# Package ‘multimark’

**June 30, 2017**

**Type** Package

**Title** Capture-Mark-Recapture Analysis using Multiple Non-Invasive Marks

**Version** 2.0.1

**Date** 2017-06-30

**Depends** R (>= 3.2.1)

**Imports** parallel, Matrix, coda, statmod, RMark, Brobdingnag, mvtnorm, graphics, methods, stats, utils, prodlim, sp, raster

**Description** Traditional and spatial capture-mark-recapture analysis with multiple non-invasive marks. The models implemented in ‘multimark’ combine encounter history data arising from two different non-invasive ‘marks’, such as images of left-sided and right-sided pelage patterns of bilaterally asymmetrical species, to estimate abundance and related demographic parameters while accounting for imperfect detection. Bayesian models are specified using simple formulae and fitted using Markov chain Monte Carlo. Addressing deficiencies in currently available software, ‘multimark’ also provides a user-friendly interface for performing Bayesian multimodel inference using non-spatial or spatial capture-recapture data consisting of a single conventional mark or multiple non-invasive marks.

**License** GPL-2

**LazyData** yes

**ByteCompile** TRUE

**RoxygenNote** 6.0.1

**NeedsCompilation** yes

**Author** Brett T. McClintock [aut, cre], Acho Arnold [ctb, cph] (C original matrix library, https://github.com/najela/matrix.h), Barry Brown [ctb] (Fortran original ranlib library), James Lovato [ctb] (Fortran original ranlib library), John Burkardt [ctb] (C original ranlib library, http://people.sc.fsu.edu/~jburkardt/c_src/ranlib), Cleve Moler [ctb] (C original linpack library,
Bobcat data

Example bobcat data for multimark package.
Format

The data are summarized in a 46x8 matrix containing observed encounter histories for 46 bobcats across 8 sampling occasions. Bobcats are bilaterally asymmetrical, and sampling was conducted using camera stations consisting of a single camera.

Because the left-side cannot be reconciled with the right-side, the two types of “marks” in this case are the pelage patterns on the left- and right-side of each individual. Encounter type 0 corresponds to non-detection, encounter type 1 corresponds to left-sided detection, encounter type 2 corresponds to right-sided detection.

Both-sided encounters were never observed in this dataset, hence the most appropriate multimark data type is data.type="never".

Source

See Also

multimarkClosed, processdata

Examples

data(bobcat)
The first 2 columns indicate the Cartesian x- and y-coordinate for the centroid of each grid cell, and the third column indicates whether the cell is available habitat (=1) or not (=0). The grid cells are 0.65x0.65km resolution.

Bobcats are bilaterally asymmetrical, and sampling was conducted using camera stations consisting of a single camera. Because the left-side cannot be reconciled with the right-side, the two types of “marks” in this case are the pelage patterns on the left- and right-side of each individual. Encounter type 0 corresponds to non-detection, encounter type 1 corresponds to left-sided detection, encounter type 2 corresponds to right-sided detection.

Both-sided encounters were never observed in this dataset, hence the most appropriate multimark data type is data.type="never".

The first 15 rows of bobcatSCR$Enc.Mat correspond to individuals for which both the left and right sides were known because they were physically captured for telemetry deployments prior to sampling surveys. The encounter histories for these 15 individuals are therefore known with certainty and should be specified as such using the known argument in processdataSCR and/or multimarkClosedSCR (see example below).

These data were obtained from the R package SPIM (Augustine et al. 2017) and modified by projecting onto a regular rectangular grid consisting of square grid cells (as is required by the spatial capture-recapture models in multimark).

Details

We thank B. Augustine and co-authors for making these data publicly available in the SPIM package (Augustine et al. 2017).

Examples

data(bobcatSCR)
#plot the traps and available habitat within the study area
plotSpatialData(trapCoords=bobcatSCR$trapCoords,studyArea=bobcatSCR$studyArea)

# This example is excluded from testing to reduce package check time
# Example uses unrealistically low values for nchain, iter, and burnin

# Fit spatial model to tiger data
Enc.Mat <- bobcatSCR$Enc.Mat
trapCoords <- bobcatSCR$trapCoords
studyArea <- bobcatSCR$studyArea

# specify known encounter histories
known <- c(rep(1,15),rep(0,nrow(Enc.Mat)-15))
getdensityClosedSCR  

**Calculate population density estimates**

**Description**

This function calculates posterior population density estimates from `multimarkClosedSCR` output as \(D = N/A\), where \(D\) is density, \(N\) is abundance, and \(A\) is the area of available habitat within the study area.

**Usage**

```r
getdensityClosedSCR(out)
```

**Arguments**

- `out` List of output returned by `multimarkClosedSCR`.

**Value**

An object of class `mcmc.list` containing the following:

- \(D\) Posterior samples for density.

**Author(s)**

Brett T. McClintock

**See Also**

`multimarkClosedSCR`

**Examples**

```r
# This example is excluded from testing to reduce package check time
# Example uses unrealistically low values for nchain, iter, and burnin

# Run behavior model for simulated data with constant detection probability (i.e., mod.p=c)
sim.data<-simdataClosedSCR()
Enc.Mat<-sim.data$Enc.Mat
```
getprobsCJS

Calculate posterior capture and survival probabilities

Description

This function calculates posterior capture ($p$) and survival ($\phi$) probabilities for each sampling occasion from `multimarkCJS` output.

Usage

`getprobsCJS(out, link = "probit")`

Arguments

- `out` List of output returned by `multimarkCJS`
- `link` Link function for $p$ and $\phi$. Must be "probit" or "logit". Note that `multimarkCJS` is currently implemented for the probit link only.

Value

An object of class `mcme.list` containing the following:

- `$p$` Posterior samples for capture probability ($p[c, t]$) for each release cohort ($c = 1, \ldots, T - 1$) and sampling occasion ($t = 2, \ldots, T$).
- `$\phi$` Posterior samples for survival probability ($\phi[c, k]$) for each release cohort ($c = 1, \ldots, T - 1$) and interval ($k = 1, \ldots, T - 1$).

# Calculate capture and recapture probabilities
D <- getdensityClosedSCR(example.dot)
summary(D)
```
getprobsClosed

Examples

```r
# This example is excluded from testing to reduce package check time
# Example uses unrealistically low values for nchain, iter, and burnin

# Simulate open population data with temporal variation in survival
noccas <- 5
data <- simdataCJS(noccas=noccas, phibeta=rnorm(noccas-1,1.6,0.1))

# Fit open population model with temporal variation in survival
sim.time <- multimarkCJS(data$Enc.Mat,mod.phi=-time)

# Calculate capture and survival probabilities for each cohort and time
pphi <- getprobsCJS(sim.time)
summary(pphi)
```

getprobsClosed

*Calculate posterior capture and recapture probabilities*

Description

This function calculates posterior capture \( p \) and recapture \( c \) probabilities for each sampling occasion from `multimarkClosed` output.

Usage

```r
getprobsClosed(out, link = "logit")
```

Arguments

- `out` List of output returned by `multimarkClosed`.
- `link` Link function for detection probability. Must be "logit" or "probit". Note that `multimarkClosed` is currently implemented for the logit link only.

Value

An object of class `mcmc.list` containing the following:

- `p` Posterior samples for capture probability \( p \) for each sampling occasion.
- `c` Posterior samples for recapture probability \( c \) for each sampling occasion.

getprobsClosedSCR  Calculate posterior capture and recapture probabilities

Description

This function calculates posterior spatial capture (p) and recapture (c) probabilities (at zero distance from an activity center) for each sampling occasion from multimarkClosedSCR output.

Usage

getprobsClosedSCR(out, link = "cloglog")

Arguments

out  List of output returned by multimarkClosedSCR.
link  Link function for detection probability. Must be "cloglog". Note that multimarkClosedSCR is currently implemented for the cloglog link only.

Value

An object of class mcmc.list containing the following:

p  Posterior samples for capture probability (p) for each sampling occasion (first index) and trap (second index).
c  Posterior samples for recapture probability (c) for each sampling occasion (first index) and trap (second index).

# Calculate capture and recapture probabilities
pc <- getprobsClosedSCR(example.c)
summary(pc)
```

Description

This function fits Cormack-Jolly-Seber (CJS) open population models for survival probability ($\phi$) and capture probability ($p$) for “traditional” capture-mark-recapture data consisting of a single mark type. Using Bayesian analysis methods, Markov chain Monte Carlo (MCMC) is used to draw samples from the joint posterior distribution.

Usage

```r
markCJS(Enc.Mat, covs = data.frame(), mod.p = ~1, mod.phi = ~1, 
parms = c("pbeta", "phibeta"), nchains = 1, iter = 12000, 
adapt = 1000, bin = 50, thin = 1, burnin = 2000, taccept = 0.44, 
tuneadjust = 0.95, proppbeta = 0.1, propz = 1, propsigmap = 1, 
propphibeta = 0.1, propzphi = 1, propsigmaphi = 1, pbeta0 = 0, 
psigma0 = 1, phibeta0 = 0, phiSigma0 = 1, l0p = 1, d0p = 0.01, 
l0phi = 1, d0phi = 0.01, initial.values = NULL, link = "probit", 
printlog = FALSE, ...)
```

Arguments

- **Enc.Mat** A matrix of observed encounter histories with rows corresponding to individuals and columns corresponding to sampling occasions. With a single mark type, encounter histories consist of only non-detections (0) and type 1 encounters (1).
- **covs** A data frame of temporal covariates for detection probabilities (ignored unless mms=NULL). The number of rows in the data frame must equal the number of sampling occasions. Covariate names cannot be “time”, ”age”, or “h”; these
names are reserved for temporal, behavioral, and individual effects when specifying `mod.p` and `mod.phi`.

`mod.p`  Model formula for detection probability ($p$). For example, `mod.p~1` specifies no effects (i.e., intercept only), `mod.p~time` specifies temporal effects, `mod.p~age` specifies age effects, `mod.p~h` specifies individual heterogeneity, and `mod.p~time+age` specifies additive temporal and age effects.

`mod.phi`  Model formula for survival probability ($\phi$). For example, `mod.phi~1` specifies no effects (i.e., intercept only), `mod.phi~time` specifies temporal effects, `mod.phi~age` specifies age effects, `mod.phi~h` specifies individual heterogeneity, and `mod.phi~time+age` specifies additive temporal and age effects.

`parms`  A character vector giving the names of the parameters and latent variables to monitor. Possible parameters are probit-scale detection probability parameters ("pbeta" for $p$ and "phibeta" for $\phi$), probit-scale individual heterogeneity variance terms ("sigma2_zp" for $p$ and "sigma2_zphi" for $\phi$), and probit-scale individual effects ("zp" and "zphi"). Latent variable indicators for whether each individual was alive (1) or dead (0) during each sampling occasion ("q") and the log likelihood ("loglike") may also be monitored. Setting `parms="all"` monitors all possible parameters and latent variables.

`nchains`  The number of parallel MCMC chains for the model.

`iter`  The number of MCMC iterations.

`adapt`  Ignored; no adaptive phase is needed for "probit" link.

`bin`  Ignored; no adaptive phase is needed for "probit" link.

`thin`  Thinning interval for monitored parameters.

`burnin`  Number of burn-in iterations ($0 \leq burnin < iter$).

`taccept`  Ignored; no adaptive phase is needed for "probit" link.

`tuneadjust`  Ignored; no adaptive phase is needed for "probit" link.

`propbeta`  Ignored; no adaptive phase is needed for "probit" link.

`propzp`  Ignored; no adaptive phase is needed for "probit" link.

`propsigmazp`  Ignored; no adaptive phase is needed for "probit" link.

`propzphi`  Ignored; no adaptive phase is needed for "probit" link.

`propsigmaphi`  Ignored; no adaptive phase is needed for "probit" link.

`pbeta0`  Scaler or vector (of length k) specifying mean of pbeta ~ multivariateNormal(pbeta0, pSigma0) prior. If pbeta0 is a scaler, then this value is used for all $j = 1, ..., k$. Default is pbeta0 = 0.

`pSigma0`  Scaler or k x k matrix specifying covariance matrix of pbeta ~ multivariateNormal(pbeta0, pSigma0) prior. If pSigma0 is a scaler, then this value is used for all pSigma0[j,j] for $j = 1, ..., k$ (with pSigma0[j,l] = 0 for all $j \neq l$). Default is pSigma0 = 1.

`phibeta0`  Scaler or vector (of length k) specifying mean of phibeta ~ multivariateNormal(phibeta0, phiSigma0) prior. If phibeta0 is a scaler, then this value is used for all $j = 1, ..., k$. Default is phibeta0 = 0.
phiSigma0  
Scaler or k x k matrix specifying covariance matrix of phibeta ~ multivariateNormal(phibeta0, phiSigma0) prior. If phiSigma0 is a scaler, then this value is used for all phiSigma0[j,j] for j = 1, ..., k (with phiSigma[j,j] = 0 for all j ≠ i). Default is phiSigma0 = 1.

10p  
Specifies "shape" parameter for [sigma2_zp] ~ invGamma(10p,d0p) prior. Default is 10p = 1.

d0p  
Specifies "scale" parameter for [sigma2_zp] ~ invGamma(10p,d0p) prior. Default is d0p = 0.01.

10phi  
Specifies "shape" parameter for [sigma2_zphi] ~ invGamma(10phi,d0phi) prior. Default is 10phi = 1.

d0phi  
Specifies "scale" parameter for [sigma2_zphi] ~ invGamma(10phi,d0phi) prior. Default is d0phi = 0.01.

initial.values  
Optional list of nchain list(s) specifying initial values for "pbeta", "phibeta", "sigma2_zp", "sigma2_zphi", "zp", "zphi", and "q". Default is initial.values = NULL, which causes initial values to be generated automatically.

link  
Link function for survival and capture probabilities. Only probit link is currently implemented.

printlog  
Logical indicating whether to print the progress of chains and any errors to a log file in the working directory. Ignored when nchains=1. Updates are printed to log file as 1% increments of iter of each chain are completed. With >1 chains, setting printlog=TRUE is probably most useful for Windows users because progress and errors are automatically printed to the R console for "Unix-like" machines (i.e., Mac and Linux) when printlog=FALSE. Default is printlog=FALSE.

...  
Additional "parameters" arguments for specifying mod.p and mod.phi. See RMark::make.design.data.

Details

The first time markCJS (or markClosed) is called, it will likely produce a firewall warning alerting users that R has requested the ability to accept incoming network connections. Incoming network connections are required to use parallel processing as implemented in multimarkCJS. Note that setting parms="all" is required for any markCJS model output to be used in multimodelCJS.

Value

A list containing the following:

mcmc  
Markov chain Monte Carlo object of class mcmc.list.

mod.p  
Model formula for detection probability (as specified by mod.p above).

mod.phi  
Model formula for survival probability (as specified by mod.phi above).

mod.delta  
Formula always NULL; only for internal use in multimodelCJS.

DM  
A list of design matrices for detection and survival probability respectively generated by mod.p and mod.phi, where DM$P is the design matrix for capture probability (p) and DM$phi is the design matrix for survival probability (\phi).
initial.values  A list containing the parameter and latent variable values at iteration iter for each chain. Values are provided for "pbeta", "phibeta", "sigma2_zp", "sigma2_zphi", "zp", "zphi", and "q".

mms  An object of class multimarksetup

markClosed

Fit closed population abundance models for “traditional” capture-mark-recapture data consisting of a single mark type

Description
This function fits closed population abundance models for “traditional” capture-mark-recapture data consisting of a single mark type using Bayesian analysis methods. Markov chain Monte Carlo (MCMC) is used to draw samples from the joint posterior distribution.
Usage

```r
markClosed(Enc.Mat, covs = data.frame(), mod.p = ~1, parms = c("pbeta", "N"), nchains = 1, iter = 12000, adapt = 1000, bin = 50, thin = 1,
        burnin = 2000, taccept = 0.44, tuneadjust = 0.95, proppbeta = 0.1,
        propzp = 1, propsigmap = 1, npoints = 500, a = 25, mu0 = 0,
        sigma2_mu0 = 1.75, initial.values = NULL, printlog = FALSE, ...)
```

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enc.Mat</td>
<td>A matrix of observed encounter histories with rows corresponding to individuals and columns corresponding to sampling occasions. With a single mark type, encounter histories consist of only non-detections (0) and type 1 encounters (1).</td>
</tr>
<tr>
<td>covs</td>
<td>A data frame of temporal covariates for detection probabilities (ignored unless mms=NULL). The number of rows in the data frame must equal the number of sampling occasions. Covariate names cannot be “time”, “age”, or “h”; these names are reserved for temporal, behavioral, and individual effects when specifying mod.p and mod.phi.</td>
</tr>
<tr>
<td>mod.p</td>
<td>Model formula for detection probability. For example, mod.p = ~1 specifies no effects (i.e., intercept only), mod.p ~ time specifies temporal effects, mod.p ~ c specifies behavioral response (i.e., trap “happy” or ”shy”), mod.p ~ h specifies individual heterogeneity, and mod.p ~ time + c specifies additive temporal and behavioral effects.</td>
</tr>
<tr>
<td>parms</td>
<td>A character vector giving the names of the parameters and latent variables to monitor. Possible parameters are logit-scale detection probability parameters (&quot;pbeta&quot;), population abundance (&quot;N&quot;), logit-scale individual heterogeneity variance term (&quot;sigma2_zp&quot;), and logit-scale individual effects (&quot;zp&quot;). The log posterior density (&quot;logPosterior&quot;) may also be monitored. Setting parms=&quot;all&quot; monitors all possible parameters and latent variables.</td>
</tr>
<tr>
<td>nchains</td>
<td>The number of parallel MCMC chains for the model.</td>
</tr>
<tr>
<td>iter</td>
<td>The number of MCMC iterations.</td>
</tr>
<tr>
<td>adapt</td>
<td>The number of iterations for proposal distribution adaptation. If adapt = 0 then no adaptation occurs.</td>
</tr>
<tr>
<td>bin</td>
<td>Bin length for calculating acceptance rates during adaptive phase (0 &lt; bin &lt;= iter).</td>
</tr>
<tr>
<td>thin</td>
<td>Thinning interval for monitored parameters.</td>
</tr>
<tr>
<td>burnin</td>
<td>Number of burn-in iterations (0 &lt;= burnin &lt; iter).</td>
</tr>
<tr>
<td>taccept</td>
<td>Target acceptance rate during adaptive phase (0 &lt; taccept &lt;= 1). Acceptance rate is monitored every bin iterations. Default is taccept = 0.44.</td>
</tr>
<tr>
<td>tuneadjust</td>
<td>Adjustment term during adaptive phase (0 &lt; tuneadjust &lt;= 1). If acceptance rate is less than taccept, then proposal term (proppbeta, propzp, or propsigmap) is multiplied by tuneadjust. If acceptance rate is greater than or equal to taccept, then proposal term is divided by tuneadjust. Default is tuneadjust = 0.95.</td>
</tr>
<tr>
<td>proppbeta</td>
<td>Scaler or vector (of length k) specifying the initial standard deviation of the Normal(pbeta[j], proppbeta[j]) proposal distribution. If proppbeta is a scaler, then this value is used for all j = 1, ..., k. Default is proppbeta = 0.1.</td>
</tr>
</tbody>
</table>
**propzp**
Scaler or vector (of length M) specifying the initial standard deviation of the Normal(zp[i], propzp[i]) proposal distribution. If propzp is a scalar, then this value is used for all i = 1, ..., M individuals. Default is propzp = 1.

**propsigmap**
Scaler specifying the initial Gamma(shape = 1/propsigmap, scale = sigma_zp * propsigmap) proposal distribution for sigma_zp = sqrt(sigma2_zp). Default is propsigmap = 1.

**npoints**
Number of Gauss-Hermite quadrature points to use for numerical integration. Accuracy increases with number of points, but so does computation time.

**a**
Scale parameter for \([sigma_z] \sim \text{half-Cauchy}(a)\) prior for the individual heterogeneity term sigma_zp = sqrt(sigma2_zp). Default is “uninformative” \(a = 25\).

**mu0**
Scaler or vector (of length k) specifying mean of pbeta[j] ~ Normal(mu0[j], sigma2_mu0[j]) prior. If mu0 is a scalar, then this value is used for all j = 1, ..., k. Default is mu0 = 0.

**sigma2_mu0**
Scaler or vector (of length k) specifying variance of pbeta[j] ~ Normal(mu0[j], sigma2_mu0[j]) prior. If sigma2_mu0 is a scalar, then this value is used for all j = 1, ..., k. Default is sigma2_mu0 = 1.75.

**initial.values**
Optional list of nchain list(s) specifying initial values for "pbeta", "zp", "sigma2_zp", and "N". Default is initial.values = NULL, which causes initial values to be generated automatically.

**printlog**
Logical indicating whether to print the progress of chains and any errors to a log file in the working directory. Ignored when nchains=1. Updates are printed to log file as 1% increments of iter of each chain are completed. With >1 chains, setting printlog=TRUE is probably most useful for Windows users because progress and errors are automatically printed to the R console for “Unix-like” machines (i.e., Mac and Linux) when printlog=FALSE. Default is printlog=FALSE.

**Details**
The first time markClosed (or markCJS) is called, it will likely produce a firewall warning alerting users that R has requested the ability to accept incoming network connections. Incoming network connections are required to use parallel processing as implemented in markClosed. Note that setting parms="all" is required for any markClosed model output to be used in multimodelClosed.

**Value**
A list containing the following:

- **mcmc**
  Markov chain Monte Carlo object of class mcmc.list.

- **mod.p**
  Model formula for detection probability (as specified by mod.p above).

- **mod.delta**
  Formula always NULL: only for internal use in multimodelClosed.

- **DM**
  A list of design matrices for detection probability generated for model mod.p, where DM$p is the design matrix for initial capture probability (p) and DM$c is the design matrix for recapture probability (c).

- **initial.values**
  A list containing the parameter and latent variable values at iteration iter for each chain. Values are provided for "pbeta", "zp", "sigma2_zp", and "N".

- **mms**
  An object of class multimarksetup
Description

This function fits spatial population abundance models for “traditional” capture-mark-recapture data consisting of a single mark type using Bayesian analysis methods. Markov chain Monte Carlo (MCMC) is used to draw samples from the joint posterior distribution.

Usage

markClosedSCR(Enc.Mat, trapCoords, studyArea = NULL, buffer = NULL, ncells = 1024, covs = data.frame(), mod.p = ~1, detection = "half-normal", parms = c("pbeta", "N"), nchains = 1, iter = 12000, adapt = 1000, bin = 50, thin = 1, burnin = 2000, taccept = 0.44, tuneadjust = 0.95, proppbeta = 0.1, propsigma = 1, propcenter = NULL, sigma_bounds = NULL, mu0 = 0, sigma2_mu0 = 1.75, initial.values = NULL, scalemax = 10, printlog = FALSE, ...)

Arguments

Enc.Mat A matrix containing the observed encounter histories with rows corresponding to individuals and (ntraps*noccas) columns corresponding to traps and sampling occasions. The first noccas columns correspond to trap 1, the second noccas columns correspond to trap 2, etc.
A matrix of dimension \(n_{\text{traps}} \times (2 + n_{\text{occas}})\) indicating the Cartesian coordinates and operating occasions for the traps, where rows correspond to trap, the first column the x-coordinate ("x"), and the second column the y-coordinate ("y"). The last \(n_{\text{occas}}\) columns indicate whether or not the trap was operating on each of the occasions, where '1' indicates the trap was operating and '0' indicates the trap was not operating. Ignored unless \(mms=NULL\).

**studyArea**
is a 3-column matrix containing the coordinates for the centroids a contiguous grid of cells that define the study area and available habitat. Each row corresponds to a grid cell. The first 2 columns ("x" and "y") indicate the Cartesian x- and y-coordinate for the centroid of each grid cell, and the third column ("avail") indicates whether the cell is available habitat (=1) or not (=0). All cells must have the same resolution. If \(\text{studyArea}=\text{NULL}\) (the default) and \(mms=\text{NULL}\), then a square study area grid composed of \(n_{\text{cells}}\) cells of available habitat is drawn around the bounding box of \(\text{trapCoords}\) based on \(\text{buffer}\). Ignored unless \(mms=\text{NULL}\).

**buffer**
A scaler in same units as \(\text{trapCoords}\) indicating the buffer around the bounding box of \(\text{trapCoords}\) for defining the study area when \(\text{studyArea}=\text{NULL}\). Ignored unless \(\text{studyArea}=\text{NULL}\).

**ncells**
The number of grid cells in the study area when \(\text{studyArea}=\text{NULL}\). The square root of \(n_{\text{cells}}\) must be a whole number. Default is \(n_{\text{cells}}=1024\). Ignored unless \(\text{studyArea}=\text{NULL}\) and \(mms=\text{NULL}\).

**covs**
A data frame of temporal covariates for detection probabilities. The number of rows in the data frame must equal the number of sampling occasions. Covariate names cannot be "time", "c", or "h"; these names are reserved.

**mod.p**
Model formula for detection probability. For example, \(\text{mod.p}=\sim 1\) specifies no effects (i.e., intercept only), \(\text{mod.p}=\sim \text{time}\) specifies temporal effects, \(\text{mod.p}=\sim \text{c}\) specifies behavioral response (i.e., trap "happy" or "shy"), \(\text{mod.p}=\sim \text{trap}\) specifies trap effects, and \(\text{mod.p}=\sim \text{time+c}\) specifies additive temporal and behavioral effects.

**detection**
Model for detection probability as a function of distance from activity centers. Must be "half-normal" (of the form \(\exp\left(-d^2/(2 \times \sigma^2)\right)\)), where \(d\) is distance) or "exponential" (of the form \(\exp\left(-d/\lambda\right)\)).

**parms**
A character vector giving the names of the parameters and latent variables to monitor. Possible parameters are cloglog-scale detection probability parameters ("pbeta"), population abundance ("N"), cloglog-scale distance term for the detection function ("sigma2_scr" when detection="half-normal" or "lambda" when detection="exponential"), and the probability that a randomly selected individual from the \(M = \text{nrow(Enc.Mat)}\) observed individuals belongs to the \(n\) unique individuals encountered at least once ("psi"). Individual activity centers ("centers"), and the log posterior density ("logPosterior") may also be monitored. Setting \(\text{parms}="\text{all}"\) monitors all possible parameters and latent variables.

**nchains**
The number of parallel MCMC chains for the model.

**iter**
The number of MCMC iterations.

**adapt**
The number of iterations for proposal distribution adaptation. If \(\text{adapt} = 0\) then no adaptation occurs.
bin  Bin length for calculating acceptance rates during adaptive phase (0 < bin <= iter).

thin  Thinning interval for monitored parameters.

burnin  Number of burn-in iterations (0 <= burnin < iter).

taccept  Target acceptance rate during adaptive phase (0 < taccept <= 1). Acceptance rate is monitored every $\text{bin}$ iterations. Default is taccept = 0.44.

tuneadjust  Adjustment term during adaptive phase (0 < tuneadjust <= 1). If acceptance rate is less than taccept, then proposal term (proppbeta or propsigma) is multiplied by tuneadjust. If acceptance rate is greater than or equal to taccept, then proposal term is divided by tuneadjust. Default is tuneadjust = 0.95.

proppbeta  Scaler or vector (of length k) specifying the initial standard deviation of the $\text{Normal}(\text{pbeta}[j], \text{proppbeta}[j])$ proposal distribution. If proppbeta is a scaler, then this value is used for all $j = 1, ..., k$. Default is proppbeta = 1.

propsigma  Scaler specifying the initial Gamma(shape = 1/propsigma, scale = sigma_scr * propsigma) proposal distribution for sigma_scr = sqrt(sigma2_scr). Default is propsigma=1.

propcenter  Scaler specifying the neighborhood distance when proposing updates to activity centers. When propcenter=NULL (the default), then propcenter = a*10, where a is the cell size for the study area grid, and each cell has (at most) approximately 300 neighbors.

sigma_bounds  Positive vector of length 2 for the lower and upper bounds for the $[\text{sigma_scr}] \sim \text{Uniform}([\text{sigma_bounds}[1], \text{sigma_bounds}[2])]$ (or $[\text{sqrt}(\text{lambda})]$) when detection='exponential') prior for the detection function term $\text{sigma_scr} = \sqrt{\text{sigma2_scr}}$ (or $\sqrt{\text{lambda}}$). When sigma_bounds = NULL (the default), then sigma_bounds = c(1.e-6, max(diff(range(studyArea$X)), range(studyArea$Y))))

mu0  Scaler or vector (of length k) specifying mean of $\text{pbeta}[j] \sim \text{Normal}(\mu0[j], \text{sigma2_mu0}[j])$ prior. If mu0 is a scaler, then this value is used for all $j = 1, ..., k$. Default is mu0 = 0.

sigma2_mu0  Scaler or vector (of length k) specifying variance of $\text{pbeta}[j] \sim \text{Normal}(\mu0[j], \text{sigma2_mu0}[j])$ prior. If sigma2_mu0 is a scaler, then this value is used for all $j = 1, ..., k$. Default is sigma2_mu0 = 1.75.

initial.values  Optional list of nchain list(s) specifying initial values for "pbeta", "N", "sigma2_scr", and "centers". Default is initial.values = NULL, which causes initial values to be generated automatically.

scalemax  Upper bound for internal re-scaling of grid cell centroid coordinates. Default is scalemax=10, which re-scales the centroids to be between 0 and 10. Re-scaling is done internally to avoid numerical overflows during model fitting.

printlog  Logical indicating whether to print the progress of chains and any errors to a log file in the working directory. Ignored when nchains=1. Updates are printed to log file as 1% increments of iter of each chain are completed. With >1 chains, setting printlog=TRUE is probably most useful for Windows users because progress and errors are automatically printed to the R console for "Unix-like" machines (i.e., Mac and Linux) when printlog=FALSE. Default is printlog=FALSE.

...  Additional "parameters" arguments for specifying mod.p. See make.design.data.
**Details**

The first time `markClosedSCR` is called, it will likely produce a firewall warning alerting users that R has requested the ability to accept incoming network connections. Incoming network connections are required to use parallel processing as implemented in `markClosed`. Note that setting `parms="all"` is required for any `markClosed` model output to be used in `multimodelClosedSCR`.

**Value**

A list containing the following:

- `mcmc`  
  Markov chain Monte Carlo object of class `mcmc.list`.

- `mod.p`  
  Model formula for detection probability (as specified by `mod.p` above).

- `mod.delta`  
  Formula always NULL; only for internal use in `multimodelClosedSCR`.

- `mod.det`  
  Model formula for detection function (as specified by `detection` above).

- `DM`  
  A list of design matrices for detection probability generated for model `mod.p`, where `DM$p` is the design matrix for initial capture probability (p) and `DM$c` is the design matrix for recapture probability (c).

- `initial.values`  
  A list containing the parameter and latent variable values at iteration `iter` for each chain. Values are provided for "pbeta", "N", "sigma2_scr", and "centers".

- `mms`  
  An object of class `multimarkSCRsetup`.

# Example uses unrealistically low values for `nchain`, `iter`, and `burnin`
multimarkcjs

Fit open population survival models for capture-mark-recapture data consisting of multiple non-invasive marks

Description

This function fits Cormack-Jolly-Seber (CJS) open population models for survival probability ($\phi$) and capture probability ($p$) from capture-mark-recapture data consisting of multiple non-invasive marks. Using Bayesian analysis methods, Markov chain Monte Carlo (MCMC) is used to draw samples from the joint posterior distribution.

Usage

multimarkcjs(Enc.Mat, data.type = "never", covs = data.frame(),
  mms = NULL, mod.p = ~1, mod.phi = ~1, mod.delta = ~type,
  parms = c("pbeta", "phibeta", "delta"), nchains = 1, iter = 12000,
  adapt = 1000, bin = 50, thin = 1, burnin = 2000, taccept = 0.44,
  tuneadjust = 0.95, proppbeta = 0.1, propz = 1, propsigmmap = 1,
  propphibeta = 0.1, propzphi = 1, propsigmaphi = 1, maxnmbasis = 1,
  pbeta0 = 0, pSigma0 = 1, phibeta0 = 0, phiSigma0 = 1, l0p = 1,
  d0p = 0.01, l0phi = 1, d0phi = 0.01, a0delta = 1, a0alpha = 1,
  b0alpha = 1, a0psi = 1, b0psi = 1, initial.values = NULL,
  known = integer(), link = "probit", printlog = FALSE, ...)

Arguments

Enc. Mat A matrix of observed encounter histories with rows corresponding to individuals and columns corresponding to sampling occasions (ignored unless mms=NULL).

data.type Specifies the encounter history data type. All data types include non-detections (type 0 encounter), type 1 encounter (e.g., left-side), and type 2 encounters (e.g., right-side). When both type 1 and type 2 encounters occur for the same individual within a sampling occasion, these can either be "non-simultaneous" (type 3 encounter) or "simultaneous" (type 4 encounter). Three data types are currently permitted:
data.type="never" indicates both type 1 and type 2 encounters are never observed for the same individual within a sampling occasion, and observed encounter histories therefore include only type 1 or type 2 encounters (e.g., only
Observed encounter histories can consist of non-detections (0), type 1 encounters (1), and type 2 encounters (2). Latent encounter histories consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), and type 3 encounters (3). 

data.type="sometimes" indicates both type 1 and type 2 encounters are sometimes observed (e.g., both-sided photographs are sometimes obtained, but not necessarily for all individuals). Observed encounter histories can consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), and type 4 encounters (4). Type 3 encounters can only be observed when an individual has at least one type 4 encounter. Latent encounter histories consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), type 3 encounters (3), and type 4 encounters (4). 

data.type="always" indicates both type 1 and type 2 encounters are always observed, but some encounter histories may still include only type 1 or type 2 encounters. Observed encounter histories can consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), and type 4 encounters (4). Latent encounter histories consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), and type 4 encounters (4).

covs A data frame of temporal covariates for detection probabilities (ignored unless mms=NULL). The number of rows in the data frame must equal the number of sampling occasions. Covariate names cannot be "time", "age", or "h"; these names are reserved for temporal, behavioral, and individual effects when specifying mod.p and mod.phi.

mms An optional object of class multimarksetup-class; if NULL it is created. See processdata.

mod.p Model formula for detection probability (p). For example, mod.p=~1 specifies no effects (i.e., intercept only), mod.p~time specifies temporal effects, mod.p~age specifies age effects, mod.p~h specifies individual heterogeneity, and mod.p~time+age specifies additive temporal and age effects.

mod.phi Model formula for survival probability (φ). For example, mod.phi=~1 specifies no effects (i.e., intercept only), mod.phi~time specifies temporal effects, mod.phi~age specifies age effects, mod.phi~h specifies individual heterogeneity, and mod.phi~time+age specifies additive temporal and age effects.

mod.delta Model formula for conditional probabilities of type 1 (delta_1) and type 2 (delta_2) encounters, given detection. Currently only mod.delta=~1 (i.e., δ₁ = δ₂) and mod.delta=~type (i.e., δ₁ ≠ δ₂) are implemented.

parms A character vector giving the names of the parameters and latent variables to monitor. Possible parameters are probit-scale detection probability parameters ("pbeta" for p and "phibeta" for φ), conditional probability of type 1 or type 2 encounter, given detection ("delta"), probability of simultaneous type 1 and type 2 detection, given both types encountered ("alpha"), probit-scale individual heterogeneity variance terms ("sigma2_zp" for p and "sigma2_zphi" for φ), probit-scale individual effects ("zp" and "zphi"), and the probability that a randomly selected individual from the M = nrow(Enc.Mat) observed individuals belongs to the n unique individuals encountered at least once ("psi"). Individual encounter history indices ("H"), latent variable indicators for whether each individual was alive (1) or dead (0) during each sampling occasion ("q"), and
the log likelihood ("loglike") may also be monitored. Setting `parms="all"` monitors all possible parameters and latent variables.

- `nchains` The number of parallel MCMC chains for the model.
- `iter` The number of MCMC iterations.
- `adapt` Ignored; no adaptive phase is needed for "probit" link.
- `bin` Ignored; no adaptive phase is needed for "probit" link.
- `thin` Thinning interval for monitored parameters.
- `burnin` Number of burn-in iterations (0 \(\leq\) burnin < iter).
- `taccept` Ignored; no adaptive phase is needed for "probit" link.
- `tuneadjust` Ignored; no adaptive phase is needed for "probit" link.
- `proppbeta` Ignored; no adaptive phase is needed for "probit" link.
- `propzp` Ignored; no adaptive phase is needed for "probit" link.
- `propsigmap` Ignored; no adaptive phase is needed for "probit" link.
- `propphibeta` Ignored; no adaptive phase is needed for "probit" link.
- `propzphi` Ignored; no adaptive phase is needed for "probit" link.
- `propsigmaphi` Ignored; no adaptive phase is needed for "probit" link.
- `maxnumbasis` Maximum number of basis vectors to use when proposing latent history frequency updates. Default is `maxnumbasis = 1`, but higher values can potentially improve mixing.

- `pbeta0` Scaler or vector (of length k) specifying mean of pbeta ~ multivariateNormal(pbeta0, pSigma0) prior. If pbeta0 is a scaler, then this value is used for all j = 1, ..., k. Default is pbeta0 = 0.

- `pSigma0` Scaler or k x k matrix specifying covariance matrix of pbeta ~ multivariateNormal(pbeta0, pSigma0) prior. If pSigma0 is a scaler, then this value is used for all pSigma0[j,j] for j = 1, ..., k (with pSigma[j,j] = 0 for all j \(\neq\) l). Default is pSigma0 = 1.

- `phibeta0` Scaler or vector (of length k) specifying mean of phibeta ~ multivariateNormal(phibeta0, phiSigma0) prior. If phibeta0 is a scaler, then this value is used for all j = 1, ..., k. Default is phibeta0 = 0.

- `phiSigma0` Scaler or k x k matrix specifying covariance matrix of phibeta ~ multivariateNormal(phibeta0, phiSigma0) prior. If phiSigma0 is a scaler, then this value is used for all phiSigma0[j,j] for j = 1, ..., k (with phiSigma[j,j] = 0 for all j \(\neq\) l). Default is phiSigma0 = 1.

- `l0p` Specifies "shape" parameter for [sigma2_zp] ~ invGamma(l0p,d0p) prior. Default is l0p = 1.

- `d0p` Specifies "scale" parameter for [sigma2_zp] ~ invGamma(l0p,d0p) prior. Default is d0p = 0.01.

- `l0phi` Specifies "shape" parameter for [sigma2_zphi] ~ invGamma(l0phi,d0phi) prior. Default is l0phi = 1.

- `d0phi` Specifies "scale" parameter for [sigma2_zphi] ~ invGamma(l0phi,d0phi) prior. Default is d0phi = 0.01.
Scalar or vector (of length d) specifying the prior for the conditional (on detection) probability of type 1 (delta_1), type 2 (delta_2), and both type 1 and type 2 encounters (1-delta_1-delta_2). If a0delta is a scaler, then this value is used for all a0delta[j] for j = 1, ..., d. For mod.delta="type", d=3 with [delta_1, delta_2, 1-delta_1-delta_2] ~ Dirichlet(a0delta) prior. For mod.delta="1", d=2 with [tau] ~ Beta(a0delta[1],a0delta[2]) prior, where (delta_1,delta_2,1-delta_1-delta_2) = (tau/2,tau/2,1-tau). See McClintock et al. (2013) for more details.

Specifies "shape1" parameter for [alpha] ~ Beta(a0alpha, b0alpha) prior. Only applicable when data.type = "sometimes". Default is a0alpha = 1. Note that when a0alpha = 1 and b0alpha = 1, then [alpha] ~ Unif(0,1).

Specifies "shape2" parameter for [alpha] ~ Beta(a0alpha, b0alpha) prior. Only applicable when data.type = "sometimes". Default is b0alpha = 1. Note that when a0alpha = 1 and b0alpha = 1, then [alpha] ~ Unif(0,1).

Specifies "shape1" parameter for [psi] ~ Beta(a0psi,b0psi) prior. Default is a0psi = 1.

Specifies "shape2" parameter for [psi] ~ Beta(a0psi,b0psi) prior. Default is b0psi = 1.

Optional list of nchain list(s) specifying initial values for parameters and latent variables. Default is initial.values = NULL, which causes initial values to be generated automatically. In addition to the parameters ("pbeta", "phibeta", "delta_1", "delta_2", "alpha", "sigma2_zp", "sigma2_zphi", "zp", "zphi", and "psi"), initial values can be specified for the initial latent history frequencies ("x"), initial individual encounter history indices ("H"), and initial latent variable indicators for whether each individual was alive (1) or dead (0) during each sampling occasion ("q").

Optional integer vector indicating whether the encounter history of an individual is known with certainty (i.e., the observed encounter history is the true encounter history). Encounter histories with at least one type 4 encounter are automatically assumed to be known, and known does not need to be specified unless there exist encounter histories that do not contain a type 4 encounter that happen to be known with certainty (e.g., from independent telemetry studies). If specified, known = c(v_1, v_2, ..., v_M) must be a vector of length M = nrow(Enc.Mat) where v_1 = 1 if the encounter history for individual i is known (v_i = 0 otherwise). Note that known all-zero encounter histories (e.g., '000') are ignored.

Link function for survival and capture probabilities. Only probit link is currently implemented.

Logical indicating whether to print the progress of chains and any errors to a log file in the working directory. Ignored when nchains=1. Updates are printed to log file as 1% increments of iter of each chain are completed. With >1 chains, setting printlog=TRUE is probably most useful for Windows users because progress and errors are automatically printed to the R console for "Unix-like" machines (i.e., Mac and Linux) when printlog=FALSE. Default is printlog=FALSE.
The first time `multimarkCJS` (or `multimarkClosed`) is called, it will likely produce a firewall warning alerting users that R has requested the ability to accept incoming network connections. Incoming network connections are required to use parallel processing as implemented in `multimarkCJS`. Note that setting `parms="all"` is required for any `multimarkCJS` model output to be used in `multimodelCJS`.

**multimarkClosed**

Fit closed population abundance models for capture-mark-recapture data consisting of multiple non-invasive marks

### Description

This function fits closed population abundance models for capture-mark-recapture data consisting of multiple non-invasive marks using Bayesian analysis methods. Markov chain Monte Carlo (MCMC) is used to draw samples from the joint posterior distribution.

### Usage

```r
multimarkClosed(Enc.Mat, data.type = "never", covs = data.frame(), mms = NULL, mod.p = ~1, mod.delta = ~type, parms = c("beta", "delta", "N"), nchains = 1, iter = 12000, adapt = 1000, bin = 50, thin = 1, burnin = 2000, taccept = 0.44, tuneadjust = 0.95, proppbeta = 0.1, propzp = 1, propsigmap = 1, npoints = 500, maxnumbasis = 1, a0delta = 1, a0alpha = 1, b0alpha = 1, a = 25, mu0 = 0, sigma2.mu0 = 1.75, a0psi = 1, b0psi = 1, initial.values = NULL, known = integer(), printlog = FALSE, ...)```

### Arguments

- **Enc.Mat**
  A matrix of observed encounter histories with rows corresponding to individuals and columns corresponding to sampling occasions (ignored unless mms=NULL).

- **data.type**
  Specifies the encounter history data type. All data types include non-detections (type 0 encounter), type 1 encounter (e.g., left-side), and type 2 encounters (e.g., right-side). When both type 1 and type 2 encounters occur for the same individual within a sampling occasion, these can either be "non-simultaneous" (type 3 encounter) or "simultaneous" (type 4 encounter). Three data types are currently permitted:
data_type="never" indicates both type 1 and type 2 encounters are never observed for the same individual within a sampling occasion, and observed encounter histories therefore include only type 1 or type 2 encounters (e.g., only left- and right-sided photographs were collected). Observed encounter histories can consist of non-detections (0), type 1 encounters (1), and type 2 encounters (2). See bobcat. Latent encounter histories consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), and type 3 encounters (3).

data_type="sometimes" indicates both type 1 and type 2 encounters are sometimes observed (e.g., both-sided photographs are sometimes obtained, but not necessarily for all individuals). Observed encounter histories can consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), type 3 encounters (3), and type 4 encounters (4). Type 3 encounters can only be observed when an individual has at least one type 4 encounter. Latent encounter histories consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), type 3 encounters (3), and type 4 encounters (4).

data_type="always" indicates both type 1 and type 2 encounters are always observed, but some encounter histories may still include only type 1 or type 2 encounters. Observed encounter histories can consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), and type 4 encounters (4). Latent encounter histories consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), and type 4 encounters (4).

covs A data frame of temporal covariates for detection probabilities (ignored unless mms=NULL). The number of rows in the data frame must equal the number of sampling occasions. Covariate names cannot be "time", "c", or "h"; these names are reserved for temporal, behavioral, and individual effects when specifying mod.p and mod.phi.

mms An optional object of class multimarksetup-class; if NULL it is created. See processdata.

mod.p Model formula for detection probability. For example, mod.p~1 specifies no effects (i.e., intercept only), mod.p~time specifies temporal effects, mod.p~c specifies behavioral response (i.e., trap "happy" or "shy"), mod.p~h specifies individual heterogeneity, and mod.p~time+c specifies additive temporal and behavioral effects.

mod.delta Model formula for conditional probabilities of type 1 (delta_1) and type 2 (delta_2) encounters, given detection. Currently only mod.delta=-1 (i.e., \( \delta_1 = \delta_2 \)) and mod.delta=~type (i.e., \( \delta_1 \neq \delta_2 \)) are implemented.

parms A character vector giving the names of the parameters and latent variables to monitor. Possible parameters are logit-scale detection probability parameters ("pbeta"), population abundance ("N"), conditional probability of type 1 or type 2 encounter, given detection ("delta"), probability of simultaneous type 1 and type 2 detection, given both types encountered ("alpha"), logit-scale individual heterogeneity variance term ("sigma2_zp"), logit-scale individual effects ("zp"), and the probability that a randomly selected individual from the \( M = nrow(Enc.Mat) \) observed individuals belongs to the \( n \) unique individuals encountered at least once ("psi"). Individual encounter history indices ("h") and the log posterior density ("logPosterior") may also be monitored. Setting parms="all" monitors all possible parameters and latent variables.

mu0  Scaler or vector (of length k) specifying mean of pbeta[j] \sim \text{Normal}(\mu0[j], 
\sigma2_mu0[j]) prior. If mu0 is a scaler, then this value is used for all \( j = 1, ..., k \). Default is \( \mu0 = 0 \).

sigma2_mu0  Scaler or vector (of length k) specifying variance of pbeta[j] \sim \text{Normal}(\mu0[j], 
\sigma2_mu0[j]) prior. If sigma2_mu0 is a scaler, then this value is used for all \( j = 1, ..., k \). Default is \( \sigma2_{mu0} = 1.75 \).

a0psi  Specifies "shape1" parameter for [psi] \sim \text{Beta}(a0psi,b0psi) prior. Default is \( a0psi = 1 \).

b0psi  Specifies "shape2" parameter for [psi] \sim \text{Beta}(a0psi,b0psi) prior. Default is \( b0psi = 1 \).

initial.values  Optional list of nchain list(s) specifying initial values for parameters and latent variables. Default is initial.values = NULL, which causes initial values to be generated automatically. In addition to the parameters ("pbeta", "N", "delta_1", "delta_2", "alpha", "sigma2_zp", "zp", and "psi"), initial values can be specified for the initial latent history frequencies ("x") and initial individual encounter history indices ("H").

known  Optional integer vector indicating whether the encounter history of an individual is known with certainty (i.e., the observed encounter history is the true encounter history). Encounter histories with at least one type 4 encounter are automatically assumed to be known, and known does not need to be specified unless there exist encounter histories that do not contain a type 4 encounter that happen to be known with certainty (e.g., from independent telemetry studies). If specified, known = c(v_1,v_2,...,v_M) must be a vector of length M = nrow(Enc.Mat) where v_i = 1 if the encounter history for individual i is known (v_i = 0 otherwise). Note that known all-zero encounter histories (e.g., ‘000’) are ignored.

printlog  Logical indicating whether to print the progress of chains and any errors to a log file in the working directory. Ignored when nchains=1. Updates are printed to log file as 1% increments of iter of each chain are completed. With >1 chains, setting printlog=TRUE is probably most useful for Windows users because progress and errors are automatically printed to the R console for "Unix-like" machines (i.e., Mac and Linux) when printlog=FALSE. Default is printlog=FALSE.

Details
The first time multimarkClosed (or multimarkCJS) is called, it will likely produce a firewall warning alerting users that R has requested the ability to accept incoming network connections. Incoming network connections are required to use parallel processing as implemented in multimarkClosed. Note that setting parms="all" is required for any multimarkClosed model output to be used in multimodelClosed.

Value
A list containing the following:

mcmc  Markov chain Monte Carlo object of class mcmc.list.

mod.p  Model formula for detection probability (as specified by mod.p above).
mod.delta  Model formula for conditional probability of type 1 or type 2 encounter, given detection (as specified by mod.delta above).

DM  A list of design matrices for detection probability generated for model mod.p, where DM$p is the design matrix for initial capture probability (p) and DM$c is the design matrix for recapture probability (c).

initial.values  A list containing the parameter and latent variable values at iteration iter for each chain. Values are provided for "pbeta", "N", "delta_1", "delta_2", "alpha", "sigma2_zp", "zp", "psi", "x", and "H".

mms  An object of class multimarksetup

multimarkClosedSCR  Fit spatially-explicit population abundance models for capture-mark-recapture data consisting of multiple non-invasive marks

Description

This function fits spatially-explicit population abundance models for capture-mark-recapture data consisting of multiple non-invasive marks using Bayesian analysis methods. Markov chain Monte Carlo (MCMC) is used to draw samples from the joint posterior distribution.

Usage

multimarkClosedSCR(Enc.Mat, trapCoords, studyArea = NULL, buffer = NULL,
ncells = 1024, data.type = "never", covs = data.frame(), mms = NULL,
mod.p = ~1, mod.delta = ~type, detection = "half-normal",
parms = c("pbeta", "delta", "N"), nchains = 1, iter = 12000,
adapt = 1000, bin = 50, thin = 1, burnin = 2000, taccept = 0.44,
tuneadjust = 0.95, proppbeta = 0.1, propsigma = 1, propcenter = NULL,
maxnumbasis = 1, a0delta = 1, a0alpha = 1, b0alpha = 1,
sigma.bounds = NULL, mu0 = 0, sigma2_mu0 = 1.75, a0psi = 1,
b0psi = 1, initial.values = NULL, known = integer(), scalemax = 10,
printlog = FALSE, ...)

Arguments

Enc.Mat A matrix containing the observed encounter histories with rows corresponding to individuals and (ntraps*noccas) columns corresponding to traps and sampling occasions. The first noccas columns correspond to trap 1, the second noccas columns correspond to trap 2, etc. Ignored unless mms=NULL.

trapCoords A matrix of dimension ntraps x (2 + noccas) indicating the Cartesian coordinates and operating occasions for the traps, where rows correspond to trap, the first column the x-coordinate ("x"), and the second column the y-coordinate ("y"). The last noccas columns indicate whether or not the trap was operating on each of the occasions, where '1' indicates the trap was operating and '0' indicates the trap was not operating. Ignored unless mms=NULL.

studyArea is a 3-column matrix containing the coordinates for the centroids of a contiguous grid of cells that define the study area and available habitat. Each row corresponds to a grid cell. The first 2 columns ("x" and "y") indicate the Cartesian x- and y-coordinate for the centroid of each grid cell, and the third column ("avail") indicates whether the cell is available habitat (=1) or not (=0). All cells must be square and have the same resolution. If studyArea=NULL (the default) and mms=NULL, then a square study area grid composed of ncells cells of available habitat is drawn around the bounding box of trapCoords based on buffer. Ignored unless mms=NULL.

buffer A scaler in same units as trapCoords indicating the buffer around the bounding box of trapCoords for defining the study area when studyArea=NULL. Ignored unless studyArea=NULL and mms=NULL.
ncells
The number of grid cells in the study area when studyArea=NULL. The square root of ncells must be a whole number. Default is ncells=1024. Ignored unless studyArea=NULL and mms=NULL.

data.type
Specifies the encounter history data type. All data types include non-detections (type 0 encounter), type 1 encounter (e.g., left-side), and type 2 encounters (e.g., right-side). When both type 1 and type 2 encounters occur for the same individual within a sampling occasion, these can either be "non-simultaneous" (type 3 encounter) or "simultaneous" (type 4 encounter). Three data types are currently permitted:

data.type="never" indicates both type 1 and type 2 encounters are never observed for the same individual within a sampling occasion, and observed encounter histories therefore include only type 1 or type 2 encounters (e.g., only left- and right-sided photographs were collected). Observed encounter histories can consist of non-detections (0), type 1 encounters (1), and type 2 encounters (2). See bobcat. Latent encounter histories consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), and type 3 encounters (3).

data.type="sometimes" indicates both type 1 and type 2 encounters are sometimes observed (e.g., both-sided photographs are sometimes obtained, but not necessarily for all individuals). Observed encounter histories can consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), type 3 encounters (3), and type 4 encounters (4). Type 3 encounters can only be observed when an individual has at least one type 4 encounter. Latent encounter histories consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), type 3 encounters (3), and type 4 encounters (4).

data.type="always" indicates both type 1 and type 2 encounters are always observed, but some encounter histories may still include only type 1 or type 2 encounters. Observed encounter histories can consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), and type 4 encounters (4). Latent encounter histories consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), and type 4 encounters (4).

covs
A data frame of temporal covariates for detection probabilities (ignored unless mms=NULL). The number of rows in the data frame must equal the number of sampling occasions. Covariate names cannot be "time", "c", or "h"; these names are reserved.

mms
An optional object of class multimarkSCRsetup-class; if NULL it is created. See processdataSCR.

mod.p
Model formula for detection probability as a function of distance from activity centers. For example, mod.p=~1 specifies no effects (i.e., intercept only) other than distance, mod.p~time specifies temporal effects, mod.p~c specifies behavioral reponse (i.e., trap "happy" or "shy"), mod.p~trap specifies trap effects, and mod.p~time+c specifies additive temporal and behavioral effects.

mod.delta
Model formula for conditional probabilities of type 1 (delta_1) and type 2 (delta_2) encounters, given detection. Currently only mod.delta=~1 (i.e., δ₁ = δ₂) and mod.delta=~type (i.e., δ₁ ≠ δ₂) are implemented.

detection
Model for detection probability as a function of distance from activity centers . Must be "half-normal" (of the form exp (−d²/(2 * σ²)), where d is distance) or "exponential" (of the form exp (−d/λ)).
multimarkClosedSCR

**parms**
A character vector giving the names of the parameters and latent variables to monitor. Possible parameters are cloglog-scale detection probability parameters ("pbeta"), population abundance ("n"), conditional probability of type 1 or type 2 encounter, given detection ("delta"), probability of simultaneous type 1 and type 2 detection, given both types encountered ("alpha"), cloglog-scale distance term for the detection function ("sigma2_scr" when detection="half-normal" or "lambda" when detection="exponential"), and the probability that a randomly selected individual from the M = nrow(Enc.Mat) observed individuals belongs to the n unique individuals encountered at least once ("psi"). Individual activity centers ("centers"), encounter history indices ("h"), and the log posterior density ("logposterior") may also be monitored. Setting parms="all" monitors all possible parameters and latent variables.

**nchains**
The number of parallel MCMC chains for the model.

**iter**
The number of MCMC iterations.

**adapt**
The number of iterations for proposal distribution adaptation. If adapt = 0 then no adaptation occurs.

**bin**
Bin length for calculating acceptance rates during adaptive phase (0 < bin <= iter).

**thin**
Thinning interval for monitored parameters.

**burnin**
Number of burn-in iterations (0 <= burnin < iter).

**taccept**
Target acceptance rate during adaptive phase (0 < taccept <= 1). Acceptance rate is monitored every bin iterations. Default is taccept = 0.44.

**tuneadjust**
Adjustment term during adaptive phase (0 < tuneadjust <= 1). If acceptance rate is less than taccept, then proposal term (proppbeta or propsigma) is multiplied by tuneadjust. If acceptance rate is greater than or equal to taccept, then proposal term is divided by tuneadjust. Default is tuneadjust = 0.95.

**proppbeta**
Scaler or vector (of length k) specifying the initial standard deviation of the Normal(pbeta[j], proppbeta[j]) proposal distribution. If proppbeta is a scaler, then this value is used for all j = 1, ..., k. Default is proppbeta = 0.1.

**propsigma**
Scaler specifying the initial Gamma(shape = 1/propsigma, scale = sigma_scr * propsigma) proposal distribution for sigma_scr = sqrt(sigma2_scr) (or sqrt(lambda) = lambda if detection="exponential"). Default is propsigma=1.

**propcenter**
Scaler specifying the neighborhood distance when proposing updates to activity centers. When propcenter=NULL (the default), then propcenter = a*10, where a is the cell size for the study area grid, and each cell has (at most) approximately 300 neighbors.

**maxnumbasis**
Maximum number of basis vectors to use when proposing latent history frequency updates. Default is maxnumbasis = 1, but higher values can potentially improve mixing.

**a0delta**
Scaler or vector (of length d) specifying the prior for the conditional (on detection) probability of type 1 (delta_1), type 2 (delta_2), and both type 1 and type 2 encounters (1-delta_1-delta_2). If a0delta is a scaler, then this value is used for all a0delta[j] for j = 1, ..., d. For mod.delta="type", d=3 with [delta_1, delta_2, 1-delta_1-delta_2] ~ Dirichlet(a0delta) prior. For mod.delta="1", d=2 with [tau] ~ Beta(a0delta[1],a0delta[2]) prior, where (delta_1,delta_2,1-delta_1-delta_2) = (tau/2,tau/2,1-tau). See McClintock et al. (2013) for more details.
a0alpha  Specifies "shape1" parameter for [alpha] ~ Beta(a0alpha, b0alpha) prior. Only
applicable when data.type = "sometimes". Default is a0alpha = 1. Note
that when a0alpha = 1 and b0alpha = 1, then [alpha] ~ Unif(0,1).

b0alpha  Specifies "shape2" parameter for [alpha] ~ Beta(a0alpha, b0alpha) prior. Only
applicable when data.type = "sometimes". Default is b0alpha = 1. Note
that when a0alpha = 1 and b0alpha = 1, then [alpha] ~ Unif(0,1).

sigma_bounds Positive vector of length 2 for the lower and upper bounds for the [sigma_scr] ~
Uniform(sigma_bounds[1], sigma_bounds[2]) (or [sqrt(lambda)] when detection='exponential')
prior for the detection function term sigma_scr = sqrt(sigma2_scr) (or sqrt(lambda)).
When sigma_bounds = NULL (the default), then sigma_bounds = c(1.e-6, max(diff(range(studyArea))),
mu0 Scaler or vector (of length k) specifying mean of pbeta[j] ~ Normal(mu0[j],
sigma2_mu0[j]) prior. If mu0 is a scaler, then this value is used for all j = 1, ..., k. Default is mu0 = 0.

sigma2_mu0 Scaler or vector (of length k) specifying variance of pbeta[j] ~ Normal(mu0[j],
sigma2_mu0[j]) prior. If sigma2_mu0 is a scaler, then this value is used for all j = 1, ..., k. Default is sigma2_mu0 = 1.75.

a0psi Specifies "shape1" parameter for [psi] ~ Beta(a0psi,b0psi) prior. Default is
a0psi = 1.

b0psi Specifies "shape2" parameter for [psi] ~ Beta(a0psi,b0psi) prior. Default is
b0psi = 1.

initial.values Optional list of nchain list(s) specifying initial values for parameters and la-
tent variables. Default is initial.values = NULL, which causes initial values to
be generated automatically. In addition to the parameters ("pbeta", "N", ",delta_1", "delta_2", "alpha", "sigma2_scr", "centers", and "psi"),
initial values can be specified for the initial latent history frequencies ("x") and initial
individual encounter history indices ("H").

known Optional integer vector indicating whether the encounter history of an individual
is known with certainty (i.e., the observed encounter history is the true encounter
history). Encounter histories with at least one type 4 encounter are automatically
assumed to be known, and known does not need to be specified unless there exist
encounter histories that do not contain a type 4 encounter that happen to be
known with certainty (e.g., from independent telemetry studies). If specified,
known = c(v_1,v_2,...,v_M) must be a vector of length M = nrow(Enc.Mat)
where v_i = 1 if the encounter history for individual i is known (v_i = 0 otherwise).
Note that known all-zero encounter histories (e.g., '000') are ignored.

scalemax Upper bound for internal re-scaling of grid cell centroid coordinates. Default is
scalemax=10, which re-scales the centroids to be between 0 and 10. Re-scaling
is done internally to avoid numerical overflows during model fitting. Ignored
unless mms=NULL.

printlog Logical indicating whether to print the progress of chains and any errors to a log
file in the working directory. Ignored when nchains=1. Updates are printed to
log file as 1% increments of iter of each chain are completed. With >1 chains,
setting printlog=TRUE is probably most useful for Windows users because
progress and errors are automatically printed to the R console for "Unix-like"
machines (i.e., Mac and Linux) when printlog=FALSE. Default is printlog=FALSE.

... Additional "parameters" arguments for specifying mod.p. See make.design.data.
Details

The first time `multimarkClosedSCR` is called, it will likely produce a firewall warning alerting users that R has requested the ability to accept incoming network connections. Incoming network connections are required to use parallel processing as implemented in `multimarkClosedSCR`. Note that setting `parms="all"` is required for any `multimarkClosedSCR` model output to be used in `multimodelClosedSCR`.

Value

A list containing the following:

- `mcmc`: Markov chain Monte Carlo object of class `mcmc.list`.
- `mod.p`: Model formula for detection probability (as specified by `mod.p` above).
- `mod.delta`: Model formula for conditional probability of type 1 or type 2 encounter, given detection (as specified by `mod.delta` above).
- `mod.det`: Model formula for detection function (as specified by detection above).
- `DM`: A list of design matrices for detection probability generated for model `mod.p`, where `DM$p` is the design matrix for initial capture probability (p) and `DM$c` is the design matrix for recapture probability (c).
- `initial.values`: A list containing the parameter and latent variable values at iteration iter for each chain. Values are provided for "pbeta", "N", "delta_1", "delta_2", "alpha", "sigma2_scr", "centers", "psi", "x", and "H".
- `mms`: An object of class `multimarkSCRsetup`.

multimarkSCRsetup-class

Class "multimarkSCRsetup"

Description

A class of spatial 'mulitmark' model inputs

Slots

Enc.Mat Object of class "matrix". The observed encounter histories (with rows corresponding to individuals and columns corresponding to sampling occasions).

data.type Object of class "character". The encounter history data type ("never", "sometimes", or "always").

vAll.hists Object of class "integer". An ordered vector containing all possible encounter histories in sequence.

Aprime Object of class "sparseMatrix". Transpose of the A matrix mapping latent encounter histories to observed histories.

indBasis Object of class "numeric". An ordered vector of the indices of the three encounter histories updated by each basis vector.

ncolbasis Object of class "integer". The number of needed basis vectors.

knownx Object of class "integer". Frequencies of known encounter histories.

c Object of class "integer". Sampling occasion of first capture for each encounter history.
Description

A class of 'multitmark' model inputs

Slots

Enc.Mat  Object of class "matrix". The observed encounter histories (with rows corresponding to individuals and columns corresponding to sampling occasions).
data.type  Object of class "character". The encounter history data type ("never", "sometimes", or "always").
vAll.hists  Object of class "integer". An ordered vector containing all possible encounter histories in sequence.
Aprime  Object of class "sparseMatrix". Transpose of the A matrix mapping latent encounter histories to observed histories.
**multimodelCJS**

- **indBasis** Object of class "numeric". An ordered vector of the indices of the three encounter histories updated by each basis vector.
- **ncolbasis** Object of class "integer". The number of needed basis vectors.
- **knownx** Object of class "integer". Frequencies of known encounter histories.
- **C** Object of class "integer". Sampling occasion of first capture for each encounter history.
- **L** Object of class "integer". Sampling occasion of last capture for each encounter history.
- **naivex** Object of class "integer". "Naive" latent history frequencies assuming a one-to-one mapping with Enc.Mat.
- **covs** Object of class "data.frame". Temporal covariates for detection probability (the number of rows in the data frame must equal the number of sampling occasions).

**Objects from the Class**

Objects can be created by calls of the form `processdata(Enc.Mat, ...)` or `new("multimarksetup", ...)`.  

**Methods**

No methods defined with class "multimarksetup".

**multimodelCJS**

*Multimodel inference for 'multimark' open population survival models*

**Description**

This function performs Bayesian multimodel inference for a set of 'multimark' open population survival (i.e., Cormack-Jolly-Seber) models using the reversible jump Markov chain Monte Carlo (RJMCMC) algorithm proposed by Barker & Link (2013).

**Usage**

```R
multimodelCJS(modlist, modprior = rep(1/length(modlist), length(modlist)),
  monparms = "phi", miter = NULL, mburnin = 0, mthin = 1, M1 = NULL,
  pbetapropsd = 1, zppropsd = NULL, phibetapropsd = 1,
  zphipropsd = NULL, sigppropshape = 1, sigpropscale = 0.01,
  sigphipropshape = 1, sigphipropscale = 0.01, printlog = FALSE)
```
**Arguments**

**modlist**  
A list of individual model output lists returned by `multimarkCJS`. The models must have the same number of chains and MCMC iterations.

**modprior**  
Vector of length `length(modlist)` containing prior model probabilities. Default is `modprior = rep(1/length(modlist), length(modlist))`.

**monparms**  
Parameters to monitor. Only parameters common to all models can be monitored (e.g., "pbeta\{(Intercept)\}", "phibeta\{(Intercept)\}", "psi"), but derived survival ("phi") and capture ("p") probabilities can also be monitored. Default is `monparms = "phi"`.

**miter**  
The number of RJMCMC iterations per chain. If `NULL`, then the number of MCMC iterations for each individual model chain is used.

**mburnin**  
Number of burn-in iterations (\(0 \leq \text{mburnin} < \text{miter}\)).

**mthin**  
Thinning interval for monitored parameters.

**M1**  
Integer vector indicating the initial model for each chain, where `M1_j = i` initializes the RJMCMC algorithm for chain `j` in the model corresponding to `modlist[[i]]` for `i = 1, ..., length(modlist)`. If `NULL`, the algorithm for all chains is initialized in the most general model. Default is `M1 = NULL`.

**pbetapropsd**  
Scaler specifying the standard deviation of the Normal(0, `pbetapropsd`) proposal distribution for "pbeta" parameters. Default is `pbetapropsd = 1`. See Barker & Link (2013) for more details.

**zppropsd**  
Scaler specifying the standard deviation of the Normal(0, `zppropsd`) proposal distribution for "zp" parameters. Only applies if at least one (but not all) model(s) include individual heterogeneity in detection probability. If `NULL`, `zppropsd = sqrt(sigma2_zp)` is used. Default is `zppropsd = NULL`. See Barker & Link (2013) for more details.

**phibetapropsd**  
Scaler specifying the standard deviation of the Normal(0, `phibetapropsd`) proposal distribution for "phibeta" parameters. Default is `phibetapropsd = 1`. See Barker & Link (2013) for more details.

**zphipropsd**  
Scaler specifying the standard deviation of the Normal(0, `zphipropsd`) proposal distribution for "zphi" parameters. Only applies if at least one (but not all) model(s) include individual heterogeneity in survival probability. If `NULL`, `zphipropsd = sqrt(sigma2_zphi)` is used. Default is `zphipropsd = NULL`. See Barker & Link (2013) for more details.

**sigppropshape**  
Scaler specifying the shape parameter of the invGamma(shape = `sigppropshape`, scale = `sigppropscale`) proposal distribution for "sigma2_zp". Only applies if at least one (but not all) model(s) include individual heterogeneity in detection probability. Default is `sigppropshape = 1`. See Barker & Link (2013) for more details.

**sigppropscale**  
Scaler specifying the scale parameter of the invGamma(shape = `sigppropshape`, scale = `sigppropscale`) proposal distribution for "sigma2_zp". Only applies if at least one (but not all) model(s) include individual heterogeneity in detection probability. Default is `sigppropscale = 0.01`. See Barker & Link (2013) for more details.
sigphipropshape
Scalor specifying the shape parameter of the invGamma(shape = sigphipropshape, scale = sigphipropscale) proposal distribution for "sigma2_zphi". Only applies if at least one (but not all) model(s) include individual heterogeneity in survival probability. Default is sigphipropshape=1. See Barker & Link (2013) for more details.

sigphipropscale
Scalor specifying the scale parameter of the invGamma(shape = sigphipropshape, scale = sigphipropscale) proposal distribution for "sigma_zphi". Only applies if at least one (but not all) model(s) include individual heterogeneity in survival probability. Default is sigphipropscale=0.01. See Barker & Link (2013) for more details.

printlog
Logical indicating whether to print the progress of chains and any errors to a log file in the working directory. Ignored when nchains=1. Updates are printed to log file as 1% increments of iter of each chain are completed. With >1 chains, setting printlog=TRUE is probably most useful for Windows users because progress and errors are automatically printed to the R console for "Unix-like" machines (i.e., Mac and Linux) when printlog=FALSE. Default is printlog=FALSE.

Details
Note that setting parms="all" is required when fitting individual multimarkCJS models to be included in modlist.

Value
A list containing the following:

rjmc
Reversible jump Markov chain Monte Carlo object of class mcmc.list. Includes RJMCMC output for monitored parameters and the current model at each iteration ("m").

pos.prob
A list of calculated posterior model probabilities for each chain, including the overall posterior model probabilities across all chains.

**multimodelClosed**  
*Multimodel inference for 'multimark' closed population abundance models*

**Description**

This function performs Bayesian multimodel inference for a set of 'multimark' closed population abundance models using the reversible jump Markov chain Monte Carlo (RJMCMC) algorithm proposed by Barker & Link (2013).

**Usage**

```r
multimodelClosed(modlist, modprior = rep(1/length(modlist), length(modlist)),
monparms = "N", miter = NULL, mburnin = 0, mthin = 1, M1 = NULL,
phetapropsd = 1, zppropsd = NULL, sigppropshape = 6,
sigppropscale = 4, printlog = FALSE)
```
Arguments

modlist A list of individual model output lists returned by `multimarkClosed` or `markClosed`. The models must have the same number of chains and MCMC iterations.

modprior Vector of length `length(modlist)` containing prior model probabilities. Default is `modprior = rep(1/length(modlist), length(modlist))`.

monparms Parameters to monitor. Only parameters common to all models can be monitored (e.g., "pbeta[(Intercept)]", "N"), but derived capture ("p") and recapture ("c") probabilities can also be monitored. Default is `monparms = "N"`.

mite The number of RJMCMC iterations per chain. If NULL, then the number of MCMC iterations for each individual model chain is used.

mburnin Number of burn-in iterations (0 <= mburnin < miter).

mthin Thinning interval for monitored parameters.

M1 Integer vector indicating the initial model for each chain, where `M1[j]=i` initializes the RJMCMC algorithm for chain `j` in the model corresponding to `modlist[[i]]` for `i=1,..., length(modlist)`. If NULL, the algorithm for all chains is initialized in the most general model. Default is `M1=NULL`.

pbetapropsd Scaler specifying the standard deviation of the Normal(0, pbetapropsd) proposal distribution for "pbeta" parameters. Default is `pbetapropsd=1`. See Barker & Link (2013) for more details.

zppropsd Scaler specifying the standard deviation of the Normal(0, zppropsd) proposal distribution for "zp" parameters. Only applies if at least one (but not all) model(s) include individual heterogeneity in detection probability. If NULL, `zppropsd = sqrt(sigma2_zp)` is used. Default is `zppropsd=NULL`. See Barker & Link (2013) for more details.

sigppropshape Scaler specifying the shape parameter of the invGamma(shape = sigppropshape, scale = sigppropscale) proposal distribution for `sigma_zp`. Only applies if at least one (but not all) model(s) include individual heterogeneity in detection probability. Default is `sigppropshape=6`. See Barker & Link (2013) for more details.

sigppropscale Scaler specifying the scale parameter of the invGamma(shape = sigppropshape, scale = sigppropscale) proposal distribution for `sigma_zp`. Only applies if at least one (but not all) model(s) include individual heterogeneity in detection probability. Default is `sigppropscale=4`. See Barker & Link (2013) for more details.

printlog Logical indicating whether to print the progress of chains and any errors to a log file in the working directory. Ignored when `nchains=1`. Updates are printed to log file as 1% increments of `iter` of each chain are completed. With >1 chains, setting `printlog=TRUE` is probably most useful for Windows users because progress and errors are automatically printed to the R console for "Unix-like" machines (i.e., Mac and Linux) when `printlog=FALSE`. Default is `printlog=FALSE`.

Details

Note that setting `parms="all"` is required when fitting individual `multimarkClosed` or `markClosed` models to be included in `modlist`. 
Value

A list containing the following:

- rjmc: Reversible jump Markov chain Monte Carlo object of class \texttt{mcmc.list}. Includes RJMCMC output for monitored parameters and the current model at each iteration ("M").

- pos.prob: A list of calculated posterior model probabilities for each chain, including the overall posterior model probabilities across all chains.

multimodelClosedSCR  
Multimodel inference for 'multimark' spatial population abundance models

Description
This function performs Bayesian multimodel inference for a set of 'multimark' spatial population abundance models using the reversible jump Markov chain Monte Carlo (RJMCMC) algorithm proposed by Barker & Link (2013).

Usage
```r
multimodelClosedSCR(modlist, modprior = rep(1/length(modlist), length(modlist)), monparms = "N", miter = NULL, mburnin = 0, mthinn = 1, m1 = NULL, pbetapropsd = 1, sigpropmean = 0.8, sigpropsd = 0.4, printlog = FALSE)
```

Arguments
- `modlist`: A list of individual model output lists returned by `multimarkClosedSCR` or `markClosedSCR`. The models must have the same number of chains and MCMC iterations.
- `modprior`: Vector of length `length(modlist)` containing prior model probabilities. Default is `modprior = rep(1/length(modlist), length(modlist))`.
- `monparms`: Parameters to monitor. Only parameters common to all models can be monitored (e.g., "pbeta[(Intercept)]", "N", "sigma2_scr"), but derived density ("D") as well as capture ("p") and recapture ("c") probabilities (at distance zero from activity centers) can also be monitored. Default is `monpars = "N"`.
- `miter`: The number of RJMCMC iterations per chain. If NULL, then the number of MCMC iterations for each individual model chain is used.
- `mburnin`: Number of burn-in iterations (0 <= mburnin < miter).
- `mthinn`: Thinning interval for monitored parameters.
- `m1`: Integer vector indicating the initial model for each chain, where `M1[j]` initializes the RJMCMC algorithm for chain `j` in the model corresponding to `modlist[[i]]` for `i=1,...,length(modlist)`. If NULL, the algorithm for all chains is initialized in the most general model. Default is `M1=NULL`.
- `pbetapropsd`: Scaler specifying the standard deviation of the Normal(0, pbetapropsd) proposal distribution for "pbeta" parameters. Default is `pbetapropsd=1`. See Barker & Link (2013) for more details.
- `sigpropmean`: Scaler specifying the mean of the inverse Gamma proposal distribution for `sigma2_scr` (or `lambda` if detection="exponential"). Only applies if models do not have the same detection function (i.e., "half-normal" or "exponential"). Default is `sigpropmean=0.8`. See Barker & Link (2013) for more details.
sigprospd  Scaler specifying the standard deviation of the inverse Gamma proposal distribution for sigma2_scr (or lambda if detection="exponential"). Only applies if models do not have the same detection function (i.e., “half-normal” or “exponential”). Default is sigprospd=0.4. See Barker & Link (2013) for more details.

printlog  Logical indicating whether to print the progress of chains and any errors to a log file in the working directory. Ignored when nchains=1. Updates are printed to log file as 1% increments of iter of each chain are completed. With >1 chains, setting printlog=TRUE is probably most useful for Windows users because progress and errors are automatically printed to the R console for "Unix-like" machines (i.e., Mac and Linux) when printlog=FALSE. Default is printlog=FALSE.

Details

Note that setting parms="all" is required when fitting individual multimarkClosedSCR or markClosedSCR models to be included in modlist.

Value

A list containing the following:

rjmcmc  Reversible jump Markov chain Monte Carlo object of class mcmc.list. Includes RJMCMC output for monitored parameters and the current model at each iteration ("M").

plotSpatialData  
Plot spatial capture-mark-recapture data

Description

This function plots the study area grid, available habitat, and trap coordinates for spatial capture-recapture studies. Activity centers and capture locations can also be plotted.

Usage

plotSpatialData(mms = NULL, trapCoords, studyArea, centers = NULL, trapLines = FALSE)

Arguments

mms    An optional object of class multimarkSCRsetup-class from which the (re-scaled) study area and trap coordinates are plotted.

trapCoords A matrix of dimension ntraps x (2 + noccas) indicating the Cartesian coordinates and operating occasions for the traps, where rows correspond to trap, the first column the x-coordinate, and the second column the y-coordinate. The last noccas columns indicate whether or not the trap was operating on each of the occasions, where '1' indicates the trap was operating and '0' indicates the trap was not operating. Ignored unless mms=NULL.

studyArea A 3-column matrix defining the study area and available habitat. Each row corresponds to a grid cell. The first 2 columns indicate the Cartesian x- and y-coordinate for the centroid of each grid cell, and the third column indicates whether the cell is available habitat (=1) or not (=0). All cells must have the same resolution. Ignored unless mms=NULL.
An optional vector indicating the grid cell (i.e., the row of `studyArea`) that contains the true (latent) activity centers for each individual. If `mms` is provided, then `centers` must be of length `nrow(Enc.Mat)` (i.e., a center must be provided for each observed individual).

Logical indicating whether to draw lines from activity centers to respective traps at which each individual was captured. Default is `trapLines=FALSE`. Ignored when `mms=NULL` or `centers=NULL`.

Brett T. McClintock

#Plot the tiger example data
plotSpatialData(trapCoords=tiger$trapCoords,studyArea=tiger$studyArea)

This function generates an object of class `multimarksetup` that is required to fit `multimark` models.

`processdata(Enc.Mat, data.type = "never", covs = data.frame(), known = integer())`

A matrix of observed encounter histories with rows corresponding to individuals and columns corresponding to sampling occasions (ignored unless `mms=NULL`).

Specifies the encounter history data type. All data types include non-detections (type 0 encounter), type 1 encounter (e.g., left-side), and type 2 encounters (e.g., right-side). When both type 1 and type 2 encounters occur for the same individual within a sampling occasion, these can either be "non-simultaneous" (type 3 encounter) or "simultaneous" (type 4 encounter). Three data types are currently permitted:

data.type="never" indicates both type 1 and type 2 encounters are never observed for the same individual within a sampling occasion, and observed encounter histories therefore include only type 1 or type 2 encounters (e.g., only left- and right-sided photographs were collected). Observed encounter histories can consist of non-detections (0), type 1 encounters (1), and type 2 encounters (2). See `bobcat`. Latent encounter histories consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), and type 3 encounters (3).
processdata

data.type="sometimes" indicates both type 1 and type 2 encounters are sometimes observed (e.g., both-sided photographs are sometimes obtained, but not necessarily for all individuals). Observed encounter histories can consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), type 3 encounters (3), and type 4 encounters (4). Type 3 encounters can only be observed when an individual has at least one type 4 encounter. Latent encounter histories consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), type 3 encounters (3), and type 4 encounters (4).

data.type="always" indicates both type 1 and type 2 encounters are always observed, but some encounter histories may still include only type 1 or type 2 encounters. Observed encounter histories can consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), and type 4 encounters (4). Latent encounter histories consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), and type 4 encounters (4).

covs

A data frame of temporal covariates for detection probabilities (ignored unless mms=NULL). The number of rows in the data frame must equal the number of sampling occasions. Covariate names cannot be "time", "age", or "h"; these names are reserved for temporal, behavioral, and individual effects when specifying mod.p and mod.phi.

known

Optional integer vector indicating whether the encounter history of an individual is known with certainty (i.e., the observed encounter history is the true encounter history). Encounter histories with at least one type 4 encounter are automatically assumed to be known, and known does not need to be specified unless there exist encounter histories that do not contain a type 4 encounter that happen to be known with certainty (e.g., from independent telemetry studies). If specified, known = c(v_1,v_2,...,v_M) must be a vector of length M = nrow(Enc.Mat) where v_i = 1 if the encounter history for individual i is known (v_i = 0 otherwise). Note that known all-zero encounter histories (e.g., '000') are ignored.

Value

An object of class multimarksetup.

processdataSCR  Generate model inputs for fitting spatial 'multimark' models

Description

This function generates an object of class multimarkSCRsetup that is required to fit spatial 'multimark' models.

Usage

processdataSCR(Enc.Mat, trapCoords, studyArea = NULL, buffer = NULL, ncells = NULL, data.type = "never", covs = data.frame(), known = integer(), scalemax = 10)

Arguments

Enc.Mat A matrix containing the observed encounter histories with rows corresponding to individuals and (ntraps*nocca) columns corresponding to traps and sampling occasions. The first nocca columns correspond to trap 1, the second nocca columns correspond to trap 2, etc. Ignored unless mms=NONE.

trapCoords A matrix of dimension ntraps x (2 + nocca) indicating the Cartesian coordinates and operating occasions for the traps, where rows correspond to trap, the first column the x-coordinate, and the second column the y-coordinate. The last nocca columns indicate whether or not the trap was operating on each of the occasions, where '1' indicates the trap was operating and '0' indicates the trap was not operating.

studyArea is a 3-column matrix containing the coordinates for the centroids of a contiguous grid of cells that define the study area and available habitat. Each row corresponds to a grid cell. The first 2 columns indicate the Cartesian x- and y-coordinate for the centroid of each grid cell, and the third column indicates whether the cell is available habitat (=1) or not (=0). All cells must be square and have the same resolution. If studyArea=NULL (the default), then a square
study area grid composed of ncells cells of available habitat is drawn around the bounding box of trapCoords based on buffer.

**buffer**
A scaler in same units as trapCoords indicating the buffer around the bounding box of trapCoords for defining the study area when studyArea=NULL. Ignored unless studyArea=NULL.

**ncells**
The number of grid cells in the study area when studyArea=NULL. The square root of ncells must be a whole number. Default is \( \sqrt{1024} \). Ignored unless studyArea=NULL.

**data.type**
Specifies the encounter history data type. All data types include non-detections (type 0 encounter), type 1 encounter (e.g., left-side), and type 2 encounters (e.g., right-side). When both type 1 and type 2 encounters occur for the same individual within a sampling occasion, these can either be "non-simultaneous" (type 3 encounter) or "simultaneous" (type 4 encounter). Three data types are currently permitted:

- **data.type="never"** indicates both type 1 and type 2 encounters are never observed for the same individual within a sampling occasion, and observed encounter histories therefore include only type 1 or type 2 encounters (e.g., only left- and right-sided photographs were collected). Observed encounter histories can consist of non-detections (0), type 1 encounters (1), and type 2 encounters (2). See bobcat. Latent encounter histories consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), and type 3 encounters (3).

- **data.type="sometimes"** indicates both type 1 and type 2 encounters are sometimes observed (e.g., both-sided photographs are sometimes obtained, but not necessarily for all individuals). Observed encounter histories can consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), type 3 encounters (3), and type 4 encounters (4). Type 3 encounters can only be observed when an individual has at least one type 4 encounter. Latent encounter histories consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), type 3 encounters (3), and type 4 encounters (4).

- **data.type="always"** indicates both type 1 and type 2 encounters are always observed, but some encounter histories may still include only type 1 or type 2 encounters. Observed encounter histories can consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), and type 4 encounters (4). Latent encounter histories consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), and type 4 encounters (4).

**covs**
A data frame of temporal covariates for detection probabilities (ignored unless mms=NULL). The number of rows in the data frame must equal the number of sampling occasions. Covariate names cannot be "time", "age", or "h"; these names are reserved for temporal, behavioral, and individual effects when specifying mod.p and mod.phi.

**known**
Optional integer vector indicating whether the encounter history of an individual is known with certainty (i.e., the observed encounter history is the true encounter history). Encounter histories with at least one type 4 encounter are automatically assumed to be known, and known does not need to be specified unless there exist encounter histories that do not contain a type 4 encounter that happen to be known with certainty (e.g., from independent telemetry studies). If specified, known = c(v_1, v_2, \ldots, v_M) must be a vector of length \( M = nrow(Enc.Mat) \).
where $v_{i} = 1$ if the encounter history for individual $i$ is known ($v_{i} = 0$ otherwise). Note that known all-zero encounter histories (e.g., '000') are ignored.

- **scalemax**: Upper bound for internal re-scaling of grid cell centroid coordinates. Default is $\text{scalemax}=10$, which re-scales the centroids to be between 0 and 10. Re-scaling is done internally to avoid numerical overflows during model fitting.

**Value**

An object of class `multimarkSCRsetup`.

**Examples**

```r
# simulate data for data.type="sometimes" using defaults
data<-simdataCJS(data.type="sometimes")
```
Simulate closed population capture-mark-recapture data arising from multiple non-invasive marks

This function generates encounter histories from simulated closed population capture-mark-recapture data consisting of multiple non-invasive marks.

Usage

\[
simdataClosed(N = 100, noccas = 5, pbeta = -0.4, tau = 0, \sigma_{R,zp} = 0, delta_1 = 0.4, delta_2 = 0.4, alpha = 0.5, \text{data.type} = "never", \text{link} = "logit")
\]

Arguments

- **N**
  - True population size or abundance.
- **noccas**
  - The number of sampling occasions.
- **pbeta**
  - Logit- or probit-scale intercept term(s) for capture probability (p). Must be a scalar or vector of length `noccas`.
- **tau**
  - Additive logit- or probit-scale behavioral effect term for recapture probability (c).
- **sigma2_zp**
  - Logit- or probit-scale individual heterogeneity variance term.
- **delta_1**
  - Conditional probability of type 1 encounter, given detection.
- **delta_2**
  - Conditional probability of type 2 encounter, given detection.
- **alpha**
  - Conditional probability of simultaneous type 1 and type 2 detection, given both types encountered. Only applies when `data.type = "sometimes"`.
- **data.type**
  - Specifies the encounter history data type. All data types include non-detections (type 0 encounter), type 1 encounter (e.g., left-side), and type 2 encounters (e.g., right-side). When both type 1 and type 2 encounters occur for the same individual within a sampling occasion, these can either be "non-simultaneous" (type 3 encounter) or "simultaneous" (type 4 encounter). Three data types are currently permitted:
    - `data.type="never"` indicates both type 1 and type 2 encounters are never observed for the same individual within a sampling occasion, and observed encounter histories therefore include only type 1 or type 2 encounters (e.g., only left- and right-sided photographs were collected). Observed encounter histories can consist of non-detections (0), type 1 encounters (1), and type 2 encounters (2). See `bobcat`. Latent encounter histories consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), and type 3 encounters (3).
    - `data.type="sometimes"` indicates both type 1 and type 2 encounters are sometimes observed (e.g., both-sided photographs are sometimes obtained, but not
necessarily for all individuals). Observed encounter histories can consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), type 3 encounters (3), and type 4 encounters (4). Type 3 encounters can only be observed when an individual has at least one type 4 encounter. Latent encounter histories consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), type 3 encounters (3), and type 4 encounters (4).

data.type="always" indicates both type 1 and type 2 encounters are always observed, but some encounter histories may still include only type 1 or type 2 encounters. Observed encounter histories can consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), and type 4 encounters (4). Latent encounter histories consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), and type 4 encounters (4).

**Value**

A list containing the following:

- `Enc.Mat` A matrix containing the observed encounter histories with rows corresponding to individuals and columns corresponding to sampling occasions.
- `trueEnc.Mat` A matrix containing the true (latent) encounter histories with rows corresponding to individuals and columns corresponding to sampling occasions.

simdataClosedSCR

Simulate spatially-explicit capture-mark-recapture data from a (demographically) closed population with multiple non-invasive marks

Description

This function generates encounter histories from spatially-explicit capture-mark-recapture data consisting of multiple non-invasive marks.

Usage

```
simdataClosedSCR(N = 30, ntraps = 9, noccas = 5, pbeta = 0.25,
    tau = 0, sigma2_scr = 0.75, lambda = 0.75, delta_1 = 0.4,
    delta_2 = 0.4, alpha = 0.5, data.type = "never",
    detection = "half-normal", spatialInputs = NULL, buffer = 3 *
    sqrt(sigma2_scr), ncells = 1024, scalemax = 10, plot = TRUE)
```

Arguments

- **N**: True population size or abundance.
- **ntraps**: The number of traps. If `trapCoords=NULL`, the square root of `ntraps` must be a whole number in order to create a regular grid of trap coordinates on a square.
- **noccas**: Scaler indicating the number of sampling occasions per trap.
- **pbeta**: Complementary loglog-scale intercept term for detection probability (p). Must be a scaler or vector of length `noccas`.
- **tau**: Additive complementary loglog-scale behavioral effect term for recapture probability (c).
- **sigma2_scr**: Complementary loglog-scale term for effect of distance in the “half-normal” detection function. Ignored unless `detection="half-normal"`.
- **lambda**: Complementary loglog-scale term for effect of distance in the “exponential” detection function. Ignored unless `detection="exponential"`.
- **delta_1**: Conditional probability of type 1 encounter, given detection.
- **delta_2**: Conditional probability of type 2 encounter, given detection.
- **alpha**: Conditional probability of simultaneous type 1 and type 2 detection, given both types encountered. Only applies when `data.type="sometimes"`.
- **data.type**: Specifies the encounter history data type. All data types include non-detections (type 0 encounter), type 1 encounter (e.g., left-side), and type 2 encounters (e.g., right-side). When both type 1 and type 2 encounters occur for the same individual within a sampling occasion, these can either be "non-simultaneous" (type 3 encounter) or "simultaneous" (type 4 encounter). Three data types are currently permitted: `data.type="never"` indicates both type 1 and type 2 encounters are never observed for the same individual within a sampling occasion, and observed encounter histories therefore include only type 1 or type 2 encounters (e.g., only...
left- and right-sided photographs were collected). Observed encounter histories can consist of non-detections (0), type 1 encounters (1), and type 2 encounters (2). See *bobcat*. Latent encounter histories consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), and type 3 encounters (3).

data.type="sometimes" indicates both type 1 and type 2 encounters are sometimes observed (e.g., both-sided photographs are sometimes obtained, but not necessarily for all individuals). Observed encounter histories can consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), type 3 encounters (3), and type 4 encounters (4). Type 3 encounters can only be observed when an individual has at least one type 4 encounter. Latent encounter histories consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), type 3 encounters (3), and type 4 encounters (4).

data.type="always" indicates both type 1 and type 2 encounters are always observed, but some encounter histories may still include only type 1 or type 2 encounters. Observed encounter histories can consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), and type 4 encounters (4). Latent encounter histories consist of non-detections (0), type 1 encounters (1), type 2 encounters (2), and type 4 encounters (4).

detection Model for detection probability as a function of distance from activity centers. Must be "half-normal" (of the form $\exp \left( -d^2 / (2 \times \sigma^2) \right)$, where $d$ is distance) or "exponential" (of the form $\exp \left( -d / \lambda \right)$).

spatialInputs A list of length 3 composed of objects named trapCoords, studyArea, and centers:

- **trapCoords** is a matrix of dimension $n$traps x ($2 + noccas$) indicating the Cartesian coordinates and operating occasions for the traps, where rows correspond to trap, the first column the x-coordinate ("x"), and the second column the y-coordinate ("y"). The last $noccas$ columns indicate whether or not the trap was operating on each of the occasions, where '1' indicates the trap was operating and '0' indicates the trap was not operating.

- **studyArea** is a 3-column matrix defining the study area and available habitat. Each row corresponds to a grid cell. The first 2 columns ("x" and "y") indicate the Cartesian x- and y-coordinate for the centroid of each grid cell, and the third column ("avail") indicates whether the cell is available habitat (=1) or not (=0). All grid cells must have the same resolution.

- **centers** is a N-vector indicating the grid cell (i.e., the row of studyArea) that contains the true (latent) activity centers for each individual in the population.

If **spatialInputs=NULL** (the default), then all traps are assumed to be operating on all occasions, the study area is assumed to be composed of **ncells** grid cells, grid cells within buffer of the trap array are assumed to be available habitat, and the activity centers are randomly assigned to grid cells of available habitat.

buffer A scaler indicating the buffer around the bounding box of trapCoords for defining the study area and available habitat when **spatialInputs=NULL**. Default is **buffer=3*sqrt(sigma2_scr)**. Ignored unless **spatialInputs=NULL**.

ncells The number of grid cells in the study area when **studyArea=NULL**. The square root of ncells must be a whole number. Default is **ncells=1024**. Ignored unless **spatialInputs=NULL**.
scalemax  Upper bound for grid cell centroid x- and y-coordinates. Default is scalemax=10, which scales the x- and y-coordinates to be between 0 and 10. Ignored unless spatialinputs=NULL.

plot  Logical indicating whether to plot the simulated trap coordinates, study area, and activity centers using plotSpatialData. Default is plot=TRUE

Details

Please be very careful when specifying your own spatialInputs; multimarkClosedSCR and markClosedSCR do little to verify that these make sense during model fitting.

Value

A list containing the following:

Enc.Mat  Matrix containing the observed encounter histories with rows corresponding to individuals and (ntraps*noccas) columns corresponding to traps and sampling occasions. The first noccas columns correspond to trap 1, the second noccas columns correspond to trap 2, etc.

trueEnc.Mat  Matrix containing the true (latent) encounter histories with rows corresponding to individuals and (ntraps*noccas) columns corresponding to traps and sampling occasions. The first noccas columns correspond to trap 1, the second noccas columns correspond to trap 2, etc.

spatialInputs  List of length 2 with objects named trapCoords and studyArea:

trapCoords is a matrix of dimension ntraps x (2 + noccas) indicating the Cartesian coordinates and operating occasions for the traps, where rows correspond to trap, the first column the x-coordinate, and the second column the y-coordinate. The last noccas columns indicate whether or not the trap was operating on each of the occasions, where ‘1’ indicates the trap was operating and ‘0’ indicates the trap was not operating.

studyArea is a 3-column matrix containing the coordinates for the centroids a contiguous grid of cells that define the study area and available habitat. Each row corresponds to a grid cell. The first 2 columns indicate the Cartesian X- and Y-coordinate for the centroid of each grid cell, and the third column indicates whether the cell is available habitat (=1) or not (=0). All cells must have the same resolution.

centers  N-vector indicating the grid cell (i.e., the row of spatialInputs$studyArea) that contains the true (latent) activity centers for each individual in the population.

### Description

Example tiger data for `multimark` package.

### Format

These spatial capture-recapture data with a single mark type are summarized in a list of length 3 containing the following objects:

- `encMat` is a 44 x (noccas*ntraps) matrix containing observed encounter histories for 44 tigers across noccas=48 sampling occasions and ntraps=120 traps.

- `trapCoords` is a matrix of dimension ntraps x (2 + noccas) indicating the Cartesian coordinates and operating occasions for the traps, where rows correspond to trap, the first column the x-coordinate, and the second column the y-coordinate. The last noccas columns indicate whether or not the trap was operating on each of the occasions, where ‘1’ indicates the trap was operating and ‘0’ indicates the trap was not operating.

- `studyArea` is a 3-column matrix containing the coordinates for the centroids of the contiguous grid of cells that define the study area and available habitat. Each row corresponds to a grid cell. The first 2 columns indicate the Cartesian x- and y-coordinate for the centroid of each grid cell, and the third column indicates whether the cell is available habitat (=1) or not (=0). The grid cells are 0.336 km^2 resolution.

These data were obtained from the R package `SPACECAP` and modified by projecting onto a regular rectangular grid consisting of square grid cells (as is required by the spatial capture-recapture models in `multimark`).

### Details

We thank Ullas Karanth, Wildlife Conservation Society, for providing the tiger data for use as an example with this package.
