Package ‘nanotime’

September 4, 2020

Type Package
Title Nanosecond-Resolution Time Support for R
Version 0.3.2
Date 2020-09-03
Author Dirk Eddelbuettel and Leonardo Silvestri
Maintainer Dirk Eddelbuettel <edd@debian.org>
Description Full 64-bit resolution date and time functionality with nanosecond granularity is provided, with easy transition to and from the standard 'POSIXct' type. Three additional classes offer interval, period and duration functionality for nanosecond-resolution timestamps.
Imports methods, bit64, RcppCCTZ (>= 0.2.9), zoo
Suggests tinytest, data.table, xts
LinkingTo Rcpp, RcppCCTZ, RcppDate
License GPL (>= 2)
RoxygenNote 7.1.1
Collate 'nanotime.R' 'nanoival.R' 'nanoduration.R' 'nanoperiod.R'
   'RcppExports.R'
Encoding UTF-8
NeedsCompilation yes
Repository CRAN
Date/Publication 2020-09-04 05:12:19 UTC

all.equal.nanoduration

Test if Two Objects are (Nearly) Equal

Description

Compare target and current testing 'near equality'. If they are different, comparison is still made to some extent, and a report of the differences is returned. Do not use all.equal directly in if expressions—either use isTRUE(all.equal(....)) or identical if appropriate.

Usage

```r
## S3 method for class 'nanoduration'
all.equal(
  target, current, tolerance = sqrt(.Machine$double.eps), scale = NULL, countEQ = FALSE, formatFUN = function(err, what) format(err), ...
  check.attributes = TRUE
)

## S4 method for signature 'nanoduration'
all.equal(
  target, current, tolerance = sqrt(.Machine$double.eps), scale = NULL,
```
all.equal.nanoival

```r
  countEQ = FALSE,
  formatFUN = function(err, what) format(err),
...
  check.attributes = TRUE
}
```

**Arguments**

- `target, current` nanoduration arguments to be compared
- `tolerance` numeric >= 0. Differences smaller than tolerance are not reported. The default value is close to 1.5e-8.
- `scale` NULL or numeric > 0, typically of length 1 or length(target). See ‘Details’.
- `countEQ` logical indicating if the target == current cases should be counted when computing the mean (absolute or relative) differences. The default, FALSE may seem misleading in cases where target and current only differ in a few places; see the extensive example.
- `formatFUN` a function of two arguments, err, the relative, absolute or scaled error, and what, a character string indicating the _kind_ of error; maybe used, e.g., to format relative and absolute errors differently.
- `...` further arguments for different methods
- `check.attributes` logical indicating if the attributes of target and current (other than the names) should be compared.

**See Also**

`identical, isTRUE, ==, and all` for exact equality testing.

all.equal.nanoival  Test if Two Objects are (Nearly) Equal

**Description**

Compare target and current testing ‘near equality’. If they are different, comparison is still made to some extent, and a report of the differences is returned. Do not use all.equal directly in if expressions—either use isTRUE(all.equal(....)) or identical if appropriate.

**Usage**

```r
## S3 method for class 'nanoival'
all.equal(target, current, ..., check.attributes = TRUE)

## S4 method for signature 'nanoival'
all.equal(target, current, ..., check.attributes = TRUE)
```
all.equal.nanoperiod

Test if Two Objects are (Nearly) Equal

Description

Compare target and current testing ‘near equality’. If they are different, comparison is still made to some extent, and a report of the differences is returned. Do not use all.equal directly in if expressions—either use isTRUE(all.equal(....)) or identical if appropriate.

Usage

## S3 method for class 'nanoperiod'
all.equal(target, current, ..., check.attributes = TRUE)

## S4 method for signature 'nanoperiod'
all.equal(target, current, ..., check.attributes = TRUE)

Arguments

target, current
    nanoperiod arguments to be compared
...
    further arguments for different methods
check.attributes
    logical indicating if the attributes of target and current (other than the names) should be compared.

See Also

identical, isTRUE, ==, and all for exact equality testing.
**Description**

Compare target and current testing ‘near equality’. If they are different, comparison is still made to some extent, and a report of the differences is returned. Do not use all.equal directly in if expressions—either use isTRUE(all.equal(....)) or identical if appropriate.

**Usage**

```r
## S3 method for class 'nanotime'
all.equal(
  target,
  current,
  tolerance = sqrt(.Machine$double.eps),
  scale = NULL,
  countEQ = FALSE,
  formatFUN = function(err, what) format(err),
  ..., 
  check.attributes = TRUE
)
```

```r
## S4 method for signature 'nanotime'
all.equal(
  target,
  current,
  tolerance = sqrt(.Machine$double.eps),
  scale = NULL,
  countEQ = FALSE,
  formatFUN = function(err, what) format(err),
  ..., 
  check.attributes = TRUE
)
```

**Arguments**

- `target`, `current` nanotime arguments to be compared
- `tolerance` numeric >= 0. Differences smaller than tolerance are not reported. The default value is close to 1.5e-8.
- `scale` NULL or numeric > 0, typically of length 1 or length(target). See ‘Details’.
- `countEQ` logical indicating if the target == current cases should be counted when computing the mean (absolute or relative) differences. The default, FALSE may seem misleading in cases where target and current only differ in a few places; see the extensive example.
formatFUN  a function of two arguments, err, the relative, absolute or scaled error, and what, a character string indicating the _kind_ of error; maybe used, e.g., to format relative and absolute errors differently.

...  further arguments for different methods

check.attributes  logical indicating if the attributes of target and current (other than the names) should be compared.

**intersect.nanoival, nanoival-method**  
*Set operations*

**Description**

Performs set intersection, union and difference between vectors of temporal types from the nanotime package.

**Usage**

```r
## S4 method for signature 'nanoival, nanoival'
intersect(x, y)

## S4 method for signature 'nanoival, nanoival'
union(x, y)

## S4 method for signature 'nanoival, nanoival'
setdiff(x, y)

## S4 method for signature 'nanotime, nanoival'
intersect.idx(x, y)

## S4 method for signature 'nanotime, nanoival'
setdiff.idx(x, y)
```

## S3 method for class 'nanotime'

x %in% table

## S4 method for signature 'nanotime, nanoival'
intersect(x, y)

## S4 method for signature 'nanotime, nanoival'
setdiff(x, y)

## S4 method for signature 'nanotime, nanoival'
setdiff.idx(x, y)
```
# S4 method for signature 'nanotime,nanotime'
intersect(x, y)

# S4 method for signature 'nanotime,nanotime'
union(x, y)

# S4 method for signature 'nanotime,nanotime'
setdiff(x, y)

## Arguments

x, y       a temporal type
table nanoival: used in %in%

## Details

Set operations between nanoival operands allow the construction of complex interval vectors (i.e. a nanoival vector can specify any number of inclusions and exclusions of time). Set operations between nanotime and nanoival allow to subset time vectors with interval vectors. In addition to the generic set functions, the function intersect.idx is defined which returns the indices of the intersection, and the operator %in% is overloaded for nanotime-nanoival which returns a logical vector that indicates which elements belong to the interval vector.

## Value

intersect, union, setdiff return temporal types that are the result of the intersection. For instance, set operations on two nanoival return a nanoival, whereas intersection between a nanoival and a nanotime returns a nanotime. intersect.idx return a list of vectors representing the element indices that intersect and setdiff.idx returns a vector representing the element indices to be removed.

## Examples

```r
## Not run:
## a vector of 'nanotime' can be subsetted by a 'nanoival' which is equivalent to 'intersect':
one_second <- 1e9
a <- seq(nanotime("2012-12-12 12:12:12+00:00"), length.out=10, by=one_second)
idx <- c(as.nanoival("-2012-12-12 12:12:14+00:00 -> 2012-12-12 12:12:18+00:00-"),
         as.nanoival("+2012-12-12 12:12:18+00:00 -> 2012-12-12 12:12:20+00:00+"))
a[idx]
intersect(a, idx)

## 'nanoival' also has the set operations 'union', 'intersect', 'setdiff':
a <- seq(nanotime("2012-12-12 12:12:12+00:00"), length.out=10, by=one_second)
i <- as.nanoival("-2012-12-12 12:12:14+00:00 -> 2012-12-12 12:12:18+00:00-")
setdiff(a, i)

i1 <- as.nanoival("+2012-12-12 12:12:14+00:00 -> 2012-12-12 12:12:17+00:00-")
i2 <- as.nanoival("+2012-12-12 12:12:16+00:00 -> 2012-12-12 12:12:18+00:00-")
union(i1, i2)
```
## 'intersect.idx' returns the indices of the intersection:

```r
a <- seq(nanotime("2012-12-12 12:12:12+00:00"), length.out=10, by=one_second)
idx <- as.nanoival("+2012-12-12 12:12:14+00:00 -> 2012-12-12 12:12:19+00:00+")
idx_intersect <- intersect.idx(a, idx)
```

## Intersection can be performed using these indices:

```r
a[idx_intersect$x]
```

## which is equivalent to:

```r
a[idx]
```

## The logical vector indicating intersection can be obtained like this:

```r
a %in% idx
```

## End(Not run)

---

### is.unsorted, nanoival-method

*Test if a nanoival vector is Not Sorted*

#### Description

Test if an object is not sorted (in increasing order), without the cost of sorting it.

#### Usage

```r
## S4 method for signature 'nanoival'
is.unsorted(x, na.rm = FALSE, strictly = FALSE)
```

#### Arguments

- `x`: a nanoival vector
- `na.rm`: logical. Should missing values be removed before checking?
- `strictly`: logical indicating if the check should be for *strictly* increasing values.

#### See Also

`sort`
Description

The type `nanoduration` is a length of time (implemented as an S4 class) with nanosecond precision. It is a count of nanoseconds and may be negative. The expected arithmetic operations are provided, including sequence generation.

Usage

```r
nanoduration(hours, minutes, seconds, nanoseconds)
```

```r
## S4 method for signature 'character'
as.nanoduration(x)
```

```r
## S4 method for signature 'integer64'
as.nanoduration(x)
```

```r
## S4 method for signature 'numeric'
as.nanoduration(x)
```

```r
## S4 method for signature 'integer'
as.nanoduration(x)
```

```r
## S4 method for signature '\NULL\'
as.nanoduration(x)
```

```r
## S4 method for signature 'missing'
as.nanoduration(x)
```

```r
## S4 method for signature 'nanoduration'
show(object)
```

```r
## S4 method for signature 'nanoduration'
print(x, quote = FALSE, ...)
```

```r
## S3 method for class 'nanoduration'
format(x, ...)
```

```r
## S3 method for class 'nanoduration'
as.integer64(x, ...)
```

```r
## S4 method for signature 'nanoduration'
as.character(x)
```

```r
## S4 method for signature 'nanoduration'
```
is.na(x)

NA_nanoduration

Arguments

- **hours**: number of hours
- **minutes**: number of minutes
- **seconds**: number of seconds
- **nanoseconds**: number of nanoseconds
- **x**: a nanoduration object
- **object**: argument for method show
- **quote**: indicates if the output of print should be quoted
- **...**: further arguments passed to or from methods.
- **e1**: Operand of class nanoival
- **e2**: Operand of class nanoival
- **na.rm**: if TRUE NA values are removed for the computation
- **i**: index specifying elements to extract or replace.
- **j**: Required for [ signature but ignored here
- **drop**: Required for [ signature but ignored here
- **value**: argument for nanoduration-class
Format

An object of class `nanoduration` of length 1.

Details

A `nanoduration` can be constructed with the function `as.nanoduration` which can take the types `integer64`, `integer` and `numeric` (all indicating the count in nanosecond units) or the type `character`.

It can also be constructed by specifying with individual arguments the hours, minutes, seconds and nanoseconds with a call to `nanoduration`.

A `nanoduration` is displayed as hours, minutes, seconds and nanoseconds like this: `110:12:34.123_453_001`. The nanosecond precision displayed is adjusted as necessary, so e.g. 1 second is displayed as `00:00:01`.

Value

A `nanoduration` object

as.nanoduration("10:03:02.999_999_999")
as.nanoduration(36182999999999)

## arithmetic:
as.nanoduration(10e9) - as.nanoduration(9e9)
as.nanoduration(10e9) + as.nanoduration(-9e9)
as.nanoduration("24:00:00") / 2
as.nanoduration("24:00:00") / as.nanoduration("12:00:00")
```
nanoival-class

Interval type with nanosecond precision

Description

nanoival is a time interval type (an S4 class) with nanosecond precision. One of its purposes is to allow quick subsetting of a nanotime vector. nanoival is composed of a nanotime pair which defines the start and end of the time interval. Additionally, it has a pair of logical values which determine if the start and end of the time interval are open (true) or closed (false).

Usage

nanoival(start, end, sopen = FALSE, eopen = TRUE)

## S4 method for signature 'nanoival'
nanoival.start(x)

## S4 method for signature 'nanoival'
nanoival.end(x)

## S4 method for signature 'nanoival'

</tbody>
</table>

Format

An object of class nanoival of length 1.
Details

An interval object can be constructed with the constructor `nanoival` which takes as arguments two `nanotime` objects that define the start and the end of the interval, together with two logical arguments that define if the start and the end of the interval are open (true) or closed (false) (note that these objects can all be a vector, and therefore the interval object is not necessarily scalar). Alternatively, an interval can be constructed with a character: the format follows that of `nanotime`; the start time is preceeded by either - or + indicating if the interval start is open (-) or closed (+); the start and end times are separated by an arrow `->`; the end is folloed by either - or + which have the same semantics as the start time.

The most important set of methods defined for `interval` are set functions `intersect`, `union` and `setdiff`.

Additionally, `interval` allows the subsetting into a `nanotime` vector. Note that subsetting is allowed only if the `nanotime` vector is sorted.

Finally, accessors are provided to get the interval start (`start`), the end (`end`), the open/close status of the start (`sopen`) and the open/close status of the end (`eopen`). The former return a `nanotime` while the latter return a `logical`.

Value

A `nanoival` object

Output Format

Formatting and character conversion for `nanoival` objects is identical to `nanotime` objects. The default format is ISO3339 compliant: `%Y-%m-%dT%H:%M:%ES%ez`. It specifies a standard ISO 8601 part for date and time — as well as nine digits of precision for fractional seconds (down to nanoseconds) and an offset (typically zero as we default to UTC). It can be overridden by using `options()` with the key of `nanotimeFormat` and a suitable value. Similarly, `nanotimeTz` can be used to select a different timezone.

Examples

```r
## Not run:
## creating a `nanoival`, with the start time included (`+`) and the end
## time excluded (`-`) as.nanoival("+2012-03-01T21:21:00.000000001+00:00->2015-01-01T21:22:00.000000999+04:00-")

## a `nanoival` can also be created with a pair of `nanotime` objects, a start
## and an end, and optionally two logicals determining if the interval start(end) are open
```

## or closed; by default the start is closed and end is open:
start <- nanotime("2012-03-01T21:21:00.000000001+00:00")
end <- nanotime("2013-03-01T21:21:00.000000001+00:00")
nanoival(start, end)

## a vector of 'nanotime' can be subsetted by a 'nanoival':
one_second <- 1e9
a <- seq(nanotime("2012-12-12 12:12:12+00:00"), length.out=10, by=one_second)
idx <- c(as.nanoival("-2012-12-12 12:12:10+00:00 -> 2012-12-12 12:12:14+00:00-"),
         as.nanoival("+2012-12-12 12:12:18+00:00 -> 2012-12-12 12:12:20+00:00+"))
a[idx]

## End(Not run)

nanoperiod-class  

Period type with nanosecond precision

**Description**

nanoperiod is a length of time type (implemented as an S4 class) with nanosecond precision. It differs from nanoduration because it is capable of representing calendar months and days. It can thus represent years (12 months) and weeks (7 days). A period is a somewhat abstract representation of time: it is only when anchored to a point in time and in a specific time zone that it is possible to convert it to a specific duration. This means that many of the operations involving periods need the additional argument tz.

**Usage**

nanoperiod(months = 0, days = 0, duration = as.nanoduration(0))

NA_nanoperiod_

### Arguments

- **months**: Used in the constructor to indicate the number of months of the nanoperiod.
- **days**: Used in the constructor to indicate the number of days of the nanoperiod.
- **duration**: Used in the constructor to indicate the duration component of the nanoperiod.
- **x, value**: An object of class nanoperiod.
- **object**: Argument for method show.
- **quote**: Indicates if the output of print should be quoted.
- **...**: Further arguments.
- **i**: Index specifying elements to extract or replace.
- **j**: Required for [ signature but ignored here.
- **drop**: Required for [ signature but ignored here.
- **e1**: Operand of class nanoperiod.
- **e2**: Operand of class nanoperiod.
- **tz**: Character indicating a timezone.

### Format

An object of class nanoperiod of length 1.

### Constructors

The true constructor is

### Output Format

A nanoperiod is displayed as months, days, and nanoduration like this: 10m2d/10:12:34.123_453_000.

### Details

Adding or subtracting nanoperiod and nanotime require a timezone as third argument. For this reason it is not possible to use the binary operator `code+`. Instead the functions `plus` and `minus` are defined.

## Not run:
p <- nanoperiod(months=12, days=7, duration="01:00:00")
print(p)

# when adding a \code{nanoperiod} to a \code{nanotime} or to a
# \code{nanoival}, a time zone must be specified:
y <- nanotime("1970-01-01T00:00:00+00:00")
plus(y, p, tz="America/Chicago")

## End(Not run)

### nanoperiod.month, nanoperiod-method

#### Nanoperiod accessors

Description
These functions allow access to the components of a nanoperiod

Usage
## S4 method for signature 'nanoperiod'
nanoperiod.month(x)

## S4 method for signature 'nanoperiod'
nanoperiod.day(x)

## S4 method for signature 'nanoperiod'
nanoperiod.nanoduration(x)

Arguments

- \code{x} A nanoperiod

Value

nanoperiod.month and nanoperiod.day return an integer64 whereas nanoperiod.nanoduration returns a nanoduration
nanotime-class

**Author(s)**

Dirk Eddelbuettel

Arguments

... further arguments passed to or from methods.
format A character string. Can also be set via options("nanotimeFormat") and uses '%Y-%m-%d %H:%M:%S %z' as a default and fallback
tz character specifying a timezone which is required for as.POSIXct, as.POSIXlt and can be specified for as.nanotime, format and print; it can also be set via options("nanotimeTz") and uses 'UTC' as a default and fallback

x, from nanotime objects
quote indicates if the output of print should be quoted
object argument for method show
e1 Operand of class nanotime
e2 Operand of class nanotime
digits Required for Math2 signature but ignored here
na.rm a logical indicating whether missing values should be removed.
z Required for Complex signature but ignored here
i index specifying elements to extract or replace.
j Required for [ signature but ignored here
drop Required for [ signature but ignored here
value argument for nanotime-class

Format

An object of class nanotime of length 1.

Details

Notice that the conversion from POSIXct explicitly sets the last three digits to zero. Nanosecond time stored in a 64-bit integer has nineteen digits precision where doubles (which are used internally for POSIXct as well) only have sixteen digits. So rather than showing three more (essentially random) digits it is constructed such that these three additional digits are zeros.
Value

A nanotime object

Caveats

Working with dates and times is difficult. One needs a representation of both time points and time duration. In R, think of Date or POSIXct objects for the former, and difftime for the later. Here we have time points nanotime, an interval type nanoival and two flavors of duration which are a simple count of nanoseconds nanoduration and a calendar duration that is able to track concepts such as months and days nanoperiod. Point in time and intervals are all based on durations relative to the epoch of January 1, 1970.

Input and Output Format

Formatting and character conversion for nanotime objects is done by functions from the RcppCCTZ package relying on code from its embedded CCTZ library. The default format is ISO3339 compliant: %Y-%m-%dT%H:%M:%S%z. It specifies a standard ISO 8601 part for date and time — as well as nine digits of precision for fractional seconds (down to nanoseconds) and on offset (typically zero as we default to UTC). It can be overridden by using options() with the key of nanotimeFormat and a suitable value. Similarly, nanotimeTz can be used to select a different timezone.

For input, some slack it cut, and various shortened formats are accepted by default such as 2020-03-10 or 2020-03-10 18:16:00, or 2020-03-10 18:16:00.001 (and the ‘T’ separator is optional.

tz parameter usage in constructors

The tz parameter is allowed only when constructing a nanotime from a character. This is because any numeric, Date and POSIXct is de facto considered an offset since the epoch. On the contrary, a character is considered interpretable and hence if it does not contain a timezone in its representation, it is possible to specify the tz argument to specify in which timezone it should be interpreted. This is useful in particular if one wants to convert a Date to be aligned to the beginning of the day in a specific timezone; in this case one should convert the Date to a character before calling the nanotime constructor with the desired timezone.

Examples

```r
## Not run:
x <- nanotime(1)
print(x)
as.nanotime("1970-01-01T00:00:00.00000001+00:00")
as.nanotime("2020-03-10 Europe/Berlin")
```
nano_time

```r
as.nanotime("2020-03-10 18:31:23.001", tz="America/New_York")
x <- x + 1
print(x)
format(x)
x <- x + 10
print(x)
format(x)
nanotime(Sys.time()) + 1:3  # three elements each 1 ns apart
seq(x, by=as.nanoperiod("1d"), length.out=5, tz="Asia/Tokyo")
```

## End(Not run)

---

**nano_ceiling**

**Rounding down or up a nanotime type**

**Description**

The functions `nano_floor` and `nano_ceiling` round down or up, respectively. Although the underlying implementation of `nanotime` has negative numbers for values before 1970-01-01 UTC, the rounding is always done backward in time for `nano_floor` and forward in time for `nano_ceiling`. The functions take a `nanotime` argument `x` which is the instance to round, together with a second argument `precision` which indicates an arbitrary precision to which the rounding should be performed. This argument can be either a `nanoduration` or a `nanoperiod`. In the latter case, the argument `tz` must also be specified in order to give the `nanoperiod` a meaning. Finally, the `nanotime` argument `origin` can be optionally specified to fix the rounding to a specific point in time.

**Usage**

```r
nano_ceiling(x, precision, ...)
nano_floor(x, precision, ...)
```

## S4 method for signature 'nanotime,nanoduration'

```r
nano_ceiling(x, precision, origin = nanotime())
```

## S4 method for signature 'nanotime,nanoduration'

```r
nano_floor(x, precision, origin = nanotime())
```

## S4 method for signature 'nanotime,nanoperiod'

```r
nano_ceiling(x, precision, origin = nanotime(), tz)
```

## S4 method for signature 'nanotime,nanoperiod'

```r
nano_floor(x, precision, origin = nanotime(), tz)
```
Arguments

x          a nanotime object which must be sorted

precision a nanoduration or nanoperiod object indicating the rounding precision

...   for future additional arguments

origin   a nanotime scalar indicating the origin at which the rounding is considered

tz       a character scalar indicating the time zone in which to conduct the rounding

Details

This flexible rounding must be understood in the context of a vector. The rounding precision can then be considered as an interval that defines a grid over which the elements are either assigned to the starting value of the interval to which they belong (nano_floor) or the ending value of the interval to which they belong (nano_ceiling). This allows for a grouping of a nanotime vector on which a statistic may then be run. In the examples below, such a use case is shown in the context of a data.table object.

If "business" concepts such as month or days are needed, the argument precision must be of type period. It is then mandatory to specify the timezone argument tz as this ensures timezone correctness of the intervals including for example for the rare hourly transitions of some countries going from a timezone with a whole hour difference with UTC to one with a fractional hour difference. In the case of a period, the functions align the rounding if the precision is an integer divisor of a larger quantity. For instance, if one specifies a rounding of 6 hours, a divisor of a day, the hours are aligned on days and the rounding is made to a grid at hours 0, 6, 12 and 18 in the specified timezone.

If the precision is not a divisor, the grid is aligned to the nearest hour before the first element of the vector to round.

The argument origin controls the reference point of the rounding, allowing arbitrary specification of the reference point of the rounding.

Examples

```r
## Not run:
## "classic" rounding:
nano_floor(as.nanotime("2010-10-10 11:12:15 UTC"), as.nanoduration("01:00:00"))
nano_floor(as.nanotime("2010-10-10 11:12:15 UTC"), as.nanoduration("06:00:00"))
nano_floor(as.nanotime("2010-10-10 11:12:15 UTC"), as.nanoduration("00:15:00"))
nano_floor(as.nanotime("2010-10-10 11:23:15 UTC"), as.nanoduration("01:15:23"))

## controlling the reference point via the 'origin' argument:
nano_ceiling(as.nanotime("2010-10-10 11:12:15 UTC"),
              as.nanoduration("01:15:23"),
              origin=as.nanotime("2010-10-10 11:12:15 UTC"))

## using business concepts and rounding across a daylight saving change:
v <- seq(as.nanotime("2020-03-08 America/New_York"),
         by=as.nanoperiod("06:00:00"), length.out=8, tz="America/New_York")
print(nano_floor(v, as.nanoperiod("1d"), tz="America/New_York"), tz="America/New_York")

## using the concept in a 'data.table':
library(data.table)
n <- 3 * 24
idx <- seq(as.nanotime("2020-03-07 America/New_York"),
```
nano_wday

Get a component of a date time

Description

Get a component of a date time. nano_wday returns the numeric position in a week, with Sunday == 0. nano_mday returns the numeric day (i.e. a value from 1 to 31). nano_month returns the month (i.e. a value from 1 to 12). nano_year returns the year.

Usage

nano_wday(x, tz)
nano_mday(x, tz)
nano_month(x, tz)
nano_year(x, tz)

Arguments

x       a nanotime object
tz      character a string representing a timezone

Details

Note that the tz parameter is mandatory because the day boundary is different depending on the time zone and nanotime does not store the timezone as it is just an offset in nanoseconds from the epoch.

Examples

## Not run:
nano_wday(as.nanotime("2020-03-14 23:32:00-04:00"), "America/New_York")
nano_wday(as.nanotime("2020-03-14 23:32:00 America/New_York"), "Europe/Paris")
nano_mday(as.nanotime("2020-03-14 23:32:00-04:00"), "America/New_York")
nano_mday(as.nanotime("2020-03-14 23:32:00 America/New_York"), "Europe/Paris")
nano_month(as.nanotime("2020-12-31 23:32:00-04:00"), "America/New_York")
nano_month(as.nanotime("2020-12-31 23:32:00 America/New_York"), "Europe/Paris")
nano_year(as.nanotime("2020-12-31 23:32:00-04:00"), "America/New_York")
nano_year(as.nanotime("2020-12-31 23:32:00 America/New_York"), "Europe/Paris")

```r
## End(Not run)
```

### Description
Replicates the values in 'x' similarly to the default method.

### Usage
```r
## S4 method for signature 'nanoduration'
rep(x, ...)
```

### Arguments
- **x** a vector of `nanoduration`
- **...** further arguments:
  - 'times' an integer-valued vector giving the (non-negative) number of times to repeat each element if of length 'length(x)', or to repeat the whole vector if of length 1. Negative or 'NA' values are an error. A 'double' vector is accepted, other inputs being coerced to an integer or double vector.
  - 'length.out' non-negative integer. The desired length of the output vector. Other inputs will be coerced to a double vector and the first element taken. Ignored if 'NA' or invalid.
  - 'each' non-negative integer. Each element of 'x' is repeated 'each' times. Other inputs will be coerced to an integer or double vector and the first element taken. Treated as '1' if 'NA' or invalid.

### Description
Replicates the values in 'x' similarly to the default method.

### Usage
```r
## S4 method for signature 'nanoival'
rep(x, ...)
```
 Arguments

 x

 a vector of nanoperiod

 ... further arguments:

 'times' an integer-valued vector giving the (non-negative) number of times to repeat each element if of length 'length(x)', or to repeat the whole vector if of length 1. Negative or 'NA' values are an error. A 'double' vector is accepted, other inputs being coerced to an integer or double vector.

 'length.out' non-negative integer. The desired length of the output vector. Other inputs will be coerced to a double vector and the first element taken. Ignored if 'NA' or invalid.

 'each' non-negative integer. Each element of 'x' is repeated 'each' times. Other inputs will be coerced to an integer or double vector and the first element taken. Treated as '1' if 'NA' or invalid.

 Description

 Replicates the values in 'x' similarly to the default method.

 Usage

 ## S4 method for signature 'nanoperiod'
 rep(x, ...)
Replicate Elements

Description

Replicates the values in 'x' similarly to the default method.

Usage

## S4 method for signature 'nanotime'
rep(x, ...)

Arguments

x
   a vector of nanotime

... further arguments:
   'times' an integer-valued vector giving the (non-negative) number of times to repeat each element if of length 'length(x)', or to repeat the whole vector if of length 1. Negative or 'NA' values are an error. A 'double' vector is accepted, other inputs being coerced to an integer or double vector.
   'length.out' non-negative integer. The desired length of the output vector. Other inputs will be coerced to a double vector and the first element taken. Ignored if 'NA' or invalid.
   'each' non-negative integer. Each element of 'x' is repeated 'each' times. Other inputs will be coerced to an integer or double vector and the first element taken. Treated as '1' if 'NA' or invalid.

Sequence Generation

Description

Generate a sequence of nanoival

Usage

## S4 method for signature 'nanoival'
seq(from, to = NULL, by = NULL, length.out = NULL, along.with = NULL, ...)
Arguments
from, to the starting and (maximal) end values of the sequence
by nanoduration or nanoperiod increment of the sequence; note that if the class is nanoperiod the additional argument tz must be specified and is of character type indicating a timezone
length.out an integer desired length of the sequence
along.with take the length from the length of this argument.
... arguments passed to or from methods; the only interesting additional argument is tz where the to argument is of type nanoperiod

Examples
## Not run:
from <- as.nanoival("-2018-01-14T13:00:00+00:00 -> 2018-01-14T15:00:00+00:00+")
seq(from, by=as.nanoperiod("1m"), length.out=5, tz="America/New_York")
## End(Not run)

seq.nanoduration  Sequence Generation

Description
Generate a sequence of nanoduration

Usage
## S3 method for class 'nanoduration'
seq(from = NULL, by = NULL, length.out = NULL, along.with = NULL, ...)

Arguments
from, to the starting and (maximal) end values of the sequence
by the increment of the sequence
length.out integer indicating the desired length of the sequence
along.with take the length from the length of this argument.
... arguments passed to or from methods

Examples
seq(from=as.nanoduration(0), by=as.nanoduration("01:00:00"), length.out=10)
**seq.nanotime**  

**Sequence Generation**

**Description**

Generate a sequence of nanotime

**Usage**

```r
## S3 method for class 'nanotime'
seq(from, to = NULL, by = NULL, length.out = NULL, along.with = NULL, ...)

## S4 method for signature 'nanotime'
seq(from, to = NULL, by = NULL, length.out = NULL, along.with = NULL, ...)
```

**Arguments**

- `from, to` the starting and (maximal) end values of the sequence
- `by` nanoduration or nanoperiod increment of the sequence; note that if the class is nanoperiod the additional argument `tz` must be specified and is of character type indicating a timezone
- `length.out` integer indicating the desired length of the sequence
- `along.with` take the length from the length of this argument.
- `...` arguments passed to or from methods; the only interesting additional argument is `tz` where the `to` argument is of type nanoperiod

**Examples**

```r
## Not run:
from <- as.nanotime("2018-01-14T12:44:00+00:00")
to <- as.nanotime("2019-01-14T12:44:00+00:00")
seq(from, to, by=as.nanoperiod("1m"), tz="America/New_York")
seq(from, by=as.nanoperiod("1y"), length.out=4, tz="Europe/London")

## End(Not run)
```

**sort,nanoival-method**  

**Sorting or Ordering Vectors**

**Description**

Sort (or _order_) a vector of nanoival into ascending or descending order
Usage

```r
## S4 method for signature 'nanoival'
sort(x, decreasing = FALSE)
```

Arguments

- `x`: a vector of `nanoival`
- `decreasing`: logical. Should the sort be increasing or decreasing?

See Also

- `is.unsorted`
