Package ‘mlogit’

October 13, 2022

Version 1.1-1
Date 2020-10-01
Title Multinomial Logit Models
Depends R (>= 2.10), dfidx
Imports Formula, zoo, lmtest, statmod, MASS, Rdpack
Suggests knitr, car, nnet, lattice, AER, ggplot2, texreg, rmarkdown

VignetteBuilder knitr
Encoding UTF-8
License GPL (>= 2)

URL https://cran.r-project.org/package=mlogit,
    https://r-forge.r-project.org/projects/mlogit/

RoxygenNote 7.1.1
RdMacros Rdpack
NeedsCompilation no
Author Yves Croissant [aut, cre]

mlogit-package

mlogit package: estimation of random utility discrete choice models by maximum likelihood

Description

mlogit provides a model description interface (enhanced formula-data), a very versatile estimation function and a testing infrastructure to deal with random utility models.

Details

For a gentle and comprehensive introduction to the package, see the package’s vignettes.

Car 3

Stated Preferences for Car Choice

Description

a sample of 4654 individuals

Format

A dataframe containing:

- choice: choice of a vehicle among 6 propositions,
- college: college education?,
- hsg2: size of household greater than 2?
- coml5: commute lower than 5 miles a day?,
- typez: body type, one of regcar (regular car), sportuv (sport utility vehicle), sportcar, stwagon (station wagon), truck, van, for each proposition z from 1 to 6,
- fuelz: fuel for proposition z, one of gasoline, methanol, cng (compressed natural gas), electric,
- pricez: price of vehicle divided by the logarithme of income,
- rangez: hundreds of miles vehicle can travel between refuelings/recharging,
- accz: acceleration, tens of seconds required to reach 30 mph from stop,
- speedz: highest attainable speed in hundreds of mph,
- pollutionz: tailpipe emissions as fraction of those for new gas vehicle,
- sizez: 0 for a mini, 1 for a subcompact, 2 for a compact and 3 for a mid–size or large vehicle,
- spacez: fraction of luggage space in comparable new gas vehicle,
- costz: cost per mile of travel (tens of cents) : home recharging for electric vehicle, station refueling otherwise,
- stationz: fraction of stations that can refuel/recharge vehicle.

Catsup

Choice of Brand for Catsup

Description

A sample of 2798 individuals

Format

A dataframe containing:

- id: individuals identifiers,
- choice: one of heinz41, heinz32, heinz28, hunts32,
- disp.z: is there a display for brand z?
- feat.z: is there a newspaper feature advertisement for brand z?
- price.z: price of brand z.

cor.mlogit

Correlation structure of the random parameters

Description

Functions that extract the correlation structure of a mlogit object

Usage

cor.mlogit(x)
cov.mlogit(x)

Arguments

- x: an mlogit object with random parameters and correlation = TRUE.

Details

These functions are deprecated; use vcov instead.
Value

A numerical matrix which returns either the correlation or the covariance matrix of the random parameters.

Cracker  
Choice of Brand for Crakers

Description

a sample of 3292 individuals cross-section

Format

A dataframe containing:

- id: individuals identifiers,
- choice: one of sunshine, keebler, nabisco, private,
- disp.z: is there a display for brand z?
- feat.z: is there a newspaper feature advertisement for brand z?
- price.z: price of brand z.

distribution

Functions used to describe the characteristics of estimated random parameters

Description

Functions used to describe the characteristics of estimated random parameters

Usage

\[\text{stdev}(x, \ldots)\]

\[\text{rg}(x, \ldots)\]

\[\text{med}(x, \ldots)\]

\[\text{mean}(x, \text{norm} = \texttt{NULL}, \ldots)\]

\[\text{med}(x, \text{norm} = \texttt{NULL}, \ldots)\]

\[\text{stddev}(x, \text{norm} = \texttt{NULL}, \ldots)\]

\[\text{rg}(x, \text{norm} = \texttt{NULL}, \ldots)\]

\[\text{mean}(x, \text{par} = \texttt{NULL}, \text{norm} = \texttt{NULL}, \ldots)\]

\[\text{med}(x, \text{par} = \texttt{NULL}, \text{norm} = \texttt{NULL}, \ldots)\]

\[\text{stdev}(x, \text{par} = \texttt{NULL}, \text{norm} = \texttt{NULL}, \ldots)\]

\[\text{rg}(x, \text{par} = \texttt{NULL}, \text{norm} = \texttt{NULL}, \ldots)\]

\[\text{qrpar}(x, \ldots)\]

\[\text{prpar}(x, \ldots)\]

\[\text{drpar}(x, \ldots)\]
qrpar(x, norm = NULL, ...)

## S3 method for class 'rpar'
prpar(x, norm = NULL, ...)

## S3 method for class 'rpar'
drpar(x, norm = NULL, ...)

## S3 method for class 'mlogit'
qrpar(x, par = 1, y = NULL, norm = NULL, ...)

## S3 method for class 'mlogit'
prpar(x, par = 1, y = NULL, norm = NULL, ...)

## S3 method for class 'mlogit'
drpar(x, par = 1, y = NULL, norm = NULL, ...)

Arguments

- **x**: a `mlogit` or a `rpar` object,
- **...**: further arguments.
- **norm**: the variable used for normalization if any : for the `mlogit` method, this should be the name of the parameter, for the `rpar` method the absolute value of the parameter,
- **par**: the required parameter(s) for the `mlogit` methods (either the name or the position of the parameter(s). If `NULL`, all the random parameters are used.
- **y**: values for which the function has to be evaluated,

Details

`rpar` objects contain all the relevant information about the distribution of random parameters. These functions enables to obtain easily descriptive statistics, density, probability and quantiles of the distribution.

`mean`, `med`, `stdev` and `rg` compute respectively the mean, the median, the standard deviation and the range of the random parameter. `qrpar`, `prpar`, `drpar` return functions that compute the quantiles, the probability and the density of the random parameters (note that `sd` and `range` are not generic function in R and that `median` is, but without `...`).

Value

- a numeric vector for `qrpar`, `drpar` and `prpar`, a numeric vector for `mean`, `stdev` and `med` and a numeric matrix for `rg`.

effects.mlogit  Marginal effects of the covariates

Description

The effects method for mlogit objects computes the marginal effects of the selected covariate on the probabilities of choosing the alternatives.

Usage

## S3 method for class 'mlogit'
effects(
  object,  
  covariate = NULL,  
  type = c("aa", "ar", "rr", "ra"),  
  data = NULL,  
  ...  
)

Arguments

- **object**: a mlogit object,
- **covariate**: the name of the covariate for which the effect should be computed,
- **type**: the effect is a ratio of two marginal variations of the probability and of the covariate; these variations can be absolute "a" or relative "r". This argument is a string that contains two letters, the first refers to the probability, the second to the covariate,
- **data**: a data.frame containing the values for which the effects should be calculated. The number of lines of this data.frame should be equal to the number of alternatives,
- **...**: further arguments.

Value

If the covariate is alternative specific, a $J \times J$ matrix is returned, $J$ being the number of alternatives. Each line contains the marginal effects of the covariate of one alternative on the probability to choose any alternative. If the covariate is individual specific, a vector of length $J$ is returned.

**Electricity**

*Stated preference data for the choice of electricity suppliers*

Description

A sample of 2308 households in the United States

Format

A dataframe containing:

- choice: the choice of the individual, one of 1, 2, 3, 4,
- id: the individual index,
- pfi: fixed price at a stated cents per kWh, with the price varying over suppliers and experiments, for scenario i=(1, 2, 3, 4),
- cli: the length of contract that the supplier offered, in years (such as 1 year or 5 years.) During this contract period, the supplier guaranteed the prices and the buyer would have to pay a penalty if he/she switched to another supplier. The supplier could offer no contract in which case either side could stop the agreement at any time. This is recorded as a contract length of 0,
- loci: is the supplier a local company,
- wki: is the supplier a well-known company,
- todi: a time-of-day rate under which the price is 11 cents per kWh from 8am to 8pm and 5 cents per kWh from 8pm to 8am. These TOD prices did not vary over suppliers or experiments: whenever the supplier was said to offer TOD, the prices were stated as above.
• seas: a seasonal rate under which the price is 10 cents per kWh in the summer, 8 cents per kWh in the winter, and 6 cents per kWh in the spring and fall. Like TOD rates, these prices did not vary. Note that the price is for the electricity only, not transmission and distribution, which is supplied by the local regulated utility.

**Fishing**

**Choice of Fishing Mode**

**Description**

A sample of 1182 individuals in the United-States for the choice of 4 alternative fishing modes.

**Format**

A dataframe containing:

- mode: recreation mode choice, one of: beach, pier, boat and charter,
- price.beach: price for beach mode,
- price.pier: price for pier mode,
- price.boat: price for private boat mode,
- price.charter: price for charter boat mode,
- catch.beach: catch rate for beach mode,
- catch.pier: catch rate for pier mode,
- catch.boat: catch rate for private boat mode,
- catch.charter: catch rate for charter boat mode,
- income: monthly income,

Game

Ranked data for gaming platforms

Description

A sample of 91 Dutch individuals

Format

A dataframe containing:

- ch.Platform: where platform is one of Xbox, PlayStation, PSPortable, GameCube, GameBoy and PC. This variable contains the ranking of the platforms from 1 to 6,
- own.Platform: these 6 variables are dummies which indicate whether the given platform is already owned by the respondent,
- age: the age of the respondent,
- hours: hours per week spent on gaming.

Details

The data are also provided in long format (use in this case data(Game2). In this case, the alternative and the choice situation are respectively indicated in the platform and chid variables.

has.intercept

Indicates whether the formula contains an intercept

Description

This is a generic which provide convenient methods for formula/Formula object and for specific fitted models

Usage

has.intercept(object, ...)

## Default S3 method:
has.intercept(object, ...)

## S3 method for class 'formula'
has.intercept(object, ...)

## S3 method for class 'Formula'
has.intercept(object, rhs = NULL, ...)

## S3 method for class 'mlogit'
has.intercept(object, ...)

Arguments

object the object
...
... further arguments
rhs for the Formula method the rhs for which one wants to know if there is an intercept may be specified

hmftest  

Hausman-McFadden Test

Description

Test the IIA hypothesis (independence of irrelevant alternatives) for a multinomial logit model.

Usage

hmftest(x, ...)

## S3 method for class 'formula'
hmftest(x, alt.subset, ...)

## S3 method for class 'mlogit'
hmftest(x, z, ...)

Arguments

x
an object of class mlogit or a formula.

... further arguments passed to mlogit for the formula method.

alt.subset a subset of alternatives,

z an object of class mlogit or a subset of alternatives for the mlogit method. This should be the same model as x estimated on a subset of alternatives.

Details

This is an implementation of the Hausman’s consistency test for multinomial logit models. If the independence of irrelevant alternatives applies, the probability ratio of every two alternatives depends only on the characteristics of these alternatives. Consequently, the results obtained on the estimation with all the alternatives or only on a subset of them are consistent, but more efficient in the first case. On the contrary, only the results obtained from the estimation on a relevant subset are consistent. To compute this test, one needs a model estimated with all the alternatives and one model estimated on a subset of alternatives. This can be done by providing two objects of class mlogit, one object of class mlogit and a character vector indicating the subset of alternatives, or a formula and a subset of alternatives.

Value

an object of class "htest".

logsum

Compute the log-sum or inclusive value/utility

Description
The logsum function computes the inclusive value, or inclusive utility, which is used to compute the surplus and to estimate the two steps nested logit model.

Usage
logsum(
  coef,
  X = NULL,
  formula = NULL,
  data = NULL,
  type = NULL,
  output = c(“chid”, “obs”)
)
Arguments

- `coef`: a numerical vector or a `mlogit` object, from which the `coef` vector is extracted,
- `X`: a matrix or a `mlogit` object from which the `model.matrix` is extracted,
- `formula`: a formula or a `mlogit` object from which the `formula` is extracted,
- `data`: a `data.frame` or a `mlogit` object from which the `model.frame` is extracted,
- `type`: either "group" or "global": if a group argument has been provided in the `mlogit.data`, the inclusive values are by default computed for every group, otherwise, a unique global inclusive value is computed for each choice situation,
- `output`: the shape of the results: if "chid", the results is a vector (if type = "global") or a matrix (if type = "region") with row number equal to the number of choice situation, if "obs" a vector of length equal to the number of lines of the data in long format is returned.

Details

The inclusive value, or inclusive utility, or log-sum is the log of the denominator of the probabilities of the multinomial logit model. If a "group" variable is provided in the "mlogit.data" function, the denominator can either be the one of the multinomial model or those of the lower model of the nested logit model.

If only one argument (`coef`) is provided, it should a `mlogit` object and in this case, the coefficients and the `model.matrix` are extracted from this model.

In order to provide a different `model.matrix`, further arguments could be used. `X` is a matrix or a `mlogit` from which the `model.matrix` is extracted. The `formula-data` interface can also be used to construct the relevant `model.matrix`.

Value

either a vector or a matrix.

### Arguments

- **outcome**: a boolean which indicates, for the fitted and the residuals methods whether a matrix (for each choice, one value for each alternative) or a vector (for each choice, only a value for the alternative chosen) should be returned,
- **...**: further arguments.
- **x, object**: an object of class mlogit
- **new**: an updated formula for the update method,
- **digits**: the number of digits,
- **width**: the width of the printing,
- **type**: one of outcome (probability of the chosen alternative), probabilities (probabilities for all the alternatives), parameters for individual-level random parameters for the fitted method, how the correlated random parameters should be displayed: "chol" for the estimated parameters (the elements of the Cholesky decomposition matrix), "cov" for the covariance matrix and "cor" for the correlation matrix and the standard deviations,
- **n, m**: see dfidx::idx()
- **newdata**: a data.frame for the predict method,
- **returnData**: for the predict method, if TRUE, the data is returned as an attribute,
- **subset**: an optional vector of coefficients to extract for the coef method,
- **fixed**: if FALSE (the default), constant coefficients are not returned,
mlogit

Multinomial logit model

Description

Estimation by maximum likelihood of the multinomial logit model, with alternative-specific and/or individual specific variables.

Usage

mlogit(
  formula,
  data,
  subset,
  weights,
  na.action,
  start = NULL,
  alt.subset = NULL,
  reflevel = NULL,
  nests = NULL,
  un.nest.el = FALSE,
  unscaled = FALSE,
  heterosc = FALSE,
  rpar = NULL,
  probit = FALSE,
  R = 40,
  correlation = FALSE,
  halton = NULL,
  random.nb = NULL,
  panel = FALSE,
  estimate = TRUE,
  seed = 10,
  ...
)

Arguments

formula a symbolic description of the model to be estimated,
data the data: an mlogit.data object or an ordinary data.frame,
subset an optional vector specifying a subset of observations for mlogit,
weights an optional vector of weights,
na.action a function which indicates what should happen when the data contains NAs,
start a vector of starting values,
alt.subset a vector of character strings containing the subset of alternative on which the model should be estimated,
The base alternative (the one for which the coefficients of individual-specific variables are normalized to 0),

- **nests**: a named list of characters vectors, each names being a nest, the corresponding vector being the set of alternatives that belong to this nest,

- **un.nest.el**: a boolean, if TRUE, the hypothesis of unique elasticity is imposed for nested logit models,

- **unscaled**: a boolean, if TRUE, the unscaled version of the nested logit model is estimated,

- **heterosc**: a boolean, if TRUE, the heteroscedastic logit model is estimated,

- **rpar**: a named vector whose names are the random parameters and values the distribution: 'n' for normal, 'l' for log-normal, 't' for truncated normal, 'u' for uniform,

- **probit**: if TRUE, a multinomial porbit model is estimated,

- **R**: the number of function evaluation for the gaussian quadrature method used if heterosc = TRUE, the number of draws of pseudo-random numbers if rpar is not NULL,

- **correlation**: only relevant if rpar is not NULL, if true, the correlation between random parameters is taken into account,

- **halton**: only relevant if rpar is not NULL, if not NULL, halton sequence is used instead of pseudo-random numbers. If halton = NA, some default values are used for the prime of the sequence (actually, the primes are used in order) and for the number of elements dropped. Otherwise, halton should be a list with elements prime (the primes used) and drop (the number of elements dropped).

- **random.nb**: only relevant if rpar is not NULL, a user-supplied matrix of random,

- **panel**: only relevant if rpar is not NULL and if the data are repeated observations of the same unit; if TRUE, the mixed-logit model is estimated using panel techniques,

- **estimate**: a boolean indicating whether the model should be estimated or not: if not, the model.frame is returned,

- **seed**: the seed to use for random numbers (for mixed logit and probit models),

- **...**: further arguments passed to mlogit.data or mlogit.optim.

Details

For how to use the formula argument, see Formula().

The data argument may be an ordinary data.frame. In this case, some supplementary arguments should be provided and are passed to mlogit.data(). Note that it is not necessary to indicate the choice argument as it is deduced from the formula.

The model is estimated using the mlogit.optim() function.

The basic multinomial logit model and three important extensions of this model may be estimated. If heterosc=TRUE, the heteroscedastic logit model is estimated. J - 1 extra coefficients are estimated that represent the scale parameter for J - 1 alternatives, the scale parameter for the reference alternative being normalized to 1. The probabilities don’t have a closed form, they are estimated using a gaussian quadrature method.

If nests is not NULL, the nested logit model is estimated.
If `rpar` is not `NULL`, the random parameter model is estimated. The probabilities are approximated using simulations with `R` draws and halton sequences are used if `halton` is not `NULL`. Pseudo-random numbers are drawn from a standard normal and the relevant transformations are performed to obtain numbers drawn from a normal, log-normal, censored-normal or uniform distribution. If `correlation = TRUE`, the correlation between the random parameters are taken into account by estimating the components of the cholesky decomposition of the covariance matrix. With `G` random parameters, without correlation `G` standard deviations are estimated, with correlation `G * (G + 1) /2` coefficients are estimated.

**Value**

An object of class "mlogit", a list with elements:

- `coefficients`: the named vector of coefficients,
- `logLik`: the value of the log-likelihood,
- `hessian`: the hessian of the log-likelihood at convergence,
- `gradient`: the gradient of the log-likelihood at convergence,
- `call`: the matched call,
- `est.stat`: some information about the estimation (time used, optimisation method),
- `freq`: the frequency of choice,
- `residuals`: the residuals,
- `fitted.values`: the fitted values,
- `formula`: the formula (a Formula object),
- `expanded.formula`: the formula (a formula object),
- `model`: the model frame used,
- `index`: the index of the choice and of the alternatives.

`mlogit.data()` to shape the data. `nnet::multinom()` from package `nnet` performs the estimation of the multinomial logit model with individual specific variables. `mlogit.optim()` details about the optimization function.
Examples

```r
## Cameron and Trivedi's Microeconometrics p.493 There are two
## alternative specific variables : price and catch one individual
## specific variable (income) and four fishing mode : beach, pier, boat,
## charter

data("Fishing", package = "mlogit")
Fish <- dfidx(Fishing, varying = 2:9, shape = "wide", choice = "mode")

## a pure "conditional" model
summary(mlogit(mode ~ price + catch, data = Fish))

## a pure "multinomial model"
summary(mlogit(mode ~ 0 | income, data = Fish))

## which can also be estimated using multinom (package nnet)
summary(nnet::multinom(mode ~ income, data = Fishing))

## a "mixed" model
m <- mlogit(mode ~ price + catch | income, data = Fish)
summary(m)

## same model with charter as the reference level
m <- mlogit(mode ~ price + catch | income, data = Fish, reflevel = "charter")

## same model with a subset of alternatives : charter, pier, beach
m <- mlogit(mode ~ price + catch | income, data = Fish, alt.subset = c("charter", "pier", "beach"))

## model on unbalanced data i.e. for some observations, some
## alternatives are missing
# a data.frame in wide format with two missing prices
Fishing2 <- Fishing
Fishing2[1, "price.pier"] <- Fishing2[3, "price.beach"] <- NA
mlogit(mode ~ price + catch | income, Fishing2, shape = "wide", varying = 2:9)

# a data.frame in long format with three missing lines
data("TravelMode", package = "AER")
Tr2 <- TravelMode[-c(2, 7, 9),]
mlogit(choice ~ wait + gcost | income + size, Tr2)

## An heteroscedastic logit model
data("TravelMode", package = "AER")
hl <- mlogit(choice ~ wait + travel + vcost, TravelMode, heterosc = TRUE)

## A nested logit model

mlogit-deprecated

Some deprecated functions, especially mlogit.data, index and mFormula

Description

mlogit.data is deprecated, use dfidx::dfidx() instead, mFormula is replaced by Formula::Formula()
and zoo::index() by idx.

Usage

mlogit.data(
    data,
    choice = NULL,
    shape = c("long", "wide"),
    varying = NULL,
    sep = ".",
    alt.var = NULL,
    chid.var = NULL,
alt.levels = NULL,
id.var = NULL,
group.var = NULL,
opposite = NULL,
drop.index = FALSE,
ranked = FALSE,
subset = NULL,
...

mFormula(object)

## S3 method for class 'formula'
mFormula(object)

## Default S3 method:
mFormula(object)

## S3 method for class 'mFormula'
model.matrix(object, data, ...)

is.mFormula(object)

## S3 method for class 'dfidx'
index(x, ...)

## S3 method for class 'mlogit'
index(x, ...)

Arguments

data a data.frame,
choice the variable indicating the choice made: it can be either a logical vector, a numerical vector with 0 where the alternative is not chosen, a factor with level 'yes' when the alternative is chosen
shape the shape of the data.frame: whether long if each row is an alternative or wide if each row is an observation,
varying the indexes of the variables that are alternative specific,
sep the separator of the variable name and the alternative name (only relevant for a wide data.frame),
alt.var the name of the variable that contains the alternative index (for a long data.frame only) or the name under which the alternative index will be stored (the default name is alt),
chid.var the name of the variable that contains the choice index or the name under which the choice index will be stored,
alt.levels the name of the alternatives: if null, for a wide data.frame, they are guessed from the variable names and the choice variable (both should be the same), for
a long data.frame, they are guessed from the alt.var argument,

id.var the name of the variable that contains the individual index if any,
group.var the name of the variable that contains the group index if any,
opposite returns the opposite of the specified variables,
drop.index should the index variables be dropped from the data.frame,
ranked a logical value which is true if the response is a rank,
subset a logical expression which defines the subset of observations to be selected,
... further arguments passed to reshape.
x, object a formula, a dfidx or a mlogit object,
drop a boolean, equal to FALSE if one wants that a data.frame is always returned.

Value

mlogit.data now returns a dfidx object, mFormula simply calls Formula::Formula() and returns a Formula object.

stats::reshape()
mlogit.optim

Arguments

- **logLik**: the likelihood function to be maximized,
- **start**: the initial value of the vector of coefficients,
- **method**: the method used, one of 'nr' for Newton-Raphson, 'bhhh' for Berndt-Hausman-Hall-Hall and 'bfgs',
- **iterlim**: the maximum number of iterations,
- **tol**: the value of the criteria for the gradient,
- **ftol**: the value of the criteria for the function,
- **steptol**: the value of the criteria for the step,
- **print.level**: one of (0, 1, 2), the details of the printing messages. If 'print.level = 0', no information about the optimization process is provided, if 'print.level = 1' the value of the likelihood, the step and the stopping criteria is printing, if 'print.level = 2' the vectors of the parameters and the gradient are also printed.
- **constPar**: a numeric or a character vector which indicates that some parameters should be treated as constant,
- **...**: further arguments passed to f.

Details

The optimization is performed by updating, at each iteration, the vector of parameters by the amount step * direction, where step is a positive scalar and direction = H^{-1} * g, where g is the gradient and H^{-1} is an estimation of the inverse of the hessian. The choice of H^{-1} depends on the method chosen:

- if method = 'nr', H is the hessian (i.e. is the second derivatives matrix of the likelihood function),
- if method = 'bhhh', H is the outer-product of the individual contributions of each individual to the gradient,
- if method = 'bfgs', H^{-1} is updated at each iteration using a formula that uses the variations of the vector of parameters and the gradient. The initial value of the matrix is the inverse of the outer-product of the gradient (i.e. the bhhh estimator of the hessian).

The initial step is 1 and, if the new value of the function is less than the previous value, it is divided by two, until a higher value is obtained.

The routine stops when the gradient is sufficiently close to 0. The criteria is g * H^{-1} * g which is compared to the tol argument. It also may stop if the number of iterations equals iterlim.

The function f has a initial.value argument which is the initial value of the likelihood. The function is then evaluated a first time with a step equals to one. If the value is lower than the initial value, the step is divided by two until the likelihood increases. The gradient is then computed and the function returns as attributes the gradient is the step. This method is more efficient than other functions available for R:

For the optim and the maxLik functions, the function and the gradient should be provided as separate functions. But, for multinomial logit models, both depends on the probabilities which are the most time-consuming elements of the model to compute.
For the \texttt{nlm} function, the function returns the gradient as an attribute. The gradient is therefore computed at each iteration, even when the function is computed with a step that is unable to increase the value of the likelihood.

Previous versions of \texttt{mlogit} depended on the 'maxLik' package. We kept the same interface, namely the \texttt{start}, \texttt{method}, \texttt{iterlim}, \texttt{tol}, \texttt{print.level} and \texttt{constPar} arguments.

The default method is 'bfgs', which is known to perform well, even if the likelihood function is not well behaved and the default value for \texttt{print.level} = 1, which means moderate printing.

A special default behavior is performed if a simple multinomial logit model is estimated. Indeed, for this model, the likelihood function is concave, the analytical hessian is simple to write and the optimization is straightforward. Therefore, in this case, the default method is 'nr' and \texttt{print.level} = 0.

**Value**

A list that contains the followings elements:

- \texttt{optimum}: the value of the function at the optimum, with attributes: \texttt{gradient} a matrix that contains the contribution of each individual to the gradient, \texttt{gradient} the gradient and, if \texttt{method} = 'nr', \texttt{hessian} the hessian,
- \texttt{coefficients}: the vector of the parameters at the optimum,
- \texttt{est.stat}: a list that contains some information about the optimization: 'nb.iter' the number of iterations, 'eps' the value of the stoping criteria, 'method' the method of optimization method used, 'message'

**Mode**

**Mode Choice**

**Description**

A sample of 453 individuals for 4 transport modes.

**Format**

A dataframe containing:

- \texttt{choice}: one of car, carpool, bus or rail,
- \texttt{cost.z}: cost of mode \texttt{z},
- \texttt{time.z}: time of mode \texttt{z}.

**Source**

Kenneth Train’s home page.
Description

A sample of 3880 travellers for the Montreal-Toronto corridor

Format

A dataframe containing

- case: the individual index,
- alt: the alternative, one of train, car, bus and air,
- choice: one if the mode is chosen, zero otherwise,
- cost: monetary cost,
- ivt: in vehicle time,
- ovt: out vehicle time,
- frequency: frequency,
- income: income,
- urban: urban,
- noalt: the number of alternatives available.

**model.matrix.dfidx_mlogit**

*Compute the model matrix for RUM*

Description

Specific stuff compared to the `model.matrix.dfidx` method which simply applies the Formula method.

Usage

```r
## S3 method for class 'dfidx_mlogit'
model.matrix(object, ..., lhs = NULL, rhs = 1, dot = "separate")
```

Arguments

- `object` the object
- `...`, `lhs`, `rhs`, `dot`

see the Formula method

Yves Croissant
Description

A sample of 632 American production units

Format

A dataframe containing:

- chid: the plant id,
- alt: the alternative,
- id: the owner id,
- choice: the chosen alternative,
- available: a dummy indicating that the alternative is available,
- env: the regulatory environment, one of 'regulated', 'deregulated' and 'public',
- post: dummy for post-combustion pollution control technology,
- cm: dummy for combustion modification technology,
- lnb: dummy for low NOx burners technology,
- age: age of the plant (in deviation from the mean age),
- vcost: variable cost,
- kcost: capital cost.

plot.mlogit

Plot of the distribution of estimated random parameters

Description

Methods for rpar and mlogit objects which provide a plot of the distribution of one or all of the estimated random parameters

Usage

## S3 method for class 'mlogit'
plot(x, par = NULL, norm = NULL, type = c("density", "probability"), ...)

## S3 method for class 'rpar'
plot(x, norm = NULL, type = c("density", "probability"), ...)

Arguments

x a mlogit or a rpar object,
par a subset of the random parameters; if NULL, all the parameters are selected,
norm the coefficient’s name for the mlogit method or the coefficient’s value for the rpar method used for normalization,
type the function to be plotted, whether the density or the probability density function,
... further arguments, passed to plot.rpar for the mlogit method and to plot for the rpar method.

Details

For the rpar method, one plot is drawn. For the mlogit method, one plot for each selected random parameter is drawn.

Author(s)

Yves Croissant

mlogit() the estimation of random parameters logit models and rpar() for the description of rpar objects and distribution for functions which return informations about the distribution of random parameters.
Risky Transportation Choices

Description

1793 choices by 561 individuals of a transport mode at Freetwon airport

Format

A dataframe containing:

- id: individual id,
- choice: 1 for the chosen mode,
- mode: one of Helicopter, WaterTaxi, Ferry, and Hovercraft,
- cost: the generalised cost of the transport mode,
- risk: the fatality rate, numbers of death per 100,000 trips,
- weight: weights,
- seats: ,
- noise: ,
- crowdness: ,
- convloc: ,
- clientele: ,
- chid: choice situation id,
- african: yes if born in Africa, no otherwise,
- lifeExp: declared life expectancy,
- dwage: declared hourly wage,
- iwage: imputed hourly wage,
- educ: level of education, one of low and high,
- fatalism: self-ranking of the degree of fatalism,
- gender: gender, one of female and male,
- age: age,
- haveChildren: yes if the traveler has children, no otherwise,
- swim: yes if the traveler knows how to swim, ‘no, otherwise.

References

rpar  

**Description**

*rpar* objects contain the relevant information about estimated random parameters. The homonymous function `rpar` object from an *mlogit* object.

**Usage**

```r
rpar(x, par = NULL, norm = NULL, ...)  
```

## S3 method for class 'rpar'

```r
print(
  x,
  digits = max(3,getOption("digits") - 2),
  width = getOption("width"),
  ...
)
```

## S3 method for class 'rpar'

```r
summary(object, ...)
```

**Arguments**

- `x, object`  
  a *mlogit* object,
- `par`  
  the name or the index of the parameters to be extracted; if `NULL`, all the parameters are selected,
- `norm`  
  the coefficient used for normalization if any,
- `...`  
  further arguments.
- `digits`  
  the number of digits
- `width`  
  the width of the printed output

**Details**

*mlogit* objects contain an element called *rpar* which contain a list of *rpar* objects, one for each estimated random parameter. The `print` method prints the name of the distribution and the parameter, the `summary` behave like the one for numeric vectors.

**Value**

A *rpar* object, which contains:

- `dist`: the name of the distribution,
- `mean`: the first parameter of the distribution,
- `sigma`: the second parameter of the distribution,
- `name`: the name of the parameter.

scoretest

The three tests for mlogit models

Description

Three tests for mlogit models: specific methods for the Wald test and the likelihood ration test and a new function for the score test

Usage

scoretest(object, ...)

## S3 method for class 'mlogit'
scoretest(object, ...)

## Default S3 method:
scoretest(object, ...)

## S3 method for class 'mlogit'
waldtest(object, ...)

## S3 method for class 'mlogit'
lrtest(object, ...)

Arguments

object an object of class mlogit or a formula,
...

two kinds of arguments can be used. If mlogit arguments are introduced, initial model is updated using these arguments. If formula or other mlogit models are introduced, the standard behavior of lmtest::waldtest() and lmtest::lrtest() is followed.

Details

The scoretest function and mlogit method for waldtest and lrtest from the lmtest package provides the infrastructure to compute the three tests of hypothesis for mlogit objects.

The first argument must be a mlogit object. If the second one is a fitted model or a formula, the behaviour of the three functions is the one of the default methods of waldtest and lrtest: the two models provided should be nested and the hypothesis tested is that the constrained model is the 'right' model.
If no second model is provided and if the model provided is the constrained model, some specific arguments of `mlogit` should be provided to describe how the initial model should be updated. If the first model is the unconstrained model, it is tested versus the 'natural' constrained model; for example, if the model is a heteroscedastic logit model, the constrained one is the multinomial logit model.

**Value**

an object of class `htest`.

**Author(s)**

Yves Croissant

**Examples**

```r
library("mlogit")
library("lmtest")
data("TravelMode", package = "AER")
ml <- mlogit(choice ~ wait + travel + vcost, TravelMode,
             shape = "long", chid.var = "individual", alt.var = "mode")
hl <- mlogit(choice ~ wait + travel + vcost, TravelMode,
             shape = "long", chid.var = "individual", alt.var = "mode",
             method = "bfgs", heterosc = TRUE)
lrtest(ml, hl)
waldtest(hl)
scoretest(ml, heterosc = TRUE)
```

---

### Train

#### Stated Preferences for Train Traveling

**Description**

A sample of 235 Dutch individuals facing 2929 choice situations

**Format**

A dataframe containing:

- id: individual identifier,
- choiceid: choice identifier,
- choice: one of 'A' or 'B',
- price_z: price of proposition z (z = 'A', 'B') in cents of guilders,
- time_z: travel time of proposition z (z = 'A', 'B') in minutes,
- comfort_z: comfort of proposition z (z = 'A', 'B'), 0, 1 or 2 in decreasing comfort order,
- change_z: number of changes for proposition z (z = 'A', 'B').

vcov.mlogit vcov method for mlogit objects

Description

The vcov method for mlogit objects extract the covariance matrix of the coefficients, the errors or the random parameters.

Usage

## S3 method for class 'mlogit'
vcov(
  object,
  what = c("coefficient", "errors", "rpar"),
  subset = c("all", "iv", "sig", "sd", "sp", "chol"),
  type = c("cov", "cor", "sd"),
  reflevel = NULL,
  ...
)

## S3 method for class 'vcov.mlogit'
print(x, ...)

## S3 method for class 'vcov.mlogit'
summary(object, ...)

## S3 method for class 'summary.vcov.mlogit'
print(
  x,
  digits = max(3,getOption("digits") - 2),
  width = getOption("width"),
  ...
)
Arguments

- **object**: a mlogit object (and a vcov.mlogit for the summary method).
- **what**: indicates which covariance matrix has to be extracted: the default value is coefficients, in this case, vcov behaves as usual. If what equals errors the covariance matrix of the errors of the model is returned. Finally, if what equals rpar, the covariance matrix of the random parameters are extracted.
- **subset**: the subset of the coefficients that have to be extracted (only relevant if what = "coefficients").
- **type**: with this argument, the covariance matrix may be returned (the default); the correlation matrix with the standard deviation on the diagonal may also be extracted.
- **reflevel**: relevant for the extraction of the errors of a multinomial probit model; in this case the covariance matrix is of error differences is returned and, with this argument, the alternative used for differentiation is indicated.
- **...**: further arguments.
- **x**: a vcov.mlogit or a summary.vcov.mlogit object.
- **digits**: the number of digits.
- **width**: the width of the printing.

Details

This new interface replaces the cor.mlogit and cov.mlogit functions which are deprecated.
