Package ‘nVennR’

May 4, 2020

Type  Package
Title  Create n-Dimensional, Quasi-Proportional Venn Diagrams
Version  0.2.2
Author  Victor Quesada [aut, cre, cph]
Maintainer  Victor Quesada <quesadavictor@uniovi.es>
Description  Provides an interface for the "nVenn" algorithm. This algorithm works for any number of sets, and usually yields pleasing and informative Venn diagrams with proportionality information. However, representing more than six sets takes a long time and is hard to interpret, unless many of the regions are empty. If you cannot make sense of the result, you may want to consider 'UpSetR'.
License  MIT + file LICENSE
Encoding  UTF-8
LazyData  true
RoxygenNote  7.1.0
Depends  R (>= 2.10)
LinkingTo  Rcpp
Imports  Rcpp
Suggests  knitr, rmarkdown, rsvg, grImport2
VignetteBuilder  knitr
NeedsCompilation  yes
Repository  CRAN
Date/Publication  2020-05-04 08:50:05 UTC

R topics documented:

createVennObj .................................................. 2
examledf .................................................. 2
getVennRegion ............................................... 3
listVennRegions ........................................... 4
### Description

Create `nVennObj` from scratch

### Usage

```r
createVennObj(nSets = 1, sNames = NULL, sSizes = NULL)
```

### Arguments

- **nSets**: Number of sets.
- **sNames**: List of names.
- **sSizes**: List of sizes for all the regions (from 0 to `2^nSets - 1`). To understand the order of the regions, one can think of a region as a binary number. Each bit tells whether the region belongs (1) or not (0) to a given set. For instance, with 4 sets we have 4 bits. The number 7 with 4 bits is 0111, which describes a region belonging to sets 2, 3, and 4 and not to set 1. To pass the values of the regions, those values are sorted according to the number describing the region. Thus, with four sets, the first element corresponds to region 0 (0000), the second to region 1 (0001), the third to region 2 (0010), ... The last corresponds to region 15 (1111), which belongs to all the sets.

### Value

`nVennObj` with set information. To plot, it must be sent to `toVenn`. Sending it to `showSVG` will render the diagram before simulation.

---

#### `exampledf`  
*Example data frame.*

### Description

A dataset containing programming preferences from 18 employees. This data set was provided by user Krantz to inquire about `nVennR`
getVennRegion

Format

A data frame with 18 rows and 3 variables:

- **Employee** Employee ID
- **SAS** Employee uses SAS
- **Python** Employee uses Python
- **R** Employee uses R

Source

---

**Description**

Get elements in a region

**Usage**

getVennRegion(nVennObj, region)

**Arguments**

- **nVennObj** Object describing an nVenn job.
- **region** Description of the region. This can be a vector with the names of the groups the region belongs to or a vector describing whether the region belongs to each set in order (i.e., c(1, 0, 0) means the region belongs to set 1 and does not belong to sets 2 and 3).

**Value**

list of the elements belonging to the specified region
listVennRegions

List elements in every region

Description
List elements in every region

Usage
listVennRegions(nVennObj, na.rm = T)

Arguments
- **nVennObj**: Object to list.
- **na.rm**: If true, empty regions are not listed.

plotVenn

Create Venn diagram using the nVenn algorithm.

Description
This algorithm is based on a simulation that compacts the figure. If the resulting diagram is not compact enough, the simulation can be tweaked in two ways: changing the number of simulation cycles (`nCycles`) and executing this function repeatedly.

Usage
plotVenn(
  sets,
  nVennObj = NULL,
  nCycles = 7000,
  sNames = NULL,
  showPlot = T,
  ...
)

Arguments
- **sets**: List of lists with the input sets.
- **nVennObj**: Object returned from previous run. If provided, the function will improve the diagram by running more cycles on the previous result. If nVennObj is provided, do not feed additional input lists, as they will be ignored.
- **nCycles**: Number of cycles for the simulation. For up to 4 sets, the default number of 7000 should be enough. Even for more complex scenarios, it may be better to run the function repeatedly, as a large number of cycles may take up too many resources.
setVennRegion

sNames
List of set names, in the same order as the input lists. If the input has tables or
data frames and the name exists, it will select the corresponding column.

showPlot
Show the result in the graphic device.

... Options for 'showSVG' If input lists have names, those names will be used for
the legend. If not, names can be provided with sNames.

Value
nVennObj with the result of the simulation. As a side effect, The result can be drawn in the graphical
device.

Examples

```r
set1 <- list(set1 = c('a', 'b', 'c'))
set2 <- list(set2 = c('e', 'f', 'c'))
set3 <- list(set3 = c('c', 'b', 'e'))
myNV <- plotVenn(list(set1, set2, set3), sNames=c("One", "Two", "Three"))
showSVG(myNV, opacity=0.2)
```

---

setVennRegion  
**Set number of elements in a region**

Description

Set number of elements in a region

Usage

```r
setVennRegion(nVennObj, region, value)
```

Arguments

- `nVennObj`: Object describing an nVenn job.
- `region`: Description of the region. This can be a vector with the names of the groups the
  region belongs to or a vector describing whether the region belongs to each set
  in order (i.e., c(1, 0, 0) means the region belongs to set 1 and does not belong
to sets 2 and 3).
- `value`: Size of the region.

Value

Modified nVennObj
Description

Show Venn diagram. Automatically called from plotVenn.

Usage

showSVG(
  nVennObj,
  opacity = 0.4,
  borderWidth = 1,
  showLegend = T,
  outFile = "",
  systemShow = FALSE,
  labelRegions = T,
  showNumbers = T,
  setColors = NULL,
  fontScale = 1
)

Arguments

- **nVennObj**: Object with nVennR information. Can be obtained from a plotVenn call.
- **opacity**: Fill opacity for the sets. Defaults to 0.4.
- **borderWidth**: Width of set borders. Defaults to 1.
- **showLegend**: Boolean stating whether the resulting figure should contain a legend. Defaults to true.
- **outFile**: File name to save SVG figure. If empty, a temp file will be created and sent to the graphic device.
- **systemShow**: Show the result in the system SVG viewer (i.e., Inkscape).
- **labelRegions**: Show region identifiers. These are numbers in parentheses inside each region indicating which sets that region belongs to. Defaults to true.
- **showNumbers**: Show how many elements belong to each region (large numbers in the figure). Defaults to true.
- **setColors**: Vector with the color of each set in order. Color names must be CSS-compatible.
- **fontScale**: Multiplier for font sizes. The font size of both numbers and region labels will be multiplied by this factor. Values larger than 2 will probably make labels clash.

Value

Nothing. Creates a Venn diagram in svg as a side effect.
