Package ‘netmeta’

July 12, 2022

Title Network Meta-Analysis using Frequentist Methods

Version 2.5-0

Date 2022-07-11

Depends R (>= 4.0.0), meta (>= 5.5-0)

Imports magic, MASS, ggplot2 (>= 3.0.0), metafor

Suggests colorspace, rgl, hasseDiagram (>= 0.1.3), grid, mvtnorm, gridExtra, igraph (>= 1.0.1), tictoc, writexl

URL https://github.com/guido-s/netmeta

https://link.springer.com/book/10.1007/978-3-319-21416-0

Description A comprehensive set of functions providing frequentist methods for network meta-analysis and supporting Schwarzer et al. (2015) <DOI:10.1007/978-3-319-21416-0>, Chapter 8 "Network Meta-Analysis";
- frequentist network meta-analysis following Rücker (2012) <DOI:10.1002/jrsm.1058>;
- net heat plot and design-based decomposition of Cochran's Q according to Krahn et al. (2013) <DOI:10.1186/1471-2288-13-35>;
- measures characterizing the flow of evidence between two treatments by König et al. (2013) <DOI:10.1002/sim.6001>;
- ranking of treatments (frequentist analogue of SUCRA) according to Rücker & Schwarzer (2015) <DOI:10.1186/s12874-015-0060-8>;
- split direct and indirect evidence to check consistency (Dias et al., 2010) <DOI:10.1002/sim.3767>, (Efthimiou et al., 2019) <DOI:10.1002/sim.8158>;
- league table with network meta-analysis results;
- additive network meta-analysis for combinations of treatments (Rücker et al., 2020) <DOI:10.1002/bimj.201800167>;
- network meta-analysis of binary data using the Mantel-Haenszel or non-central hypergeometric distribution method (Efthimiou et al., 2019) <DOI:10.1002/sim.8158>;
- 'comparison-adjusted' funnel plot (Chaimani & Salanti, 2012) <DOI:10.1002/jrsm.57>;
- automated drawing of network graphs described in Rücker & Schwarzer (2016) <DOI:10.1002/jrsm.1143>;
- rankograms and ranking by SUCRA;

Description

Details

R package **netmeta** is an add-on package for **meta** providing the following meta-analysis methods:

- frequentist network meta-analysis (function `netmeta`) based on Rücker (2012) and Rücker & Schwarzer (2014);
- net heat plot (`netheat`) and design-based decomposition of Cochran’s Q (`decomp.design`) described in Krahn et al. (2013);
- measures characterizing the flow of evidence between two treatments (`netmeasures`) described in König et al. (2013);
- ranking of treatments (`netrank`) based on P-scores (Rücker & Schwarzer, 2015) or SUCRAs (Salanti et al., 2011);
- rankograms (`rankogram`) (Salanti et al., 2011);
- partial order of treatment rankings (`netposet, plot.netposet`) and Hasse diagram (`hasse`) according to Carlsen & Bruggemann (2014) and Rücker & Schwarzer (2017);
- split direct and indirect evidence (`netsplit`) to check for consistency (Dias et al., 2010; Efthimiou et al., 2019);
- contribution of direct comparisons to network estimates (`netcontrib`) (Papakonstantinou et al., 2018; Davies et al., 2021);
- league table with network meta-analysis results (`netleague`);
- table with network, direct and indirect estimates from one or more network meta-analyses (`nettable`);
- additive network meta-analysis for combinations of treatments (`netcomb, discomb` for disconnected networks) (Rücker et al., 2020);
- calculate comparison effects of two arbitrary complex interventions in component network meta-analysis (`netcomparison`);
- calculate effect of arbitrary complex interventions in component network meta-analysis (`netcomplex`);
- network meta-analysis of binary data (`netmetabin`) using the Mantel-Haenszel or non-central hypergeometric distribution method (Efthimiou et al., 2019);
- ’comparison-adjusted’ funnel plot (`funnel.netmeta`) to assess funnel plot asymmetry in network meta-analysis (Chaimani & Salanti, 2012);
- conduct pairwise meta-analyses for all comparisons with direct evidence in a network meta-analysis (`netpairwise`); `netbind` to show these results in a forest plot;
Automated drawing of network graphs (netgraph.netmeta) described in Rücker & Schwarzer (2016);
results of several network meta-analyses can be combined with netbind to show these results in a forest plot.

Furthermore, functions and datasets from netmeta are utilised in Schwarzer et al. (2015), Chapter 8 "Network Meta-Analysis", https://link.springer.com/book/10.1007/978-3-319-21416-0. Type help(package = "netmeta") for a listing of all R functions available in netmeta. Type citation("netmeta") on how to cite netmeta in publications.

To report problems and bugs
- type bug.report(package = "netmeta") if you do not use RStudio,
- send an email to Guido Schwarzer <sc@imbi.uni-freiburg.de> if you use RStudio.

The development version of netmeta is available on GitHub https://github.com/guido-s/netmeta.

as.data.frame.netconnection

Create a data frame from an object of class netconnection

**Description**

The `as.data.frame` method returns a data frame containing information on membership of studies / pairwise comparisons to a (sub)network.

**Usage**

```r
## S3 method for class 'netconnection'
as.data.frame(x, ...)  
```

**Arguments**

- `x`: An object of class netconnection.
- `...`: Additional arguments (ignored).

**Value**

A data frame is returned by the function `as.data.frame`.

**Author(s)**

Guido Schwarzer <sc@imbi.uni-freiburg.de>

**See Also**

`netconnection`
Examples

# Artificial example with two subnetworks
#
t1 <- c("G", "B", "B", "D", "A", "F")
t2 <- c("B", "C", "E", "E", "H", "A")
#
nc2 <- netconnection(t1, t2)
print(nc2, details = TRUE)

as.data.frame(nc2)

Description

The `as.data.frame` method returns a data frame containing information on individual studies, e.g., estimated treatment effect and its standard error.

Usage

```r
## S3 method for class 'netmeta'
as.data.frame(x, row.names = NULL, optional = FALSE, details = FALSE, ...)
```

Arguments

- `x` An object of class `netmeta`.
- `row.names` NULL or a character vector giving the row names for the data frame.
- `optional` A logical. If TRUE, setting row names and converting column names (to syntactic names) is optional.
- `details` A logical. If TRUE, additional variables of less interest are included in data frame.
- `...` Additional arguments.

Value

A data frame is returned by the function `as.data.frame`.

#
net1 <- netmeta(TE, seTE, treat1, treat2, studlab,
data = Senn2013, sm = "MD")

as.data.frame(net1)
as.data.frame(net1, details = TRUE)
```

---

### Description

This data set comes from a systematic review of randomized controlled trials on pharmacologic treatments for chronic obstructive pulmonary disease (COPD) (Baker et al., 2009). The primary outcome, occurrence of one or more episodes of COPD exacerbation, is binary (yes / no). For this outcome, five drug treatments (fluticasone, budesonide, salmeterol, formoterol, tiotropium) and two combinations (fluticasone + salmeterol, budesonide + formoterol) were compared to placebo. The authors considered the two combinations as separate treatments instead of evaluating the individual components.

### Format

A data frame with the following columns:

- **study**: study label
- **year**: year of publication
- **id**: study ID
- **treatment**: treatment
- **exac**: one or more episodes of COPD exacerbation
- **total**: number of individuals in treatment arm

cnet1

## End(Not run)

decomp.design  

Design-based decomposition of Cochran's Q in network meta-analysis

Description

This function performs a design-based decomposition of Cochran's Q for assessing the homogeneity in the whole network, the homogeneity within designs, and the homogeneity/consistency between designs. It allows also an assessment of the consistency assumption after detaching the effect of single designs.

Usage

decomp.design(
  x,
  tau.preset = x$tau.preset,
  warn = TRUE,
  nchar.trts = x$nchar.trts
)

Arguments

  x          An object of class netmeta.
  tau.preset An optional value for the square-root of the between-study variance \( \tau^2 \) (see Details).
warn A logical indicating whether warnings should be printed.
nchar.trts A numeric defining the minimum number of characters used to create unique treatment names.

Details

In the context of network meta-analysis and the assessment of the homogeneity and consistency assumption, a generalized Cochran’s Q statistic for multivariate meta-analysis can be used as shown in Krahn et al. (2013). This Q statistic can be decomposed in a sum of within-design Q statistics and one between-designs Q statistic that incorporates the concept of design inconsistency, see Higgins et al. (2012).

For assessing the inconsistency in a random effects model, the between-designs Q statistic can be calculated based on a full design-by-treatment interaction random effects model (see Higgins et al., 2012). This Q statistic will be automatically given in the output ($\tau^2$ estimated by the method of moments (see Jackson et al., 2012). Alternatively, the square-root of the between-study variance can be prespecified by argument tau.preset to obtain a between-designs Q statistic (in Q.inc.random), its design-specific contributions Q.inc.design.random.preset as well as residuals after detaching of single designs (residuals.inc.detach.random.preset).

Since an inconsistent treatment effect of one design can simultaneously inflate several residuals, Krahn et al. (2013) suggest for locating the inconsistency in a network to fit a set of extended models allowing for example for a deviating effect of each study design in turn. The recalculated between-designs Q statistics are given in list component Q.inc.detach. The change of the inconsistency contribution of single designs can be investigated in more detail by a net heat plot (see function netheat). Designs where only one treatment is involved in other designs of the network or where the removal of corresponding studies would lead to a splitting of the network do not contribute to the inconsistency assessment. These designs are not included in Q.inc.detach.

Value

Network meta-analysis with a single design: NULL. Otherwise, a list containing the following components:

- Q.decomp Data frame with Q statistics (variable Q) based on the common effects model to assess the homogeneity/consistency in the whole network, within designs, and between designs. Corresponding degrees of freedom (df) and p-values (p.val) are also given.
- Q.het.design Data frame with design-specific decomposition of the within-designs Q statistic (Q) of the common effects model, corresponding degrees of freedom (df) and p-values (p.val) are given.
- Q.inc.detach Data frame with between-designs Q statistics (Q) of the common effects model after detaching of single designs, corresponding degrees of freedom (df) and p-values (p.val) are given.
- Q.inc.design A named vector with contributions of single designs to the between design Q statistic given in Q.decomp.
- Q.inc.random Data frame with between-designs Q statistic (Q) based on a random effects model with square-root of between-study variance tau.within estimated embedded in a full design-by-treatment interaction model, corresponding degrees of freedom (df) and p-value (p.val).
Q.inc.random.preset
Data frame with between-designs Q statistic (Q) based on a random effects model with prespecified square-root of between-study variance tau.preset in the case if argument tau.preset is not NULL, corresponding degrees of freedom (df) and p-value (p.val).

Q.inc.design.random.preset
A named vector with contributions of single designs to the between design Q statistic based on a random effects model with prespecified square-root of between-study variance tau.preset in the case if argument tau.preset is given.

residuals.inc.detach
Matrix with residuals, i.e. design-specific direct estimates minus the corresponding network estimates after detaching the design of the column.

residuals.inc.detach.random.preset
Matrix with residuals analogous to residuals.inc.detach but based on a random effects model with prespecified square-root of between-study variance tau.preset in the case if argument tau.preset is not NULL.

call
Function call.

version
Version of R package netmeta used to create object.

# Conduct network meta-analysis with placebo as reference treatment
dietaryfat

Network meta-analysis of dietary fat

Description

Network meta-analysis comparing the effects of two diets to control on mortality.
The data are rates, given as the number of deaths and person-years. These data are used as an example in the supplemental material of Dias et al. (2013).

Format

A data frame with the following columns:

- `treat1`: treatment 1
- `treat2`: treatment 2
- `treat3`: treatment 3
- `years1`: person years arm 1
- `years2`: person years arm 2
- `years3`: person years arm 3
- `d1`: events (deaths) arm 1
- `d2`: events (deaths) arm 2
- `d3`: events (deaths) arm 3
- `ID`: study ID

---

**discomb**

Additive network meta-analysis for combinations of treatments (disconnected networks)

---

**Description**

Some treatments in a network meta-analysis may be combinations of other treatments or have common components. The influence of individual components can be evaluated in an additive network meta-analysis model assuming that the effect of treatment combinations is the sum of the effects of its components. This function implements this additive model in a frequentist way and is particularly intended for disconnected networks.

**Usage**

discomb(
    TE,
    seTE,
    treat1,
    treat2,
studlab,
data = NULL,
subset = NULL,
inactive = NULL,
sep.comps = "+",
C.matrix,
sm,
level = gs("level"),
level.ma = gs("level.ma"),
common = gs("common"),
random = gs("random") | !is.null(tau.preset),
reference.group,
baseline.reference = TRUE,
seq = NULL,
tau.preset = NULL,
tol.multiarm = 0.001,
tol.multiarm.se = NULL,
details.chkmultiarm = FALSE,
details.chkident = FALSE,
sep.trts = ":",
nchar.comps = 666,
func.inverse = invmat,
backtransf = gs("backtransf"),
title = "",
warn = TRUE,
warn.deprecated = gs("warn.deprecated"),
nchar.trts = nchar.comps,

Arguments

**TE**

Estimate of treatment effect, i.e. difference between first and second treatment (e.g. log odds ratio, mean difference, or log hazard ratio). Or an R object created with `pairwise`.

**seTE**

Standard error of treatment estimate.

**treat1**

Label/Number for first treatment.

**treat2**

Label/Number for second treatment.

**studlab**

An optional - but important! - vector with study labels (see `netmeta`).

**data**

An optional data frame containing the study information.

**subset**

An optional vector specifying a subset of studies to be used.

**inactive**

A character string defining the inactive treatment component (see Details).

**sep.comps**

A single character to define separator between treatment components.

**C.matrix**

C matrix (see Details).

**sm**

A character string indicating underlying summary measure, e.g., "RD", "RR", "OR", "ASD", "HR", "MD", "SMD", or "ROM".

Details

Treatments in network meta-analysis (NMA) can be complex interventions. Some treatments may be combinations of others or have common components. The standard analysis provided by `netmeta` is a NMA where all existing (single or combined) treatments are considered as different nodes in the network. Exploiting the fact that some treatments are combinations of common components, an additive component network meta-analysis (CNMA) model can be used to evaluate the influence of individual components. This model assumes that the effect of a treatment combination is the sum of the effects of its components which implies that common components cancel out in comparisons.

This R function can be used for disconnected networks. Use `netmeta` and `netcomb` for connected networks.

The additive CNMA model has been implemented using Bayesian methods (Mills et al., 2012; Welton et al., 2013). This function implements the additive model in a frequentist way (Rücker et al., 2020).

The underlying multivariate model is given by

\[ \delta = B\theta, \theta = C\beta \]

with

- \( \delta \) vector of true treatment effects (differences) from individual studies,
- \( B \) design matrix describing the structure of the network,
- \( \theta \) parameter vector that represents the existing combined treatments,
- \( C \) matrix describing how the treatments are composed,
- \( \beta \) parameter vector representing the treatment components.

All parameters are estimated using weighted least squares regression.

Argument `inactive` can be used to specify a single component that does not have any therapeutic value. Accordingly, it is assumed that the treatment effect of the combination of this component with an additional treatment component is equal to the treatment effect of the additional component alone.

Argument `sep.comps` can be used to specify the separator between individual components. By default, the matrix \( C \) is calculated internally from treatment names. However, it is possible to specify a different matrix using argument `C.matrix`.

By default, component names are not abbreviated in printouts. However, in order to get more concise printouts, argument `nchar.comps` can be used to define the minimum number of characters for abbreviated component names (see `abbreviate`, argument `minlength`). R function `treats` is utilised internally to create abbreviated component names.

Value

An object of classes `discomb` and `netcomb` with corresponding `print`, `summary`, and `forest` functions. The object is a list containing the following components:

- `studlab` Study labels.
- `treat1` Label/Number for first treatment.
treat2  Label/Number for second treatment.
TE  Estimate of treatment effect, i.e. difference between first and second treatment.
seTE  Standard error of treatment estimate.
seTE.adj.common, seTE.adj.random  Standard error of treatment estimate, adjusted for multi-arm studies.
event1  Number of events in first treatment group.
event2  Number of events in second treatment group.
n1  Number of observations in first treatment group.
n2  Number of observations in second treatment group.
k  Total number of studies.
m  Total number of pairwise comparisons.
n  Total number of treatments.
d  Total number of designs (corresponding to the unique set of treatments compared within studies).
c  Total number of components.
trts  Treatments included in network meta-analysis.
comps  Unique list of components present in the network.
TE.cnma.common, TE.cnma.random  A vector of length $m$ of consistent treatment effects estimated by the additive (common and random effects) model.
seTE.cnma.common, seTE.cnma.random  A vector of length $m$ with standard errors estimated by the additive (common and random effects) model.
lower.cnma.common, lower.cnma.random  A vector of length $m$ of lower confidence interval limits for consistent treatment effects estimated by the additive (common and random effects) model.
upper.cnma.common, upper.cnma.random  A vector of length $m$ of upper confidence interval limits for consistent treatment effects estimated by the additive (common and random effects) model.
statistic.cnma.common, statistic.cnma.random  A vector of length $m$ of z-values for the test of an overall effect estimated by the additive (common and random effects) model.
pval.cnma.common, pval.cnma.random  A vector of length $m$ of p-values for the test of an overall effect estimated by the additive (common and random effects) model.
TE.common, TE.random  $nxn$ matrix with overall treatment effects estimated by the additive (common and random effects) model.
seTE.common, seTE.random  $nxn$ matrix with standard errors estimated by the additive (common and random effects) model.
lower.common, upper.common, lower.random, upper.random  $nxn$ matrices with lower and upper confidence interval limits estimated by the additive (common and random effects) model.
statistic.common, pval.common, statistic.random, pval.random

n x n matrices with z-values and p-values for test of overall effect estimated by
the additive (common and random effects) model.

Comp.common, Comp.random

A vector of component effects (common and random effects model).

seComp.common, seComp.random

A vector with corresponding standard errors (common and random effects model).

lower.Comp.common, lower.Comp.random

A vector with lower confidence limits for components (common and random
effects model).

upper.Comp.common, upper.Comp.random

A vector with upper confidence limits for components (common and random
effects model).

statistic.Comp.common, statistic.Comp.random

A vector with z-values for the overall effect of components (common and random
effects model).

pval.Comp.common, pval.Comp.random

A vector with p-values for the overall effect of components (common and random
effects model).

Comb.common, Comb.random

A vector of combination effects (common and random effects model).

seComb.common, seComb.random

A vector with corresponding standard errors (common and random effects model).

lower.Comb.common, lower.Comb.random

A vector with lower confidence limits for combinations (common and random
effects model).

upper.Comb.common, upper.Comb.random

A vector with upper confidence limits for combinations (common and random
effects model).

statistic.Comb.common, statistic.Comb.random

A vector with z-values for the overall effect of combinations (common and random
effects model).

pval.Comb.common, pval.Comb.random

A vector with p-values for the overall effect of combinations (common and random
effects model).

Q.additive

Overall heterogeneity / inconsistency statistic (additive model).

df.Q.additive

Degrees of freedom for test of heterogeneity / inconsistency (additive model).

pval.Q.additive

P-value for test of heterogeneity / inconsistency (additive model).

tau

Square-root of between-study variance (additive model).

I2

I-squared (additive model).

Q.standard

Overall heterogeneity / inconsistency statistic (standard model).

df.Q.standard

Degrees of freedom for test of heterogeneity / inconsistency (standard model).

pval.Q.standard

P-value for test of heterogeneity / inconsistency (standard model).
Q.diff  Test statistic for difference in goodness of fit between standard and additive model.
df.Q.diff  Degrees of freedom for difference in goodness of fit between standard and additive model.
pval.Q.diff  P-value for difference in goodness of fit between standard and additive model.
X.matrix  Design matrix ($mxn$).
B.matrix  Edge-vertex incidence matrix ($mxn$).
C.matrix  As defined above.
sm  Summary measure.
level.ma  Level for confidence intervals.
common, random, tau.preset  As defined above.
sep.trts  A character used in comparison names as separator between treatment labels.
nchar.comps  A numeric defining the minimum number of characters used to create unique component names.
inactive, sep.comps  As defined above.
backtransf  A logical indicating whether results should be back transformed in printouts and forest plots.
title  Title of meta-analysis / systematic review.
x  As defined above.
call  Function call.
version  Version of R package netmeta used to create object.

Note
This function calculates effects for individual components and complex interventions present in the network.
R function netcomplex can be used to calculate the effect for arbitrary complex interventions in a component network meta-analysis. Furthermore, R function netcomparison can be used to calculate the effect for comparisons of two arbitrary complex intervention in a component network meta-analysis.

---

**Dogliotti2014**

*Network meta-analysis of antithrombotic treatments in patients with non-valvular atrial fibrillation*

---

**Description**

This data set comes from a systematic review aiming to determine the effects of eight antithrombotic treatments in reducing the incidence of major thrombotic events in patients with non-valvular atrial fibrillation (Dogliotti et al., 2014). The review included 20 studies (79,808 participants), four of which were three-arm studies. The primary outcome is stroke reduction.

**Format**

A data frame with the following columns:

- **study**: study label
- **id**: study ID
- **treatment**: treatment
- **stroke**: number of strokes
- **total**: number of individuals in treatment arm

**Source**

**See Also**

pairwise, metabin, netmetabin

**Examples**

```r
data(Dogliotti2014)
Dogliotti2014

## Not run:
# Transform data from long arm-based format to contrast-based
# format. Argument 'sm' has to be used for odds ratio as summary
```
# measure; by default the risk ratio is used in the metabin
# function called internally.
#
p1 <- pairwise(treatment, stroke, total, studlab = study,
data = Dogliotti2014, sm = "OR")
#
# Conduct Mantel-Haenszel network meta-analysis
#
netmetabin(p1, ref = "plac")

## End(Not run)

---

**Dong2013**

*Network meta-analysis for chronic obstructive pulmonary disease*

---

**Description**

Network meta-analysis comparing inhaled medications in patients with chronic obstructive pulmonary disease.

**Format**

A data frame with the following columns:

- `id`: study ID
- `treatment`: treatment
- `death`: mortality
- `randomized`: number of individuals in treatment arm

**Source**

**See Also**

`pairwise`, `metabin`, `netmetabin`

**Examples**

data(Dong2013)

# Only consider first ten studies (to reduce runtime of example)
#
first10 <- subset(Dong2013, id <= 10)

# Transform data from long arm-based format to contrast-based
# format. Argument 'sm' has to be used for odds ratio as summary
# measure; by default the risk ratio is used in the metabin
# function called internally.
#
p1 <- pairwise(treatment, death, randomized, studlab = id,
   data = first10, sm = "OR")

# Conduct Mantel-Haenszel network meta-analysis
#
netmetabin(p1, ref = "plac")

## Not run:
# Conduct Mantel-Haenszel network meta-analysis for the whole
# dataset
#
p2 <- pairwise(treatment, death, randomized, studlab = id,
   data = Dong2013, sm = "OR")
netmetabin(p2, ref = "plac")

## End(Not run)

forest.netbind                Forest plot showing results of two or more network meta-analyses

Description

Forest plot to show network estimates of two or more network meta-analyses.

Usage

## S3 method for class 'netbind'
forest(
x,
pooled = ifelse(x$x$random, "random", "common"),
equal.size = TRUE,
leftcols = "studlab",
leftlabs = "Treatment",
rightcols = c("effect", "ci"),
rightlabs = NULL,
subset.treatments,
digits = gs("digits.forest"),
digits.prop = max(gs("digits.pval") - 2, 2),
backtransf = x$x$backtransf,
lab.NA = "",
smlab,
...
)

## S3 method for class 'netbind'
plot(x, ...)
Arguments

x An object of class netbind.
pooled A character string indicating whether results for the common ("common") or random effects model ("random") should be plotted. Can be abbreviated.
equal.size A logical indicating whether all squares should be of equal size. Otherwise, the square size is proportional to the precision of estimates.
leftcols A character vector specifying columns to be plotted on the left side of the forest plot (see Details).
leftlabs A character vector specifying labels for columns on left side of the forest plot.
rightcols A character vector specifying columns to be plotted on the right side of the forest plot (see Details).
rightlabs A character vector specifying labels for columns on right side of the forest plot.
subset.treatments A character vector specifying treatments to show in forest plot as comparators to the reference.
digits Minimal number of significant digits for treatment effects and confidence intervals, see print.default.
digits.prop Minimal number of significant digits for the direct evidence proportion.
backtransf A logical indicating whether results should be back transformed in forest plots. If backtransf = TRUE, results for sm = "OR" are presented as odds ratios rather than log odds ratios, for example.
lab.NA A character string to label missing values.
smlab A label printed at top of figure. By default, text indicating either common or random effects model is printed.
... Additional arguments for forest.meta function.

Details

A forest plot, also called confidence interval plot, is drawn in the active graphics window.

The arguments leftcols and rightcols can be used to specify columns which are plotted on the left and right side of the forest plot, respectively. If argument rightcols is FALSE, no columns will be plotted on the right side.

For more information see help page of forest.meta function.

    col.study = c("red", "black"),
    col.square = c("red", "black"))
forest(nb1,
    col.by = "black", addrow.subgroups = FALSE,
    fontsize = 10, spacing = 0.7, squaresize = 0.9,
    label.left = "Favours Placebo",
    label.right = "Favours other"
)

Description

Draws a forest plot in the active graphics window (using grid graphics system).

Usage

## S3 method for class 'netcomb'
forest(
    x,
    pooled = ifelse(x$random, "random", "common"),
    reference.group = x$reference.group,
    baseline.reference = x$baseline.reference,
    leftcols = "studlab",
)
leftlabs = "Treatment",
rightcols = c("effect", "ci"),
rightlabs = NULL,
digits = gs("digits.forest"),
smlab = NULL,
lab.NA = ".",
add.data,
drop.reference.group = FALSE,
weight.study = "same",
...)

## S3 method for class 'netcomb'
plot(x, ...)

Arguments

x An object of class netcomb.
pooled A character string indicating whether results for the common ("common") or random effects model ("random") should be plotted. Can be abbreviated.
reference.group Reference treatment(s).
baseline.reference A logical indicating whether results should be expressed as comparisons of other treatments versus the reference treatment (default) or vice versa.
leftcols A character vector specifying (additional) columns to be plotted on the left side of the forest plot or a logical value (see forest.meta help page for details).
leftlabs A character vector specifying labels for (additional) columns on left side of the forest plot (see forest.meta help page for details).
rightcols A character vector specifying (additional) columns to be plotted on the right side of the forest plot or a logical value (see forest.meta help page for details).
rightlabs A character vector specifying labels for (additional) columns on right side of the forest plot (see forest.meta help page for details).
digits Minimal number of significant digits for treatment effects and confidence intervals, see print.default.
smlab A label printed at top of figure. By default, text indicating either common or random effects model is printed.
sortvar An optional vector used to sort the individual studies (must be of same length as the total number of treatments).
backtransf A logical indicating whether results should be back transformed in forest plots. If backtransf = TRUE, results for sm = "OR" are presented as odds ratios rather than log odds ratios, for example.
lab.NA A character string to label missing values.
add.data  An optional data frame with additional columns to print in forest plot (see Details).
drop.reference.group  A logical indicating whether the reference group should be printed in the forest plot.
weight.study  A character string indicating weighting used to determine size of squares or diamonds.
...  Additional arguments for forest.meta function.

Details
A forest plot, also called confidence interval plot, is drawn in the active graphics window.
Argument sortvar can be either a numeric or character vector with length of number of treatments. If sortvar is numeric the order function is utilised internally to determine the order of values. If sortvar is character it must be a permutation of the treatment names. It is also possible to sort by treatment comparisons (sortvar = TE, etc.), standard error (sortvar = seTE), and number of studies with direct treatment comparisons (sortvar = k).
Argument add.data can be used to add additional columns to the forest plot. This argument must be a data frame with the same row names as the treatment effects matrices in R object x, i.e., x$TE.common or x$TE.random.
For more information see help page of forest.meta function.

forest.netmeta

Forest plot for network meta-analysis

Description

Draws a forest plot in the active graphics window (using grid graphics system).

Usage

```r
## S3 method for class 'netmeta'
forest(x, 
pooled = ifelse(x$random, "random", "common"), 
reference.group = x$reference.group, 
baseline.reference = x$baseline.reference, 
labels = x$trts, 
equal.size = TRUE, 
leftcols = "studlab", 
leftlabs, 
rightcols = c("effect", "ci"), 
rightlabs, 
digits = gs("digits.forest"), 
small.values = x$small.values, 
nsim = 1000, 
digits.prop = 2, 
smlab = NULL, 
sortvar = x$seq, 
backtransf = x$backtransf, 
lab.NA = ".", 
add.data, 
drop.reference.group = FALSE, 
col.by = "black", 
print.subgroup.name = FALSE, 
... )
```

```r
## S3 method for class 'netmeta'
plot(x, ...)
```

Arguments

- **x**: An object of class netmeta.
- **pooled**: A character string indicating whether results for the common ("common") or random effects model ("random") should be plotted. Can be abbreviated.
reference.group
Reference treatment(s).

baseline.reference
A logical indicating whether results should be expressed as comparisons of other treatments versus the reference treatment (default) or vice versa.

labels
An optional vector with treatment labels.

equal.size
A logical indicating whether all squares should be of equal size. Otherwise, the square size is proportional to the precision of estimates.

leftcols
A character vector specifying columns to be plotted on the left side of the forest plot or a logical value (see Details).

leftlabs
A character vector specifying labels for (additional) columns on left side of the forest plot (see Details).

rightcols
A character vector specifying columns to be plotted on the right side of the forest plot or a logical value (see Details).

rightlabs
A character vector specifying labels for (additional) columns on right side of the forest plot (see Details).

digits
Minimal number of significant digits for treatment effects and confidence intervals, see print.default.

small.values
A character string specifying whether small treatment effects indicate a beneficial ("good") or harmful ("bad") effect, can be abbreviated; see netrank.

nsim
Number of simulations to calculate SUCRAs.

digits.prop
Minimal number of significant digits for P-scores, SUCRAs and direct evidence proportions, see print.default and netrank.

smlab
A label printed at top of figure. By default, text indicating either common or random effects model is printed.

sortvar
An optional vector used to sort treatments (must be of same length as the total number of treatments).

backtransf
A logical indicating whether results should be back transformed in forest plots. If backtransf = TRUE, results for sm = "OR" are presented as odds ratios rather than log odds ratios, for example.

lab.NA
A character string to label missing values.

add.data
An optional data frame with additional columns to print in forest plot (see Details).

drop.reference.group
A logical indicating whether the reference group should be printed in the forest plot.

col.by
The colour to print information on subgroups.

print.subgroup.name
A logical indicating whether the name of the grouping variable should be printed in front of the group labels.

...
Additional arguments for forest.meta function.
A forest plot, also called confidence interval plot, is drawn in the active graphics window.

Argument `sortvar` can be either a numeric or character vector with length of number of treatments. If `sortvar` is numeric the `order` function is utilised internally to determine the order of values. If `sortvar` is character it must be a permutation of the treatment names. It is also possible to provide either `sortvar = Pscore`, `sortvar = "Pscore"`, `sortvar = -Pscore`, or `sortvar = "-Pscore"` in order to sort treatments according to the ranking generated by `netrank` which is called internally. It is also possible to use "SUCRA" instead of "Pscore". Similar expressions are possible to sort by treatment comparisons (sortvar = TE, etc.), standard error (sortvar = seTE), number of studies with direct treatment comparisons (sortvar = k), and direct evidence proportion (sortvar = prop.direct, see also `netmeasures`).

The arguments `leftcols` and `rightcols` can be used to specify columns which are plotted on the left and right side of the forest plot, respectively. The following columns are available:

<table>
<thead>
<tr>
<th>Name</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;studlab&quot;</td>
<td>Treatments</td>
</tr>
<tr>
<td>&quot;TE&quot;</td>
<td>Network estimates (either from common or random effects model)</td>
</tr>
<tr>
<td>&quot;seTE&quot;</td>
<td>Corresponding standard errors</td>
</tr>
<tr>
<td>&quot;Pscore&quot;</td>
<td>P-scores (see <code>netrank</code>)</td>
</tr>
<tr>
<td>&quot;SUCRA&quot;</td>
<td>SUCRAs (see <code>netrank</code>)</td>
</tr>
<tr>
<td>&quot;n.trts&quot;</td>
<td>Number of participants per treatment arm</td>
</tr>
<tr>
<td>&quot;k&quot;</td>
<td>Number of studies in pairwise comparisons</td>
</tr>
<tr>
<td>&quot;prop.direct&quot;</td>
<td>Direct evidence proportions (see <code>netmeasures</code>)</td>
</tr>
<tr>
<td>&quot;effect&quot;</td>
<td>(Back-transformed) network estimates</td>
</tr>
<tr>
<td>&quot;ci&quot;</td>
<td>Confidence intervals</td>
</tr>
<tr>
<td>&quot;effect.ci&quot;</td>
<td>(Back-transformed) network estimates and confidence intervals</td>
</tr>
</tbody>
</table>

As a sidenote, the rather odd column name "studlab" to describe the treatment comparisons comes from internally calling `forest.meta` which uses study labels as the essential information.

Argument `add.data` can be used to add additional columns to the forest plot. This argument must be a data frame with row names equal to the treatment names in R object `x`, i.e., `x$trts`.

See help page of `forest.meta` for more information on the generation of forest plots and additional arguments.

**forest.netsplit**

*Forest plot for direct and indirect evidence*

**Description**

Forest plot to show direct and indirect evidence in network meta-analysis. Furthermore, estimates from network meta-analysis as well as prediction intervals can be printed.

**Usage**

```r
## S3 method for class 'netsplit'
forest(
x,
pooled = ifelse(x$x$random, "random", "common"),
show = "both",
subgroup = "comparison",
overall = TRUE,
direct = TRUE,
indirect = TRUE,
prediction = x$prediction,
only.reference = FALSE,
sortvar = NULL,
text.overall = "Network estimate",
text.direct = "Direct estimate",
text.indirect = "Indirect estimate",
text.predict = "Prediction interval",
type.overall,
type.direct,
type.indirect,
col.square = "gray",
col.square.lines = col.square,
col.inside = "white",
col.diamond = "gray",
col.diamond.lines = "black",
col.predict = "red",
col.predict.lines = "black",
equal.size = TRUE,
leftcols,
leftlabs,
rightcols = c("effect", "ci"),
rightlabs = NULL,
digits = gs("digits.forest"),
digits.prop = max(gs("digits.pval") - 2, 2),
backtransf = x$backtransf,
```

```r
```
```r
lab.NA = '"',
smlab,
...
)

## S3 method for class 'netsplit'
plot(x, ...)

Arguments

x An object of class netsplit.
pooled A character string indicating whether results for the common ("common") or random effects model ("random") should be plotted. Can be abbreviated.
show A character string indicating which comparisons should be printed (see Details).
subgroup A character string indicating which layout should be used in forest plot: subgroups by comparisons ("comparison") or subgroups by estimates ("estimate"). Can be abbreviated.
overall A logical indicating whether network meta-analysis estimates should be printed.
direct A logical indicating whether direct estimates should be printed.
indirect A logical indicating whether indirect estimates should be printed.
prediction A logical indicating whether prediction intervals should be printed.
only.reference A logical indicating whether only comparisons with the reference group should be printed.
sortvar An optional vector used to sort comparisons (must be of same length as the total number of comparisons).
text.overall A character string used in the plot to label the network estimates.
text.direct A character string used in the plot to label the direct estimates.
text.indirect A character string used in the plot to label the indirect estimates.
text.predict A character string used in the plot to label the prediction interval.
type.overall A character string specifying how to plot treatment effects and confidence intervals for the overall network evidence.
type.direct A character string specifying how to plot treatment effects and confidence intervals for the direct evidence.
type.indirect A character string specifying how to plot treatment effects and confidence intervals for the indirect evidence.
col.square The colour for squares.
col.square.lines The colour for the outer lines of squares.
col.inside The colour for results and confidence limits if confidence limits are completely within squares squares.
col.diamond The colour of diamonds.
col.diamond.lines The colour of the outer lines of diamonds.
col.predict Background colour of prediction intervals.
col.predict.lines Colour of outer lines of prediction intervals.
equal.size A logical indicating whether all squares should be of equal size. Otherwise, the square size is proportional to the precision of estimates.
leftcols A character vector specifying columns to be plotted on the left side of the forest plot (see Details).
leftlabs A character vector specifying labels for columns on left side of the forest plot.
rightcols A character vector specifying columns to be plotted on the right side of the forest plot (see Details).
rightlabs A character vector specifying labels for columns on right side of the forest plot.
digits Minimal number of significant digits for treatment effects and confidence intervals, see print.default.
digits.prop Minimal number of significant digits for the direct evidence proportion.
backtransf A logical indicating whether results should be back transformed in forest plots. If backtransf = TRUE, results for sm = "OR" are presented as odds ratios rather than log odds ratios, for example.
lab.NA A character string to label missing values.
smlab A label printed at top of figure. By default, text indicating either common or random effects model is printed.
... Additional arguments for forest.meta function.

Details

A forest plot, also called confidence interval plot, is drawn in the active graphics window. The arguments leftcols and rightcols can be used to specify columns which are plotted on the left and right side of the forest plot, respectively. If argument rightcols is FALSE, no columns will be plotted on the right side.

If direct estimates are included in the forest plot (direct = TRUE, default), the following columns will be printed on the left side of the forest plot: the comparisons (column "studlab" in forest.meta), number of pairwise comparisons ("k"), direct evidence proportion ("k"), and I^2 from pairwise comparison ("I2").

If direct estimates are not included in the forest plot (direct = FALSE), only the comparisons ("studlab") are printed on the left side of the forest plot.

For more information see help page of forest.meta function.

Argument show determines which comparisons are printed:

"all" All comparisons
"both" Only comparisons contributing both direct and indirect evidence
"with.direct" Comparisons providing direct evidence
"direct.only" Comparisons providing only direct evidence
"indirect.only" Comparisons providing only indirect evidence

# show = "with.direct")

# Forest plot only showing network estimates compared to reference
# group and prediction intervals
# forest(ns1, fontsize = 8, spacing = 0.75,
# show = "ref", prediction = TRUE, direct = FALSE, indirect = FALSE)

## End(Not run)

Description

Network meta-analysis comparing the effects of a number of treatments for Parkinson’s disease.
The data are the mean lost work-time reduction in patients given dopamine agonists as adjunct therapy in Parkinson’s disease (Franchini et al. 2012). The data are given as sample size, mean and standard deviation in each trial arm. Treatments are placebo and four active drugs. These data are used as an example in the supplemental material of Dias et al. (2013) where placebo is coded as 1 and the four active drugs as 2 to 5.

Format

A data frame with the following columns:

- **Study**: study label
- **Treatment1**: treatment 1
  - **y1**: treatment effect arm 1
  - **sd1**: Standard deviation arm 1
  - **n1**: Sample size arm 1
- **Treatment2**: treatment 2
  - **y2**: treatment effect arm 2
  - **sd2**: Standard deviation arm 2
  - **n2**: Sample size arm 2
- **Treatment3**: treatment 3
  - **y3**: treatment effect arm 3
  - **sd3**: Standard deviation arm 3
  - **n3**: Sample size arm 3

funnel.netmeta

`funnel.netmeta` 'Comparison-adjusted' funnel plot

Description

Draw a ‘comparison-adjusted’ funnel plot to assess funnel plot asymmetry in network meta-analysis.

Usage

```r
## S3 method for class 'netmeta'
funnel(
  x,
  order,
  pooled = ifelse(x$random, "random", "common"),
  xlab = NULL,
  level = x$level,
  pch,
  col = "black",
  legend = TRUE,
  pos.legend = "topright",
  pos.tests = "topleft",
  lump.comparator = FALSE,
  text.comparator = "comparator",
  method.bias,
  text.linreg = "(Egger)",
  text.rank = "(Begg-Mazumdar)",
  text.mm = "(Thompson-Sharp)",
  sep.trts = x$sep.trts,
  nchar.trts = x$nchar.trts,
  backtransf = x$backtransf,
  digits.pval = gs("digits.pval")
  warn.deprecated = gs("warn.deprecated")
  linreg = FALSE,
  rank = FALSE,
  mm = FALSE,
  ...
)
```
Arguments

x     An object of class netmeta.
order A mandatory character or numerical vector specifying the order of treatments or list of comparators (see Details).
pooled A character string indicating whether results for the common ("common") or random effects model ("random") should be plotted. Can be abbreviated.
xlab  A label for the x-axis.
level The confidence level utilised in the plot. For the funnel plot, confidence limits are not drawn if yaxis = "size".
pch   The plotting symbol(s) used for individual studies within direct comparisons.
col   The colour(s) used for individual studies within direct comparisons.
legend A logical indicating whether a legend with information on direct comparisons should be added to the plot.
pos.legend The position of the legend describing plotting symbols and colours for direct comparisons.
pos.tests The position of results for test(s) of funnel plot asymmetry.
lump.comparator A logical indicating whether comparators should be lumped, e.g., to specify inactive treatments. Information on direct comparisons should be added to the plot.
text.comparator A character string used in the plot to label the comparator if lump.comparator is TRUE.
method.bias A character vector indicating which test(s) for funnel plot asymmetry to use. Admissible values are "Begg", "Egger", and "Thompson", can be abbreviated. See function metabias.
text.linreg A character string used in the plot to label the Egger test for funnel plot asymmetry.
text.rank A character string used in the plot to label the Begg test for funnel plot asymmetry.
text.mm A character string used in the plot to label the Thompson-Sharp test for funnel plot asymmetry.
sep.trts A character used in comparison names as separator between treatment labels.
nchar.trts A numeric defining the minimum number of characters used to create unique treatment names (see netmeta).
backtransf A logical indicating whether results for relative summary measures (argument sm equal to "OR", "RR", "HR", or "IRR") should be back transformed in funnel plots. If backtransf = TRUE, results for sm = "OR" are printed as odds ratios rather than log odds ratios, for example.
digits.pval Minimal number of significant digits for p-value of test(s) for funnel plot asymmetry.
warn.deprecated
A logical indicating whether warnings should be printed if deprecated arguments are used.

linreg
Deprecated argument (replaced by method.bias).

rank
Deprecated argument (replaced by method.bias).

mm
Deprecated argument (replaced by method.bias).

... Additional graphical arguments passed as arguments to funnel.meta.

Details
A 'comparison-adjusted' funnel plot (Chaimani & Salanti, 2012) is drawn in the active graphics window.

Argument order is mandatory to determine the order of treatments (Chaimani et al., 2013):

"Before using this plot, investigators should order the treatments in a meaningful way and make assumptions about how small studies differ from large ones. For example, if they anticipate that newer treatments are favored in small trials, then they could name the treatments from oldest to newest so that all comparisons refer to 'old versus new intervention'. Other possibilities include defining the comparisons so that all refer to an active treatment versus placebo or sponsored versus non-sponsored intervention."

Alternatively, it is possible to only provide a single or few treatment name(s) in argument order to define the comparator(s). In this case only comparisons with this / these treatment(s) will be considered. If argument lump.comparator is TRUE, all comparators will be lumped into a single group. The text for this group can be specified with argument text.comparator.

In the funnel plot, if yaxis is "se", the standard error of the treatment estimates is plotted on the y-axis which is likely to be the best choice (Sterne & Egger, 2001). Other possible choices for yaxis are "invvar" (inverse of the variance), "invse" (inverse of the standard error), and "size" (study size).

Value
A data frame with the following columns:

studlab Study label.
treat1 Label/Number for first treatment.
treat2 Label/Number for second treatment.
comparison Treatment comparison.
TE Estimate of treatment effect, e.g., log odds ratio.
TE.direct Pooled estimate from direct evidence.
TE.adj ‘Comparison-adjusted’ treatment effect (TE - TE.direct).
seTE Standard error of treatment estimate.
pch Plotting symbol(s).
col Colour of plotting symbol(s).

Network meta-analysis on blood loss during liver transplantation

Description

Network meta-analysis comparing the effects of a number of interventions for decreasing blood loss and blood transfusion requirements during liver transplantation.

Format

A data frame with the following columns:

- **study**
  - study information (first author, year)
- **treatment**
  - treatment
- **death**
  - mortality at 60 days post-transplantation
- **n**
  - number of individuals in treatment arm

**Hasse diagram**

**Description**

This function generates a Hasse diagram for a partial order of treatment ranks in a network meta-analysis.

**Usage**

```r
hasse(x, pooled = ifelse(x$random, "random", "common"), newpage = TRUE)
```

**Arguments**

- `x` An object of class netposet (mandatory).
- `pooled` A character string indicating whether Hasse diagram show be drawn for common ("common") or random effects model ("random"). Can be abbreviated.
- `newpage` A logical value indicating whether a new figure should be printed in an existing graphics window. Otherwise, the Hasse diagram is added to the existing figure.
Details

Generate a Hasse diagram (Carlsen & Bruggemann, 2014) for a partial order of treatment ranks in a network meta-analysis (Rücker & Schwarzer, 2017).

This R function is a wrapper function for R function hasse in R package hasseDiagram (Krzysztof Ciomek, https://github.com/kciomek/hasseDiagram), i.e., function hasse can only be used if R package hasseDiagram is installed.

#  
po <- netposet(netrank(net1), netrank(net2), outcomes = outcomes)  
# Hasse diagram  
#  
hasse(po)  
## End(Not run)
Arguments

- x: A `netmeta` object.
- method: A character string indicating which method is used to derive the hat matrix. Either "Ruecker", "Krahn" or "Davies" (can be abbreviated, see Details).
- type: A character string indicating which specific hat matrix should be derived (can be abbreviated, see Details).
- common: A logical indicating whether a hat matrix should be printed for the common effects network meta-analysis.
- random: A logical indicating whether a hat matrix should be printed for the random effects network meta-analysis.
- nchar.trts: A numeric defining the minimum number of characters used to create unique treatment names.
- nchar.studlab: A numeric defining the minimum number of characters used to create unique study labels.
- digits: Minimal number of significant digits, see `print.default`.
- legend: A logical indicating whether a legend should be printed.
- legend.studlab: A logical indicating whether a legend should be printed for abbreviated study labels.
- ... Additional arguments (ignored).

Details

This auxiliary function can be used to derive various hat matrices from a network meta-analysis object.

**Hat matrix by Ruecker (2012):**

This hat matrix is estimated if method = "Ruecker".

Let n be the number of different treatments (nodes, vertices) in a network and let m be the number of existing comparisons (edges) between the treatments. If there are only two-arm studies, m is equal to the number of studies, k. Let seTE.adj.common and seTE.adj.random be the vectors of adjusted standard errors under the common and random effects model (see `netmeta`). Let W be the m x m diagonal matrix that contains the inverse variance 1 / seTE.adj.common^2 or 1 / seTE.adj.random^2.

The given comparisons define the network structure. Therefrom an m x n design matrix X (edge-vertex incidence matrix) is formed; for more precise information, see Ruecker (2012). Moreover, the n x n Laplacian matrix L and its Moore-Penrose pseudoinverse L^+ are calculated (both matrices play an important role in graph theory and electrical network theory). Using these matrices, the variances based on both direct and indirect comparisons can be estimated. The hat matrix H is estimated by H = XL^+X^TW = X(X^TWX)^+X^TW.

**Hat matrices by Krahn et al. (2013):**

One of the following hat matrices is estimated if method = "Krahn".

Use of type = "design" (default) results in a hat matrix of dimension n(n-1)/2 x d, where d is the sum of the number of independent comparisons from each design.

Use of type = "studies" results in a hat matrix of dimension n(n-1)/2 x l, where l is the number of independent pairwise comparisons, i.e., a three-arm study contributes two pairwise comparisons.
Hat matrices by Davies et al. (2021):

One of three hat matrices is estimated if method = "Davies".

Here, we focus on the hat matrix of the aggregate (two-step) version of the graph theoretical NMA model. In the first step, a pairwise meta-analysis is performed across each edge using the adjusted weights (these account for correlations due to multi-arm trials). From this we obtain direct treatment effect estimates (and corresponding aggregate weights) associated with each edge. In step two, we combine these direct estimates in a network meta analysis to obtain the network estimates. This is done using weighted least squares regression. The hat matrix associated with this second step is called the aggregate hat matrix.

All three versions of the aggregate hat matrix contain the same information: the second two can be derived directly from the first. They differ in their dimensionality.

Each row of the hat matrix that represents a treatment comparison \((ij)\) describes the flow of evidence through each edge for that comparison. This defines a directed acyclic 'flow graph' from node \(i\) to node \(j\).

1. Use of type = "short" (default) results in a hat matrix of dimension \(e \times e\), where \(e\) is the number of (unique) edges (direct comparisons) in the network. This is the aggregate hat matrix described in Davies et al. (2021). Each row and column represents a pair of treatments for which there is at least one direct comparison.

2. Use of type = "long" results in a hat matrix of dimension \(n(n-1)/2 \times e\). There is a row for every possible pair of treatments in the network - regardless of whether there is direct evidence for this comparison. Each column represents a pair of treatments for which there is at least one direct comparison. The extra rows can be calculated from the short hat matrix using consistency equations.

3. Use of type = "full" results in a hat matrix of dimension \(n(n-1)/2 \times n(n-1)/2\). In comparison to the long hat matrix, columns of zeroes are added for comparisons that do not have any direct evidence. Therefore, there is a row and column for every pair of treatments in the network. This hat matrix is used to calculate the transition matrices for the random walk in netconrib.

Value

A list with two hat matrices: common (common effects model) and random (random effects model).

### invmat

*Moore-Penrose Pseudoinverse of a Matrix*

**Description**

Calculates the Moore-Penrose pseudoinverse of a square matrix `X`.

**Usage**

```r
invmat(X)
```

**Arguments**

- `X`: A square matrix.

**Details**

This function is used by default in R package `netmeta` to calculate the Moore-Penrose pseudoinverse `L^+` of the Laplacian matrix `L` (Rücker, 2012):

\[
L^+ = (X - J/n)^{-1} + J/n
\]

with identity matrix `J` of dimension `nxn`.

**Value**

The Moore-Penrose pseudoinverse for matrix `X`.

**Author(s)**

Linde2016  Network meta-analysis of primary care depression treatments

Description
Network meta-analysis of 22 treatments (including placebo and usual care) for the primary care of depression.
**Format**

A data frame with the following columns:

- `id`: Study ID
- `author`: First author
- `year`: Year of publication
- `treat1`: First treatment (abbreviated)
- `treat2`: Second treatment (abbreviated)
- `treat1.long`: First treatment
- `treat2.long`: Second treatment
- `lnOR`: Response after treatment (log odds ratio)
- `selnOR`: Standard error of log odds ratio
- `resp1`: Responder (first treatment)
- `n1`: Sample size (first treatment)
- `resp2`: Responder (second treatment)
- `n2`: Sample size (second treatment)

```
metabias.netmeta  Test of funnel plot asymmetry in network meta-analysis

Description

Test of funnel plot asymmetry in network meta-analysis

Usage

## S3 method for class 'netmeta'
metabias(
  x,
  order,
  pooled = ifelse(x$random, "random", "common"),
  method.bias = "Egger",
  lump.comparator = FALSE,
  ...
)

Arguments

x  An object of class netmeta.

order  A mandatory character or numerical vector specifying the order of treatments or list of comparators (see Details).

pooled  A character string indicating whether results for the common ("common") or random effects model ("random") should be used in test of funnel plot asymmetry. Can be abbreviated.

method.bias  A character vector indicating which test(s) for funnel plot asymmetry to use. Admissible values are "Begg", "Egger", and "Thompson", can be abbreviated. See function metabias.meta.

lump.comparator  A logical indicating whether comparators should be lumped, e.g., to specify inactive treatments. Information on direct comparisons should be added to the plot.

...  Additional arguments (passed on to metabias.meta).
Test of funnel plot asymmetry in network meta-analysis

Argument order is mandatory to determine the order of treatments (Chaimani et al., 2013):

“[…] investigators should order the treatments in a meaningful way and make assumptions about how small studies differ from large ones. For example, if they anticipate that newer treatments are favored in small trials, then they could name the treatments from oldest to newest so that all comparisons refer to ‘old versus new intervention’. Other possibilities include defining the comparisons so that all refer to an active treatment versus placebo or sponsored versus non-sponsored intervention.”

Alternatively, it is possible to only provide a single or few treatment name(s) in argument order to define the comparator(s). In this case only comparisons with this / these treatment(s) will be considered. If argument lump.comparator is TRUE, all comparators will be lumped into a single group.

A list with class metabias containing the following components if a test for funnel plot asymmetry is conducted:

- statistic: Test statistic.
- df: The degrees of freedom of the test statistic in the case that it follows a t distribution.
- pval: The p-value for the test.
- estimate: Estimates used to calculate test statistic.
- method: A character string indicating what type of test was used.
- title: Title of Cochrane review.
- complab: Comparison label.
- outclab: Outcome label.
- var.model: A character string indicating whether none, multiplicative, or additive residual heterogeneity variance was assumed.
- method.bias: As defined above.
- x: Network meta-analysis object.
- version: Version of R package meta used to create object.
- version.netmeta: Version of R package netmeta used to create object.

Or a list with the following elements if test is not conducted due to the number of studies:

- k: Number of comparisons.
- k.min: Minimum number of comparisons to perform test for funnel plot asymmetry.
- version: Version of R package meta used to create object.
- version.netmeta: Version of R package netmeta used to create object.

**netbind**

*Combine network meta-analysis objects*

**Description**

This function can be used to combine network meta-analysis objects which is especially useful to generate a forest plot with results of several network meta-analyses.
netbind

Usage

netbind(
  ..., 
  name, 
  common, 
  random, 
  col.study = "black", 
  col.inside = "white", 
  col.square = "gray", 
  col.square.lines = col.square, 
  backtransf, 
  reference.group, 
  baseline.reference, 
  warn.deprecated = gs("warn.deprecated"), 
  fixed, 
  comb.fixed, 
  comb.random 
)

Arguments

... Any number of network meta-analysis objects or a single list with network meta-
analyses.

name An optional character vector providing descriptive names for network meta-
analyses objects.

common A logical indicating whether results for the common effects model should be 
reported.

random A logical indicating whether results for the random effects model should be 
reported.

col.study The colour for network estimates and confidence limits.

col.inside The colour for network estimates and confidence limits if confidence limits are 
completely within squares.

col.square The colour for squares.

col.square.lines The colour for the outer lines of squares.

backtransf A logical indicating whether results should be back transformed. If backtransf 
= TRUE (default), results for sm = "OR" are printed as odds ratios rather than log 
odds ratios, for example.

baseline.reference A logical indicating whether results should be expressed as comparisons of other 
treatments versus the reference treatment (default) or vice versa. This argument 
is only considered if reference.group has been specified.
warn.deprecated
A logical indicating whether warnings should be printed if deprecated arguments are used.

fixed
Deprecated argument; replaced by common.

comb.fixed
Deprecated argument; replaced by common.

comb.random
Deprecated argument; replaced by random.

Value
An object of class "netbind" with corresponding forest function. The object is a list containing the following components:

common
A data frame with results for the common effects model.

random
A data frame with results for the random effects model.

sm
Summary measure used in network meta-analyses.

level.ma
Level for confidence intervals.

reference.group, baseline.reference
As defined above.

# Combine results of standard NMA and CNMA
netcomb

Additive network meta-analysis for combinations of treatments

Description

Some treatments in a network meta-analysis may be combinations of other treatments or have common components. The influence of individual components can be evaluated in an additive network meta-analysis model assuming that the effect of treatment combinations is the sum of the effects of its components. This function implements this additive model in a frequentist way.

Usage

```r
netcomb(
  x,
  inactive = NULL,
  sep.comps = "*",
  C.matrix,
  common = x$common,
  random = x$random | !is.null(tau.preset),
  tau.preset = NULL,
  details.chkident = FALSE,
  nchar.comps = x$nchar.trts,
  func.inverse = invmat,
  warn.deprecated = gs("warn.deprecated"),
  ...
)
```

Arguments

- `x`: An object of class netmeta.
- `inactive`: A character string defining the inactive treatment component (see Details).
- `sep.comps`: A single character to define separator between treatment components.
- `C.matrix`: C matrix (see Details).
- `common`: A logical indicating whether a common effects network meta-analysis should be conducted.
- `random`: A logical indicating whether a random effects network meta-analysis should be conducted.
netcomb

tau.preset An optional value for the square-root of the between-study variance $\tau^2$.
details.chkident A logical indicating whether details on unidentifiable components should be printed.
nchar.comps A numeric defining the minimum number of characters used to create unique names for components (see Details).
func.inverse R function used to calculate the pseudoinverse of the Laplacian matrix $L$ (see \texttt{netmeta}).
warn.deprecated A logical indicating whether warnings should be printed if deprecated arguments are used.
... Additional arguments (to catch deprecated arguments).

Details

Treatments in network meta-analysis (NMA) can be complex interventions. Some treatments may be combinations of others or have common components. The standard analysis provided by \texttt{netmeta} is a NMA where all existing (single or combined) treatments are considered as different nodes in the network. Exploiting the fact that some treatments are combinations of common components, an additive component network meta-analysis (CNMA) model can be used to evaluate the influence of individual components. This model assumes that the effect of a treatment combination is the sum of the effects of its components which implies that common components cancel out in comparisons.

The additive CNMA model has been implemented using Bayesian methods (Mills et al., 2012; Welton et al., 2013). This function implements the additive model in a frequentist way (Rücker et al., 2020).

The underlying multivariate model is given by

$$\delta = B\theta, \theta = C\beta$$

with

- $\delta$ vector of true treatment effects (differences) from individual studies,
- $B$ design matrix describing the structure of the network,
- $\theta$ parameter vector that represents the existing combined treatments,
- $C$ matrix describing how the treatments are composed,
- $\beta$ parameter vector representing the treatment components.

All parameters are estimated using weighted least squares regression.

Argument \texttt{inactive} can be used to specify a single component that does not have any therapeutic value. Accordingly, it is assumed that the treatment effect of the combination of this component with an additional treatment component is equal to the treatment effect of the additional component alone.

Argument \texttt{sep.comps} can be used to specify the separator between individual components. By default, the matrix $C$ is calculated internally from treatment names. However, it is possible to specify a different matrix using argument \texttt{C.matrix}. 
By default, component names are not abbreviated in printouts. However, in order to get more concise printouts, argument nchar.comps can be used to define the minimum number of characters for abbreviated component names (see `abbreviate`, argument `minlength`). R function `treats` is utilised internally to create abbreviated component names.

**Value**

An object of class `netcomb` with corresponding `print`, `summary`, and `forest` functions. The object is a list containing the following components:

- `studlab`: Study labels.
- `treat1`: Label/Number for first treatment.
- `treat2`: Label/Number for second treatment.
- `TE`: Estimate of treatment effect, i.e. difference between first and second treatment.
- `seTE`: Standard error of treatment estimate.
- `seTE.adj.common`, `seTE.adj.random`: Standard error of treatment estimate, adjusted for multi-arm studies.
- `design`: Design of study providing pairwise comparison.
- `event1`: Number of events in first treatment group.
- `event2`: Number of events in second treatment group.
- `n1`: Number of observations in first treatment group.
- `n2`: Number of observations in second treatment group.
- `k`: Total number of studies.
- `m`: Total number of pairwise comparisons.
- `n`: Total number of treatments.
- `d`: Total number of designs (corresponding to the unique set of treatments compared within studies).
- `c`: Total number of components.
- `trts`: Treatments included in network meta-analysis.
- `k.trts`: Number of studies evaluating a treatment.
- `n.trts`: Number of observations receiving a treatment (if arguments `n1` and `n2` are provided).
- `events.trts`: Number of events observed for a treatment (if arguments `event1` and `event2` are provided).
- `studies`: Study labels coerced into a factor with its levels sorted alphabetically.
- `narms`: Number of arms for each study.
- `designs`: Unique list of designs present in the network. A design corresponds to the set of treatments compared within a study.
- `comps`: Unique list of components present in the network.
- `TE.nma.common`, `TE.nma.random`: A vector of length `m` of consistent treatment effects estimated by network meta-analysis (nma) (common and random effects model).
seTE.nma.common, seTE.nma.random
A vector of length $m$ of effective standard errors estimated by network meta-analysis (common and random effects model).

lower.nma.common, lower.nma.random
A vector of length $m$ of lower confidence interval limits for consistent treatment effects estimated by network meta-analysis (common and random effects model).

upper.nma.common, upper.nma.random
A vector of length $m$ of upper confidence interval limits for the consistent treatment effects estimated by network meta-analysis (common and random effects model).

statistic.nma.common, statistic.nma.random
A vector of length $m$ of z-values for test of treatment effect for individual comparisons (common and random effects model).

pval.nma.common, pval.nma.random
A vector of length $m$ of p-values for test of treatment effect for individual comparisons (common and random effects model).

TE.cnma.common, TE.cnma.random
A vector of length $m$ of consistent treatment effects estimated by the additive (common and random effects) model.

seTE.cnma.common, seTE.cnma.random
A vector of length $m$ with standard errors estimated by the additive (common and random effects) model.

lower.cnma.common, lower.cnma.random
A vector of length $m$ of lower confidence interval limits for consistent treatment effects estimated by the additive (common and random effects) model.

upper.cnma.common, upper.cnma.random
A vector of length $m$ of upper confidence interval limits for consistent treatment effects estimated by the additive (common and random effects) model.

statistic.cnma.common, statistic.cnma.random
A vector of length $m$ of z-values for the test of an overall effect estimated by the additive (common and random effects) model.

pval.cnma.common, pval.cnma.random
A vector of length $m$ of p-values for the test of an overall effect estimated by the additive (common and random effects) model.

TE.common, TE.random
$n \times n$ matrix with overall treatment effects estimated by the additive (common and random effects) model.

seTE.common, seTE.random
$n \times n$ matrix with standard errors estimated by the additive (common and random effects) model.

lower.common, upper.common, lower.random, upper.random
$n \times n$ matrices with lower and upper confidence interval limits estimated by the additive (common and random effects) model.

statistic.common, pval.common, statistic.random, pval.random
$n \times n$ matrices with z-values and p-values for test of overall effect estimated by the additive (common and random effects) model.
netcomb

Comp.common, Comp.random
A vector of component effects (common and random effects model).

seComp.common, seComp.random
A vector with corresponding standard errors (common and random effects model).

lower.Comp.common, lower.Comp.random
A vector with lower confidence limits for components (common and random effects model).

upper.Comp.common, upper.Comp.random
A vector with upper confidence limits for components (common and random effects model).

statistic.Comp.common, statistic.Comp.random
A vector with z-values for the overall effect of components (common and random effects model).

pval.Comp.common, pval.Comp.random
A vector with p-values for the overall effect of components (common and random effects model).

Comb.common, Comb.random
A vector of combination effects (common and random effects model).

seComb.common, seComb.random
A vector with corresponding standard errors (common and random effects model).

lower.Comb.common, lower.Comb.random
A vector with lower confidence limits for combinations (common and random effects model).

upper.Comb.common, upper.Comb.random
A vector with upper confidence limits for combinations (common and random effects model).

statistic.Comb.common, statistic.Comb.random
A vector with z-values for the overall effect of combinations (common and random effects model).

pval.Comb.common, pval.Comb.random
A vector with p-values for the overall effect of combinations (common and random effects model).

Q.additive
Overall heterogeneity / inconsistency statistic (additive model).

df.Q.additive
Degrees of freedom for test of heterogeneity / inconsistency (additive model).

pval.Q.additive
P-value for test of heterogeneity / inconsistency (additive model).

tau
Square-root of between-study variance (additive model).

I2, lower.I2, upper.I2
I-squared, lower and upper confidence limits.

Q.standard
Overall heterogeneity / inconsistency statistic (standard model).

df.Q.standard
Degrees of freedom for test of heterogeneity / inconsistency (standard model).

pval.Q.standard
P-value for test of heterogeneity / inconsistency (standard model).

Q.diff
Test statistic for difference in goodness of fit between standard and additive model.
Degrees of freedom for difference in goodness of fit between standard and additive model.

P-value for difference in goodness of fit between standard and additive model.

Adjacency matrix ($n \times n$).

Edge-vertex incidence matrix ($m \times n$).

As defined above.

Summary measure.

Level for confidence intervals.

As defined above.

A character used in comparison names as separator between treatment labels.

A numeric defining the minimum number of characters used to create unique component names.

As defined above.

A logical indicating whether results should be back transformed in printouts and forest plots.

Title of meta-analysis / systematic review.

As defined above.

Function call.

Version of R package netmeta used to create object.

This function calculates effects for individual components and complex interventions present in the network.

R function `netcomplex` can be used to calculate the effect for arbitrary complex interventions in a component network meta-analysis. Furthermore, R function `netcomparison` can be used to calculate the effect for comparisons of two arbitrary complex intervention in a component network meta-analysis.

## End(Not run)

calculate comparison effects of two arbitrary complex interventions
in component network meta-analysis

Description

Calculate comparison effects of two arbitrary complex interventions (i.e., combinations of several components) in component network meta-analysis.

Usage

netcomparison(
  x,
  treat1,
  treat2,
  common = x$common,
  random = x$random,
  level = x$level.ma,
  nchar.comps = x$nchar.comps,
  warn.deprecated = gs("warn.deprecated"),
  ...
)

## S3 method for class 'netcomparison'
print(
  x,
  common = x$common,
  random = x$random,
  backtransf = x$backtransf,
  nchar.comps = x$nchar.comps,
  digits = gs("digits"),
  digits.stat = gs("digits.stat"),
  digits.pval = gs("digits.pval"),
  scientific.pval = gs("scientific.pval"),
  zero.pval = gs("zero.pval"),
)
Arguments

x	An object of class netcomb or netcomparison (print function).
treat1	A character vector defining the first complex intervention(s).
treat2	A character vector defining the second complex intervention(s).
common	A logical indicating whether results for common effects model should be conducted.
random	A logical indicating whether results for random effects model should be conducted.
level	The level used to calculate confidence intervals for combinations of components.
nchar.comps	A numeric defining the minimum number of characters used to create unique names for components (see Details).
warn.deprecated	A logical indicating whether warnings should be printed if deprecated arguments are used.
... 	Additional arguments (to catch deprecated arguments).
backtransf	A logical indicating whether printed results should be back transformed. If backtransf=TRUE, results for sm="OR" are printed as odds ratios rather than log odds ratios.
digits	Minimal number of significant digits, see print.default.
digits.stat	Minimal number of significant digits for z-value of test for overall effect, see print.default.
digits.pval	Minimal number of significant digits for p-values, see print.default.
scientific.pval	A logical specifying whether p-values should be printed in scientific notation, e.g., 1.2345e-01 instead of 0.12345.
zero.pval	A logical specifying whether p-values should be printed with a leading zero.
JAMA.pval	A logical specifying whether p-values for test of combination effect should be printed according to JAMA reporting standards.
big.mark	A character used as thousands separator.
legend	A logical indicating whether a legend should be printed.

Details

R functions netcomb and discomb calculate effects for individual components and complex interventions present in the component network meta-analysis (CNMA). This function can be used to
calculate the effect for comparisons of two arbitrary complex interventions defined by arguments `treat1` and `treat2`.

All complex interventions occurring in the network are considered for the first complex intervention if argument `treat1` is missing. The reference group defined in the (C)NMA is used as second complex intervention if argument `treat2` is missing. The first complex intervention in the (C)NMA is used if the reference group is not defined.

The following matrices are needed to calculate comparison effects of arbitrary complex interventions, (Rücker et al., 2020, Section 3.2):

- B matrix describing how comparisons are composed by complex interventions,
- C matrix describing how the complex interventions are composed by the components.

Internally, both matrices are constructed based on arguments `x`, `treat1` and `treat2`.

By default, component names are not abbreviated in printouts. However, in order to get more concise printouts, argument `nchar.comps` can be used to define the minimum number of characters for abbreviated component names (see `abbreviate`, argument `minlength`). R function `treats` is utilised internally to create abbreviated component names.

**Value**

A list is returned by the function `netcomparison` with the following elements:

- `comparison` Comparison.
- `TE.common`, `TE.random` A vector of comparison effects (common and random effects model).
- `seTE.common`, `seTE.random` A vector with corresponding standard errors (common and random effects model).
- `lower.common`, `lower.random` A vector with lower confidence limits for comparisons (common and random effects model).
- `upper.common`, `upper.random` A vector with upper confidence limits for comparisons (common and random effects model).
- `statistic.common`, `statistic.random` A vector with z-values for the overall effect of comparisons (common and random effects model).
- `pval.common`, `pval.random` A vector with p-values for the overall effect of comparisons (common and random effects model).
- `trts` Treatments included in comparisons.
- `comps` Components included in comparisons.
- `treat1`, `treat2` A defined above.
- `common`, `random` A defined above.
- `level`, `nchar.comps`, `backtransf`, `x` A defined above.
- `B.matrix` B matrix.
- `C.matrix` C matrix.
Note

R function `netcomplex` can be used to calculate the effect for arbitrary complex interventions in a component network meta-analysis.

## S3 method for class 'netcomplex'

```r
print(
  x,
  common = x$common,
  random = x$random,
  backtransf = x$backtransf,
  nchar.comps = x$nchar.comps,
  digits = gs("digits"),
  digits.stat = gs("digits.stat"),
  digits.pval = gs("digits.pval"),
  ...,
)
```
scientific.pval = gs("scientific.pval"),
zero.pval = gs("zero.pval"),
JAMA.pval = gs("JAMA.pval"),
big.mark = gs("big.mark"),
legend = TRUE,
warn.deprecated = gs("warn.deprecated"),
...
)

Arguments

x An object of class netcomb or netcomplex (print function).
complex A matrix, vector or single numeric defining the complex intervention(s) (see Details).
common A logical indicating whether results for common effects model should be conducted.
random A logical indicating whether results for random effects model should be conducted.
level The level used to calculate confidence intervals for combinations of components.
nchar.comps A numeric defining the minimum number of characters used to create unique names for components (see Details).
warn.deprecated A logical indicating whether warnings should be printed if deprecated arguments are used.
... Additional arguments (to catch deprecated arguments).
backtransf A logical indicating whether printed results should be back transformed. If backtransf=TRUE, results for sm="OR" are printed as odds ratios rather than log odds ratios.
digits Minimal number of significant digits, see print.default.
digits.stat Minimal number of significant digits for z-value of test for overall effect, see print.default.
digits.pval Minimal number of significant digits for p-values, see print.default.
scientific.pval A logical specifying whether p-values should be printed in scientific notation, e.g., 1.2345e-01 instead of 0.12345.
zero.pval A logical specifying whether p-values should be printed with a leading zero.
JAMA.pval A logical specifying whether p-values for test of combination effect should be printed according to JAMA reporting standards.
big.mark A character used as thousands separator.
legend A logical indicating whether a legend should be printed.
Details

R functions `netcomb` and `discomb` only report results for complex interventions present in the network. This function can be used to calculate the effect for arbitrary complex interventions.

Complex interventions can be specified using argument `complex`:

- a character vector with definition of complex interventions,
- a single numeric defining the number of components to combine in a complex intervention,
- a dedicated C matrix.

In order to calculate effects of arbitrary complex interventions, a C matrix is needed which describes how the complex interventions are composed by the components (Rücker et al., 2020, Section 3.2). The C matrix is constructed internally if not provided by argument `complex`. All complex interventions occurring in the network are considered if argument `complex` is missing.

By default, component names are not abbreviated in printouts. However, in order to get more concise printouts, argument `nchar.comps` can be used to define the minimum number of characters for abbreviated component names (see `abbreviate`, argument `minlength`). R function `treats` is utilised internally to create abbreviated component names.

Value

A list is returned by the function `netcomplex` with the following elements:

- `complex` Complex intervention(s).
- `Comb.common`, `Comb.random` A vector of combination effects (common and random effects model).
- `seComb.common`, `seComb.random` A vector with corresponding standard errors (common and random effects model).
- `lower.Comb.common`, `lower.Comb.random` A vector with lower confidence limits for combinations (common and random effects model).
- `upper.Comb.common`, `upper.Comb.random` A vector with upper confidence limits for combinations (common and random effects model).
- `statistic.Comb.common`, `statistic.Comb.random` A vector with z-values for the overall effect of combinations (common and random effects model).
- `pval.Comb.common`, `pval.Comb.random` A vector with p-values for the overall effect of combinations (common and random effects model).
- `common`, `random` A defined above.
- `level`, `nchar.comps`, `backtransf`, `x` A defined above.
- `C.matrix` C matrix.

Note

R function `netcomparison` can be used to calculate the effect for comparisons of two arbitrary complex intervention in a component network meta-analysis.

---

**netconnection**  
*Get information on network connectivity (number of subnetworks, distance matrix)*

**Description**

To determine the network structure and to test whether a given network is fully connected. Network information is provided as a triple of vectors `treat1`, `treat2`, and `studlab` where each row corresponds to an existing pairwise treatment comparison (`treat1`, `treat2`) in a study (`studlab`). The function calculates the number of subnetworks (connectivity components; value of 1 corresponds to a fully connected network) and the distance matrix (in block-diagonal form in the case of subnetworks). If some treatments are combinations of other treatments or have common components, an analysis based on the additive network meta-analysis model might be possible, see `discomb` function.

**Usage**

```r
netconnection(
  treat1,
  treat2,
  studlab,
  data = NULL,
  subset = NULL,
  sep.trts = ":",
  nchar.trts = 666,
  title = "",
  details.disconnected = FALSE,
  warn = FALSE
)
```

## S3 method for class 'netconnection'
print(
  x,
  ...,
)
digits = max(4, .Options$digits - 3),
nchar.trts = x$nchar.trts,
details = FALSE,
details.disconnected = x$details.disconnected,
...
)

Arguments

treat1    Label / number for first treatment or a data frame created with pairwise.
treat2    Label / number for second treatment.
studlab   An optional - but important! - vector with study labels (see Details).
data      An optional data frame containing the study information.
subset    An optional vector specifying a subset of studies to be used.
sep.trts   A character used in comparison names as separator between treatment labels.
nchar.trts A numeric defining the minimum number of characters used to create unique
treatment names.
title     Title of meta-analysis / systematic review.
details.disconnected  A logical indicating whether to print more details for disconnected networks.
warn      A logical indicating whether warnings should be printed.
x         An object of class netconnection.
digits    Minimal number of significant digits, see print.default.
details   A logical indicating whether to print the distance matrix.
...       Additional arguments (ignored at the moment)

Value

An object of class netconnection with corresponding print function. The object is a list contain-
ing the following components:

treat1, treat2, studlab, title, warn, nchar.trts
As defined above.
k       Total number of studies.
m       Total number of pairwise comparisons.
n       Total number of treatments.
n.subnets Number of subnetworks; equal to 1 for a fully connected network.
D.matrix Distance matrix.
A.matrix Adjacency matrix.
L.matrix Laplace matrix.
call     Function call.
version  Version of R package netmeta used to create object.

## S3 method for class 'netcontrib'
print(
  x,
  common = x$x$common,
  random = x$x$random,
  digits = 4,
  nchar.trts = x$nchar.trts,
  legend = TRUE,
  warn.deprecated = gs("warn.deprecated"),
  ...)

Arguments

- **x**: An object of class netmeta or netcontrib.
**Details**

In network meta-analysis (NMA), it is important to assess the influence of limitations or other characteristics of individual studies on the estimates obtained from the network. To this end, the contribution matrix shows how much each direct treatment effect contributes to each treatment effect estimate from network meta-analysis.

We use ideas from graph theory to derive the proportion that is contributed by each direct treatment effect. We start with the 'projection' matrix in a two-step network meta-analysis model, called the H matrix, which is analogous to the hat matrix in a linear regression model. H entries are translated to proportion contributions based on the observation that the rows of H can be interpreted as flow networks. A stream is defined as the composition of a path and its associated flow (Papakonstantinou et al., 2018).

To account for multi-arm trials, we use the H matrix from a two-step (aggregate) version of the graph theoretical NMA model (Davies et al., 2021). This H matrix can be obtained from `hatmatrix` with argument method = "davies".

Two methods are implemented to estimate the streams and as a result, the proportion contributions:

1. If argument method = "randomwalk", an analytical random-walk (RW) approach is used (Davies et al., 2021). Here, the "full" version of the aggregate H matrix (`hatmatrix` with arguments method = "davies" and type = "full") is used to define RW transition matrices. For each pair of treatments (ij) in the network, the elements in the corresponding row of H-full define a transition matrix from node i to node j. We use the `igraph` package to find every (directed) path from node i to node j. The flow through each path is then equal to the probability that a walker takes that path. This is simply the product of the transition probabilities associated with each edge along the path.

2. If argument method = "shortestpath", an iterative algorithm is used (Papakonstantinou et al., 2018). Broadly speaking, each iteration of the algorithm consists of the following steps: (i) A path in the evidence flow network is selected. (ii) The minimum flow through the edges making up the path...
path is identified. This is assigned as the flow associated with the path. (iii) The flow of the path is subtracted from the values of flow in the edges that make up that path. This means that the edge corresponding to the minimum flow in that path is removed from the graph. (iv) A new path is then selected from the remaining graph. The process repeats until all the evidence flow in the edges has been assigned to a path.

In the original F1000 paper (Papakonstantinou et al., 2018), the hat matrix used did not account for correlations due to multi-arm trials. For reproducibility the result of this version can be obtained by specifying `hatmatrix.F1000 = TRUE` for `method = "shortestpath"`. For other purposes, this method is not recommended.

Once the streams have been identified (either by method (1) or (2)), the proportion contribution of each direct comparison is equal to the sum over the flow of evidence in each path containing that edge divided by the number of edges that make up that path.

By default, treatment names are not abbreviated in printouts. However, in order to get more concise printouts, argument `nchar.trts` can be used to define the minimum number of characters for abbreviated treatment names (see `abbreviate`, argument `minlength`). R function `treats` is utilised internally to create abbreviated treatment names.

Calculation of network contributions can be compute-intensive for the random-walk approach in large networks. Crude information on the computation progress is printed if argument `verbose` is `TRUE`. In addition, computation times are printed if R package `tictoc` is installed.

Value

An object of class `netcontrib` with corresponding `print` function. The object is a list containing the following components:

- `common` Numeric matrix of percentage contributions of direct comparisons for each network comparison for the common effects model.
- `random` Numeric matrix of percentage contributions of direct comparisons for each network comparison for the random effects model.
- `x` As defined above.
- `tictoc.common` Computation times under common effects model (if R package `tictoc` is installed).
- `tictoc.random` Computation times under random effects model (if R package `tictoc` is installed).

with the contribution matrices for common and random NMA. Each matrix has the percentage contributions of each direct comparison as columns for each network comparison, direct or indirect as rows.

### Netdistance

*Calculate distance matrix for an adjacency matrix*

**Description**

Calculate distance matrix for an adjacency matrix based on distance algorithm by Müller et al. (1987).

**Usage**

```r
netdistance(x)
```

**Arguments**

- `x` Either a netmeta object or an adjacency matrix.

**netgraph.discomb**

Network graph for objects of class discomb

**Description**

This function generates a graph of the evidence network.

**Usage**

```r
## S3 method for class 'discomb'
netgraph(x, ...)
```

**Arguments**

- `x` An object of class discomb.
- `...` Additional arguments passed on to `netgraph.netmeta` (see Details).
Details

The following arguments are used internally and cannot be specified by the user: thickness, seq, iterate.

Examples

```r
data(Linde2016)

# Only consider studies including Face-to-face PST (to reduce
# runtime of example)
# face <- subset(Linde2016, id %in% c(16, 24, 49, 118))

# Conduct random effects network meta-analysis
# net1 <- netmeta(lnOR, selnOR, treat1, treat2, id, 
# data = face, ref = "placebo", sm = "OR", common = FALSE)

# Additive model for treatment components (with placebo as inactive treatment)
# ncl <- netcomb(net1, inactive = "placebo")
netgraph(ncl)
```

Description

This function generates a graph of the evidence network.
Usage

```
## S3 method for class 'netconnection'
netgraph(
  x, seq,
  col = seq_len(x$n.subnets),
  reference.group = NULL,
  plastic = FALSE,
  ...
)
```

Arguments

- `x`: An object of class `netconnection`.
- `seq`: A character or numerical vector specifying the sequence of treatments arrangement (anticlockwise if `start.layout = "circle"`).
- `col`: A single color (or vector of colors) for lines connecting treatments (edges) if argument plastic = FALSE (see Details).
- `reference.group`: Reference treatment (only relevant for disconnected networks).
- `plastic`: A logical indicating whether the appearance of the comparisons should be in '3D look'.
- `...`: Additional arguments passed on to `netgraph.netmeta` (see Details).

Details

Argument `col` can be a single color for all edges, a vector of length equal to the number of edges, or a vector of length equal to the number of subnetworks. Argument `reference.group` is only considered in disconnected networks, i.e., if more than one (sub)network exists, and if argument `col` provides colors for subnetworks. In this case, the first color provided in argument `col` defines the color for the subnetwork with the reference treatment.

The following arguments for network graphs are used internally and cannot be specified by the user: `thickness`, `seq`, `iterate`.

```
#
nc1 <- netconnection(t1, t2)
print(nc1, details = TRUE)

netgraph(nc1, plastic = TRUE)

netgraph.netimpact Network graph for objects of class netimpact

Description

This function generates a graph of the evidence network.

Usage

## S3 method for class 'netimpact'
netgraph(
  x,
  col.ignore = "red",
  number.of.studies = TRUE,
  main,
  sub,
  multiarm = FALSE,
  col.multiarm = NULL,
  alpha.transparency = 0.5,
  col.ignore.multiarm = "transparent",
  col = "slateblue",
  ...
)

Arguments

x An object of class netimpact.
col.ignore A character string indicating color for comparisons removed from network, either "transparent" or any color defined in colours.
number.of.studies A logical indicating whether number of studies should be added to network graph.
main Main title.
sub Subtitle.
multiarm A logical indicating whether multi-arm studies should be marked in plot.
col.multiarm Either a function from R package colorspace or grDevice to define colors for multi-arm studies or a character vector with colors to highlight multi-arm studies.
alpha.transparency
   The alpha transparency of colors used to highlight multi-arm studies (0 means
   transparent and 1 means opaque).

col.ignore.multiarm
   A character string indicating color to mark multi-arm studies removed from net-
   work, either "transparent" or any color defined in colours.

col
   A single color (or vector of colors) for lines connecting treatments (edges) if
   argument plastic = FALSE. Length of the vector must be equal to the number
   of edges.

... Additional arguments passed on to netgraph.netmeta.

  col.points = "red",
  cex.points = 1,
  pch.points = 20,
  bg.points = "gray",
  number.of.studies = FALSE,
  cex.number.of.studies = cex,
  col.number.of.studies = "white",
  bg.number.of.studies = "black",
  pos.number.of.studies = 0.5,
  start.layout = ifelse(dim == "2d", "circle", "eigen"),
  eig1 = 2,
  eig2 = 3,
  eig3 = 4,
  iterate,
  tol = 1e-04,
  maxit = 500,
  allfigures = FALSE,
  A.matrix = x$A.matrix,
  N.matrix = sign(A.matrix),
  D.matrix = netdistance(N.matrix),
  xpos = NULL,
  ypos = NULL,
)
Arguments

- **x**
  - An object of class `netmeta` (mandatory).
- **seq**
  - A character or numerical vector specifying the sequence of treatments arrangement (anticlockwise if `start.layout = "circle"`).
- **labels**
  - An optional vector with treatment labels.
- **cex**
  - The magnification to be used for treatment labels.
- **adj**
  - One, two, or three values in [0, 1] (or a vector / matrix with length / number of rows equal to the number of treatments) specifying the x (and optionally y and z) adjustment for treatment labels.
- **srt.labels**
  - The character string "orthogonal" (can be abbreviated), a single numeric or numerical vector with value(s) between -180 and 180 specifying the angle to rotate treatment labels (see Details).
- **offset**
  - Distance between edges (i.e. treatments) in graph and treatment labels for 2-D plots (value of 0.0175 corresponds to a difference of 1.75% of the range on x- and y-axis).
- **scale**
  - Additional space added outside of edges (i.e. treatments). Increase this value for larger treatment labels (value of 1.10 corresponds to an additional space of 10% around the network graph).
- **col**
  - A single color (or vector of colors) for lines connecting treatments (edges) if argument `plastic = FALSE`. Length of the vector must be equal to the number of edges (see list element 'comparisons' in `netmeta`).
- **plastic**
  - A logical indicating whether the appearance of the comparisons should be in '3D look' (not to be confused with argument `dim`).
- **thickness**
  - Either a character variable to determine the method to plot line widths (see Details) or a matrix of the same dimension and row and column names as argument `A.matrix` with information on line width.
- **lwd**
  - A numeric for scaling the line width of comparisons.
- **lwd.min**
  - Minimum line width in network graph. All connections with line widths below this values will be set to `lwd.min`.
- **lwd.max**
  - Maximum line width in network graph. The connection with the largest value according to argument `thickness` will be set to this value.
- **dim**
  - A character string indicating whether a 2- or 3-dimensional plot should be produced, either "2d" or "3d".
- **rotate**
  - A single numeric with value between -180 and 180 specifying the angle to rotate nodes in a circular network.
- **highlight**
  - A character vector identifying comparisons that should be marked in the network graph, e.g. `highlight = "treat1:treat2"`.
- **col.highlight**
  - Color(s) to highlight the comparisons given by `highlight`. 

```r
zpos = NULL,
figure = TRUE,
...
)
```
scale.highlight
   Scaling factor(s) for the line width(s) to highlight the comparisons given by
   highlight.

multiarm
   A logical indicating whether multi-arm studies should be marked in plot.

col.multiarm
   Either a function from R package colorspace or grDevice to define colors for
   multi-arm studies or a character vector with colors to highlight multi-arm stud-
   ies.

alpha.transparency
   The alpha transparency of colors used to highlight multi-arm studies (0 means
   transparent and 1 means opaque).

points
   A logical indicating whether points should be printed at nodes (i.e. treatments)
   of the network graph.

col.points, cex.points, pch.points, bg.points
   Corresponding color, size, type, and background color for points. Can be a
   vector with length equal to the number of treatments.

number.of.studies
   A logical indicating whether number of studies should be added to network
   graph.

cex.number.of.studies
   The magnification to be used for number of studies.

col.number.of.studies
   Color for number of studies.

bg.number.of.studies
   Color for shadow around number of studies.

pos.number.of.studies
   A single value (or vector of values) in [0, 1] specifying the position of the num-
   ber of studies on the lines connecting treatments (edges). Length of the vector
   must be equal to the number of edges.

start.layout
   A character string indicating which starting layout is used if iterate = TRUE.
   If "circle" (default), the iteration starts with a circular ordering of the vertices;
   if "eigen", eigenvectors of the Laplacian matrix are used, calculated via generic
   function eigen (spectral decomposition); if "prcomp", eigenvectors of the Lapla-
   cian matrix are calculated via generic function prcomp (principal component
   analysis); if "random", a random layout is used, drawn from a bivariate normal.

eig1
   A numeric indicating which eigenvector is used as x coordinate if start = "eigen"
   or "prcomp" and iterate = TRUE. Default is 2, the eigenvector to the
   second-smallest eigenvalue of the Laplacian matrix.

eig2
   A numeric indicating which eigenvector is used as y-coordinate if start = "eigen"
   or "prcomp" and iterate = TRUE. Default is 3, the eigenvector to the third-
   smallest eigenvalue of the Laplacian matrix.

eig3
   A numeric indicating which eigenvector is used as z-coordinate if start = "eigen"
   or "prcomp" and iterate = TRUE. Default is 4, the eigenvector to the fourth-
   smallest eigenvalue of the Laplacian matrix.

iterate
   A logical indicating whether the stress majorization algorithm is carried out for
   optimization of the layout.
tol  A numeric for the tolerance for convergence if iterate = TRUE.
maxit  An integer defining the maximum number of iteration steps if iterate = TRUE.
allfigures  A logical indicating whether all iteration steps are shown if iterate = TRUE. May slow down calculations if set to TRUE (especially if plastic = TRUE).
A.matrix  Adjacency matrix (nxn) characterizing the structure of the network graph. Row and column names must be the same set of values as provided by argument seq.
N.matrix  Neighborhood matrix (nxn) replacing A.matrix if neighborhood is to be specified differently from node adjacency in the network graph, for example content-based. Row and column names must be the same set of values as provided by argument seq.
D.matrix  Distance matrix (nxn) replacing A.matrix and N.matrix if distances should be provided directly. Row and column names must be the same set of values as provided by argument seq.
xpos  Vector (n) of x coordinates.
ypos  Vector (n) of y coordinates.
zpos  Vector (n) of z coordinates.
figure  A logical indicating whether network graph should be shown.
...  Additional graphical arguments.

Details

The network is laid out in the plane, where the nodes in the graph layout correspond to the treatments and edges display the observed treatment comparisons. For the default setting, nodes are placed on a circle. Other starting layouts are "eigen", "prcomp", and "random" (Rücker & Schwarzer 2015). If iterate = TRUE, the layout is further optimized using the stress majorization algorithm. This algorithm specifies an 'ideal' distance (e.g., the graph distance) between two nodes in the plane. In the optimal layout, these distances are best approximated in the sense of least squares. Starting from an initial layout, the optimum is approximated in an iterative process called stress majorization (Kamada and Kawai 1989, Michailidis and de Leeuw 2001, Hu 2012). The starting layout can be chosen as a circle or coming from eigenvectors of the Laplacian matrix (corresponding to Hall's algorithm, Hall 1970), calculated in different ways, or random. Moreover, it can be chosen whether the iteration steps are shown (argument allfigures = TRUE).

An optimized circular presentation which typically has a reduced (sometimes minimal) number of crossings can be achieved by using argument seq = "optimal" in combination with argument start.layout. Note, is it not possible of prespecify the best value for argument start.layout for any situation as the result depends on the network structure.

Argument thickness providing the line width of the nodes (comparisons) can be a matrix of the same dimension as argument A.matrix or any of the following character variables:

- Same line width (argument lwd) for all comparisons (thickness = "equal")
- Proportional to number of studies comparing two treatments (thickness = "number.of.studies")
- Proportional to inverse standard error of common effects model comparing two treatments (thickness = "se.common")
- Proportional to inverse standard error of random effects model comparing two treatments (thickness = "se.random")
• Weight from common effects model comparing two treatments (thickness = "w.common")
• Weight from random effects model comparing two treatments (thickness = "w.random")

Only evidence from direct treatment comparisons is considered to determine the line width if argument thickness is equal to any but the first method. By default, thickness = "se.common" is used if start.layout = "circle", iterate = FALSE, and plastic = TRUE. Otherwise, the same line width is used.

Argument srt.labels can be used to specific the rotation (in degrees) of the treatment labels. If srt.labels is equal to "orthogonal", treatment labels are orthogonal to the circle. If srt.labels is a single numeric, all labels are rotated by this degree. If srt.labels is a numeric vector, it must be of the same length as the number of treatments and labels are rotated counter-clockwise starting on the right side. Finally, if srt.labels is a named numeric vector, it must be of the same length as the number of treatments and the names must be equal to the treatment names (and treatment labels are rotated according to the specified values).

Further, a couple of graphical parameters can be specified, such as color and appearance of the edges (treatments) and the nodes (comparisons), whether special comparisons should be highlighted and whether multi-arm studies should be indicated as colored polygons. By default, if R package colorspace is available the sequential_hcl function is used to highlight multi-arm studies; otherwise the rainbow is used.

In order to generate 3-D plots (argument dim = "3d"), R package rgl is necessary. Note, under macOS the X.Org X Window System must be available (see https://www.xquartz.org).

Value

A data frame containing the following columns:

labels Treatment labels.
seq Sequence of treatment labels.
xpos Position of treatment / edge on x-axis.
ypos Position of treatment / edge on y-axis.
zpos Position of treatment / edge on z-axis (for 3-D plots).
xpos.labels Position of treatment labels on x-axis (for 2-D plots).
ypos.labels Position of treatment labels on y-axis (for 2-D plots).
adj.x Adjustment for treatment label on x-axis.
adj.y Adjustment for treatment label on y-axis.
adj.z Adjustment for treatment label on z-axis (for 3-D plots).

Description

This function creates a net heat plot, a graphical tool for locating inconsistency in network meta-analyses.

Usage

```r
netheat(
  x,
  random = FALSE,
  tau.preset = NULL,
  showall = TRUE,
  nchar.trts = x$nchar.trts,
  ...
)
```

Arguments

- `x`: An object of class `netmeta`.
- `random`: A logical indicating whether the net heat plot should be based on a random effects model.
- `tau.preset`: An optional value for the square-root of the between-study variance $\tau^2$ for a random effects model on which the net heat plot will be based.
- `showall`: A logical indicating whether results should be shown for all designs or only a sensible subset (see Details).
- `nchar.trts`: A numeric defining the minimum number of characters used to create unique treatment names.
- `...`: Additional arguments.

Details

The net heat plot is a matrix visualization proposed by Krahn et al. (2013) that highlights hot spots of inconsistency between specific direct evidence in the whole network and renders transparent possible drivers.

In this plot, the area of a gray square displays the contribution of the direct estimate of one design in the column to a network estimate in a row. In combination, the colors show the detailed change in inconsistency when relaxing the assumption of consistency for the effects of single designs. The colors on the diagonal represent the inconsistency contribution of the corresponding design. The colors on the off-diagonal are associated with the change in inconsistency between direct and indirect evidence in a network estimate in the row after relaxing the consistency assumption for the
effect of one design in the column. Cool colors indicate an increase and warm colors a decrease: the stronger the intensity of the color, the greater the difference between the inconsistency before and after the detachment. So, a blue colored element indicates that the evidence of the design in the column supports the evidence in the row. A clustering procedure is applied to the heat matrix in order to find warm colored hot spots of inconsistency. In the case that the colors of a column corresponding to design $d$ are identical to the colors on the diagonal, the detaching of the effect of design $d$ dissolves the total inconsistency in the network.

The pairwise contrasts corresponding to designs of three- or multi-arm studies are marked by '_-' following the treatments of the design.

Designs where only one treatment is involved in other designs of the network or where the removal of corresponding studies would lead to a splitting of the network do not contribute to the inconsistency assessment. By default (showall = TRUE), these designs are not incorporated into the net heat plot. If showall = FALSE, additional designs with minimal contribution to the inconsistency $Q$ statistic are not incorporated (i.e., designs with $\text{abs(Q.inc.design)} < .\text{Machine}\$double$.\text{eps}*0.5$).

In the case of random = TRUE, the net heat plot is based on a random effects model generalised for multivariate meta-analysis in which the between-study variance $\tau^2$ is estimated by the method of moments (see Jackson et al., 2012) and embedded in a full design-by-treatment interaction model (see Higgins et al., 2012).

netimpact

Determine the importance of individual studies in network meta-analysis

Description

This function measures the importance of individual studies in network meta-analysis by the reduction of the precision if the study is removed / ignored from the network.

Usage

netimpact(
  x,
  seTE.ignore = 100 * max(x$seTE, na.rm = TRUE),
  event.ignore = 0.01,
  verbose = FALSE
)

Arguments

x  An object of class netmeta.

seTE.ignore  Assumed (large) standard error in order to mimicking the removal of individual studies from the network meta-analysis (ignored for netmetabin objects).

event.ignore  Assumed event number mimicking the removal of individual studies from the network meta-analysis (considered for netmetabin objects).

verbose  A logical indicating whether information on the estimation progress should be printed.

Value

An object of class "netimpact" with corresponding netgraph and print function. The object is a list containing the following components:
impact.common A matrix with contributions of individual studies (columns) to comparisons (rows) under the common effects model.

impact.random A matrix with contributions of individual studies (columns) to comparisons (rows) under the random effects model.

ignored.comparisons List with comparisons of ignored study.

seTE.ignore, event.ignore, x As defined above.

nets List of all network meta-analyses (removing a single study).

version Version of R package netmeta used to create object.

            n = list(n1, n2, n3),
            mean = list(y1, y2, y3),
            sd = list(sd1, sd2, sd3),
            data = subset(Franchini2012, Study %in% studies[1:2]),
            studlab = Study)

net1 <- netmeta(pl)
ni1 <- netimpact(net1, verbose = TRUE)
ni1

netgraph(ni1)
Usage

```r
netleague(
  x,
  y,
  common = x$common,
  random = x$random,
  seq = x$seq,
  ci = TRUE,
  backtransf = TRUE,
  direct = FALSE,
  digits = gs("digits"),
  big.mark = gs("big.mark"),
  text.NA = ".",
  bracket = gs("CIbracket"),
  separator = gs("CIseparator"),
  lower.blank = gs("Cilower.blank"),
  upper.blank = gs("CIupper.blank"),
  writexl = !missing(path),
  path = "leaguetable.xlsx",
  overwrite = FALSE,
  warn.deprecated = gs("warn.deprecated"),
  ...
)
```

## S3 method for class 'netleague'

```r
print(
  x,
  common = x$x$common,
  random = x$x$random,
  warn.deprecated = gs("warn.deprecated"),
  ...
)
```

Arguments

- **x**: An object of class netmeta or netleague (mandatory).
- **y**: An object of class netmeta (optional).
- **common**: A logical indicating whether a league table should be printed for the common effects network meta-analysis.
- **random**: A logical indicating whether a league table should be printed for the random effects network meta-analysis.
- **seq**: A character or numerical vector specifying the sequence of treatments in rows and columns of a league table.
- **ci**: A logical indicating whether confidence intervals should be shown.
- **backtransf**: A logical indicating whether printed results should be back transformed. If `backtransf = TRUE`, results for `sm = "OR"` are printed as odds ratios rather than log odds ratios, for example.

Details

A league table is a square matrix showing all pairwise comparisons in a network meta-analysis (Hutton et al., 2015). Typically, both treatment estimates and confidence intervals are shown.

If argument \( y \) is not provided, the league table contains the network estimates from network meta-analysis object \( x \) in the lower triangle and the direct treatment estimates from pairwise comparisons in the upper triangle. Note, for the random-effects model, the direct treatment estimates are based on the common between-study variance \( \tau^2 \) from the network meta-analysis, i.e. the square of list element \( x$tau \).

If argument \( y \) is provided, the league table contains information on treatment comparisons from network meta-analysis object \( x \) in the lower triangle and from network meta-analysis object \( y \) in the upper triangle. This is, for example, useful to print information on efficacy and safety in the same league table.

By default, an R object with the league tables is generated. Alternatively, an Excel file is created if argument \( \text{writexl} = \text{TRUE} \).

This implementation reports pairwise comparisons of the treatment in the row versus the treatment in the column in the lower triangle and column versus row in the upper triangle. This is a common presentation for network meta-analyses which allows to easily compare direction and magnitude of treatment effects. For example, given treatments A, B, and C, the results reported in the first row and second column as well as second row and first column are from the pairwise comparison A versus B. Note, this presentation is different from the printout of a network meta-analysis object.
which reports opposite pairwise comparisons in the lower and upper triangle, e.g., A versus B in the first row and second column and B versus A in the second row and first column.

If the same network meta-analysis object is used for arguments \( x \) and \( y \), reciprocal treatment estimates will be shown in the upper triangle (see examples), e.g., the comparison B versus A.

R function `netrank` can be used to change the order of rows and columns in the league table (see examples).

**Value**

An object of class `netleague` with corresponding `print` function if `writexl = FALSE`. The object is a list containing the league tables in list elements 'common' and 'random'. An Excel file is created if `writexl = TRUE`. In this case, NULL is returned in R.

**netmatrix**  
*Create a matrix with additional information for pairwise comparisons*

**Description**

Auxiliary function to create a matrix with additional information for pairwise comparisons.
Usage

`netmatrix(
  x,
  var,
  levels,
  labels = levels,
  func = "mode",
  ties.method = "random"
)`

Arguments

- **x**: A `netmeta` object.
- **var**: Variable with additional information.
- **levels**: An optional vector of the values that `var` might have taken (see `factor`).
- **labels**: An optional vector with labels for `var` (see `factor`).
- **func**: A character string with the function name to summarize values within pairwise comparisons; see Details.
- **ties.method**: A character string describing how ties are handled if `func = "mode"`; see Details.

Details

For each pairwise comparison, unique values will be calculated for the variable `var` based on the argument `func`: "mode" (most common value), "min" (minimum value), "max", "mean", "median", and "sum". In order to determine the most common value, the argument `ties.method` can be used in the case of ties with "first" meaning that the first / smallest value will be selected; similar for "last" (last / largest value) and "random" (random selection).

Value

A matrix with the same row and column names as the adjacency matrix `x$A.matrix`.

labels = paste0(trts, " (n=", n.trts, ")"),
offset = 0.025)
```

---

**netmeasures**  
Measures for characterizing a network meta-analysis

**Description**

This function provides measures for quantifying the direct evidence proportion, the mean path length and the minimal parallelism (the latter on aggregated and study level) of mixed treatment comparisons (network estimates) as well as the evidence flow per design, see König et al. (2013). These measures support the critical evaluation of the network meta-analysis results by rendering transparent the process of data pooling.

**Usage**

```r
netmeasures(
  x,
  random = x$random | !missing(tau.preset),
  tau.preset = x$tau.preset,
  warn = TRUE,
  warn.deprecated = gs("warn.deprecated"),
  ...
)
```

**Arguments**

- `x` An object of class `netmeta`.
- `random` A logical indicating whether random effects model should be used to calculate network measures.
Details

The direct evidence proportion gives the absolute contribution of direct effect estimates combined for two-arm and multi-arm studies to one network estimate.

Concerning indirectness, comparisons with a mean path length beyond two should be interpreted with particular caution, as more than two direct comparisons have to be combined serially on average.

Large indices of parallelism, either on study-level or on aggregated level, can be considered as supporting the validity of a network meta-analysis if there is only a small amount of heterogeneity.

The network estimates for two treatments are linear combinations of direct effect estimates comparing these or other treatments. The linear coefficients can be seen as the generalization of weights known from classical meta-analysis. These coefficients are given in the projection matrix $H$ of the underlying model. For multi-arm studies, the coefficients depend on the choice of the study-specific baseline treatment, but the absolute flow of evidence can be made explicit for each design as shown in König et al. (2013) and is given in $H_{tilde}$.

All measures are calculated based on the common effects meta-analysis by default. In the case that in function netmeta the argument random = TRUE, all measures are calculated for a random effects model. The value of the square-root of the between-study variance $\tau^2$ can also be prespecified by argument tau.preset in function netmeta.

Value

A list containing the following components:

random, tau.preset

- As defined above.

proportion

- A named vector of the direct evidence proportion of each network estimate.

meanpath

- A named vector of the mean path length of each network estimate.

minpar

- A named vector of the minimal parallelism on aggregated level of each network estimate.

minpar.study

- A named vector of the minimal parallelism on study level of each network estimate.

$H_{tilde}$

- Design-based hat matrix with information on absolute evidence flow per design. The number of rows is equal to the number of possible pairwise treatment comparisons and the number of columns is equal to the number of designs.

#
## Not run:
# Conduct random effects network meta-analysis with reference
# treatment 'plac', i.e. placebo
#
# net2 <- netmeta(TE, seTE, treat1, treat2, studlab, 
# data = Senn2013, sm = "MD", reference = "plac", common = FALSE)
#
# Calculate measures based on a random effects model
#
# nm2 <- netmeasures(net2)
#
## End(Not run)
network meta-analysis uses methods that were originally developed in electrical network theory. It has been found to be equivalent to the frequentist approach to network meta-analysis which is based on weighted least squares regression (Rücker, 2012).

Print method for objects of class netmeta.

Usage

netmeta(

)

Arguments

TE Estimate of treatment effect, i.e. difference between first and second treatment (e.g. log odds ratio, mean difference, or log hazard ratio). Or an R object created with pairwise.

seTE Standard error of treatment estimate.

treat1 Label/Number for first treatment.

treat2 Label/Number for second treatment.

studlab An optional - but important! - vector with study labels (see Details).

data An optional data frame containing the study information.
subset
A character string indicating the underlying summary measure, e.g., "RD", "RR", "OR", "ASD", "HR", "MD", "SMD", or "ROM".

level
The level used to calculate confidence intervals for individual comparisons.

level.ma
The level used to calculate confidence intervals for network estimates.

common
A logical indicating whether results for the common effects model should be printed.

random
A logical indicating whether results for the random effects model should be printed.

prediction
A logical indicating whether prediction intervals should be printed.

level.predict
The level used to calculate prediction intervals for a new study.

reference.group
Reference treatment.

tol.multiarm
A numeric for the tolerance for consistency of treatment estimates in multi-arm studies which are consistent by design.

tol.multiarm.se
A numeric for the tolerance for consistency of standard errors in multi-arm studies which are consistent by design. This check is not conducted if the argument is NULL.

details.chkmultiarm
A logical indicating whether treatment estimates and / or variances of multi-arm studies with inconsistent results or negative multi-arm variances should be printed.

sep.trts
A character used in comparison names as separator between treatment labels.

nchar.trts
A numeric defining the minimum number of characters used to create unique treatment names.

nchar.studlab
A numeric defining the minimum number of characters used to create unique study labels.
func.inverse: R function used to calculate the pseudoinverse of the Laplacian matrix \( L \) (see Details).

n1: Number of observations in first treatment group.
n2: Number of observations in second treatment group.
event1: Number of events in first treatment group.
event2: Number of events in second treatment group.
incr: Numerical value added to cell frequencies (for details, see `pairwise`).
sd1: Standard deviation in first treatment group.
sd2: Standard deviation in second treatment group.
time1: Person time at risk in first treatment group.
time2: Person time at risk in second treatment group.
backtransf: A logical indicating whether results should be back transformed in printouts and forest plots. If `backtransf = TRUE`, results for `sm = "OR"` are presented as odds ratios rather than log odds ratios, for example.
title: Title of meta-analysis / systematic review.
keepdata: A logical indicating whether original data (set) should be kept in netmeta object.
control: An optional list to control the iterative process to estimate the between-study variance \( \tau^2 \). This argument is passed on to `rma.mv`.
warn: A logical indicating whether warnings should be printed (e.g., if studies are excluded from meta-analysis due to zero standard errors).
warn.deprecated: A logical indicating whether warnings should be printed if deprecated arguments are used.
nchar: Deprecated argument (replaced by `nchar.trts`).
...: Additional arguments.
x: An object of class `netmeta`.
header: A logical indicating whether information on title of meta-analysis, comparison and outcome should be printed at the beginning of the printout.
digits: Minimal number of significant digits, see `print.default`.
digits.stat: Minimal number of significant digits for tests of overall effect, see `print.default`.
digits.pval: Minimal number of significant digits for p-value of overall effects, see `print.default`.
digits.pval.Q: Minimal number of significant digits for p-value of heterogeneity tests, see `print.default`.
digits.Q: Minimal number of significant digits for heterogeneity statistics, see `print.default`.
digits.tau2: Minimal number of significant digits for between-study variance, see `print.default`.
digits.tau: Minimal number of significant digits for square root of between-study variance, see `print.default`.
digits.I2: Minimal number of significant digits for I-squared statistic, see `print.default`.
scientific.pval: A logical specifying whether p-values should be printed in scientific notation, e.g., 1.2345e-01 instead of 0.12345.
Network meta-analysis using R package netmeta is described in detail in Schwarzer et al. (2015), Chapter 8.

Let $n$ be the number of different treatments (nodes, vertices) in a network and let $m$ be the number of existing comparisons (edges) between the treatments. If there are only two-arm studies, $m$ is the number of studies. Let $TE$ and $seTE$ be the vectors of observed effects and their standard errors. Let $W$ be the $m \times m$ diagonal matrix that contains the inverse variance $1 / seTE^2$.

The given comparisons define the network structure. Therefrom an $m \times n$ design matrix $X$ (edge-vertex incidence matrix) is formed; for more precise information, see Rücker (2012). Moreover, the $n \times n$ Laplacian matrix $L$ and its Moore-Penrose pseudoinverse $L^+$ are calculated (both matrices play an important role in graph theory and electrical network theory). Using these matrices, the variances based on both direct and indirect comparisons can be estimated. Moreover, the hat matrix $H$ can be estimated by $H = XL+X^tW = X(X^t W X)^+X^tW$ and finally consistent treatment effects can be estimated by applying the hat matrix to the observed (potentially inconsistent) effects. $H$ is a projection matrix which maps the observed effects onto the consistent (n-1)-dimensional subspace. This is the Aitken estimator (Senn et al., 2013). As in pairwise meta-analysis, the $Q$ statistic measures the deviation from consistency. $Q$ can be separated into parts for each pairwise meta-analysis and a part for remaining inconsistency between comparisons.

Often multi-arm studies are included in a network meta-analysis. In multi-arm studies, the treatment effects on different comparisons are not independent, but correlated. This is accounted for by reweighting all comparisons of each multi-arm study. The method is described in Rücker (2012) and Rücker and Schwarzer (2014).

Comparisons belonging to multi-arm studies are identified by identical study labels (argument studlab). It is therefore important to use identical study labels for all comparisons belonging to the same multi-arm study, e.g., study label "Willms1999" for the three-arm study in the data example (Senn et al., 2013). The function netmeta then automatically accounts for within-study correlation by reweighting all comparisons of each multi-arm study.

Data entry for this function is in contrast-based format, that is, data are given as contrasts (differences) between two treatments (argument TE) with standard error (argument seTE). In principle, meta-analysis functions from R package meta, e.g. metabin for binary outcomes or metacont for continuous outcomes, can be used to calculate treatment effects separately for each treatment comparison which is a rather tedious enterprise. If data are provided in arm-based format, that is, data are given for each treatment arm separately (e.g. number of events and participants for binary outcomes), a much more convenient way to transform data into contrast-based form is available. Function pairwise can automatically transform data with binary outcomes (using the metabin function from R package meta), continuous outcomes (metacont function), incidence rates (metainc function), and generic outcomes (metagen function). Additional arguments of these functions can be provided (see help page of function pairwise).
Note, all pairwise comparisons must be provided for a multi-arm study. Consider a multi-arm study of \( p \) treatments with known variances. For this study, treatment effects and standard errors must be provided for each of \( p(p - 1) / 2 \) possible comparisons. For instance, a three-arm study contributes three pairwise comparisons, a four-arm study even six pairwise comparisons. Function \texttt{pairwise} automatically calculates all pairwise comparisons for multi-arm studies.

A simple random effects model assuming that a constant heterogeneity variance is added to each comparison of the network can be defined via a generalised methods of moments estimate of the between-studies variance \( \tau^2 \) (Jackson et al., 2012). This is added to the observed sampling variance \( seTE^2 \) of each comparison in the network (before appropriate adjustment for multi-arm studies). Then, as in standard pairwise meta-analysis, the procedure is repeated with the resulting enlarged standard errors.

For the random-effects model, the direct treatment estimates are based on the common between-study variance \( \tau^2 \) from the network meta-analysis.

Internally, both common and random effects models are calculated regardless of values choosen for arguments \texttt{common} and \texttt{random}. Accordingly, the network estimates for the random effects model can be extracted from component \texttt{TE.random} of an object of class "netmeta" even if argument \texttt{random} = \texttt{FALSE}. However, all functions in R package \texttt{netmeta} will adequately consider the values for \texttt{common} and \texttt{random}. E.g. function \texttt{print.summary.netmeta} will not print results for the random effects model if \texttt{random} = \texttt{FALSE}.

By default, treatment names are not abbreviated in printouts. However, in order to get more concise printouts, argument \texttt{nchar.trts} can be used to define the minimum number of characters for abbreviated treatment names (see \texttt{abbreviate}, argument \texttt{minlength}). R function \texttt{treats} is utilised internally to create abbreviated treatment names.

Names of treatment comparisons are created by concatenating treatment labels of pairwise comparisons using \texttt{sep.trts} as separator (see \texttt{paste}). These comparison names are used in the covariance matrices \texttt{Cov.common} and \texttt{Cov.random} and in some R functions, e.g. \texttt{decomp.design}. By default, a colon is used as the separator. If any treatment label contains a colon the following characters are used as separator (in consecutive order): ":", ":", "/", ":", ":", ":", and ":". If all of these characters are used in treatment labels, a corresponding error message is printed asking the user to specify a different separator.

\textbf{Value}

An object of class \texttt{netmeta} with corresponding \texttt{print}, \texttt{summary}, \texttt{forest}, and \texttt{netrank} functions. The object is a list containing the following components:

- \texttt{studlab}, \texttt{treat1}, \texttt{treat2}, \texttt{TE}, \texttt{seTE}
  As defined above.
- \texttt{seTE.adj.common}, \texttt{seTE.adj.random}
  Standard error of treatment estimate, adjusted for multi-arm studies.
- \texttt{design}
  Design of study providing pairwise comparison.
- \texttt{n1}, \texttt{n2}, \texttt{event1}, \texttt{event2}, \texttt{incr}
  As defined above.
- \texttt{mean1}, \texttt{mean2}, \texttt{sd1}, \texttt{sd2}, \texttt{time1}, \texttt{time2}
  As defined above.
- \texttt{sd1}, \texttt{sd2}, \texttt{time1}, \texttt{time2}
  As defined above.
\[ \text{k} \quad \text{Total number of studies.} \\
\text{m} \quad \text{Total number of pairwise comparisons.} \\
\text{n} \quad \text{Total number of treatments.} \\
\text{d} \quad \text{Total number of designs (corresponding to the unique set of treatments compared within studies).} \\
\text{trts} \quad \text{Treatments included in network meta-analysis.} \\
\text{k.trts} \quad \text{Number of studies evaluating a treatment.} \\
\text{n.trts} \quad \text{Number of observations receiving a treatment (if arguments n1 and n2 are provided).} \\
\text{events.trts} \quad \text{Number of events observed for a treatment (if arguments event1 and event2 are provided).} \\
\text{multiarm} \quad \text{Logical vector to identify pairwise comparisons from multi-arm studies.} \\
\text{n.arms} \quad \text{Number of treatment arms in study providing pairwise comparison.} \\

\quad \text{A vector of length } m \text{ of p-values for test of treatment effect for individual comparisons (common / random effects model).} \\
\text{leverage.common} \\
\quad \text{A vector of length } m \text{ of leverages, interpretable as factors by which variances are reduced using information from the whole network.} \\
\text{w.common}, \text{w.random} \\
\quad \text{A vector of length } m \text{ of weights of individual studies (common / random effects model).} \]
Q.common  A vector of length $m$ of contributions to total heterogeneity / inconsistency statistic.

TE.common, TE.random  
$n \times n$ matrix with estimated overall treatment effects (common / random effects model).

seTE.common, seTE.random  
$n \times n$ matrix with standard errors (common / random effects model).

lower.common, upper.common, lower.random, upper.random  
$n \times n$ matrices with lower and upper confidence interval limits (common / random effects model).

statistic.common, pval.common, statistic.random, pval.random  
$n \times n$ matrices with z-value and p-value for test of overall treatment effect (common / random effects model).

seTE.predict  
$n \times n$ matrix with standard errors for prediction intervals.

lower.predict, upper.predict  
$n \times n$ matrices with lower and upper prediction interval limits.

prop.direct.common, prop.direct.random  
A named vector of the direct evidence proportion of each network estimate. (common effects / random effects model).

TE.direct.common, TE.direct.random  
$n \times n$ matrix with estimated treatment effects from direct evidence (common effects / random effects model).

seTE.direct.common, seTE.direct.random  
$n \times n$ matrix with estimated standard errors from direct evidence (common effects / random effects model).

lower.direct.common, upper.direct.common, lower.direct.random, upper.direct.random  
$n \times n$ matrices with lower and upper confidence interval limits from direct evidence (common / random effects model).

upper.direct.random  
$n \times n$ matrices with lower and upper confidence interval limits from direct evidence (common effects / random effects model).

statistic.direct.common, pval.direct.common, statistic.direct.random, pval.direct.random  
$n \times n$ matrices with z-value and p-value for test of overall treatment effect from direct evidence (common / random effects model).

pval.direct.random  
$n \times n$ matrices with z-value and p-value for test of overall treatment effect from direct evidence (common / random effects model).

TE.indirect.common, TE.indirect.random  
$n \times n$ matrix with estimated treatment effects from indirect evidence (common / random effects model).

seTE.indirect.common, seTE.indirect.random  
$n \times n$ matrix with estimated standard errors from indirect evidence (common / random effects model).

lower.indirect.common, upper.indirect.common, lower.indirect.random, upper.indirect.random  
$n \times n$ matrices with lower and upper confidence interval limits from indirect evidence (common / random effects model).
upper.indirect.random

*nxn* matrices with lower and upper confidence interval limits from indirect evidence (common / random effects model).

statistic.indirect.common, pval.indirect.common, statistic.indirect.random,

*nxn* matrices with z-value and p-value for test of overall treatment effect from indirect evidence (common / random effects model).

pval.indirect.random

*nxn* matrices with z-value and p-value for test of overall treatment effect from indirect evidence (common / random effects model).

Q

Overall heterogeneity / inconsistency statistic.

df.Q

Degrees of freedom for test of heterogeneity / inconsistency.

pval.Q

P-value for test of heterogeneity / inconsistency.

I2, lower.I2, upper.I2

I-squared, lower and upper confidence limits.

tau

Square-root of between-study variance.

Q.heterogeneity

Overall heterogeneity statistic.

df.Q.heterogeneity

Degrees of freedom for test of overall heterogeneity.

pval.Q.heterogeneity

P-value for test of overall heterogeneity.

Q.inconsistency

Overall inconsistency statistic.

df.Q.inconsistency

Degrees of freedom for test of overall inconsistency.

pval.Q.inconsistency

P-value for test of overall inconsistency.

Q.decomp

Data frame with columns 'treat1', 'treat2', 'Q', 'df' and 'pval.Q', providing heterogeneity statistics for each pairwise meta-analysis of direct comparisons.

A.matrix

Adjacency matrix (*nxn*).

X.matrix

Design matrix (*m xn*).

B.matrix

Edge-vertex incidence matrix (*m xn*).

L.matrix.common, L.matrix.random

Laplacian matrix (*nxn*).

Lplus.matrix.common, Lplus.matrix.random

Moore-Penrose pseudoinverse of the Laplacian matrix (*nxn*).

Q.matrix

Matrix of heterogeneity statistics for pairwise meta-analyses, where direct comparisons exist (*nxn*).

G.matrix

Matrix with variances and covariances of comparisons (*m xn*). G is defined as \(BL+B^\dagger\).

H.matrix.common, H.matrix.random

Hat matrix (*m xn*), defined as \(H = GW = BL+B^\dagger W\).

n.matrix

*nxn* matrix with number of observations in direct comparisons (if arguments n1 and n2 are provided).
events.matrix  \( n \times n \) matrix with number of events in direct comparisons (if arguments \( \text{event1} \) and \( \text{event2} \) are provided).

\( \text{P.common, P.random} \)  \( n \times n \) matrix with direct evidence proportions (common / random effects model).

\( \text{Cov.common} \)  Variance-covariance matrix (common effects model)

\( \text{Cov.random} \)  Variance-covariance matrix (random effects model)

\( \text{sm, level, level.ma} \)  As defined above.

\( \text{common, random} \)  As defined above.

\( \text{prediction, level.predict} \)  As defined above.

\( \text{reference.group, baseline.reference, small.values, all.treatments} \)  As defined above.

\( \text{seq, tau.preset, tol.multiarm, tol.multiarm.se} \)  As defined above.

\( \text{details.chkmultiarm, sep.trts, nchar.trts} \)  As defined above.

\( \text{backtransf, title, warn, warn.deprecated} \)  As defined above.

\( \text{call} \)  Function call.

\( \text{version} \)  Version of R package netmeta used to create object.

**Note**

R function `rma.mv` from R package `metafor` (Viechtbauer 2010) is called internally to estimate the between-study variance \( \tau^2 \) for the (restricted) maximum likelihood method. For binary outcomes, incidence rates, and the mean difference, the variance-covariance matrix is calculated if arguments \( \text{event1, event2, n1, and n2} \) (binary outcomes); \( \text{event1, event2, time1, and time2} \) (incidence rates); \( \text{n1, n2, sd1, and sd2} \) (mean difference) are provided. For data sets preprocessed with `pairwise` the respective variables are selected automatically.

netmetabin

Network meta-analysis of binary outcome data

Description

Provides three models for the network meta-analysis of binary data (Mantel-Haenszel method, based on the non-central hypergeometric distribution, and the inverse variance method).
netmetabin

Usage

netmetabin(
  event1,
  n1,
  event2,
  n2,
  treat1,
  treat2,
  studlab,
  data = NULL,
  subset = NULL,
  sm,
  method = "MH",
  cc.pooled = FALSE,
  incr,
  allincr,
  addincr,
  allstudies,
  level = gs("level"),
  level.ma = gs("level.ma"),
  common = gs("common"),
  random = method == "Inverse" & (gs("random") | !is.null(tau.preset)),
  prediction = FALSE,
  level.predict = gs("level.predict"),
  reference.group = "",
  baseline.reference = TRUE,
  all.treatments = NULL,
  seq = NULL,
  tau.preset = NULL,
  tol.multiarm = 0.001,
  tol.multiarm.se = NULL,
  details.chkmultiarm = FALSE,
  details.chkdata = TRUE,
  sep.trts = ":",
  nchar.trts = 666,
  func.inverse = invmat,
  backtransf = gs("backtransf"),
  title = "",
  keepdata = gs("keepdata"),
  warn = TRUE,
  warn.deprecated = gs("warn.deprecated"),
  ...
)

Arguments

event1  Number of events (first treatment).
n1      Number of observations (first treatment).
event2
Number of events (second treatment).
n2
Number of observations (second treatment)
treat1
Label/Number for first treatment.
treat2
Label/Number for second treatment.
studlab
An optional - but important! - vector with study labels (see Details).
data
An optional data frame containing the study information.
subset
An optional vector specifying a subset of studies to be used.
sm
A character string indicating underlying summary measure, i.e., "RD", "RR", "OR", "ASD".
method
A character string indicating which method is to be used for pooling of studies. One of "Inverse", "MH", or "NCH", can be abbreviated.
cc.pooled
A logical indicating whether incr should be used as a continuity correction, when calculating the network meta-analysis estimates.
incr
A numerical value which is added to each cell count, i.e., to the numbers of events and non-events, of all treatment arms in studies with zero events or non-events in any of the treatment arms ("continuity correction").
allincr
A logical indicating whether incr should be added to each cell count of all studies if a continuity correction was used for at least one study (only considered if method = "Inverse"). If FALSE (default), incr is used as continuity correction only for studies with zero events or zero non-events in any of the treatment arms.
addincr
A logical indicating whether incr should be added to each cell count of all studies, irrespective of zero cell counts (only considered if method = "Inverse").
allstudies
A logical indicating whether studies with zero events or non-events in all treatment arms should be included in an inverse variance meta-analysis (applies only if method = "Inverse" and sm is equal to either "RR" or "OR").
level
The level used to calculate confidence intervals for individual studies.
level.ma
The level used to calculate confidence intervals for network estimates.
common
A logical indicating whether a common effects network meta-analysis should be conducted.
random
A logical indicating whether a random effects network meta-analysis should be conducted.
prediction
A logical indicating whether a prediction interval should be printed (only considered if method = "Inverse").
level.predict
The level used to calculate prediction interval for a new study (only considered if method = "Inverse").
reference.group
Reference treatment.
baseline.reference
A logical indicating whether results should be expressed as comparisons of other treatments versus the reference treatment (default) or vice versa. This argument is only considered if reference.group has been specified.
all.treatments A logical or "NULL". If TRUE, matrices with all treatment effects, and confidence limits will be printed.

seq A character or numerical vector specifying the sequence of treatments in printouts.

tau.preset An optional value for manually setting the square-root of the between-study variance \( \tau^2 \) (only considered if method = "Inverse").

tol.multiarm A numeric for the tolerance for consistency of treatment estimates in multi-arm studies which are consistent by design (only considered if method = "Inverse").

tol.multiarm.se A numeric for the tolerance for consistency of standard errors in multi-arm studies which are consistent by design (only considered if the argument is not NULL and method = "Inverse").

details.chkmultiarm A logical indicating whether treatment estimates and / or variances of multi-arm studies with inconsistent results or negative multi-arm variances should be printed (only considered if method = "Inverse").

details.chkdata A logical indicating whether number of events and participants of studies with inconsistent data should be printed.

sep.trts A character used in comparison names as separator between treatment labels.

nchar.trts A numeric defining the minimum number of characters used to create unique treatment names (see Details).

func.inverse R function used to calculate the pseudoinverse of the Laplacian matrix \( L \) (see netmeta).

backtransf A logical indicating whether results should be back transformed in printouts and forest plots. If backtransf = TRUE, results for sm = "OR" are presented as odds ratios rather than log odds ratios, for example.

title Title of meta-analysis / systematic review.

keepdata A logical indicating whether original data (set) should be kept in netmeta object.

warn A logical indicating whether warnings should be printed (e.g., if studies are excluded from meta-analysis due to zero standard errors).

warn.deprecated A logical indicating whether warnings should be printed if deprecated arguments are used.

Details

This function implements three models for the network meta-analysis of binary data:

- The Mantel-Haenszel network meta-analysis model, as described in Efthimiou et al. (2019) (method = "MH");
- a network meta-analysis model using the non-central hypergeometric distribution with the Breslow approximation, as described in Stijnen et al. (2010) (method = "NCH");
• the inverse variance method for network meta-analysis (method = "Inverse"), also provided by netmeta.

Comparisons belonging to multi-arm studies are identified by identical study labels (argument studlab). It is therefore important to use identical study labels for all comparisons belonging to the same multi-arm study.

Data entry for this function is in contrast-based format, that is, each line of the data corresponds to a single pairwise comparison between two treatments (arguments treat1, treat2, event1, n1, event2, and n2). If data are provided in arm-based format, that is, number of events and participants are given for each treatment arm separately, function pairwise can be used to transform the data to contrast-based format (see help page of function pairwise).

Note, all pairwise comparisons must be provided for a multi-arm study. Consider a multi-arm study of \( p \) treatments with known variances. For this study, the number of events and observations must be provided for each treatment, for each of \( p(p - 1)/2 \) possible comparisons in separate lines in the data. For instance, a three-arm study contributes three pairwise comparisons, a four-arm study even six pairwise comparisons. Function pairwise automatically calculates all pairwise comparisons for multi-arm studies.

For method = "Inverse", both common and random effects models are calculated regardless of values choosen for arguments common and random. Accordingly, the network estimates for the random effects model can be extracted from component \( TE.random \) of an object of class "netmeta" even if argument random = FALSE. However, all functions in R package netmeta will adequately consider the values for common and random. E.g. function print.summary.netmeta will not print results for the random effects model if random = FALSE.

For the random-effects model, the direct treatment estimates are based on the common between-study variance \( \tau^2 \) from the network meta-analysis.

For method = "MH" and method = "NCH", only a common effects model is available.

By default, treatment names are not abbreviated in printouts. However, in order to get more concise printouts, argument nchar.trts can be used to define the minimum number of characters for abbreviated treatment names (see abbreviate, argument minlength). R function treats is utilised internally to create abbreviated treatment names.

Names of treatment comparisons are created by concatenating treatment labels of pairwise comparisons using sep.trts as separator (see paste). These comparison names are used in the covariance matrices Cov.common and Cov.random and in some R functions, e.g, decop.design. By default, a colon is used as the separator. If any treatment label contains a colon the following characters are used as separator (in consecutive order): ";", ",", "/", "+", ".", "|", and "*". If all of these characters are used in treatment labels, a corresponding error message is printed asking the user to specify a different separator.

Value

An object of class netmetabin and netmeta with corresponding print, summary, forest, and netrank functions. The object is a list containing the following components:

studlab, treat1, treat2
As defined above.

n1, n2, event1, event2
As defined above.
TE Estimate of treatment effect, i.e. difference between first and second treatment (e.g. log odds ratio).

seTE Standard error of treatment estimate.

k Total number of studies.

m Total number of pairwise comparisons.

n Total number of treatments.

d Total number of designs (corresponding to the unique set of treatments compared within studies).

trts Treatments included in network meta-analysis.

k.trts Number of studies evaluating a treatment.

n.trts Number of observations receiving a treatment.

events.trts Number of events observed for a treatment.

studies Study labels coerced into a factor with its levels sorted alphabetically.

narms Number of arms for each study.

designs Unique list of designs present in the network. A design corresponds to the set of treatments compared within a study.

TE.common, seTE.common
\( nxn \) matrix with estimated overall treatment effects and standard errors for common effects model.

lower.common, upper.common
\( nxn \) matrices with lower and upper confidence interval limits for common effects model.

statistic.common, pval.common
\( nxn \) matrices with z-value and p-value for test of overall treatment effect under common effects model.

TE.random, seTE.random
\( nxn \) matrix with estimated overall treatment effects and standard errors for random effects model (only available if method = "Inverse").

lower.random, upper.random
\( nxn \) matrices with lower and upper confidence interval limits for random effects model (only available if method = "Inverse").

statistic.random, pval.random
\( nxn \) matrices with z-value and p-value for test of overall treatment effect under random effects model (only available if method = "Inverse").

TE.direct.common, seTE.direct.common
\( nxn \) matrix with estimated treatment effects and standard errors from direct evidence under common effects model.

lower.direct.common, upper.direct.common
\( nxn \) matrices with lower and upper confidence interval limits from direct evidence under common effects model.

statistic.direct.common, pval.direct.common
\( nxn \) matrices with z-value and p-value for test of overall treatment effect from direct evidence under common effects model.
TE.direct.random, seTE.direct.random

$n \times n$ matrix with estimated treatment effects and standard errors from direct evidence under random effects model (only available if method = "Inverse").

lower.direct.random, upper.direct.random

$n \times n$ matrices with lower and upper confidence interval limits from direct evidence under random effects model (only available if method = "Inverse").

statistic.direct.random, pval.direct.random

$n \times n$ matrices with z-value and p-value for test of overall treatment effect from direct evidence under random effects model (only available if method = "Inverse").

$Q$

Overall heterogeneity / inconsistency statistic. (only available if method = "Inverse")

df.Q

Degrees of freedom for test of heterogeneity / inconsistency.

pval.Q

P-value for test of heterogeneity / inconsistency.

$I^2$, lower.I2, upper.I2

I-squared, lower and upper confidence limits (only available if method = "Inverse").

tau

Square-root of between-study variance (only available if method = "Inverse").

Q.heterogeneity

Overall heterogeneity statistic. (only available if method = "Inverse")

df.Q.heterogeneity

Degrees of freedom for test of overall heterogeneity.

pval.Q.heterogeneity

P-value for test of overall heterogeneity.

Q.inconsistency

Overall inconsistency statistic.

df.Q.inconsistency

Degrees of freedom for test of overall inconsistency.

pval.Q.inconsistency

P-value for test of overall inconsistency.

A.matrix

Adjacency matrix ($n \times n$).

H.matrix

Hat matrix ($m \times m$)

n.matrix

$n \times n$ matrix with number of observations in direct comparisons.

events.matrix

$n \times n$ matrix with number of events in direct comparisons.

sm, method, level, level.ma

As defined above.

incr, allincr, addincr, allstudies, cc.pooled

As defined above.

common, random

As defined above.

prediction, level.predict

As defined above.

reference.group, baseline.reference, all.treatments

As defined above.

seq, tau.preset, tol.multiarm, tol.multiarm.se

As defined above.

details.chkmultiarm, details.chkdata

As defined above.
sep.trts, nchar.trts
   As defined above.
backtransf, title, warn, warn.deprecated
   As defined above.
data
   Data set (in contrast-based format).
data.design
   List with data in arm-based format (each list element corresponds to a single
design).
call
   Function call.
version
   Version of R package netmeta used to create object.

**netpairwise**

*Conduct pairwise meta-analyses for all comparisons with direct evidence in a network meta-analysis*

### Description

Conduct pairwise meta-analyses for all comparisons with direct evidence in a network meta-analysis.

### Usage

```r
netpairwise(x,
             separate = FALSE,
             common = x$common,
```
Arguments

x                An object of class netmeta or netpairwise.
separate         A logical indicating whether results for pairwise comparisons should be printed
                 as separate meta-analyses or as subgroups which is more concise.
common           A logical indicating whether a common effects network meta-analysis should be
                 conducted.
random           A logical indicating whether a random effects network meta-analysis should be
                 conducted.
level            The level used to calculate confidence intervals for individual comparisons.
level.ma         The level used to calculate confidence intervals for pooled estimates.
prediction       A logical indicating whether prediction intervals should be printed.
level.predict    The level used to calculate prediction intervals for a new study.
baseline.reference
  A logical indicating whether results should be expressed as comparisons of other
  treatments versus the reference treatment (default) or vice versa. This argument
  is only considered if reference.group has been specified.

method.tau
  A character string indicating which method is used to estimate the between-
  study variance $\tau^2$ and its square root $\tau$. Either "DL", "REML", or "ML", can be
  abbreviated.

sep.trts
  A character used in comparison names as separator between treatment labels.

nchar.trts
  A numeric defining the minimum number of characters used to create unique
  treatment names (see Details).

backtransf
  A logical indicating whether results should be back transformed in printouts and
  forest plots. If backtransf = TRUE, results for sm = "OR" are presented as odds
  ratios rather than log odds ratios, for example.

warn.deprecated
  A logical indicating whether warnings should be printed if deprecated arguments
  are used.

...
  Additional arguments (passed on to metagen or print functions and to catch
  deprecated arguments).

object
  An object of class netpairwise.

Details

Conduct pairwise meta-analyses for all comparisons with direct evidence in a network meta-analysis.
In contrast to netmeta and netsplit, unadjusted standard errors are used in the calculations and
the between-study heterogeneity variance is allowed to differ between comparisons.

The R function metagen is called internally.

Value

Either a single metagen object with pairwise comparisons as subgroups or a list with metagen
objects for each direct pairwise comparison.

Note

This function must not be confused with pairwise which can be used as a pre-processing step
to convert data from arm-based to contrast-based format by calculating all pairwise comparisons
within a study.

**netposet**

*Partial order of treatments in network meta-analysis*

**Description**

Partial order of treatments in network meta-analysis. The set of treatments in a network is called a partially ordered set (in short, a *poset*), if different outcomes provide different treatment ranking lists.

**Usage**

netposet(
  ..., outcomes, treatments, small.values, common, random, fixed, comb.fixed,
netposet

## S3 method for class 'netposet'
print(x, pooled = ifelse(x$random, "random", "common"), ...)

### Arguments

... See details.
outcomes A character vector with outcome names.
treatments A character vector with treatment names.
small.values See details.
common A logical indicating whether to show results for the common effects model.
random A logical indicating whether to show results for the random effects model.
fixed Ignored deprecated argument (replaced by common).
comb.fixed Ignored deprecated argument (replaced by common).
comb.random Ignored deprecated argument (replaced by random).
x An object of class netposet.
pooled A character string indicating whether Hasse diagram should be drawn for common ("common") or random effects model ("random"). Can be abbreviated.

### Details

In network meta-analysis, frequently different outcomes are considered which may each provide a different ordering of treatments. The concept of a partially ordered set (in short, a poset, Carlsen & Bruggemann, 2014) of treatments can be used to gain further insights in situations with apparently conflicting orderings. This implementation for rankings in network meta-analysis is described in Rücker & Schwarzer (2017).

In function netposet, argument ...() can be any of the following:

- arbitrary number of netrank objects providing P-scores;
- arbitrary number of netmeta objects;
- single ranking matrix with each column providing P-scores (Rücker & Schwarzer 2015) or SUCRA values (Salanti et al. 2011) for an outcome and rows corresponding to treatments.

Note, albeit in general a ranking matrix is not constrained to have values between 0 and 1, netposet stops with an error in this case as this function expects a matrix with P-scores or SUCRA values.

Argument outcomes can be used to label outcomes. If argument outcomes is missing,

- column names of the ranking matrix are used as outcome labels (if first argument is a ranking matrix and column names are available);
- capital letters 'A', 'B',... are used as outcome labels and a corresponding warning is printed.

Argument treatments can be used to provide treatment labels if the first argument is a ranking matrix. If argument treatment is missing,
• row names of the ranking matrix are used as treatment labels (if available);
• letters ‘a’, ‘b’, . . . are used as treatment labels and a corresponding warning is printed.

If argument ...{} consists of netmeta objects, netrank is called internally to calculate P-scores.
In this case, argument small.values can be used to specify for each outcome whether small values
are good or bad; see netrank. This argument is ignored for a ranking matrix and netrank objects.
Arguments common and random can be used to define whether results should be printed and plotted
for common and random effects model. If netmeta and netrank objects are provided in argument
...{}, values for common and random within these objects are considered; if these values are not
unique, argument common or random are set to TRUE.

In function print.netposet, argument ...{} is passed on to the printing function.

Value

An object of class netposet with corresponding print, plot, and hasse functions. The object is
a list containing the following components:

- P.common: Ranking matrix with rows corresponding to treatments and columns correspond-
ing to outcomes (common effects model).
- M0.common: Hasse matrix skipping unnecessary paths (common effects model).
- M.common: "Full" Hasse matrix (common effects model).
- O.common: Matrix with information about partial ordering (common effects model).
- P.random: Ranking matrix with rows corresponding to treatments and columns correspond-
ing to outcomes (random effects model).
- M0.random: Hasse matrix skipping unnecessary paths (random effects model).
- M.random: "Full" Hasse matrix (random effects model).
- O.random: Matrix with information about partial ordering (random effects model).
- small.values, common, random
  As defined above.
- call: Function call.
- version: Version of R package netmeta used to create object.

# frequentist method to rank treatments in network
#### Description

Ranking treatments in frequentist network meta-analysis with and without resampling methods.
Usage

netrank(
  x,
  small.values = x$small.values,
  method,
  nsim,
  common = x$common,
  random = x$random,
  warn.deprecated = gs("warn.deprecated"),
  ...
)

## S3 method for class 'netrank'
print(
  x,
  common = x$common,
  random = x$random,
  sort = TRUE,
  digits = gs("digits.prop"),
  warn.deprecated = gs("warn.deprecated"),
  ...
)

Arguments

x An object of class netmeta or rankogram.
small.values A character string specifying whether small treatment effects indicate a beneficial ("good") or harmful ("bad") effect, can be abbreviated.
method A character string specifying whether the "P-score" or "SUCRA" ranking metric will be calculated.
nsim Number of simulations to calculate SUCRAs.
common A logical indicating whether to print P-scores or SUCRAs for the common effects model.
random A logical indicating whether to print P-scores or SUCRAs for the random effects model.
warn.deprecated A logical indicating whether warnings should be printed if deprecated arguments are used.
... Additional arguments passed on to print.data.frame function (used internally).
sort A logical indicating whether printout should be sorted by decreasing P-score.
digits Minimal number of significant digits, see print.default.

Details

Treatments are ranked based on a network meta-analysis. Ranking is performed by a ranking metric: P-score or SUCRA.
P-scores are based solely on the point estimates and standard errors of the network estimates. They measure the extent of certainty that a treatment is better than another treatment, averaged over all competing treatments (Rücker and Schwarzer 2015).

The Surface Under the Cumulative RAnking curve (SUCRA) is the rank of treatment \( i \) within the range of treatments, measured on a scale from 0 (worst) to 1 (best) (Salanti et al. 2011). A resampling method is used to calculate SUCRAs for frequentist network meta-analysis. The number of simulations is determined by argument nsim.

The interpretation of P-scores and SUCRAs is comparable.

The P-score of treatment \( i \) is defined as the mean of all \( 1 - P[j] \) where \( P[j] \) denotes the one-sided P-value of accepting the alternative hypothesis that treatment \( i \) is better than one of the competing treatments \( j \). Thus, if treatment \( i \) is better than many other treatments, many of these P-values will be small and the P-score will be large. Vice versa, if treatment \( i \) is worse than most other treatments, the P-score is small.

The P-score of treatment \( i \) can be interpreted as the mean extent of certainty that treatment \( i \) is better than another treatment.

**Value**

An object of class netrank with corresponding print function. The object is a list containing the following components:

- **ranking.common**: A named numeric vector with P-scores or SUCRAs for the common effects model.
- **Pmatrix.common**: Numeric matrix based on pairwise one-sided p-values for the common effects model.
- **ranking.random**: A named numeric vector with P-scores or SUCRAs for the random effects model.
- **Pmatrix.random**: Numeric matrix based on pairwise one-sided p-values of the random effects model.
- **small.values, method, x**: As defined above.
- **version**: Version of R package netmeta used to create object.

Arguments

x An object of class netmeta or netsplit.

method A character string indicating which method to split direct and indirect
evidence is to be used. Either "Back-calculation" or "SIDDE", can be abbreviated. See
Details.

upper A logical indicating whether treatment comparisons should be selected from
the lower or upper triangle of the treatment effect matrices (see list elements
TE.common and TE.random in the netmeta object). Ignored if argument order
is provided.

**reference.group**
Reference treatment. Ignored if argument `order` is provided.

**baseline.reference**
A logical indicating whether results should be expressed as comparisons of other treatments versus the reference treatment or vice versa. This argument is only considered if `reference.group` is not equal to "" and argument `order` is not provided.

**order**
A optional character or numerical vector specifying the order of treatments in comparisons.

**sep.trts**
A character string used in comparison names as separator between treatment labels, e.g., " vs ".

**quote.trts**
A character used to print around treatment labels.

**tol.direct**
A numeric defining the maximum deviation of the direct evidence proportion from 0 or 1 to classify a comparison as providing only indirect or direct evidence, respectively.

**common**
A logical indicating whether results for the common effects network meta-analysis should be printed.

**random**
A logical indicating whether results for the random effects network meta-analysis should be printed.

**backtransf**
A logical indicating whether printed results should be back transformed. For example, if `backtransf = TRUE`, results for `sm = "OR"` are printed as odds ratios rather than log odds ratios.

**warn**
A logical indicating whether warnings should be printed.

**warn.deprecated**
A logical indicating whether warnings should be printed if deprecated arguments are used.

**verbose**
A logical indicating whether progress information should be printed.

... Additional arguments.

**show**
A character string indicating which comparisons should be printed (see Details).

**overall**
A logical indicating whether estimates from network meta-analysis should be printed in addition to direct and indirect estimates.

**ci**
A logical indicating whether confidence intervals should be printed in addition to treatment estimates.

**test**
A logical indicating whether results of a test comparing direct and indirect estimates should be printed.

**only.reference**
A logical indicating whether only comparisons with the reference group should be printed.

**sortvar**
An optional vector used to sort comparisons (must be of same length as the total number of comparisons).

**nchar.trts**
A numeric defining the minimum number of characters used to create unique treatment names.
digits Minimal number of significant digits, see print.default.
digits.stat Minimal number of significant digits for z-value of test of agreement between
direct and indirect evidence, see print.default.
digits.pval Minimal number of significant digits for p-value of test of agreement between
direct and indirect evidence, see print.default.
digits.prop Minimal number of significant digits for direct evidence proportions, see print.default.
text.NA A character string specifying text printed for missing values.
scientific.pval A logical specifying whether p-values should be printed in scientific notation,
e.g., 1.2345e-01 instead of 0.12345.
big.mark A character used as thousands separator.
legend A logical indicating whether a legend should be printed.
indent A logical indicating whether items in the legend should be indented.

Details

A comparison of direct and indirect treatment estimates can serve as check for consistency of net-
work meta-analysis (Dias et al., 2010).

This function provides two methods to derive indirect estimates:

• Separate Indirect from Direct Evidence (SIDE) using a back-calculation method. The direct
evidence proportion as described in König et al. (2013) is used in the calculation of the indirect
evidence;

• Separate Indirect from Direct Design Evidence (SIDDE) as described in Efthimiou et al.
(2019).

Note, for the back-calculation method, indirect treatment estimates are already calculated in netmeta
and this function combines and prints these estimates in a user-friendly way. Furthermore, this
method is not available for the Mantel-Haenszel and non-central hypergeometric distribution ap-
proach implemented in netmetabin.

For the random-effects model, the direct treatment estimates are based on the common between-
study variance $\tau^2$ from the network meta-analysis, i.e. the square of list element $x$\$tau.

Argument show determines which comparisons are printed:

"all" All comparisons
"both" Only comparisons contributing both direct and indirect evidence
"with.direct" Comparisons providing direct evidence
"direct.only" Comparisons providing only direct evidence
"indirect.only" Comparisons providing only indirect evidence

The SIDDE approach can be compute-intensive in large networks. Crude information on the com-
putation progress is printed for SIDDE if argument verbose is TRUE. In addition, computation times
are printed if R package tictoc is installed.
Value

An object of class netsplit with corresponding print and forest functions. The object is a list containing the following components:

- **common, random**: As defined above.
- **comparison**: A vector with treatment comparisons.
- **prop.common, prop.random**: A vector with direct evidence proportions (common / random effects model).
- **common, random**: Results of network meta-analysis (common / random effects model), i.e., data frame with columns comparison, TE, seTE, lower, upper, z, and p.
- **direct.common, direct.random**: Network meta-analysis results based on direct evidence (common / random effects model), i.e., data frame with columns comparison, TE, seTE, lower, upper, z, and p.
- **indirect.common, indirect.random**: Network meta-analysis results based on indirect evidence (common / random effects model), i.e., data frame with columns comparison, TE, seTE, lower, upper, z, and p.
- **compare.common, compare.random**: Comparison of direct and indirect evidence in network meta-analysis (common / random effects model), i.e., data frame with columns comparison, TE, seTE, lower, upper, z, and p.
- **sm**: A character string indicating underlying summary measure
- **level.ma**: The level used to calculate confidence intervals for pooled estimates.
- **tictoc**: Computation times for SIDDE approach (if R package tictoc is installed).
- **version**: Version of R package netmeta used to create object.

Table with network meta-analysis results

Description

Construct a table with network, direct and indirect estimates from one or more network meta-analyses.

Usage

```r
nettable(
  ..., 
  name = NULL, 
  method = NULL, 
  order = NULL, 
  common, 
  random, 
  upper = TRUE, 
  reference.group = NULL, 
  baseline.reference = NULL, 
  backtransf = NULL, 
  digits = gs("digits"), 
  digits.I2 = gs("digits.I2"), 
  digits.pval = gs("digits.pval"), 
  scientific.pval = gs("scientific.pval"), 
  zero.pval = gs("zero.pval"), 
  JAMA.pval = gs("JAMA.pval"), 
  big.mark = gs("big.mark"), 
  text.NA = ".", 
  bracket = gs("CIbracket"), 
  separator = gs("CIseparator"), 
  lower.blank = gs("CILower.blank"), 
  upper.blank = gs("CIUpper.blank"), 
  tol.direct = 5e-04, 
  writexl = !missing(path), 
  path = "nettable.xlsx", 
  overwrite = FALSE, 
  warn = FALSE, 
  verbose = FALSE
)
```

## S3 method for class 'nettable'

print(x, common = x$x$common, random = x$x$random, ...)

Arguments

... Any number of network meta-analysis objects or a single list with network meta-analyses.
name
An optional character vector providing descriptive names for network meta-
analysis objects.

method
A character string indicating which method to split direct and indirect evidence
is to be used. Either "Back-calculation" or "SIDDE", can be abbreviated. See
Details.

order
A optional character or numerical vector specifying the order of treatments in
comparisons.

common
A logical indicating whether table for the common effects network meta-analysis
should be printed.

random
A logical indicating whether table for the random effects network meta-analysis
should be printed.

upper
A logical indicating whether treatment comparisons should be selected from
the lower or upper triangle of the treatment effect matrices (see list elements
TE.common and TE.random in the netmeta object). Ignored if argument order
is provided.

reference.group
Reference treatment. Ignored if argument order is provided.

baseline.reference
A logical indicating whether results should be expressed as comparisons of other
treatments versus the reference treatment or vice versa. This argument is only
considered if reference.group is not equal to "" and argument order is not
provided.

backtransf
A logical indicating whether printed results should be back transformed. For
example, if backtransf = TRUE, results for sm = "OR" are printed as odds ratios
rather than log odds ratios.

digits
Minimal number of significant digits, see print.default.

digits.I2
Minimal number of significant digits for I-squared statistic, see print.default.

digits.pval
Minimal number of significant digits for p-value of test of agreement between
direct and indirect evidence, see print.default.

scientific.pval
A logical specifying whether p-values should be printed in scientific notation,
e.g., 1.2345e-01 instead of 0.12345.

zero.pval
A logical specifying whether p-values should be printed with a leading zero.

JAMA.pval
A logical specifying whether p-values for test of overall effect should be printed
according to JAMA reporting standards.

big.mark
A character used as thousands separator.

text.NA
A character string specifying text printed for missing values.

bracket
A character with bracket symbol to print lower confidence interval: "[", "]", "\{",
"\}".

separator
A character string with information on separator between lower and upper con-
fi dence interval.

lower.blank
A logical indicating whether blanks between left bracket and lower confidence
limit should be printed.
upper.blank  A logical indicating whether blanks between separator and upper confidence limit should be printed.
tol.direct   A numeric defining the maximum deviation of the direct evidence proportion from 0 or 1 to classify a comparison as providing only indirect or direct evidence, respectively.
writexl     A logical indicating whether an Excel file should be created (R package writexl must be available).
path        A character string specifying the filename of the Excel file.
overwrite   A logical indicating whether an existing Excel file should be overwritten.
warn        A logical indicating whether warnings should be printed.
verbose     A logical indicating whether progress information should be printed.
x           An object of class nettable.

Details

Construct a table with network, direct and indirect estimates from one or more network meta-analyses. The table looks very similar to the statistical part of a GRADE table for a network meta-analysis (Puhan et al., 2014).

By default, an R object with the network tables is generated. Alternatively, an Excel file is created if argument writexl = TRUE.

Two methods to derive indirect estimates are available:

- Separate Indirect from Direct Evidence (SIDE) using a back-calculation method. The direct evidence proportion as described in König et al. (2013) is used in the calculation of the indirect evidence;
- Separate Indirect from Direct Design Evidence (SIDDE) as described in Efthimiou et al. (2019).

Note, for the back-calculation method, indirect treatment estimates are already calculated in netmeta and this function combines and prints these estimates in a user-friendly way. Furthermore, this method is not available for the Mantel-Haenszel and non-central hypergeometric distribution approach implemented in netmetabin.

For the random-effects model, the direct treatment estimates are based on the common between-study variance $\tau^2$ from the network meta-analysis, i.e. the square of list element x$^\tau$.

The SIDDE approach can be compute-intensive in large networks. Crude information on the computation progress is printed for SIDDE if argument verbose is TRUE.

Value

An object of class nettable with corresponding print function if argument writexl = FALSE. The object is a list containing the network tables in list elements 'common' and 'random'. An Excel file is created if writexl = TRUE. In this case, NULL is returned in R.

## End(Not run)
Description

This function transforms data that are given in wide or long arm-based format (e.g., input format for WinBUGS) to a contrast-based format that is needed as input to R function netmeta. The function can transform data with binary, continuous, or generic outcomes as well as incidence rates from arm-based to contrast-based format.

Usage

```r
pairwise(
  treat,
  event,
  n,
  mean,
  sd,
  TE,
  seTE,
  time,
  data = NULL,
  studlab,
  incr = gs("incr"),
  allincr = gs("allincr"),
  addincr = gs("addincr"),
  allstudies = gs("allstudies"),
  reference.group,
  keep.all.comparisons,
  warn = FALSE,
  ...
)
```

Arguments

- **treat**: A list or vector with treatment information for individual treatment arms (see Details).
- **event**: A list or vector with information on number of events for individual treatment arms (see Details).
- **n**: A list or vector with information on number of observations for individual treatment arms (see Details).
- **mean**: A list or vector with estimated means for individual treatment arms (see Details).
- **sd**: A list or vector with information on the standard deviation for individual treatment arms (see Details).
- **TE**: A list or vector with estimated treatment effects for individual treatment arms (see Details).
- **seTE**: A list or vector with standard errors of estimated treatment effect for individual treatment arms (see Details).
- **time**: A list or vector with information on person time at risk for individual treatment arms (see Details).
data  An optional data frame containing the study information.
studlab  A vector with study labels (optional).
incr  A numerical value which is added to cell frequencies for studies with a zero cell count, see Details.
allincr  A logical indicating if incr is added to cell frequencies of all studies if at least one study has a zero cell count. If FALSE (default), incr is added only to cell frequencies of studies with a zero cell count.
addincr  A logical indicating if incr is added to cell frequencies of all studies irrespective of zero cell counts.
allstudies  A logical indicating if studies with zero or all events in two treatment arms are to be included in the meta-analysis (applies only if sm is equal to "RR" or "OR").
reference.group  Reference treatment (first treatment is used if argument is missing).
keep.all.comparisons  A logical indicating whether all pairwise comparisons or only comparisons with the study-specific reference group should be kept ('basic parameters').
warn  A logical indicating whether warnings should be printed (e.g., if studies are excluded due to only providing a single treatment arm).

Details

R function netmeta expects data in a contrast-based format, where each row corresponds to a comparison of two treatments and contains a measure of the treatment effect comparing two treatments with standard error, labels for the two treatments and an optional study label. In contrast-based format, a three-arm study contributes three rows with treatment comparison and corresponding standard error for pairwise comparison A vs B, A vs C, and B vs C whereas a four-arm study contributes six rows / pairwise comparisons: A vs B, A vs C, . . . , C vs D.

Other programs for network meta-analysis in WinBUGS and Stata require data in an arm-based format, i.e. treatment estimate for each treatment arm instead of a difference of two treatments. A common (wide) arm-based format consists of one data row per study, containing treatment and other necessary information for all study arms. For example, a four-arm study contributes one row with four treatment estimates and corresponding standard errors for treatments A, B, C, and D. Another possible arm-based format is a long format where each row corresponds to a single study arm. Accordingly, in the long arm-based format a study contributes as many rows as treatments considered in the study.

The pairwise function transforms data given in (wide or long) arm-based format into the contrast-based format which consists of pairwise comparisons and is needed as input to the netmeta function.

The pairwise function can transform data with binary outcomes (using the metabin function from R package meta), continuous outcomes (metacont function), incidence rates (metainc function), and generic outcomes (metagen function). Depending on the outcome, the following arguments are mandatory:

- treat, event, n (see metabin);
- treat, n, mean, sd (see metacont);
- treat, event, time (see metainc);
- treat, TE, seTE (see metagen).

Argument treat is mandatory to identify the individual treatments. The other arguments contain outcome specific data. These arguments must be either lists (wide arm-based format, i.e., one row per study) or vectors (long arm-based format, i.e., multiple rows per study) of the same length.

For the wide arm-based format, each list consists of as many vectors of the same length as the multi-arm study with the largest number of treatments. If a single multi-arm study has five arms, five vectors have to be provided for each lists. Two-arm studies have entries with NA for the third and subsequent vectors. Each list entry is a vector with information for each individual study; i.e., the length of this vector corresponds to the total number of studies incorporated in the network meta-analysis. Typically, list elements are part of a data frame (argument data, optional); see Examples. An optional vector with study labels can be provided which can be part of the data frame.

In the long arm-based format, argument studlab is mandatory to identify rows contributing to individual studies.

Additional arguments for meta-analysis functions can be provided using argument ‘...’. The most important argument is sm defining the summary measure. More information on this and other arguments is given in the help pages of R functions metabin, metacont, metainc, and metagen, respectively.

For standardised mean differences (argument sm = "SMD"), equations (4) and (5) in Crippa & Orsini (2016) are used to calculate SMDs and standard errors. These equations guarantee consistent SMDs and standard errors for multi-arm studies. Note, the summary measure is actually Cohen’s d as Hedges’ g is not consistent in multi-arm studies.

For binary outcomes, 0.5 is added to all cell frequencies (odds ratio) or only the number of events (risk ratio) for studies with a zero cell count. For odds ratio and risk ratio, treatment estimates and standard errors are only calculated for studies with zero or all events in both groups if allstudies is TRUE. This continuity correction is used both to calculate individual study results with confidence limits and to conduct meta-analysis based on the inverse variance method. For the risk difference, 0.5 is only added to all cell frequencies to calculate the standard error.

For incidence rates, 0.5 is added to all cell frequencies for the incidence rate ratio as summary measure. For the incidence risk difference, 0.5 is only added to all cell frequencies to calculate the standard error.

The value of pairwise is a data frame with as many rows as there are pairwise comparisons. For each study with p treatments, p*(p-1) / 2 contrasts are generated. Each row contains the treatment effect (TE), its standard error (seTE), the treatments compared ((treat1), (treat2)) and the study label ((studLab)). Further columns are added according to type of data.

All variables from the original dataset are also part of the output dataset. If data are provided in the long arm-based format, the value of a variable can differ between treatment arms; for example, the mean age or percentage of women in the treatment arm. In this situation, two variables instead of one variable will be included in the output dataset. The values "1" and "2" are added to the names for these variables, e.g. "mean.age1" and "mean.age2" for the mean age.

In general, any variable names in the original dataset that are identical to the main variable names (i.e., "TE", "seTE", ...) will be renamed to variable names with ending ".orig".
A reduced data set with basic comparisons (Rücker & Schwarzer, 2014) can be generated using argument `keep.all.comparisons = FALSE`. Furthermore, the reference group for the basic comparisons can be specified with argument `reference.group`.

**Value**

A data frame with the following columns:

- **TE**: Treatment estimate comparing treatment 'treat1' and 'treat2'.
- **seTE**: Standard error of treatment estimate.
- **studlab**: Study labels.
- **treat1**: First treatment in comparison.
- **treat2**: Second treatment in comparison.
- **event1**: Number of events for first treatment arm (for metabin and metainc).
- **event2**: Number of events for second treatment arm (for metabin and metainc).
- **n1**: Number of observations for first treatment arm (for metabin and metacont).
- **n2**: Number of observations for second treatment arm (for metabin and metacont).
- **mean1**: Estimated mean for first treatment arm (for metacont).
- **mean2**: Estimated mean for second treatment arm (for metacont).
- **sd1**: Standard deviation for first treatment arm (for metacont).
- **sd2**: Standard deviation for second treatment arm (for metacont).
- **TE1**: Estimated treatment effect for first treatment arm (for metagen).
- **TE2**: Estimated treatment effect for second treatment arm (for metagen).
- **seTE1**: Standard error of estimated treatment effect for first treatment arm (for metagen).
- **seTE2**: Standard error of estimated treatment effect for second treatment arm (for metagen).
- **time1**: Person time at risk for first treatment arm (for metainc).
- **time2**: Person time at risk for second treatment arm (for metainc).

All variables from the original dataset are also part of the output dataset; see Details.

**Note**

This function must not be confused with `netpairwise` which can be used to conduct pairwise meta-analyses for all comparisons with direct evidence in a network meta-analysis.

  arrows = FALSE,
```
length = 0.05,
grid = TRUE,
col.grid = "gray",
lty.grid = 2,
lwd.grid = 1,
...
)

Arguments

x  An object of class netmeta (mandatory).

plottype A character string indicating whether a scatter plot or biplot should be produced, either "scatter" or "biplot". Can be abbreviated.
pooled A character string indicating whether scatter plot should be drawn for common ("common") or random effects model ("random"). Can be abbreviated.
dim A character string indicating whether a 2- or 3-dimensional plot should be produced, either "2d" or "3d". Can be abbreviated.

sel.x A numeric specifying number of outcome to use for the x-axis in a scatterplot (argument is not considered for a biplot).

sel.y A numeric specifying number of outcome to use for the y-axis in a scatterplot (argument is not considered for a biplot).

sel.z A numeric specifying number of outcome to use for the z-axis in a scatterplot (argument is not considered for a biplot).
cex The magnification to be used for treatment labels and points.
col Colour(s) of treatment labels and points.
cex.text The magnification to be used for treatment labels.
col.text Colour(s) of treatment labels.
adj.x Value(s) in \([0,1]\) to specify adjustment of treatment labels on x-axis (only considered in 2-D plots); see text.

adj.y Value(s) in \([0,1]\) to specify adjustment of treatment labels on y-axis (only considered in 2-D plots); see text.

offset.x Offset(s) of treatment labels on x-axis (only considered in 2-D plots).

offset.y Offset(s) of treatment labels on y-axis (only considered in 2-D plots).
pch Plot symbol(s) for points; no points printed if equal to NULL.

cex.points Magnification(s) to be used for points.
col.points Colour(s) of points.
col.lines Line colour.
lty.lines Line type.
lwd.lines Line width.
arrows A logical indicating whether arrows should be printed (only considered in 2-D plots).

length Length of arrows; see arrows.
grid A logical indicating whether grid lines should be added to plot.
col.grid Colour of grid lines.
lty.grid Line type of grid lines.
lwd.grid Line width of grid lines.
... Additional graphical arguments.

Details

By default (arguments plottype = "scatter" and dim = "2d"), a scatter plot is created showing P-scores (see netrank) for the first two outcomes considered in the generation of a partially ordered set of treatment ranks (using netposet). In addition to the P-scores, the partially order of treatment ranks is shown as lines connecting treatments which is analogous to a Hasse diagram. If argument dim = "3d"), a 3-D scatter plot is generated showing P-scores for the first three outcomes.

To overcome the restriction of two or three dimension, a biplot (Gabriel, 1971) can be generated using argument plottype = "biplot". This is essentially a scatter plot using the first two (dim = "2d") or three (dim = "3d") components in a principal components analysis (using prcomp). Note, if only two / three outcomes are considered in a netposet object, a 2-D / 3-D scatter plot is generated instead of a biplot as a principal component analysis is superfluous in such a situation.

Arguments sel.x and sel.y can be used to select different outcomes to show on x- and y-axis in a 2-D scatter plot; argument sel.z can be used accordingly in a 3-D scatter plot. These arguments are ignored for a biplot.

Note, in order to generate 3-D plots (argument dim = "3d"), R package rgl is necessary. Note, under macOS the X.Org X Window System must be available (see https://www.xquartz.org).

## End(Not run)

---

**plot.netrank**

_plot treatment ranking(s) of network meta-analyses_

**Description**

Produce an image plot of treatment ranking(s) generated with R function `netrank`.

**Usage**

```r
## S3 method for class 'netrank'
plot(
    ..., 
    name, 
    common, 
    random, 
    seq, 
    low = "red", 
    mid = "yellow", 
    high = "green", 
    col = "black", 
    main, 
    main.size = 14, 
    main.col = col, 
    main.face = "bold", 
    legend = TRUE, 
    axis.size = 12, 
    axis.col = col, 
    axis.face = "plain", 
    na.value = "grey50", 
    angle = 45, 
    
```
hjust.x = 1,
vjust.x = 1,
hjust.y = 1,
vjust.y = 0,
nchar.trts,
digits = 3,
fixed,
comb.fixed,
comb.random,
warn.deprecated = gs("warn.deprecated")
}

Arguments

... A single netrank object or a list of netrank objects.
name An optional character vector providing descriptive names for the network meta-
analysis objects.
common A logical indicating whether results for the common effects model should be
plotted.
random A logical indicating whether results for the random effects model should be
plotted.
seq A character or numerical vector specifying the sequence of treatments on the
x-axis.
low A character string defining the colour for a P-score of 0, see scale_fill_gradient2.
mid A character string defining the colour for a P-score of 0.5, see scale_fill_gradient2.
high A character string defining the colour for a P-score of 1, see scale_fill_gradient2.
col Colour of text.
main Title.
main.size Font size of title, see element_text.
main.col Colour of title, see element_text.
main.face Font face of title, see element_text.
legend A logical indicating whether a legend should be printed.
axis.size Font size of axis text, see element_text.
axis.col Colour of axis text, see element_text.
axis.face Font face of axis text, see element_text.
na.value Colour for missing values, see scale_fill_gradient2.
angle Angle for text on x-axis, see element_text.
hjust.x A numeric between 0 and 1 with horizontal justification of text on x-axis, see
element_text.
vjust.x A numeric between 0 and 1 with vertical justification of text on x-axis, see
element_text.
hjust.y A numeric between 0 and 1 with horizontal justification of text on y-axis, see
element_text.
plot.netrank

vjust.y A numeric between 0 and 1 with vertical justification of text on y-axis, see `element_text`

nchar.trts A numeric defining the minimum number of characters used to create unique treatment names.

digits Minimal number of significant digits, see `print.default`

fixed Deprecated argument (replaced by 'common').

comb.fixed Deprecated argument (replaced by 'common').

comb.random Deprecated argument (replaced by 'random').

warn.deprecated A logical indicating whether warnings should be printed if deprecated arguments are used.

Details

This function produces an image plot of network rankings (Palpacuer et al., 2018, Figure 4). Note, a scatter plot of two network rankings can be generated with `plot.netposet`.

By default, treatments are ordered by decreasing P-scores of the first network meta-analysis object. Argument seq can be used to specify a different treatment order.

Value

A ggplot2 object or NULL if no ranking was conducted.

#
net4 <- netmeta(p4, common = FALSE, seq = trts, ref = "Placebo")
plot.rankogram

Plot rankograms

Description
This function produces a rankogram, i.e., an image plot of ranking probabilities for all treatments.

Usage
## S3 method for class 'rankogram'
plot(
  x,
  type = if (cumulative.rankprob) "step" else "bar",
  pooled = ifelse(x$random, "random", "common"),
  sort = TRUE,
  trts,
  cumulative.rankprob = x$cumulative.rankprob,
  ylim,
  ylab,
  nchar.trts = x$nchar.trts,
  ...
)

Arguments
x An object of class rankogram.

type A character string specifying whether a "bar" chart, a "line" graph, or "step" functions should be drawn. Can be abbreviated.
plot.rankogram

pooled
A character string indicating whether results for the common ("common") or random effects model ("random") should be plotted. Can be abbreviated.

sort
A logical indicating whether treatments should be sorted by decreasing SU-CRAs.

trts
Treatment(s) to show in rankogram.

cumulative.rankprob
A logical indicating whether cumulative ranking probabilities should be shown.

ylim
The y limits (min, max) of the plot.

ylab
A label for the y-axis.

nchar.trts
A numeric defining the minimum number of characters used to create unique treatment names.

... Additional graphical arguments (ignored at the moment).

Details
This function produces an image plot of (cumulative) ranking probabilities for all treatments as a bar graph, a line graph or as step functions (argument type).
By default (argument pooled), results for the random effects model are shown if a network meta-analysis was conducted for both the common and random effects model.
Treatments are sorted according to their mean effects if argument sort = TRUE (default). A subset of treatments can be specified using argument trts.
Cumulative ranking probabilities are shown if cumulative.rankprob = TRUE. By default, step functions are shown for cumulative ranking probabilities.

print.decomp.design

Print method for objects of class decomp.design

Description

Print method for objects of class decomp.design.

Usage

## S3 method for class 'decomp.design'
print(
  x,
  digits.Q = gs("digits.Q"),
  showall = FALSE,
  digits.pval.Q = gs("digits.pval.Q"),
  digits.tau2 = gs("digits.tau2"),
  scientific.pval = gs("scientific.pval"),
  big.mark = gs("big.mark"),
  nchar.trts = x$nchar.trts,
  legend = TRUE,
  ...
)

Arguments

x                An object of class decomp.design.
digits.Q        Minimal number of significant digits for Q statistics, see print.default.
showall         A logical indicating whether results should be shown for all designs or only
digits.pval.Q   designs contributing to chi-squared statistics (default).
digits.tau2     Minimal number of significant digits for between-study variance, see
scientific.pval print.default.
big.mark         A logical specifying whether p-values should be printed in scientific notation,
nchar.trts      e.g., 1.2345e-01 instead of 0.12345.
legend           A character used as thousands separator.
...              A numeric defining the minimum number of characters used to create unique
treatment names.
...              A logical indicating whether a legend should be printed.
...              Additional arguments (ignored at the moment).

JAMA.pval = gs("JAMA.pval"),
big.mark = gs("big.mark"),
text.tau2 = gs("text.tau2"),
text.tau = gs("text.tau"),
text.I2 = gs("text.I2"),
legend = TRUE,
warn.deprecated = gs("warn.deprecated"),
...)
```

Arguments

- **x** An object of class netcomb or summary.netcomb.
- **common** A logical indicating whether results for the common effects model should be printed.
- **random** A logical indicating whether results for the random effects model should be printed.
- **backtransf** A logical indicating whether results should be back transformed in printouts and forest plots. If `backtransf = TRUE`, results for `sm = "OR"` are presented as odds ratios rather than log odds ratios, for example.
nchar.comps A numeric defining the minimum number of characters used to create unique names for components.
digits Minimal number of significant digits, see print.default.
digits.stat Minimal number of significant digits for z- or t-value, see print.default.
digits.pval Minimal number of significant digits for p-value of overall treatment effect, see print.default.
digits.pval.Q Minimal number of significant digits for p-value of heterogeneity tests, see print.default.
digits.Q Minimal number of significant digits for heterogeneity statistics, see print.default.
digits.tau2 Minimal number of significant digits for between-study variance, see print.default.
digits.tau Minimal number of significant digits for square root of between-study variance, see print.default.
digits.I2 Minimal number of significant digits for I-squared statistic, see print.default.
scientific.pval A logical specifying whether p-values should be printed in scientific notation, e.g., 1.2345e-01 instead of 0.12345.
zero.pval A logical specifying whether p-values should be printed with a leading zero.
JAMA.pval A logical specifying whether p-values for test of component or combination effect should be printed according to JAMA reporting standards.
big.mark A character used as thousands separator.
text.tau2 Text printed to identify between-study variance $\tau^2$.
text.tau Text printed to identify $\tau$, the square root of the between-study variance $\tau^2$.
text.I2 Text printed to identify heterogeneity statistic $I^2$.
legend A logical indicating whether a legend should be printed.
warn.deprecated A logical indicating whether warnings should be printed if deprecated arguments are used.
... Additional arguments (to catch deprecated arguments).

### Arguments

- **x**: An object of class `summary.netmeta`.
- **sortvar**: An optional vector used to sort individual studies (must be of same length as `x$TE`).
- **common**: A logical indicating whether results for the common effects model should be printed.
- **random**: A logical indicating whether results for the random effects model should be printed.
- **prediction**: A logical indicating whether prediction intervals should be printed.
- **reference.group**: Reference treatment.
- **baseline.reference**: A logical indicating whether results should be expressed as comparisons of other treatments versus the reference treatment (default) or vice versa. This argument is only considered if `reference.group` has been specified.
all.treatments  A logical or "NULL". If TRUE, matrices with all treatment effects, and confidence limits will be printed.
details        A logical indicating whether further details for individual studies should be printed.
nma            A logical indicating whether summary results of network meta-analysis should be printed.
backtransf     A logical indicating whether results should be back transformed in printouts and forest plots. If backtransf = TRUE, results for sm = "OR" are presented as odds ratios rather than log odds ratios, for example.
nchar.trts     A numeric defining the minimum number of characters used to create unique treatment names.
nchar.studlab  A numeric defining the minimum number of characters used to create unique study labels.
digits         Minimal number of significant digits, see print.default.
digits.se      Minimal number of significant digits for standard deviations and standard errors, see print.default.
digits.pval.Q  Minimal number of significant digits for p-value of heterogeneity tests, see print.default.
digits.Q       Minimal number of significant digits for heterogeneity statistics, see print.default.
digits.tau2    Minimal number of significant digits for between-study variance, see print.default.
digits.I2      Minimal number of significant digits for I-squared statistic, see print.default.
scientific.pval A logical specifying whether p-values should be printed in scientific notation, e.g., 1.2345e-01 instead of 0.12345.
big.mark       A character used as thousands separator.
truncate       An optional vector used to truncate the printout of results for individual studies (must be a logical vector of length corresponding to the number of pairwise comparisons $x$TE or contain numerical values).
text.truncate  A character string printed if study results were truncated from the printout.
legend         A logical indicating whether a legend should be printed.
warn.deprecated A logical indicating whether warnings should be printed if deprecated arguments are used.
...             Additional arguments.

**rankogram**

*Calculate rankogram*

**Description**

This function calculates the probabilities of each treatment being at each possible rank and the SUCRAs (Surface Under the Cumulative RAning curve) in frequentist network meta-analysis.

**Usage**

`rankogram()`
Arguments

- **x**: An object of class `netmeta`.
- **nsim**: Number of simulations.
- **common**: A logical indicating to compute ranking probabilities and SUCRAs for the common effects model.
- **random**: A logical indicating to compute ranking probabilities and SUCRAs for the random effects model.
- **small.values**: A character string specifying whether small treatment effects indicate a beneficial ("good") or harmful ("bad") effect, can be abbreviated.
- **cumulative.rankprob**: A logical indicating whether cumulative ranking probabilities should be printed.
- **nchar.trts**: A numeric defining the minimum number of characters used to create unique treatment names.
- **warn.deprecated**: A logical indicating whether warnings should be printed if deprecated arguments are used.
- **...**: Additional arguments for printing.
- **digits**: Minimal number of significant digits, see `print.default`.
- **legend**: A logical indicating whether a legend should be printed.
Details

We derive a matrix showing the probability of each treatment being at each possible rank. To this aim, we use resampling from a multivariate normal distribution with estimated network effects as means and corresponding estimated variance covariance matrix. We then summarise them using the ranking metric SUCRAs (Surface Under the Cumulative RAnking curve).

Value

An object of class `rankogram` with corresponding `print` and `plot` function. The object is a list containing the following components:

- `ranking.matrix.common` Numeric matrix giving the probability of each treatment being at each possible rank for the common effects model.
- `ranking.common` SUCRA values for the common effects model.
- `ranking.matrix.random` Numeric matrix giving the probability of each treatment being at each possible rank for the random effects model.
- `ranking.random` SUCRA values for the random effects model.
- `cumrank.matrix.common` Numeric matrix giving the cumulative ranking probability of each treatment for the common effects model.
- `cumrank.matrix.random` Numeric matrix giving the cumulative ranking probability of each treatment for the random effects model.
- `nsim, common, random` As defined above
- `small.values, x` As defined above

Network meta-analysis in diabetes

Description

Network meta-analysis in diabetes comparing effects of a number of drugs on the HbA1c value.
These data are used as an example in Senn et al. (2013) and have been preprocessed for use in R
package netmeta.

Format

A data frame with the following columns:

- **TE** treatment effect
- **seTE** standard error of treatment effect
- **treat1** treatment 1
- **treat2** treatment 2
- **treat1.long** treatment 1 (full treatment names)
- **treat2.long** treatment 2 (full treatment names)
- **studlab** Study label

Details

Treatment labels provided by columns treat1 and treat2 have been abbreviated:

- acar = Acarbose
- benf = Benfluorex
- metf = Metformin
- migl = Miglitol
- piog = Pioglitazone
- plac = Placebo
- rosi = Rosiglitazone
- sita = Sitagliptin
- sulf = Sulfonylurea
- vild = Vildagliptin

Full treatment names are available in columns `treat1.long` and `treat2.long`.

Network meta-analysis of interventions for smoking cessation

Description

Network meta-analysis comparing the effects of a number of interventions for smoking cessation. These data are used as an example in Dias et al. (2013), page 651.

Format

A data frame with the following columns:

- `event1` number of individuals with successful smoking cessation in arm 1
- `n1` number of individuals in arm 1
- `event2` number of individuals with successful smoking cessation in arm 2
- `n2` number of individuals in arm 2
- `event3` number of individuals with successful smoking cessation in arm 3
- `n3` number of individuals in arm 3
- `treat1` treatment 1
- `treat2` treatment 2
- `treat3` treatment 3

Stowe2010

Network meta-analysis of adjuvant treatments to levodopa therapy for Parkinson’s disease

Description

This data set contains data from a Cochrane review assessing efficacy and safety of three drug classes as adjuvant treatment to levodopa therapy in patients with Parkinson’s disease and motor complications (Stowe et al., 2010). The authors conducted three pairwise meta-analyses comparing dopamine agonists, catechol-O-methyl transferase inhibitors (COMTIs), and monoamine oxidase type B inhibitors (MAOBIIs), respectively, with placebo.

The primary outcome was the mean reduction of the time spent in a relatively immobile ’off’ phase (mean off-time), calculated in hours per day. Relative treatment effects were expressed as mean difference. Data on this outcome were available for 5,331 patients from 28 studies comparing an active treatment with placebo and one three-arm study comparing two active treatments with placebo.

Format

A data frame with the following columns:

**Description**
The subset method returns a subset of a pairwise object.

**Usage**
```r
## S3 method for class 'pairwise'
subset(x, subset, ...)
```

**Arguments**
- `x`: An object of class `pairwise`.
- `subset`: A logical expression indicating elements or rows to keep: missing values are taken as false.
- `...`: Additional arguments.

**Value**
A pairwise object is returned.

### Description

Summary method for objects of class `netmeta`.

#### Usage

```r
## S3 method for class 'netmeta'
summary(
  object,
  common = object$common,
  random = object$random,
  prediction = object$prediction,
  reference.group = object$reference.group,
  baseline.reference = object$baseline.reference,
  all.treatments = object$all.treatments,
  warn.deprecated = gs("warn.deprecated"),
  ...)
```

#### Arguments

- **object**: An object of class `netmeta`.
- **common**: A logical indicating whether results for the common effects model should be printed.
- **random**: A logical indicating whether results for the random effects model should be printed.
- **prediction**: A logical indicating whether prediction intervals should be printed.
- **reference.group**: Reference treatment.
- **baseline.reference**: A logical indicating whether results should be expressed as comparisons of other treatments versus the reference treatment (default) or vice versa. This argument is only considered if `reference.group` has been specified.
- **all.treatments**: A logical or "NULL". If TRUE, matrices with all treatment effects, and confidence limits will be printed.
- **warn.deprecated**: A logical indicating whether warnings should be printed if deprecated arguments are used.
- **...**: Additional arguments (to catch deprecated arguments).
Value

A list is returned with the following elements:

- **comparison**
  Results for pairwise comparisons (data frame with columns studlab, treat1, treat2, TE, seTE, lower, upper, z, p).

- **comparison.nma.common**
  Results for pairwise comparisons based on common effects model (data frame with columns studlab, treat1, treat2, TE, seTE, lower, upper, z, p, leverage).

- **comparison.nma.random**
  Results for pairwise comparisons based on random effects model (data frame with columns studlab, treat1, treat2, TE, seTE, lower, upper, z, p).

- **common**
  Results for common effects model (a list with elements TE, seTE, lower, upper, z, p).

- **random**
  Results for random effects model (a list with elements TE, seTE, lower, upper, z, p).

- **predict**
  Prediction intervals (a list with elements seTE, lower, upper).

- **studies**
  Study labels coerced into a factor with its levels sorted alphabetically.

- **narms**
  Number of arms for each study.

- **k**
  Total number of studies.

- **m**
  Total number of pairwise comparisons.

- **n**
  Total number of treatments.

- **d**
  Total number of designs (corresponding to the unique set of treatments compared within studies).

- **Q**
  Overall heterogeneity / inconsistency statistic.

- **df.Q**
  Degrees of freedom for test of heterogeneity / inconsistency.

- **pval.Q**
  P-value for test of heterogeneity / inconsistency.

- **I2, lower.I2, upper.I2**
  I-squared, lower and upper confidence limits.

- **tau**
  Square-root of between-study variance.

- **Q.heterogeneity**
  Overall heterogeneity statistic.

- **df.Q.heterogeneity**
  Degrees of freedom for test of overall heterogeneity.

- **pval.Q.heterogeneity**
  P-value for test of overall heterogeneity.

- **Q.inconsistency**
  Overall inconsistency statistic.

- **df.Q.inconsistency**
  Degrees of freedom for test of overall inconsistency.

- **pval.Q.inconsistency**
  P-value for test of overall inconsistency.

- **sm**
  A character string indicating underlying summary measure.
method A character string indicating which method is to be used for pooling of studies.
level The level used to calculate confidence intervals for individual studies.
level.ma The level used to calculate confidence intervals for pooled estimates.
common, random As defined above.
prediction, level.predict As defined above.
reference.group, baseline.reference As defined above.
all.treatments, backtransf As defined above.
ci.lab Label for confidence interval.
seq A character specifying the sequence of treatments.
tau.preset An optional value for the square-root of the between-study variance $\tau^2$.
sep.trts A character used in comparison names as separator between treatment labels.
nchar.trts A numeric defining the minimum number of characters used to create unique treatment names.
title Title of meta-analysis / systematic review.
call Function call.
version Version of R package netmeta used to create object.

treats  

**Abbreviate treatment names**

Description

Auxiliary functions to create uniquely abbreviated treatment names.

Usage

```r
treats(x, nchar.trts = 8, row = TRUE)
comps(x, trts, sep.trts, nchar.trts = 8, row = TRUE)
```

Arguments

- `x`: A vector with treatment or comparison names or a matrix with treatment or comparison names as row and / or column names.
- `nchar.trts`: A numeric defining the minimum number of characters used to create unique treatment names.
- `row`: A logical indicating whether row or column names should be used (only considered if argument `x` is a matrix).
- `trts`: A character vector with treatment names.
- `sep.trts`: A character used in comparison names as separator between treatment labels.

Details

These auxiliary functions can be used to create uniquely abbreviated treatment names (and are used internally in several R functions for this purpose).

In order to construct uniquely abbreviated treatment names, `treats` uses `substring` to extract the first `nchar.trts` characters. If these abbreviated treatment names are not unique, `abbreviate` with argument `minlength = nchar.trts` is used.

In order to construct comparisons with uniquely abbreviated treatment names, `comps` calls `treats` internally.
