.
- **tables**: logical; for LD type, return the observed, expected, and standardized residual tables for each item combination?
- **verbose**: logical; allow information to be printed to the console?
- **Theta**: a matrix of factor scores used for statistics that require empirical estimates (i.e., Q3). If supplied, arguments typically passed to fscores() will be ignored and these values will be used instead.
suppress a numeric value indicating which parameter local dependency combinations to flag as being too high. Absolute values for the standardized estimates greater than this value will be returned, while all values less than this value will be set to NA

theta_lim range for the integration grid

quadpts number of quadrature nodes to use. The default is extracted from model (if available) or generated automatically if not available

fold logical; apply the sum ‘folding’ described by Edwards et al. (2018) for the JSI statistic?

... additional arguments to be passed to fscores()

  data.frame(X2, df, p, row.names='Pearson-X2')
}```
\textbf{SAT12 Description of SAT12 data}

\textbf{Description}

Data obtained from the TESTFACT (Woods et al., 2003) manual, with 32 response pattern scored items for a grade 12 science assessment test (SAT) measuring topics of chemistry, biology, and physics. The scoring key for these data is \([1, 4, 5, 2, 3, 1, 2, 1, 3, 1, 2, 4, 2, 1, 5, 3, 4, 4, 1, 4, 3, 3, 4, 1, 3, 5, 1, 3, 1, 5, 4, 5] \), respectively. However, careful analysis using the nominal response model suggests that the scoring key for item 32 may be incorrect, and should be changed from 5 to 3.
Description

A 4-item data set borrowed from ltm package in R, first example of the grm() function. See more complete documentation therein.

x <- mirt(Science, 1)
show(x)

## End(Not run)
```
Simultaneous Item Bias Test (SIBTEST)

Description

Classical test theory approach to detecting unidirectional and bidirectional (with one crossing location) DIF. This family of statistics is intended for unidimensional tests, and applies a regression-corrected matched-total score approach to quantify the response bias between two groups. Can be used for DIF, DBF, and DTF testing.

Usage

SIBTEST(dat, group, suspect_set, match_set, focal_name = unique(group)[2], guess_correction = 0, Jmin = 5, na.rm = FALSE, LiStout1996 = FALSE, permute = 1000, pk_focal = FALSE, correction = TRUE, details = FALSE, plot = "none", ...)

Arguments

dat integer-based dataset to be tested, containing dichotomous or polytomous responses

group a vector indicating group membership with the same length as the number of rows in dat

suspect_set an integer vector indicating which items to inspect with SIBTEST. Including only one value will perform a DIF test, while including more than one will perform a simultaneous bundle test (DBF); including all non-matched items will perform DTF. If missing, a simultaneous test using all the items not listed in match_set will be used (i.e., DTF)

match_set an integer vector indicating which items to use as the items which are matched (i.e., contain no DIF). These are analogous to 'anchor' items in the likelihood method to locate DIF. If missing, all items other than the items found in the suspect_set will be used

focal_name name of the focal group; e.g., 'focal'. If not specified then one will be selected automatically using unique(group)[2]

guess_correction a vector of numbers from 0 to 1 indicating how much to correct the items for guessing. It's length should be the same as ncol(dat)

Jmin the minimum number of observations required when splitting the data into focal and reference groups conditioned on the matched set

na.rm logical; remove rows in dat with any missing values? If TRUE, rows with missing data will be removed, as well as the corresponding elements in the group input

LiStout1996 logical; perform the crossing test for non-compensatory bias using Li and Stout’s (1996) permutation approach? Default is FALSE, which uses the Chalmers (2018) mixed degrees of freedom method
permute number of permutations to perform when LiStout1996 = TRUE. Default is 1000
pk_focal logical; using the group weights from the focal group instead of the total sample? Default is FALSE as per Shealy and Stout’s recommendation
correction logical; apply the composite correction for the difference between focal composite scores using the true-score regression technique? Default is TRUE, reflecting Shealy and Stout’s linear extrapolation method
details logical; return a data.frame containing the details required to compute SIBTEST?
plot a character input indicating the type of plot to construct. Options are 'none' (default), 'observed' for the scaled focal subtest scores against the matched subtest scores, 'weights' for the proportion weights used (i.e., the proportion of observations at each matched score), 'difference' for the difference between the scaled focal subtest scores against the matched subtest scores, and 'wdifference' for the conditional differences multiplied by each respective weight. Note that the last plot reflects the components used in SIBTEST, and therefore the sum of these plotted observations will equal the beta coefficient for SIBTEST
... additional plotting arguments to be passed

Details

SIBTEST is similar to the Mantel-Haenszel approach for detecting DIF but uses a regression correction based on the KR-20/coefficient alpha reliability index to correct the observed differences when the latent trait distributions are not equal. Function supports the standard SIBTEST for dichotomous and polytomous data (compensatory) and supports crossing DIF testing (i.e., non-compensatory/non-uniform) using the asymptotic sampling distribution version of the Crossing-SIBTEST (CSIBTEST) statistic described by Chalmers (2018) and the permutation method described by Li and Stout (1996). For convenience, the beta coefficient for CSIBTEST is always reported as an absolute value.

simdata

Simulate response patterns

Description

Simulates response patterns for compensatory and noncompensatory MIRT models from multivariate normally distributed factor ($\theta$) scores, or from a user input matrix of $\theta$'s.

Usage

simdata(a, d, N, itemtype, sigma = NULL, mu = NULL, guess = 0,
upper = 1, nominal = NULL, t = NULL, Theta = NULL,
gpcm_mats = list(), returnList = FALSE, model = NULL,
equal.K = TRUE, which.items = NULL, mins = 0, lca_cats = NULL,
prob.list = NULL)
Arguments

**a**  
a matrix/vector of slope parameters. If slopes are to be constrained to zero then use NA or simply set them equal to 0

**d**  
a matrix/vector of intercepts. The matrix should have as many columns as the item with the largest number of categories, and filled empty locations with NA. When a vector is used the test is assumed to consist only of dichotomous items (because only one intercept per item is provided). When itemtype = 'lca' intercepts will not be used

**N**  
sample size

**itemtype**  
a character vector of length nrow(a) (or 1, if all the item types are the same) specifying the type of items to simulate. Inputs can either be the same as the inputs found in the itemtype argument in mirt or the internal classes defined by the package. Typical itemtype inputs that are passed to mirt are used then these will be converted into the respective internal classes automatically.

If the internal class of the object is specified instead, the inputs can be 'dich', 'graded', 'gpcm', 'sequential', nominal, nested logit, partially compensatory, generalized graded unfolding model, and latent class analysis model. Note that for the gpcm, nominal, and nested logit models there should be as many parameters as desired categories, however to parametrized them for meaningful interpretation the first category intercept should equal 0 for these models (second column for 'nestlogit', since first column is for the correct item traceline). For nested logit models the 'correct' category is always the lowest category (i.e., == 1). It may be helpful to use mod2values on data-sets that have already been estimated to understand the itemtypes more intimately

**sigma**  
a covariance matrix of the underlying distribution. Default is the identity matrix. Used when Theta is not supplied

**mu**  
a mean vector of the underlying distribution. Default is a vector of zeros. Used when Theta is not supplied

**guess**  
a vector of guessing parameters for each item; only applicable for dichotomous items. Must be either a scalar value that will affect all of the dichotomous items, or a vector with as many values as to be simulated items

**upper**  
same as guess, but for upper bound parameters

**nominal**  
a matrix of specific item category slopes for nominal models. Should be the dimensions as the intercept specification with one less column, with NA in locations where not applicable. Note that during estimation the first slope will be constrained to 0 and the last will be constrained to the number of categories minus 1, so it is best to set these as the values for the first and last categories as well

**t**  
matrix of t-values for the 'ggum' itemtype, where each row corresponds to a given item. Also determines the number of categories, where NA can be used for non-applicable categories

**Theta**  
a user specified matrix of the underlying ability parameters, where nrow(Theta) == N and ncol(Theta) == ncol(a). When this is supplied the N input is not required
gpcm_mats   a list of matrices specifying the scoring scheme for generalized partial credit models (see mirt for details)
returnList  logical; return a list containing the data, item objects defined by mirt containing the population parameters and item structure, and the latent trait matrix Theta? Default is FALSE
model      a single group object, typically returned by functions such as mirt or bfactor. Supplying this will render all other parameter elements (excluding theTheta, N, mu, and sigma inputs) redundant (unless explicitly provided)
equal.K    logical; when a model input is supplied, should the generated data contain the same number of categories as the original data indicated by extract.mirt(model, 'K')? Default is TRUE, which will redraw data until this condition is satisfied
which.items an integer vector used to indicate which items to simulate when a model input is included. Default simulates all items
mins       an integer vector (or single value to be used for each item) indicating what the lowest category should be. If model is supplied then this will be extracted from slot(mod, 'Data')$mins, otherwise the default is 0
lca_cats   a vector indicating how many categories each lca item should have. If not supplied then it is assumed that 2 categories should be generated for each item
prob.list  an optional list containing matrix/data.frames of probabilities values for each category to be simulated. This is useful when creating customized probability functions to be sampled from

Details

Returns a data matrix simulated from the parameters, or a list containing the data, item objects, and Theta matrix.

**SingleGroupClass-class**

*Class* "SingleGroupClass"

**Description**

Defines the object returned from *mirt* when model is exploratory.

**Slots**

*Call*: function call

*Data*: list of data, sometimes in different forms

*Options*: list of estimation options

*Fit*: a list of fit information

*Model*: a list of model-based information

*ParObjects*: a list of the S4 objects used during estimation

*OptimInfo*: a list of arguments from the optimization process

*Internals*: a list of internal arguments for secondary computations (inspecting this object is generally not required)

*vcov*: a matrix represented the asymptotic covariance matrix of the parameter estimates

*time*: a data.frame indicating the breakdown of computation times in seconds
### Methods

- **anova** signature(object = "SingleGroupClass")
- **coef** signature(object = "SingleGroupClass")
- **plot** signature(x = "SingleGroupClass", y = "missing")
- **print** signature(x = "SingleGroupClass")
- **residuals** signature(object = "SingleGroupClass")
- **show** signature(object = "SingleGroupClass")
- **summary** signature(object = "SingleGroupClass")

### Author(s)

### References

---

**summary-method**

**Summary of model object**

### Description

Transforms coefficients into a standardized factor loading's metric. For MixedClass objects, the fixed and random coefficients are printed. Note that while the output to the console is rounded to three digits, the returned list of objects is not. For simulations, use `output <- summary(mod, verbose = FALSE)` to suppress the console messages.

### Usage

```r
## S4 method for signature 'SingleGroupClass'
summary(object, rotate = "oblimin",
    Target = NULL, suppress = 0, verbose = TRUE, ...)
```

### Arguments

- **object** an object of class SingleGroupClass, MultipleGroupClass, or MixedClass
- **rotate** a string indicating which rotation to use for exploratory models, primarily from the GPArotation package (see documentation therein).
  Rotations currently supported are: 'promax', 'oblimin', 'varimax', 'quartimin', 'targetT', 'targetQ', 'pstT', 'pstQ', 'oblimax', 'entropy', 'quartimax', 'simplimax', 'bentlerT', 'bentlerQ', 'tandemI', 'tandemII', 'geominT', 'geominQ', 'cft', 'cfQ', 'infomaxT', 'infomaxQ', 'mccammon', 'bifactorT', 'bifactorQ'.
  For models that are not exploratory this input will automatically be set to 'none'

---
Target  
a dummy variable matrix indicating a target rotation pattern. This is required for rotations such as 'targetT', 'targetQ', 'pstT', and 'pstQ'
suppress  
a numeric value indicating which (possibly rotated) factor loadings should be suppressed. Typical values are around .3 in most statistical software. Default is 0 for no suppression
verbose  
logical; allow information to be printed to the console?

Examples

## Not run:
x <- mirt(Science, 2)
summary(x)
summary(x, rotate = 'varimax')

## End(Not run)

testinfo  
Function to calculate test information

Description

Given an estimated model compute the test information.

Usage

testinfo(x, Theta, degrees = NULL, group = NULL, individual = FALSE,
        which.items = 1:extract.mirt(x, "nitems"))

Arguments

x  
an object of class 'SingleGroupClass', or an object of class 'MultipleGroupClass' if a suitable group input were supplied
Theta  
a matrix of latent trait values
degrees  
a vector of angles in degrees that are between 0 and 90. Only applicable when the input object is multidimensional
thetaComb

Create all possible combinations of vector input

Description

This function constructs all possible k-way combinations of an input vector. It is primarily useful when used in conjunction with the mirt function, though users may have other uses for it as well. See expand.grid for more flexible combination formats.
Usage

thetaComb(theta, nfact, intercept = FALSE)

Arguments

theta    the vector from which all possible combinations should be obtained
nfact    the number of observations (and therefore the number of columns to return in
         the matrix of combinations)
intercept logical; should a vector of 1’s be appended to the first column of the result to
         include an intercept design component? Default is FALSE

Value

a matrix with all possible combinations

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

References

Examples

# all possible joint combinations for the vector -4 to 4
thetaComb(-4:4, 2)

# all possible binary combinations for four observations
thetaComb(c(0,1), 4)

# all possible binary combinations for four observations (with intercept)
thetaComb(c(0,1), 4, intercept=TRUE)

traditional2mirt  Convert traditional IRT metric into slope-intercept form used in mirt

Description

This is a helper function for users who have previously available traditional/classical IRT parameters and want to know the equivalent slope-intercept translation used in mirt. Note that this function assumes that the supplied models are unidimensional by definition (i.e., will have only one slope/discrimination). If there is no supported slope-intercept transformation available then the original vector of parameters will be returned by default.
Usage

```r
traditional2mirt(x, cls, ncat)
```

Arguments

- `x`: a vector of parameters to transform
- `cls`: the class or itemtype of the supplied model
- `ncat`: the number of categories implied by the IRT model

Details

Supported class transformations for the `cls` input are:

- **Rasch, 2PL, 3PL, 3PLu, 4PL**: Form must be: (discrimination, difficulty, lower-bound, upper-bound)
- **graded**: Form must be: (discrimination, difficulty 1, difficulty 2, ..., difficulty k-1)
- **gpcm**: Form must be: (discrimination, difficulty 1, difficulty 2, ..., difficulty k-1)
- **nominal**: Form must be: (discrimination 1, discrimination 2, ..., discrimination k, difficulty 1, difficulty 2, ..., difficulty k)

Value

- A named vector of slope-intercept parameters (if supported)

Examples

```r
# classical 3PL model
vec <- c(a=1.5, b=-1, g=.1, u=1)
slopeint <- traditional2mirt(vec, "3PL", ncat=2)
slopeint

# classical graded model (four category)
vec <- c(a=1.5, b1=-1, b2=0, b3=1.5)
slopeint <- traditional2mirt(vec, "graded", ncat=4)
slopeint

# classical generalize partial credit model (four category)
vec <- c(a=1.5, b1=-1, b2=0, b3=1.5)
slopeint <- traditional2mirt(vec, "gpcm", ncat=4)
slopeint

# classical nominal model (4 category)
vec <- c(a1=.5, a2 = -1, a3=1, a4=-.5, d1=1, d2=-1, d3=-.5, d4=.5)
slopeint <- traditional2mirt(vec, "nominal", ncat=4)
slopeint
```
vcov-method

Extract parameter variance covariance matrix

Description

Extract parameter variance covariance matrix

Usage

## S4 method for signature 'SingleGroupClass'
v cov(object)

Arguments

object an object of class SingleGroupClass, MultipleGroupClass, or MixedClass

References

Examples

## Not run:
x <- mirt(Science, 1, SE=TRUE)
v cov(x)

## End(Not run)

wald

Wald statistics for mirt models

Description

Compute a Wald test given an L vector or matrix of numeric contrasts. Requires that the model information matrix be computed (including SE = TRUE when using the EM method). Use wald(model) to observe how the information matrix columns are named, especially if the estimated model contains constrained parameters (e.g., 1PL).

Usage

wald(object, L, C = 0)
Arguments

object estimated object from mirt, bfactor, multipleGroup, mixedmirt, or mdirt
L a coefficient matrix with dimensions nconstrasts x npars. Omitting this value will return the column names of the information matrix used to identify the (potentially constrained) parameters
C a constant vector of population parameters to be compared along side L, where length(C) == ncol(L). By default a vector of 0’s is constructed

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>
