Package ‘nimble’

February 24, 2022

Title  MCMC, Particle Filtering, and Programmable Hierarchical Modeling

Description  A system for writing hierarchical statistical models largely compatible with 'BUGS' and 'JAGS', writing nimbleFunctions to operate models and do basic R-style math, and compiling both models and nimbleFunctions via custom-generated C++. 'NIMBLE' includes default methods for MCMC, Monte Carlo Expectation Maximization, and some other tools. The nimbleFunction system makes it easy to do things like implement new MCMC samplers from R, customize the assignment of samplers to different parts of a model from R, and compile the new samplers automatically via C++ alongside the samplers 'NIMBLE' provides. 'NIMBLE' extends the 'BUGS'/JAGS' language by making it extensible: New distributions and functions can be added, including as calls to external compiled code. Although most people think of MCMC as the main goal of the 'BUGS'/JAGS' language for writing models, one can use 'NIMBLE' for writing arbitrary other kinds of model-generic algorithms as well. A full User Manual is available at <https://r-nimble.org>.

Version  0.12.2

Date  2022-02-23

Maintainer  Christopher Paciorek <paciorek@stat.berkeley.edu>

Depends  R (>= 3.1.2)

Imports  methods, igraph, coda, R6

Suggests  testthat

SystemRequirements  GNU make

License  BSD_3_clause + file LICENSE | GPL (>= 2)

Copyright  See COPYRIGHTS file.

Note  For convenience, the package includes the necessary header files for the Eigen distribution. (This is all that is needed to use that functionality.) You can use an alternative installation of Eigen on your system or the one we provide. The license for the Eigen code is very permissive and allows us to distribute it with this package. See <http://eigen.tuxfamily.org/index.php?title=Main_Page> and also the License section on that page.

any_na

Determine if any values in a vector are NA or NaN

Description

NIMBLE language functions that can be used in either compiled or uncompiled nimbleFunctions to detect if there are any NA or NaN values in a vector.

Usage

any_na(x)

any_nan(x)
as.carAdjacency

Arguments

x                     vector of values

Author(s)

NIMBLE Development Team

as.carAdjacency      Convert CAR structural parameters to adjacency, weights, num format

Description

This will convert alternate representations of CAR process structure into (adj, weights, num) form required by dcar_normal.

Usage

as.carAdjacency(...)

Arguments

... Either: a symmetric matrix of unnormalized weights, or two lists specifying adjacency indices and the corresponding unnormalized weights.

Details

Two alternate representations are handled:

A single matrix argument will be interpreted as a matrix of symmetric unnormalized weights;

Two lists will be interpreted as (the first) a list of numeric vectors specifying the adjacency (neighboring) indices of each CAR process component, and (the second) a list of numeric vectors giving the unnormalized weights for each of these neighboring relationships.

Author(s)

Daniel Turek

See Also

CAR-Normal
as.carCM

Convert weights vector to parameters of `dcar_proper` distribution

Description

Convert weights vector to \( C \) and \( M \) parameters of `dcar_proper` distribution

Usage

as.carCM(adj, weights, num)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>adj</td>
<td>vector of indices of the adjacent locations (neighbors) of each spatial location. This is a sparse representation of the full adjacency matrix.</td>
</tr>
<tr>
<td>weights</td>
<td>vector of symmetric unnormalized weights associated with each pair of adjacent locations, of the same length as adj. This is a sparse representation of the full (unnormalized) weight matrix.</td>
</tr>
<tr>
<td>num</td>
<td>vector giving the number of neighbors of each spatial location, with length equal to the total number of locations.</td>
</tr>
</tbody>
</table>

Details

Given a symmetric matrix of unnormalized weights, this function will calculate corresponding values for the \( C \) and \( M \) arguments suitable for use in the `dcar_proper` distribution. This function can be used to transition between usage of `dcar_normal` and `dcar_proper`, since `dcar_normal` uses the `adj`, `weights`, and `num` arguments, while `dcar_proper` requires `adj`, `num`, and also the \( C \) and \( M \) as returned by this function.

Here, \( C \) is a sparse vector representation of the row-normalized adjacency matrix, and \( M \) is a vector containing the conditional variance for each region. The resulting values of \( C \) and \( M \) are guaranteed to satisfy the symmetry constraint imposed on \( C \) and \( M \), that \( M^{-1}C \) is symmetric, where \( M \) is a diagonal matrix and \( C \) is the row-normalized adjacency matrix.

Value

A named list with elements \( C \) and \( M \). These may be used as the \( C \) and \( M \) arguments to the `dcar_proper` distribution.

`CAR-Normal`, `CAR-Proper`
asRow

Description

Turns a numeric vector into a matrix that has 1 row or 1 column. Part of NIMBLE language.

Usage

asRow(x)

asCol(x)

Arguments

x

Numeric to be turned into a single row or column matrix

Details

In the NIMBLE language, some automatic determination of how to turn vectors into single-row or single-column matrices is done. For example, in A %*% x, where A is a matrix and x a vector, x will be turned into a single-column matrix unless it is known at compile time that A is a single column, in which case x will be turned into a single-row matrix. However, if it is desired that x be turned into a single row but A cannot be determined at compile time to be a single column, then one can use A %*% asRow(x) to force this conversion.

autoBlock

Automated parameter blocking procedure for efficient MCMC sampling

Description

The automated parameter blocking algorithm is no longer actively maintained. In some cases, it may not operate correctly with more recent system features and/or distributions.
Usage

autoBlock(
  Rmodel,
  autoIt = 20000,
  run = list("all", "default"),
  setSeed = TRUE,
  verbose = FALSE,
  makePlots = FALSE,
  round = TRUE
)

Arguments

Rmodel  A NIMBLE model object, created from nimbleModel.
autoIt  The number of MCMC iterations to run intermediate MCMC algorithms, through
         the course of the procedure. Default 20,000.
run     List of additional MCMC algorithms to compare against the automated blocking
         MCMC. These may be specified as: the character string ‘all’ to denote blocking
         all continuous-valued nodes; the character string ‘default’ to denote NIMBLE’s
         default MCMC configuration; a named list element consisting of a quoted code
         block, which when executed returns an MCMC configuration object for com-
         parison; a custom-specified blocking scheme, specified as a named list element
         which itself is a list of character vectors, where each character vector specifies
         the nodes in a particular block. Default is c(‘all’, ‘default’).
setSeed Logical specifying whether to call set.seed(0) prior to beginning the blocking
         procedure. Default TRUE.
verbose Logical specifying whether to output considerable details of the automated block
         procedure, through the course of execution. Default FALSE.
makePlots Logical specifying whether to plot the hierarchical clustering dendrograms, through
             the course of execution. Default FALSE.
round   Logical specifying whether to round the final output results to two decimal
         places. Default TRUE.

Details

Runs NIMBLE’s automated blocking procedure for a given model object, to dynamically determine
a blocking scheme of the continuous-valued model nodes. This blocking scheme is designed to
produce efficient MCMC sampling (defined as number of effective samples generated per second
of algorithm runtime). See Turek, et al (2015) for details of this algorithm. This also (optionally)
compares this blocked MCMC against several static MCMC algorithms, including all univariate
sampling, blocking of all continuous-valued nodes, NIMBLE’s default MCMC configuration, and
custom-specified blockings of parameters.

This method allows for fine-tuned usage of the automated blocking procedure. However, the main
entry point to the automatic blocking procedure is intended to be through either buildMCMC(....,
autoBlock = TRUE), or configureMCMC(...., autoBlock = TRUE).
Value

Returns a named list containing elements:

- `summary`: A data frame containing a numerical summary of the performance of all MCMC algorithms (including that from automated blocking)
- `autoGroups`: A list specifying the parameter blockings converged on by the automated blocking procedure
- `conf`: A NIMBLE MCMC configuration object corresponding to the results of the automated blocking procedure

buildMCEM
Builds an MCEM algorithm from a given NIMBLE model

Description
Takes a NIMBLE model and builds an MCEM algorithm for it. The user must specify which latent nodes are to be integrated out in the E-Step. All other stochastic non-data nodes will be maximized over. If the nodes do not have positive density on the entire real line, then box constraints can be used to enforce this. The M-step is done by a nimble MCMC sampler. The E-step is done by a call to R’s optim with method = \texttt{L-BFGS-B} if the nodes are constrained, or method = \texttt{BFGS} if the nodes are unconstrained.

Usage
buildMCEM(
    model,
    latentNodes,
    burnIn = 500,
    mcmcControl = list(adaptInterval = 100),
    boxConstraints = list(),
    buffer = 10^-6,
    alpha = 0.25,
    beta = 0.25,
    gamma = 0.05,
    C = 0.001,
    numReps = 300,
    forceNoConstraints = FALSE,
    verbose = TRUE
)
Arguments

```
model          a nimble model
latentNodes    character vector of the names of the stochastic nodes to integrated out. Names can be expanded, but don’t need to be. For example, if the model contains x[1],x[2] and x[3] then one could provide either latentNodes = c(’x[1]’,’x[2]’,’x[3]’) or latentNodes = ’x’.
burnIn         burn-in used for MCMC sampler in E step
mcmcControl    list passed to configureMCMC, which builds the MCMC sampler. See help(configureMCMC) for more details
boxConstraints list of box constraints for the nodes that will be maximized over. Each constraint is a list in which the first element is a character vector of node names to which the constraint applies and the second element is a vector giving the lower and upper limits. Limits of -Inf or Inf are allowed. Any nodes that are not given constrains will have their constraints automatically determined by NIMBLE
buffer         A buffer amount for extending the boxConstraints. Many functions with boundary constraints will produce NaN or -Inf when parameters are on the boundary. This problem can be prevented by shrinking the boundary a small amount.
alpha          probability of a type one error - here, the probability of accepting a parameter estimate that does not increase the likelihood. Default is 0.25.
beta           probability of a type two error - here, the probability of rejecting a parameter estimate that does increase the likelihood. Default is 0.25.
gamma          probability of deciding that the algorithm has converged, that is, that the difference between two Q functions is less than C, when in fact it has not. Default is 0.05.
C               determines when the algorithm has converged - when C falls above a (1-gamma) confidence interval around the difference in Q functions from time point t-1 to time point t, we say the algorithm has converged. Default is 0.001.
numReps        number of bootstrap samples to use for asymptotic variance calculation.
forceNoConstraints avoid any constraints even from parameter bounds implicit in the model structure (e.g., from dunif or dgamma distributions); setting this to TRUE might allow MCEM to run when the bounds of a parameter being maximized over depend on another parameter.
verbose        logical indicating whether to print additional logging information.
```

Details

`buildMCEM` calls the NIMBLE compiler to create the MCMC and objective function as nimbleFunctions. If the given model has already been used in compiling other nimbleFunctions, it is possible you will need to create a new copy of the model for buildMCEM to use. Uses an ascent-based MCEM algorithm, which includes rules for automatically increasing the number of MC samples as iterations increase, and for determining when convergence has been reached. Constraints for parameter values can be provided. If constraints are not provided, they will be automatically determined by NIMBLE. Initial values for the parameters are taken to be the values in the model at the time `buildMCEM` is called, unless the values in the compiled model are changed before running the MCEM.
**Value**

an R list with two elements:

- **run** A function that when called runs the MCEM algorithm. This function takes the arguments listed in **run Arguments** below.
- **estimateCov** An EXPERIMENTAL function that when called estimates the asymptotic covariance of the parameters. The covariance is estimated using the method of Louis (1982). This function takes the arguments listed in **estimateCov Arguments** below.

**run Arguments**

- **initM** starting number of iterations for the algorithm.

**estimateCov Arguments**

- **MLEs** named vector of MLE values. Must have a named MLE value for each stochastic, non-data, non-latent node. If the **run()** method has already been called, MLEs do not need to be provided.
- **useExistingSamples** logical argument. If **TRUE** and the **run()** method has previously been called, the covariance estimation will use MCMC samples from the last step of the MCEM algorithm. Otherwise, an MCMC algorithm will be run for 10,000 iterations, and those samples will be used. Defaults to **FALSE**.

**Examples**

```r
# Not run:
pumpCode <- nimbleCode(
  for (i in 1:N) {
    theta[i] ~ dgamma(alpha,beta);
    lambda[i] <- theta[i]*t[i];
    x[i] ~ dpois(lambda[i])
  }
  alpha ~ dexp(1.0);
  beta ~ dgamma(0.1,1.0);
)
pumpConsts <- list(N = 10,
  t = c(94.3, 15.7, 62.9, 126, 5.24,
```
buildMCMC

Create an MCMC function from a NIMBLE model, or an MCMC configuration object

Description

First required argument, which may be of class MCMCconf (an MCMC configuration object), or inherit from class modelBaseClass (a NIMBLE model object). Returns an uncompiled executable MCMC function. See details.

Usage

buildMCMC(conf, ...)

Arguments

conf An MCMC configuration object of class MCMCconf that specifies the model, samplers, monitors, and thinning intervals for the resulting MCMC function. See configureMCMC for details of creating MCMC configuration objects. Alternatively, conf may a NIMBLE model object, in which case an MCMC function corresponding to the default MCMC configuration for this model is returned.

... Additional arguments to be passed to configureMCMC if conf is a NIMBLE model object (see help(configureMCMC)).
Details
Calling buildMCMC(conf) will produce an uncompiled MCMC function object. The uncompiled
MCMC function will have arguments:

- `niter`: The number of iterations to run the MCMC.
- `thin`: The thinning interval for the monitors that were specified in the MCMC configuration. If
  this argument is provided at MCMC runtime, it will take precedence over the thin interval that was
  specified in the MCMC configuration. If omitted, the thin interval from the MCMC configuration
  will be used.
- `thin2`: The thinning interval for the second set of monitors (monitors2) that were specified in the
  MCMC configuration. If this argument is provided at MCMC runtime, it will take precedence over
  the thin2 interval that was specified in the MCMC configuration. If omitted, the thin2 interval
  from the MCMC configuration will be used.
- `reset`: Boolean specifying whether to reset the internal MCMC sampling algorithms to their initial
  state (in terms of self-adapting tuning parameters), and begin recording posterior sample chains
  anew. Specifying `reset = FALSE` allows the MCMC algorithm to continue running from where it
  left off, appending additional posterior samples to the already existing sample chains. Generally,
  `reset = FALSE` should only be used when the MCMC has already been run (default = TRUE).
- `resetMV`: Boolean specifying whether to begin recording posterior sample chains anew. This argu-
  ment is only considered when using `reset = FALSE`. Specifying `reset = FALSE, resetMV = TRUE`
  allows the MCMC algorithm to continue running from where it left off, but without appending the
  new posterior samples to the already existing samples, i.e. all previously obtained samples will be
  erased. This option can help reduce memory usage during burn-in (default = FALSE).
- `nburnin`: Number of initial, pre-thinning, MCMC iterations to discard (default = 0).
- `time`: Boolean specifying whether to record runtimes of the individual internal MCMC samplers. When
  `time = TRUE`, a vector of runtimes (measured in seconds) can be extracted from the MCMC
  using the method `mcmc$getTimes()` (default = FALSE).
- `progressBar`: Boolean specifying whether to display a progress bar during MCMC execution
  (default = TRUE). The progress bar can be permanently disabled by setting the system option
  `nimbleOptions(MCMCprogressBar = FALSE)`.

Samples corresponding to the monitors and monitors2 from the MCMCconf are stored into the
interval variables `mvSamples` and `mvSamples2`, respectively. These may be accessed and con-
verted into R matrix or list objects via: `as.matrix(mcmc$mvSamples)` `as.list(mcmc$mvSamples)`
`as.matrix(mcmc$mvSamples2)` `as.list(mcmc$mvSamples2)`

The uncompiled MCMC function may be compiled to a compiled MCMC object, taking care to
compile in the same project as the R model object, using: `Cmcmc <- compileNimble(Rmcmc, project
= Rmodel)`

The compiled function will function identically to the uncompiled object, except acting on the
compiled model object.

Calculating WAIC using an offline algorithm

Description

In addition to the core online algorithm, NIMBLE implements an offline WAIC algorithm that can be computed on the results of an MCMC. In contrast to NIMBLE’s built-in online WAIC, offline WAIC can compute only conditional WAIC and does not allow for grouping data nodes.

Usage

`calculateWAIC(mcmc, model, nburnin = 0, thin = 1)`
Arguments

- **mcmc**: An MCMC object (compiled or uncompiled) or matrix or dataframe of MCMC samples as the first argument of `calculateWAIC`.
- **model**: A model (compiled or uncompiled) as the second argument of `calculateWAIC`. Only required if `mcmc` is a matrix/dataframe of samples.
- **nburnin**: The number of pre-thinning MCMC samples to remove from the beginning of the posterior samples for offline WAIC calculation via `calculateWAIC` (default = 0). These samples are discarded in addition to any burn-in specified when running the MCMC.
- **thin**: Thinning factor interval to apply to the samples for offline WAIC calculation using `calculateWAIC` (default = 1, corresponding to no thinning).

Details

The ability to calculate WAIC post hoc after all MCMC sampling has been done has certain advantages (e.g., allowing a user to exclude additional burnin samples beyond that specified initially for the MCMC) in addition to providing compatibility with versions of NIMBLE before 0.12.0. This functionality includes the ability to call the `calculateWAIC` function on an MCMC object or matrix of samples after running an MCMC and without setting up the MCMC initially to use WAIC.

Important: The necessary variables to compute WAIC (all stochastic parent nodes of the data nodes) must have been monitored when setting up the MCMC.

See `help(waic)` for details on using NIMBLE’s recommended online algorithm for WAIC.

Offline WAIC (WAIC computed after MCMC sampling)

As an alternative to online WAIC, NIMBLE also provides a function, `calculateWAIC`, that can be called on an MCMC object or a matrix of samples, after running an MCMC. This function does not require that one set `enableWAIC = TRUE` nor `WAIC = TRUE` when calling `runMCMC`. The function checks that the necessary variables were monitored in the MCMC and returns an error if they were not. This function behaves identically to the `calculateWAIC` method of an MCMC object. Note that to use this function when using `nimbleMCMC` one would need to build the model outside of `nimbleMCMC`.

The `calculateWAIC` function requires either an MCMC object or a matrix (or dataframe) of posterior samples plus a model object. In addition, one can provide optional `nburnin` and `thin` arguments.

In addition, for compatibility with older versions of NIMBLE (prior to v0.12.0), one can also use the `calculateWAIC` method of the MCMC object to calculate WAIC after all sampling has been completed.

The `calculateWAIC()` method accepts a single argument, `nburnin`, equivalent to the `nburnin` argument of the `calculateWAIC` function described above.

The `calculateWAIC` method can only be used if the `enableWAIC` argument to `configureMCMC` or to `buildMCMC` is set to `TRUE`, or if the NIMBLE option `enableWAIC` is set to `TRUE`. If a user attempts to call `calculateWAIC` without having set `enableWAIC = TRUE` (either in the call to `configureMCMC`, or `buildMCMC`, or as a NIMBLE option), an error will occur.

The `calculateWAIC` function and method calculate the WAIC based on Equations 5, 12, and 13 in Gelman et al. (2014) (i.e., using $p_{WAIC2}$).
Note that there is not a unique value of WAIC for a model. The `calculateWAIC` function and method only provide the conditional WAIC, namely the version of WAIC where all parameters directly involved in the likelihood are treated as $\theta$ for the purposes of Equation 5 from Gelman et al. (2014). As a result, the user must set the MCMC monitors (via the `monitors` argument) to include all stochastic nodes that are parents of any data nodes; by default the MCMC monitors are only the top-level nodes of the model. For more detail on the use of different predictive distributions, see Section 2.5 from Gelman et al. (2014) or Ariyo et al. (2019). Also note that WAIC relies on a partition of the observations, i.e., 'pointwise' prediction. In `calculateWAIC` the sum over log pointwise predictive density values treats each data node as contributing a single value to the sum. When a data node is multivariate, that data node contributes a single value to the sum based on the joint density of the elements in the node. Note that if one wants the WAIC calculation via `calculateWAIC` to be based on the joint predictive density for each group of observations (e.g., grouping the observations from each person or unit in a longitudinal data context), one would need to use a multivariate distribution for the observations in each group (potentially by writing a user-defined distribution).

For more control over and flexibility in how WAIC is calculated, see `help(waic)`.

Examples
```r
code <- nimbleCode(
  for(j in 1:J) {
    for(i in 1:n)
      y[j, i] ~ dnorm(mu[j], sd = sigma)
    mu[j] ~ dnorm(mu0, sd = tau)
  }
  tau ~ dunif(0, 10)
)```
The CAR-Normal Distribution

Description

Density function and random generation for the improper (intrinsic) Gaussian conditional autoregressive (CAR) distribution.

Usage

dcar_normal(
  x,
  adj,
  weights = adj/adj,
  num,
  tau,
  c = CAR_calcNumIslands(adj, num),
  zero_mean = 0,
  log = FALSE
)

rcar_normal(
  n = 1,
  adj,
  weights = adj/adj,
num, tau, c = CAR_calcNumIslands(adj, num), zero_mean = 0
)

Arguments

x vector of values.
adj vector of indices of the adjacent locations (neighbors) of each spatial location. This is a sparse representation of the full adjacency matrix.
weights vector of symmetric unnormalized weights associated with each pair of adjacent locations, of the same length as adj. If omitted, all weights are taken to be one.
um vector giving the number of neighboring locations of each spatial location, with length equal to the total number of locations.
tau scalar precision of the Gaussian CAR prior.
c integer number of constraints to impose on the improper density function. If omitted, c is calculated as the number of disjoint groups of spatial locations in the adjacency structure, which implicitly assumes a first-order CAR process for each group. Note that c should be equal to the number of eigenvalues of the precision matrix that are zero. For example, if the neighborhood structure is based on a second-order Markov random field in one dimension then the matrix has two zero eigenvalues and in two dimensions it has three zero eigenvalues. See Rue and Held (2005) and the NIMBLE User Manual for more information.
zero_mean integer specifying whether to set the mean of all locations to zero during MCMC sampling of a node specified with this distribution in BUGS code (default 0). This argument is used only in BUGS model code when specifying models in NIMBLE. If 0, the overall process mean is included implicitly in the value of each location in a BUGS model; if 1, then during MCMC sampling, the mean of all locations is set to zero at each MCMC iteration, and a separate intercept term should be included in the BUGS model. Note that centering during MCMC as implemented in NIMBLE follows the ad hoc approach of WinBUGS and does not sample under the constraint that the mean is zero as discussed on p. 36 of Rue and Held (2005). See ‘Details’.

log logical; if TRUE, probability density is returned on the log scale.
n number of observations.

Details

When specifying a CAR distribution in BUGS model code, the zero_mean parameter should be specified as either 0 or 1 (rather than TRUE or FALSE).

Note that because the distribution is improper, rcar_normal does not generate a sample from the distribution. However, as discussed in Rue and Held (2005), it is possible to generate a sample from the distribution under constraints imposed based on the eigenvalues of the precision matrix that are zero.
Value
dcar_normal gives the density, while rcar_normal returns the current process values, since this distribution is improper.

CAR-Proper, Distributions for other standard distributions

Examples
x <- c(1, 3, 3, 4)
um <- c(1, 2, 2, 1)
adj <- c(2, 1, 3, 2, 4, 3)
weights <- c(1, 1, 1, 1, 1, 1)
lp <- dcar_normal(x, adj, weights, num, tau = 1)

The CAR-Proper Distribution

Description
Density function and random generation for the proper Gaussian conditional autoregressive (CAR) distribution.

Usage
dcar_proper(
x,
mu,
C = CAR_calcC(adj, num),
adj,
um,
M = CAR_calcM(num),
tau,
gamma,
evs = CAR_calcEVs3(C, adj, num),
log = FALSE
)
```r
car_proper(
  n = 1,
  mu,
  C = CAR_calcC(adj, num),
  adj,
  num,
  M = CAR_calcM(num),
  tau,
  gamma,
  evs = CAR_calcEVs3(C, adj, num)
)
```

**Arguments**

- `x` vector of values.
- `mu` vector of the same length as `x`, specifying the mean for each spatial location.
- `C` vector of the same length as `adj`, giving the weights associated with each pair of neighboring locations. See ‘Details’.
- `adj` vector of indices of the adjacent locations (neighbors) of each spatial location. This is a sparse representation of the full adjacency matrix.
- `num` vector giving the number of neighboring locations of each spatial location, with length equal to the number of locations.
- `M` vector giving the diagonal elements of the conditional variance matrix, with length equal to the number of locations. See ‘Details’.
- `tau` scalar precision of the Gaussian CAR prior.
- `gamma` scalar representing the overall degree of spatial dependence. See ‘Details’.
- `evs` vector of eigenvalues of the adjacency matrix implied by `C`, `adj`, and `num`. This parameter should not be provided; it will always be calculated using the adjacency information.
- `log` logical; if TRUE, probability density is returned on the log scale.
- `n` number of observations.

**Details**

If both `C` and `M` are omitted, then all weights are taken as one, and corresponding values of `C` and `M` are generated.

The `C` and `M` parameters must jointly satisfy a symmetry constraint: that \( M^{-1} \) is symmetric, where `M` is a diagonal matrix and `C` is the full weight matrix that is sparsely represented by the parameter vector `C`.

For a proper CAR model, the value of `gamma` must lie within the inverse minimum and maximum eigenvalues of \( M^{-0.5} C M^{0.5} \), where `M` is a diagonal matrix and `C` is the full weight matrix. These bounds can be calculated using the deterministic functions `carMinBound(C, adj, num, M)` and `carMaxBound(C, adj, num, M)`, or simultaneously using `carBounds(C, adj, num, M)`. In the case where `C` and `M` are omitted (all weights equal to one), the bounds on `gamma` are necessarily \((-1, 1)\).
Value

dcar_proper gives the density, and rcar_proper generates random deviates.

CAR-Normal, Distributions for other standard distributions

Examples

```r
x <- c(1, 3, 3, 4)
mu <- rep(3, 4)
adj <- c(2, 1, 3, 2, 4, 3)
num <- c(1, 2, 2, 1)

## omitting C and M uses all weights = 1
dcar_proper(x, mu, adj = adj, num = num, tau = 1, gamma = 0.95)

## equivalent to above: specifying all weights = 1,
## then using as.carCM to generate C and M arguments
weights <- rep(1, 6)
CM <- as.carCM(adj, weights, num)
C <- CM$C
M <- CM$M
dcar_proper(x, mu, C, adj, num, M, tau = 1, gamma = 0.95)

## now using non-unit weights
weights <- c(2, 2, 3, 3, 4, 4)
CM2 <- as.carCM(adj, weights, num)
C2 <- CM2$C
M2 <- CM2$M
dcar_proper(x, mu, C2, adj, num, M2, tau = 1, gamma = 0.95)
```

carBounds

Calculate bounds for the autocorrelation parameter of the dcar_proper distribution

Description

Calculate the lower and upper bounds for the gamma parameter of the dcar_proper distribution
Usage

carMaxBound(C, adj, num, M)

Arguments

C vector of the same length as adj, giving the normalized weights associated with each pair of neighboring locations.

adj vector of indices of the adjacent locations (neighbors) of each spatial location. This is a sparse representation of the full adjacency matrix.

num vector giving the number of neighboring locations of each spatial location, with length equal to the number of locations.

M vector giving the diagonal elements of the conditional variance matrix, with length equal to the number of locations.

Details

Bounds for gamma are the inverse of the minimum and maximum eigenvalues of: $M(-0.5)CM(0.5)$. The lower and upper bounds are returned in a numeric vector.

Value

A numeric vector containing the bounds (minimum and maximum allowable values) for the gamma parameter of the dcar_proper distribution.

carMaxBound Calculate the upper bound for the autocorrelation parameter of the dcar_proper distribution

Description

Calculate the upper bound for the gamma parameter of the dcar_proper distribution

Usage

carMaxBound(C, adj, num, M)
Arguments

- **C**: vector of the same length as `adj`, giving the normalized weights associated with each pair of neighboring locations.
- **adj**: vector of indices of the adjacent locations (neighbors) of each spatial location. This is a sparse representation of the full adjacency matrix.
- **num**: vector giving the number of neighboring locations of each spatial location, with length equal to the number of locations.
- **M**: vector giving the diagonal elements of the conditional variance matrix, with length equal to the number of locations.

Details

Bounds for `gamma` are the inverse of the minimum and maximum eigenvalues of $M^{(−0.5)}C M^{(0.5)}$.

Value

The upper bound (maximum allowable value) for the `gamma` parameter of the `dcar_proper` distribution.

**carMinBound**

*Calculate the lower bound for the autocorrelation parameter of the dcar_proper distribution*

Description

Calculate the lower bound for the `gamma` parameter of the `dcar_proper` distribution

Usage

```
carMinBound(C, adj, num, M)
```

Arguments

- **C**: vector of the same length as `adj`, giving the normalized weights associated with each pair of neighboring locations.
- **adj**: vector of indices of the adjacent locations (neighbors) of each spatial location. This is a sparse representation of the full adjacency matrix.
**CAR_calcNumIslands**

num vector giving the number of neighboring locations of each spatial location, with length equal to the number of locations.

M vector giving the diagonal elements of the conditional variance matrix, with length equal to the number of locations.

**Details**

Bounds for \( \gamma \) are the inverse of the minimum and maximum eigenvalues of: \( M^{(-0.5)}CM^{0.5} \).

**Value**

The lower bound (minimum allowable value) for the \( \gamma \) parameter of the \texttt{dcar\_proper} distribution.

Categorical

The Categorical Distribution

Description
Density and random generation for the categorical distribution

Usage

dcat(x, prob, log = FALSE)
rcat(n = 1, prob)

Arguments

x non-negative integer-value numeric value.
prob vector of probabilities, internally normalized to sum to one.
log logical; if TRUE, probability density is returned on the log scale.
n number of observations.

Details
See the BUGS manual for mathematical details.

Value
dcat gives the density and rcat generates random deviates.

Author(s)
Christopher Paciorek

See Also

checkInterrupt  
*Check for interrupt (e.g. Ctrl-C) during nimbleFunction execution.*  
*Part of the NIMBLE language.*

**Description**
Check for interrupt (e.g. Ctrl-C) during nimbleFunction execution. Part of the NIMBLE language.

**Usage**

```
checkInterrupt()
```

**Details**
During execution of nimbleFunctions that take a long time, it is nice to occasionally check if the user has entered an interrupt and bail out of execution if so. This function does that. During uncompiled nimbleFunction execution, it does nothing. During compiled execution, it calls R_checkUserInterrupt() of the R headers.

**ChineseRestaurantProcess**

*The Chinese Restaurant Process Distribution*

**Description**
Density and random generation for the Chinese Restaurant Process distribution.

**Usage**

```
dCRP(x, conc = 1, size, log = 0)
rCRP(n, conc = 1, size)
```

**Arguments**

- `x`  
  vector of values.
- `conc`  
  scalar concentration parameter.
- `size`  
  integer-valued length of `x` (required).
- `log`  
  logical; if TRUE, probability density is returned on the log scale.
- `n`  
  number of observations (only `n = 1` is handled currently).
Details

The Chinese restaurant process distribution is a distribution on the space of partitions of the positive integers. The distribution with concentration parameter $\alpha$ equal to conc has probability function

$$f(x_1 | x_1, \ldots, x_{i-1}) = \frac{1}{i - 1 + \alpha} \sum_{j=1}^{i-1} \delta_{x_j} + \frac{\alpha}{i - 1 + \alpha} \delta_{x^{\text{new}}},$$

where $x^{\text{new}}$ is a new integer not in $x_1, \ldots, x_{i-1}$.

If conc is not specified, it assumes the default value of 1. The conc parameter has to be larger than zero. Otherwise, NaN are returned.

Value

dCRP gives the density, and rCRP gives random generation.

Author(s)

Claudia Wehrhahn

Examples

```r
x <- rCRP(n=1, conc = 1, size=10)
dCRP(x, conc = 1, size=10)
```
codeBlockClass-class  

Class codeBlockClass

Description

Classes used internally in NIMBLE and not expected to be called directly by users.

compareMCMCs

Placeholder for compareMCMCs

Description

This function has been moved to a separate package

Usage

compareMCMCs(...)

Arguments

... arguments

compileNimble

compile NIMBLE models and nimbleFunctions

Description

compile a collection of models and nimbleFunctions: generate C++, compile the C++, load the result, and return an interface object

Usage

compileNimble(
  ..., 
  project,
  dirName = NULL,
  projectName = "",
  control = list(),
  resetFunctions = FALSE,
  showCompilerOutput = nimbleOptions("showCompilerOutput")
)
Arguments

... An arbitrary set of NIMBLE models and nimbleFunctions, or lists of them. If
given as named parameters, those names may be used in the return list.

project Optional NIMBLE model or nimbleFunction already associated with a project,
which the current units for compilation should join. If not provided, a new
project will be created and the current compilation units will be associated with
it.

dirName Optional directory name in which to generate the C++ code. If not provided, a
temporary directory will be generated using R’s tempdir function.

projectName Optional character name for labeling the project if it is new

control A list mostly for internal use. See details.

resetFunctions Logical value stating whether nimbleFunctions associated with an existing project
should all be reset for compilation purposes. See details.

showCompilerOutput Logical value indicating whether details of C++ compilation should be printed.

Details

This is the main function for calling the NIMBLE compiler. A set of compiler calls and output will
be seen. Compiling in NIMBLE does 4 things: 1. It generates C++ code files for all the model
and nimbleFunction components. 2. It calls the system’s C++ compiler. 3. It loads the compiled
object(s) into R using dyn.load. And 4. it generates R objects for using the compiled model and
nimbleFunctions.

When the units for compilation provided in ... include multiple models and/or nimbleFunctions,
models are compiled first, in the order in which they are provided. Groups of nimbleFunctions that
were specialized from the same nimbleFunction generator (the result of a call to nimbleFunction,
which then takes setup arguments and returns a specialized nimbleFunction) are then compiled as a
group, in the order of first appearance.

The behavior of adding new compilation units to an existing project is limited. For example, one
can compile a model in one call to compileNimble and then compile a nimbleFunction that uses
the model (i.e. was given the model as a setup argument) in a second call to compileNimble, with
the model provided as the project argument. Either the uncompiled or compiled model can be
provided. However, compiling a second nimbleFunction and adding it to the same project will only
work in limited circumstances. Basically, the limitations occur because it attempts to re-use already
compiled pieces, but if these do not have all the necessary information for the new compilation,
it gives up. An attempt has been made to give up in a controlled manner and provide somewhat
informative messages.

When compilation is not allowed or doesn’t work, try using resetFunctions = TRUE, which will
force recompilation of all nimbleFunctions in the new call. Previously compiled nimbleFunctions
will be unaffected, and their R interface objects should continue to work. The only cost is additional
compilation time for the current compilation call. If that doesn’t work, try re-creating the model
and/or the nimbleFunctions from their generators. An alternative possible fix is to compile multiple
units in one call, rather than sequentially in multiple calls.

The control list can contain the following named elements, each with TRUE or FALSE: debug, which
sets a debug mode for the compiler for development purposes; debugCpp, which inserts an out-
put message before every line of C++ code for debugging purposes; compileR, which determines
whether the R-only steps of compilation should be executed; writeCpp, which determines whether the C++ files should be generated; compileCpp, which determines whether the C++ should be compiled; loadSO, which determines whether the DLL or shared object should be loaded and interfaced; and returnAsList, which determines whether calls to the compiled nimbleFunction should return only the returned value of the call (returnAsList = FALSE) or whether a list including the input arguments, possibly modified, should be returned in a list with the returned value of the call at the end (returnAsList = TRUE). The control list is mostly for developer use, although returnAsArgs may be useful to a user. An example of developer use is that one can have the compiler write the C++ files but not compile them, then modify them by hand, then have the C++ compiler do the subsequent steps without over-writing the files.

See the NIMBLE User Manual for examples

Value

If there is only one compilation unit (one model or nimbleFunction), an R interface object is returned. This object can be used like the uncompiled model or nimbleFunction, but execution will call the corresponding compiled objects or functions. If there are multiple compilation units, they will be returned as a list of interface objects, in the order provided. If names were included in the arguments, or in a list if any elements of ... are lists, those names will be used for the corresponding element of the returned list. Otherwise an attempt will be made to generate names from the argument code. For example compileNimble(A = fun1, B = fun2, project = myModel) will return a list with named elements A and B, while compileNimble(fun1, fun2, project = myModel) will return a list with named elements fun1 and fun2.

Perry de Valpine

configureMCMC

Build the MCMCconf object for construction of an MCMC object

Description

Creates a default MCMC configuration for a given model.

Usage

```r
configureMCMC(
  model,
  nodes,
  control = list(),
  monitors,
  thin = 1,
  monitors2 = character(),
  thin2 = 1,
  useConjugacy = getNimbleOption("MCMCuseConjugacy"),
  onlyRW = FALSE,
)```
onlySlice = FALSE,
multivariateNodesAsScalars = getNimbleOption("MCMCmultivariateNodesAsScalars"),
enableWAIC = getNimbleOption("MCMCenableWAIC"),
controlWAIC = list(),
print = getNimbleOption("verbose"),
autoBlock = FALSE,
oldConf,
warnNoSamplerAssigned = TRUE,
...)

Arguments

model A NIMBLE model object, created from nimbleModel

nodes An optional character vector, specifying the nodes and/or variables for which samplers should be created. Nodes may be specified in their indexed form, y[1,3]. Alternatively, nodes specified without indexing will be expanded fully, e.g., x will be expanded to x[1], x[2], etc. If missing, the default value is all non-data stochastic nodes. If NULL, then no samplers are added.

control An optional list of control arguments to sampler functions. If a control list is provided, the elements will be provided to all sampler functions which utilize the named elements given. For example, the standard Metropolis-Hastings random walk sampler (sampler_RW) utilizes control list elements adaptive, adaptInterval, and scale. (Internally it also uses targetNode, but this should not generally be provided as a control list element). The default values for control list arguments for samplers (if not otherwise provided as an argument to configureMCMC() ) are in the setup code of the sampling algorithms.

monitors A character vector of node names or variable names, to record during MCMC sampling. This set of monitors will be recorded with thinning interval thin, and the samples will be stored into the mvSamples object. The default value is all top-level stochastic nodes of the model – those having no stochastic parent nodes.

thin The thinning interval for monitors. Default value is one.

monitors2 A character vector of node names or variable names, to record during MCMC sampling. This set of monitors will be recorded with thinning interval thin2, and the samples will be stored into the mvSamples2 object. The default value is an empty character vector, i.e. no values will be recorded.

thin2 The thinning interval for monitors2. Default value is one.

useConjugacy A logical argument, with default value TRUE. If specified as FALSE, then no conjugate samplers will be used, even when a node is determined to be in a conjugate relationship.

onlyRW A logical argument, with default value FALSE. If specified as TRUE, then Metropolis-Hastings random walk samplers (sampler_RW) will be assigned for all non-terminal continuous-valued nodes nodes. Discrete-valued nodes are assigned a slice sampler (sampler_slice), and terminal nodes are assigned a posterior_predictive sampler (sampler_posterior_predictive).
onlySlice  A logical argument, with default value FALSE. If specified as TRUE, then a slice sampler is assigned for all non-terminal nodes. Terminal nodes are still assigned a posterior_predictive sampler.

multivariateNodesAsScalars  A logical argument, with default value FALSE. If specified as TRUE, then non-terminal multivariate stochastic nodes will have scalar samplers assigned to each of the scalar components of the multivariate node. The default value of FALSE results in a single block sampler assigned to the entire multivariate node. Note, multivariate nodes appearing in conjugate relationships will be assigned the corresponding conjugate sampler (provided useConjugacy == TRUE), regardless of the value of this argument.

enableWAIC  A logical argument, specifying whether to enable WAIC calculations for the resulting MCMC algorithm. Defaults to the value of nimbleOptions('MCMCenableWAIC'), which in turn defaults to FALSE. Setting nimbleOptions('enableWAIC' = TRUE) will ensure that WAIC is enabled for all calls to configureMCMC and buildMCMC.

controlWAIC  A named list of inputs that control the behavior of the WAIC calculation. See help(waic).

print  A logical argument, specifying whether to print the ordered list of default samplers.

autoBlock  A logical argument specifying whether to use an automated blocking procedure to determine blocks of model nodes for joint sampling. If TRUE, an MCMC configuration object will be created and returned corresponding to the results of the automated parameter blocking. Default value is FALSE.

oldConf  An optional MCMCconf object to modify rather than creating a new MCMCconf from scratch

warnNoSamplerAssigned  A logical argument, with default value TRUE. This specifies whether to issue a warning when no sampler is assigned to a node, meaning there is no matching sampler assignment rule.

Details
See MCMCconf for details on how to manipulate the MCMCconf object

configureRJ

Configure Reversible Jump for Variable Selection

Description

Modifies an MCMC configuration object to perform a reversible jump MCMC sampling for variable selection, using a univariate normal proposal distribution. Users can control the mean and scale of the proposal. This function supports two different types of model specification: with and without indicator variables.

Usage

configureRJ(
  conf,
  targetNodes,
  indicatorNodes = NULL,
  priorProb = NULL,
  control = list(mean = NULL, scale = NULL, fixedValue = NULL)
)

Arguments

conf

An MCMCconf object.

targetNodes

A character vector, specifying the nodes and/or variables for which variable selection is to be performed. Nodes may be specified in their indexed form, 'y[1,3]'. Alternatively, nodes specified without indexing will be expanded, e.g., 'x' will be expanded to 'x[1]', 'x[2]', etc.

indicatorNodes

An optional character vector, specifying the indicator nodes and/or variables paired with targetNodes. Nodes may be specified in their indexed form, 'y[1,3]'. Alternatively, nodes specified without indexing will be expanded, e.g., 'x' will be expanded to 'x[1]', 'x[2]', etc. Nodes must be provided consistently with targetNodes. See details.

priorProb

An optional value or vector of prior probabilities for each node to be in the model. See details.

control

An optional list of control arguments:

- mean. The mean of the normal proposal distribution (default = 0).
- scale. The standard deviation of the normal proposal distribution (default = 1).
- fixedValue. Value for the variable when it is out of the model, which can be used only when priorProb is provided (default = 0). If specified when indicatorNodes is passed, a warning is given and fixedValue is ignored.
configureRJ

Details

This function modifies the samplers in MCMC configuration object for each of the nodes provided in the targetNodes argument. To these elements two samplers are assigned: a reversible jump sampler to transition the variable in/out of the model, and a modified version of the original sampler, which performs updates only when the target node is already in the model.

configureRJ can handle two different ways of writing a NIMBLE model, either with or without indicator variables. When using indicator variables, the indicatorNodes argument must be provided. Without indicator variables, the priorProb argument must be provided. In the latter case, the user can provide a non-zero value for fixedValue if desired.

Note that this functionality is intended for variable selection in regression-style models but may be useful for other situations as well. At the moment, setting a variance component to zero and thereby removing a set of random effects that are explicitly part of a model will not work because MCMC sampling in that case would need to propose values for multiple parameters (the random effects), whereas the current functionality only proposes adding/removing a single model node.

Value

NULL configureRJ modifies the input MCMC configuration object in place.

### Description

Calculations to handle censoring

### Usage

dconstraint(x, cond, log = FALSE)

rconstraint(n = 1, cond)
**Args**

- **x**  
  value indicating whether `cond` is **TRUE** or **FALSE**
- **cond**  
  logical value
- **log**  
  logical; if **TRUE**, probability density is returned on the log scale.
- **n**  
  number of observations (only `n=1` is handled currently).

**Details**

Used for working with constraints in BUGS code. See the NIMBLE manual for additional details.

**Value**

dconstraint gives the density and rconstraint generates random deviates, but these are unusual as the density is 1 if `x` matches `cond` and 0 otherwise and the deviates are simply the value of `cond`.

**Author(s)**

Christopher Paciorek

**See Also**

- *Distributions* for other standard distributions

**Examples**

```r
constr <- 3 > 2 && 4 > 0
x <- rconstraint(1, constr)
dconstraint(x, constr)
dconstraint(0, 3 > 4)
dconstraint(1, 3 > 4)
rconstraint(1, 3 > 4)
```

---

**decide**  
Makes the Metropolis-Hastings acceptance decision, based upon the input (log) Metropolis-Hastings ratio

**Description**

This function returns a logical **TRUE**/**FALSE** value, indicating whether the proposed transition should be accepted (**TRUE**) or rejected (**FALSE**).

**Usage**

```r
decide(logMetropolisRatio)
```
Arguments

logMetropolisRatio

The log of the Metropolis-Hastings ratio, which is calculated from model probabilities and forward/reverse transition probabilities. Calculated as the ratio of the model probability under the proposal to that under the current values multiplied by the ratio of the reverse transition probability to the forward transition probability.

Details

The Metropolis-Hastings accept/reject decisions is made as follows. If logMetropolisRatio is greater than 0, accept (return TRUE). Otherwise draw a uniform random number between 0 and 1 and accept if it is less that exp(logMetropolisRatio). The proposed transition will be rejected (return FALSE). If logMetropolisRatio is NA, NaN, or -Inf, a reject (FALSE) decision will be returned.

Author(s)

Daniel Turek

decideAndJump

Creates a nimbleFunction for executing the Metropolis-Hastings jumping decision, and updating values in the model, or in a carbon copy modelValues object, accordingly.

Description

This nimbleFunction generator must be specialized to three required arguments: a model, a modelValues, and a character vector of node names.

Usage

decideAndJump(model, mvSaved, target, calcNodes)

Arguments

model An uncompiled or compiled NIMBLE model object.

mvSaved A modelValues object containing identical variables and logProb variables as the model. Can be created by modelValues(model).

target A character vector providing the target node.

calcNodes A character vector representing a set of nodes in the model (and hence also the modelValues) object.
Details

Calling decideAndJump(model, mvSaved, calcNodes) will generate a specialized nimbleFunction with four required numeric arguments:

modelLP1: The model log-probability associated with the newly proposed value(s)
modelLP0: The model log-probability associated with the original value(s)
propLP1: The log-probability associated with the proposal forward-transition
propLP0: The log-probability associated with the proposal reverse-transition

Executing this function has the following effects:
– Calculate the (log) Metropolis-Hastings ratio, as \(\log MHR = \text{modelLP1} - \text{modelLP0} - \text{propLP1} + \text{propLP0}\)
– Make the proposal acceptance decision based upon the (log) Metropolis-Hastings ratio
– If the proposal is accepted, the values and associated logProbs of all calcNodes are copied from the model object into the mvSaved object
– If the proposal is rejected, the values and associated logProbs of all calcNodes are copied from the mvSaved object into the model object
– Return a logical value, indicating whether the proposal was accepted

Daniel Turek

---

**declare**

Explicitly declare a variable in run-time code of a nimbleFunction

**Description**

Explicitly declare a variable in run-time code of a nimbleFunction, for cases when its dimensions cannot be inferred before it is used. Works in R and NIMBLE.

**Usage**

```
declare(name, def)
```

**Arguments**

- **name**: Name of a variable to declare, without quotes
- **def**: NIMBLE type declaration, of the form `TYPE(nDim, sizes)`, where `TYPE` is `integer`, `double`, or `logical`, `nDim` is the number of dimensions, and `sizes` is an optional vector of sizes concatenated with `c`. If `nDim` is omitted, it defaults to 0, indicating a scalar. If `sizes` are provided, they should not be changed subsequently in the function, including by assignment. Omitting `nDim` results in a scalar. For `logical`, only scalar is currently supported.
deregisterDistributions

Details
In a run-time function of a nimbleFunction (either the run function or a function provided in
methods when calling nimbleFunction), the dimensionality and numeric type of a variable is
inferred when possible from the statement first assigning into it. E.g. A <- B + C infers that A has
numeric types, dimensions and sizes taken from B + C. However, if the first appearance of A is e.g.
A[i] <- 5, A must have been explicitly declared. In this case, declare(A, double(1)) would make
A a 1-dimensional (i.e. vector) double.

When sizes are not set, they can be set by a call to setSize or by assignment to the whole object.
Sizes are not automatically extended if assignment is made to elements beyond the current sizes. In
compiled nimbleFunctions doing so can cause a segfault and crash the R session.

This part of the NIMBLE language is needed for compilation, but it also runs in R. When run in R,
is works by the side effect of creating or modifying name in the calling environment.

Author(s)
NIMBLE development team

Examples

```r
declare(A, logical()) ## scalar logical, the only kind allowed
declare(B, integer(2, c(10, 10))) ## 10 x 10 integer matrix
declare(C, double(3)) ## 3-dimensional double array with no sizes set.
```

deregisterDistributions

Remove user-supplied distributions from use in NIMBLE BUGS models

Description
Deregister distributional information originally supplied by the user for use in BUGS model code

Usage
deregisterDistributions(distributionsNames)

Arguments
distributionsNames
  a character vector giving the names of the distributions to be deregistered

Author(s)
Christopher Paciorek
Dirichlet

The Dirichlet Distribution

Description

Density and random generation for the Dirichlet distribution

Usage

```r
ddirch(x, alpha, log = FALSE)
rdirch(n = 1, alpha)
```

Arguments

- `x`: vector of values.
- `alpha`: vector of parameters of same length as `x`.
- `log`: logical; if TRUE, probability density is returned on the log scale.
- `n`: number of observations (only n=1 is handled currently).

Details

See Gelman et al., Appendix A or the BUGS manual for mathematical details.

Value

`ddirch` gives the density and `rdirch` generates random deviates.

Author(s)

Christopher Paciorek

References

alpha <- c(1, 10, 30)
x <- rdirch(1, alpha)
ndirch(x, alpha)
```
distributionInfo

Get information about a distribution

Description

Give information about each BUGS distribution

Usage

getDistributionInfo(dist)

isUserDefined(dist)

pqDefined(dist)

gType(
  dist,
  params = NULL,
  valueOnly = is.null(params) && !includeParams,
  includeParams = !is.null(params)
)

getParamNames(dist, includeValue = TRUE)

Arguments

dist a character vector of length one, giving the name of the distribution (as used in BUGS code), e.g. 'dnorm'

params an optional character vector of names of parameters for which dimensions are desired (possibly including 'value' and alternate parameters)

valueOnly a logical indicating whether to only return the dimension of the value of the node

includeParams a logical indicating whether to return dimensions of parameters. If TRUE and 'params' is NULL then dimensions of all parameters, including the dimension of the value of the node, are returned

includeValue a logical indicating whether to return the string 'value', which is the name of the node value

Details

NIMBLE provides various functions to give information about a BUGS distribution. In some cases, functions of the same name and similar functionality operate on the node(s) of a model as well (see help(modelBaseClass)).

ggetDistributionInfo returns an internal data structure (a reference class object) providing various information about the distribution. The output is not very user-friendly, but does contain all of the information that NIMBLE has about the distribution.
distributionInfo

isdistributionInfo tests if a BUGS distribution is a discrete distribution.

isUserDefined tests if a BUGS distribution is a user-defined distribution.

pqAvail tests if a BUGS distribution provides distribution ('p') and quantile ('q') functions.

getDimension provides the dimension of the value and/or parameters of a BUGS distribution. The return value is a numeric vector with an element for each parameter/value requested.

getType provides the type (numeric, logical, integer) of the value and/or parameters of a BUGS distribution. The return value is a character vector with an element for each parameter/value requested. At present, all quantities are stored as numeric (double) values, so this function is of little practical use but could be exploited in the future.

getParamNames provides the value and/or parameter names of a BUGS distribution.

Double-Exponential
The Double Exponential (Laplace) Distribution

Description
Density, distribution function, quantile function and random generation for the double exponential
distribution, allowing non-zero location, \( \mu \), and non-unit scale, \( \sigma \), or non-unit rate, \( \tau \)

Usage
```r
ddexp(x, location = 0, scale = 1, rate = 1/scale, log = FALSE)
```
```
rdexp(n, location = 0, scale = 1, rate = 1/scale)
```
```
pdexp(
  q,
  location = 0,
  scale = 1,
  rate = 1/scale,
  lower.tail = TRUE,
  log.p = FALSE
)
```
```
qdexp(
  p,
  location = 0,
  scale = 1,
  rate = 1/scale,
  lower.tail = TRUE,
  log.p = FALSE
)
```

Arguments
- `x` vector of values.
- `location` vector of location values.
- `scale` vector of scale values.
- `rate` vector of inverse scale values.
- `log` logical; if TRUE, probability density is returned on the log scale.
- `n` number of observations.
- `q` vector of quantiles.
- `lower.tail` logical; if TRUE (default) probabilities are \( P[X \leq x] \); otherwise, \( P[X > x] \).
- `log.p` logical; if TRUE, probabilities \( p \) are given by user as \( \log(p) \).
- `p` vector of probabilities.
Details
See Gelman et al., Appendix A or the BUGS manual for mathematical details.

Value
ddexp gives the density, pdexp gives the distribution function, qdexp gives the quantile function, and rdexp generates random deviates.

Author(s)
Christopher Paciorek

Distributions for other standard distributions

Examples
x <- rdexp(50, location = 2, scale = 1)
ddexp(x, 2, 1)
Exponential Distribution

The Exponential Distribution

Description

Density, distribution function, quantile function and random generation for the exponential distribution with rate (i.e., mean of 1/rate) or scale parameterizations.

Usage

dexp_nimble(x, rate = 1/scale, scale = 1, log = FALSE)

rexp_nimble(n = 1, rate = 1/scale, scale = 1)

pexp_nimble(q, rate = 1/scale, scale = 1, lower.tail = TRUE, log.p = FALSE)

qexp_nimble(p, rate = 1/scale, scale = 1, lower.tail = TRUE, log.p = FALSE)

Arguments

x vector of values.
rate vector of rate values.
scale vector of scale values.
log logical; if TRUE, probability density is returned on the log scale.
n number of observations.
q vector of quantiles.
lower.tail logical; if TRUE (default) probabilities are \( P[X \leq x] \); otherwise, \( P[X > x] \).
log.p logical; if TRUE, probabilities p are given by user as log(p).
p vector of probabilities.

Details

NIMBLE’s exponential distribution functions use Rmath’s functions under the hood, but are parameterized to take both rate and scale and to use ‘rate’ as the core parameterization in C, unlike Rmath, which uses ‘scale’. See Gelman et al., Appendix A or the BUGS manual for mathematical details.

Value

dexp_nimble gives the density, pexp_nimble gives the distribution function, qexp_nimble gives the quantile function, and rexp_nimble generates random deviates.

Author(s)

Christopher Paciorek
extractControlElement

References

See Also

Distributions for other standard distributions

Examples

```r
x <- rexp_nimble(50, scale = 3)
dexp_nimble(x, scale = 3)
```

extractControlElement  Extract named elements from MCMC sampler control list

Description

Extract named elements from MCMC sampler control list

Usage

```r
extractControlElement(controlList, elementName, defaultValue, error)
```

Arguments

- `controlList`: control list object, which is passed as an argument to all MCMC sampler setup functions.
- `elementName`: character string, giving the name of the element to be extracted from the control list.
- `defaultValue`: default value of the control list element, giving the value to be used when the `elementName` does not exactly match the name of an element in the `controlList`.
- `error`: character string, giving the error message to be printed if no `defaultValue` is provided and `elementName` does not match the name of an element in the `controlList`.

Value

The element of `controlList` whose name matches `elementName`. If no `controlList` name matches `elementName`, then `defaultValue` is returned.

Author(s)

Daniel Turek
The Improper Uniform Distribution

Description
Improper flat distribution for use as a prior distribution in BUGS models

Usage
dflat(x, log = FALSE)
rflat(n = 1)
dhalfflat(x, log = FALSE)
rhalfflat(n = 1)

Arguments
x vector of values.
log logical; if TRUE, probability density is returned on the log scale.
n number of observations.

Value
dflat gives the pseudo-density value of 1, while rflat and rhalfflat return NaN, since one cannot simulate from an improper distribution. Similarly, dhalfflat gives a pseudo-density value of 1 when x is non-negative.

Author(s)
Christopher Paciorek

See Also
Distributions for other standard distributions

Examples
dflat(1)
getBound

Get value of bound of a stochastic node in a model

Description

Get the value of the lower or upper bound for a single stochastic node in a model.

Usage

getBound(model, node, bound, nodeFunctionIndex)

Arguments

model A NIMBLE model object
node The name of a stochastic node in the model
bound Either 'lower' or 'upper' indicating the desired bound for the node
nodeFunctionIndex For internal NIMBLE use only

Details

Standard usage is as a method of a model, in the form model$getBound(node, bound), but the usage as a simple function with the model as the first argument as above is also allowed.

For nodes that do not involve truncation of the distribution this will return the lower or upper bound of the distribution, which may be a constant or for a limited number of distributions a parameter or functional of a parameter (at the moment in NIMBLE, the only case where a bound is a parameter is for the uniform distribution. For nodes that are truncated, this will return the desired bound, which may be a functional of other quantities in the model or may be a constant.

getBUGSexampleDir

Get the directory path to one of the classic BUGS examples installed with NIMBLE package

Description

NIMBLE comes with some of the classic BUGS examples. getBUGSexampleDir looks up the location of an example from its name.

Usage

getBUGSexampleDir(example)

Arguments

example The name of the classic BUGS example.
getConditionallyIndependentSets

Get a list of conditionally independent sets of nodes in a nimble model

Description

Conditionally independent sets of nodes are typically groups of latent states whose joint probability (density) will not change even if any other non-fixed node is changed. Default fixed nodes are data nodes and parameter nodes (with no parent nodes), but this can be controlled.

Usage

getConditionallyIndependentSets(
    model,
    nodes,
    givenNodes,
    omit = integer(),
    inputType = c("latent", "param", "data"),
    stochOnly = TRUE,
    returnType = "names",
    returnScalarComponents = FALSE
)

Arguments

model

A nimble model object (uncompiled or compiled).

nodes

A vector of node names or their graph IDs that are the starting nodes from which conditionally independent sets of nodes should be found. If omitted, the default will be all latent nodes, defined as stochastic nodes that are not data and have at least one stochastic parent node (possible with determinstic nodes in between). Note that this will omit latent states that have no hyperparameters. An example is the first latent state in some state-space (time-series) models, which is sometimes declared with known prior. See type because it relates to the interpretation of nodes.

Value

Character string of the fully pathed directory of the BUGS example.

Author(s)

Christopher Paciorek

See Also

readBUGSmodel for usage in creating a model from a classic BUGS example
getConditionallyIndependentSets

givenNodes A vector of node names or their graph IDs that should be considered as fixed and hence can be conditioned on. If omitted, the default will be all data nodes and all parameter nodes, the latter defined as nodes with no stochastic parent nodes (skipping over deterministic parent nodes).

omit A vector of node names or their graph IDs that should be omitted and should block further graph exploration.

inputType The method of graph exploration depends on what the nodes argument represents. For latent, the input nodes are interpreted as latent states, from which both parent and descendent graph exploration should be done to find nodes in the same set (nodes that are NOT conditionally independent from each other). For param, the input nodes are interpreted as parameters, so graph exploration begins from the top (input) and explores descendents. For data, the input nodes are interpreted as data nodes, so graph exploration begins from the bottom (input) explores parent nodes.

stochOnly Logical for whether only stochastic nodes should be returned (default = TRUE). If FALSE, both deterministic and stochastic nodes are returned.

returnType Either names for returned nodes to be node names or ids for returned nodes to be graph IDs.

returnScalarComponents If FALSE (default), multivariate nodes are returned as full names (e.g. x[1:3]). If TRUE, they are returned as scalar elements (e.g. x[1], x[2], x[3]).

Details

This function returns sets of conditionally independent nodes. Multiple input nodes might be in the same set or different sets, and other nodes (not in nodes) will be included.

By default, deterministic dependencies of givenNodes are also counted as given nodes. This is relevant only for parent nodes. This allows the givenNodes to include only stochastic nodes. Say we have A -> B -> C -> D. A and D are givenNodes. C is a latent node. B is a deterministic node. By default, B is considered given. Otherwise, other branches that depend on B would be grouped in the same output set as C, but this is usually what is wanted. Any use of the resulting output must ensure that B is calculated when necessary, as usual with nimble’s model-generic programming. To turn off this feature, set nimbleOptions(groupDetermWithGivenInCondIndSets = FALSE).

Value

List of nodes that are in conditionally independent sets. With each set, nodes are returned in topologically sorted order. The sets themselves are returned in topologically sorted order of their first nodes.

Author(s)

Perry de Valpine

See Also

There is a non-exported function nimble:::testConditionallyIndependentSets(model, sets, initialize = TRUE) that tests whether the conditional independence of sets is valid. It should be the case that
nimble:::testConditionallyIndependentSets(model,getConditionallyIndependentSets(model),initialize = TRUE) returns TRUE.

### getDefinition

Get nimbleFunction definition

**Description**

Returns a list containing the nimbleFunction definition components (setup function, run function, and other member methods) for the supplied nimbleFunction generator or specialized instance.

**Usage**

```r
getDefinition(nf)
```

**Arguments**

- `nf` A nimbleFunction generator, or a compiled or un-compiled specialized nimble-Function.

**Author(s)**

Daniel Turek

### getNimbleOption

Get NIMBLE Option

**Description**

Allow the user to get the value of a global _option_ that affects the way in which NIMBLE operates

**Usage**

```r
getNimbleOption(x)
```

**Arguments**

- `x` a character string holding an option name

**Value**

The value of the option.

**Author(s)**

Christopher Paciorek
**getParam**

*Get value of a parameter of a stochastic node in a model*

**Description**

Get the value of a parameter for any single stochastic node in a model.

**Usage**

`getParam(model, node, param, nodeFunctionIndex)`

**Arguments**

- `model` A NIMBLE model object
- `node` The name of a stochastic node in the model
- `param` The name of a parameter for the node
- `nodeFunctionIndex` For internal NIMBLE use only

**Details**

Standard usage is as a method of a model, in the form `model$getParam(node, param)`, but the usage as a simple function with the model as the first argument as above is also allowed.

For example, suppose node `x[1:5]` follows a multivariate normal distribution (`dmnorm`) in a model declared by BUGS code. `model$getParam('x[1:5]', 'mean')` would return the current value of the mean parameter (which may be determined from other nodes). The parameter requested does not have to be part of the parameterization used to declare the node. Rather, it can be any parameter known to the distribution. For example, one can request the scale or rate parameter of a gamma distribution, regardless of which one was used to declare the node.

**getSamplesDPmeasure**

*Get posterior samples for a Dirichlet process measure*

**Description**

This function obtains posterior samples from a Dirichlet process distributed random measure of a model specified using the dCRP distribution.
getSamplesDPmeasure

Usage

getSamplesDPmeasure(
  MCMC,
  epsilon = 1e-04,
  setSeed = FALSE,
  progressBar = getNimbleOption("MCMCprogressBar")
)

Arguments

MCMC
an MCMC class object, either compiled or uncompiled.

epsilon
used for determining the truncation level of the representation of the random measure.

setSeed
Logical or numeric argument. If a single numeric value is provided, R’s random number seed will be set to this value. In the case of a logical value, if TRUE, then R’s random number seed will be set to 1. Note that specifying the argument setSeed = 0 does not prevent setting the RNG seed, but rather sets the random number generation seed to 0. Default value is FALSE.

progressBar
Logical specifying whether to display a progress bar during execution (default = TRUE). The progress bar can be permanently disabled by setting the system option nimbleOptions(MCMCprogressBar = FALSE)

Details

This function provides samples from a random measure having a Dirichlet process prior. Realizations are almost surely discrete and represented by a (finite) stick-breaking representation (Sethuraman, 1994), whose atoms (or point masses) are independent and identically distributed. This sampler can only be used with models containing a dCRP distribution.

The MCMC argument is an object of class MCMC provided by buildMCMC, or its compiled version. The MCMC should already have been run, as getSamplesDPmeasure uses the posterior samples to generate samples of the random measure. Note that the monitors associated with that MCMC must include the cluster membership variable (which has the dCRP distribution), the cluster parameter variables, all variables directly determining the dCRP concentration parameter, and any stochastic parent variables of the cluster parameter variables. See help(configureMCMC) or help(addMonitors) for information on specifying monitors for an MCMC.

The epsilon argument is optional and used to determine the truncation level of the random measure. epsilon is the tail probability of the random measure, which together with posterior samples of the concentration parameter, determines the truncation level. The default value is 1e-4.

The output is a list of matrices. Each matrix represents a sample from the random measure. In order to reduce the output’s dimensionality, the weights of identical atoms are added up. The stick-breaking weights are named weights and the atoms are named based on the cluster variables in the model.

For more details about sampling the random measure and determining its truncation level, see Section 3 in Gelfand, A.E. and Kottas, A. 2002.
getsize

runMCMC(cmcmc, niter = 1000)
outputG <- getSamplesDPmeasure(cmcmc)
## End(Not run)
```

getsize Returns number of rows of modelValues

Description
Returns the number of rows of NIMBLE modelValues object. Works in R and NIMBLE.

Usage
`getsize(container)`

Arguments
- `container` modelValues object

Details
See the User Manual or help(modelValuesBaseClass) for information about modelValues objects

Author(s)
Clifford Anderson-Bergman
Examples

mvConf <- modelValuesConf(vars = 'a', types = 'double', sizes = list(a = 1))
mv <- modelValues(mvConf)
resize(mv, 10)
getsize(mv)

-------------------

identityMatrix Create an Identity matrix (Deprecated)

Description
Returns a d-by-d identity matrix (square matrix of 0’s, with 1’s on the main diagonal).

Usage

identityMatrix(d)

Arguments

d The size of the identity matrix to return, will return a d-by-d matrix

Details
This function can be used in NIMBLE run code. It is deprecated because now one can use diag(d) instead.

Value
A d-by-d identity matrix

Author(s)
Daniel Turek

Examples

Id <- identityMatrix(d = 3)
Description

Performs initialization of nimble model node values and log probabilities

Usage

initializeModel(model, silent = FALSE)

Arguments

model A setup argument, which specializes an instance of this nimble function to a particular model.
silent logical indicating whether to suppress logging information

Details

This nimbleFunction may be used at the beginning of nimble algorithms to perform model initialization. The intended usage is to specialize an instance of this nimbleFunction in the setup function of an algorithm, then execute that specialised function at the beginning of the algorithm run function. The specialized function takes no arguments.

Executing this function ensures that all right-hand-side only nodes have been assigned real values, that all stochastic nodes have a real value, or otherwise have their simulate() method called, that all deterministic nodes have their simulate() method called, and that all log-probabilities have been calculated with the current model values. An error results if model initialization encounters a problem, for example a missing right-hand-side only node value.

Author(s)

Daniel Turek

Examples

myNewAlgorithm <- nimbleFunction(
  setup = function(model, ...) {
    my_initializeModel <- initializeModel(model)
    ....
  },
  run = function(...) {
    my_initializeModel()
    ....
  }
  )
Interval calculations

Description

Calculations to handle censoring

Usage

\[
dinterval(x, t, c, \text{log} = \text{FALSE})
\]

\[
rinterval(n = 1, t, c)
\]

Arguments

- \(x\): vector of interval indices.
- \(t\): vector of values.
- \(c\): vector of one or more values delineating the intervals.
- \(\text{log}\): logical; if \(\text{TRUE}\), probability density is returned on the log scale.
- \(n\): number of observations.

Details

Used for working with censoring in BUGS code. Taking \(c\) to define the endpoints of two or more intervals (with implicit endpoints of plus/minus infinity), \(x\) (or the return value of \(rinterval\)) gives the non-negative integer valued index of the interval in which \(t\) falls. See the NIMBLE manual for additional details.

Value

\(dinterval\) gives the density and \(rinterval\) generates random deviates, but these are unusual as the density is 1 if \(x\) indicates the interval in which \(t\) falls and 0 otherwise and the deviates are simply the interval(s) in which \(t\) falls.

Inverse-Gamma

Examples

```r
endpoints <- c(-3, 0, 3)
vals <- c(-4, -1, 1, 5)
x <- rinterval(4, vals, endpoints)
dinterval(x, vals, endpoints)
dinterval(c(1, 5, 2, 3), vals, endpoints)
```

Inverse-Gamma

The Inverse Gamma Distribution

Description

Density, distribution function, quantile function and random generation for the inverse gamma distribution with rate or scale (mean = scale / (shape - 1)) parameterizations.

Usage

```r
dinvgamma(x, shape, scale = 1, rate = 1/scale, log = FALSE)
rinvgamma(n = 1, shape, scale = 1, rate = 1/scale)
pinvgamma(
  q,
  shape,
  scale = 1,
  rate = 1/scale,
  lower.tail = TRUE,
  log.p = FALSE
)
qinvgamma(
  p,
  shape,
  scale = 1,
  rate = 1/scale,
  lower.tail = TRUE,
  log.p = FALSE
)
```

Arguments

- `x`: vector of values.
- `shape`: vector of shape values, must be positive.
- `scale`: vector of scale values, must be positive.
- `rate`: vector of rate values, must be positive.
- `log`: logical; if TRUE, probability density is returned on the log scale.
Inverse-Gamma

- **n**: number of observations.
- **q**: vector of quantiles.
- **lower.tail**: logical; if TRUE (default) probabilities are \( P[X \leq x] \); otherwise, \( P[X > x] \).
- **log.p**: logical; if TRUE, probabilities \( p \) are given by user as \( \log(p) \).
- **p**: vector of probabilities.

**Details**

The inverse gamma distribution with parameters \( \text{shape} = \alpha \) and \( \text{scale} = \sigma \) has density

\[
f(x) = \frac{s^\alpha}{\Gamma(\alpha)} x^{-\alpha - 1} e^{-s/x}
\]

for \( x \geq 0, \alpha > 0 \) and \( \sigma > 0 \). (Here \( \Gamma(\alpha) \) is the function implemented by R’s \texttt{gamma()} \) and defined in its help.

The mean and variance are \( E(X) = \frac{\sigma}{\alpha} - 1 \) and \( \text{Var}(X) = \frac{\sigma^2}{(\alpha-1)(\alpha-2)} \), with the mean defined only for \( \alpha > 1 \) and the variance only for \( \alpha > 2 \).

See Gelman et al., Appendix A or the BUGS manual for mathematical details.

**Value**

- \texttt{dinvgamma} gives the density, \texttt{pinvgamma} gives the distribution function, \texttt{qinvgamma} gives the quantile function, and \texttt{rinvgamma} generates random deviates.

**Author(s)**

Christopher Paciorek

**References**

**See Also**

- \texttt{Distributions} for other standard distributions

**Examples**

```r
x <- rinvgamma(50, shape = 1, scale = 3)
dinvgamma(x, shape = 1, scale = 3)
```
**Inverse-Wishart**

*The Inverse Wishart Distribution*

**Description**

Density and random generation for the Inverse Wishart distribution, using the Cholesky factor of either the scale matrix or the rate matrix.

**Usage**

```r
dinvwish_chol(x, cholesky, df, scale_param = TRUE, log = FALSE)
rinvwish_chol(n = 1, cholesky, df, scale_param = TRUE)
```

**Arguments**

- `x` vector of values.
- `cholesky` upper-triangular Cholesky factor of either the scale matrix (when `scale_param` is TRUE) or rate matrix (otherwise).
- `df` degrees of freedom.
- `scale_param` logical; if TRUE the Cholesky factor is that of the scale matrix; otherwise, of the rate matrix.
- `log` logical; if TRUE, probability density is returned on the log scale.
- `n` number of observations (only `n=1` is handled currently).

**Details**

See Gelman et al., Appendix A for mathematical details. The rate matrix as used here is defined as the inverse of the scale matrix, $S^{-1}$, given in Gelman et al.

**Value**

`dinvwish_chol` gives the density and `rinvwish_chol` generates random deviates.

**Author(s)**

Christopher Paciorek

```r
df <- 40
ch <- chol(matrix(c(1, .7, .7, 1), 2))
x <- rwish_chol(1, ch, df = df)
dwish_chol(x, ch, df = df)
```

Is

### Description

Checks an object to determine if it is a nimbleFunction (i.e., a function created by `nimbleFunction` using setup code).

### Usage

```r
is.nf(f, inputIsName = FALSE, where = -1)
```

### Arguments

- `f`: object to be tested
- `inputIsName`: logical indicating whether the function is provided as the character name of the function or the function object itself
- `where`: Optional argument needed due to R package namespace issues but which should not need to be provided by a user.

### See Also

- `nimbleFunction` for how to create a nimbleFunction

Is nl

### Description

Checks an object to determine if it is a nimbleList (i.e., a list created by `nlDef$new()`).

### Usage

```r
is.nl(l)
```

### Arguments

- `l`: object to be tested

### See Also

- `nlDef$new()` for creating a nimbleList
The LKJ Distribution for the Cholesky Factor of a Correlation Matrix

Description
Density and random generation for the LKJ distribution for the Cholesky factor of a correlation matrix.

Usage

dlkj_corr_cholesky(x, etap, log = FALSE)

rlkj_corr_cholesky(n = 1, etap)

Arguments

- **x**: upper-triangular Cholesky factor of a correlation matrix.
- **eta**: shape parameter.
- **p**: size of the correlation matrix (number of rows and columns); required because random generation function has no information about dimension of matrix to generate without this argument.
- **log**: logical; if TRUE, probability density is returned on the log scale.
- **n**: number of observations (only n=1 is handled currently).

Details
See Stan Development Team for mathematical details.

Value

dlkj_corr_cholesky gives the density and rlkj_corr_cholesky generates random deviates.

Author(s)
Christopher Paciorek

References
Stan Development Team. Stan Reference Functions, version 2.27.

dlkj_corr_cholesky(x, eta, 5)
```

SEE

```r
makeBoundInfo
```

Make an object of information about a model-bound pairing for getBound. Used internally

### Description

Creates a simple getBound_info object, which has a list with a boundID and a type. Unlike makeParamInfo this is more bare-bones, but keeping it for parallelism with getParam.

#### Usage

```r
makeBoundInfo(model, nodes, bound)
```

#### Arguments

- `model`: A model such as returned by `nimbleModel`.
- `nodes`: A character string naming a stochastic nodes, such as 'mu'.
- `bound`: A character string naming a bound of the distribution, either 'lower' or 'upper'.

#### Details

This is used internally by `getBound`. It is not intended for direct use by a user or even a nimble-Function programmer.

```r
makeParamInfo
```

Make an object of information about a model-parameter pairing for getParam. Used internally

### Description

Creates a simple getParam_info object, which has a list with a paramID and a type

#### Usage

```r
code`
```

#### Arguments

- `model`: A model such as returned by `nimbleModel`.
- `nodes`: A character string naming a stochastic nodes, such as 'mu'.
- `param`: A character string naming a parameter.
- `vector`: A logical indicating whether `param` is vector.

#### Details

This is used internally by `getParam`. It is not intended for direct use by a user or even a nimble-Function programmer.
Arguments

model  A model such as returned by `nimbleModel`.

nodes  A character string naming one or more stochastic nodes, such as "mu", "c('mu', 'beta[2]')", or "eta[1:3, 2]". `getParam` only works for one node at a time, but if it is indexed (nodes[i]), then `makeParamInfo` sets up the information for the entire vector nodes. The processing pathway is used by the NIMBLE compiler.

param  A character string naming a parameter of the distribution followed by node, such as "mean", "rate", "lambda", or whatever parameter names are relevant for the distribution of the node.

vector  A logical indicating whether nodes should definitely be treated as a vector in compiled code, even if it has length = 1. For type consistency, the compiler needs this option. If nodes has length > 1, this argument is ignored.

Details

This is used internally by `getParam`. It is not intended for direct use by a user or even a nimble-Function programmer.

MCMCconf-class

Class

MCMCconf

Description

Objects of this class configure an MCMC algorithm, specific to a particular model. Objects are normally created by calling `configureMCMC`. Given an MCMCconf object, the actual MCMC function can be built by calling `buildMCMC(conf)`. See documentation below for method `initialize()` for details of creating an MCMCconf object.

Methods

`addMonitors(..., ind = 1, print = TRUE)` Adds variables to the list of monitors.

Arguments:

...: One or more character vectors of indexed nodes, or variables, which are to be monitored. These are added onto the current monitors list.

print: A logical argument specifying whether to print all current monitors (default TRUE).

Details: See the `initialize()` function

`addMonitors2(..., print = TRUE)` Adds variables to the list of monitors2.

Arguments:

...: One or more character vectors of indexed nodes, or variables, which are to be monitored. These are added onto the current monitors2 list.

print: A logical argument specifying whether to print all current monitors (default TRUE).

Details: See the `initialize()` function
addSampler(target, type = "RW", control = list(), print = FALSE, name, scalarComponents = FALSE, silent = FALSE)

Adds a sampler to the list of samplers contained in the MCMCconf object.

Arguments:

target: The target node or nodes to be sampled. This may be specified as a character vector of model node and/or variable names. This argument is required.

type: The type of sampler to add, specified as either a character string or a nimbleFunction object. If the character argument type='newSamplerType', then either newSamplerType or sampler_newSamplertype must correspond to a nimbleFunction (i.e. a function returned by nimbleFunction, not a specialized nimbleFunction). Alternatively, the type argument may be provided as a nimbleFunction itself rather than its name. In that case, the 'name' argument may also be supplied to provide a meaningful name for this sampler. The default value is 'RW' which specifies scalar adaptive Metropolis-Hastings sampling with a normal proposal distribution. This default will result in an error if 'target' specifies more than one target node.

control: A list of control arguments specific to the sampler function. These will override those specified in the control list argument to configureMCMC().

print: Logical argument, specifying whether to print the details of the newly added sampler, as well as its position in the list of MCMC samplers.

name: Optional character string name for the sampler, which is used by the printSamplers method. If 'name' is not provided, the 'type' argument is used to generate the sampler name.

scalarComponents: Logical argument, indicating whether the specified sampler 'type' should be assigned independently to each scalar (univariate) component of the specified 'target' node or variable. This option should only be specified as TRUE when the sampler 'type' specifies a univariate sampler.

silent: Logical argument, specifying whether to print warning messages when assigning samplers.

...: Additional named arguments passed through ... will be used as additional control list elements.

Details: A single instance of the newly configured sampler is added to the end of the list of samplers for this MCMCconf object.

Invisibly returns a list of the current sampler configurations, which are samplerConf reference class objects.

addSamplerOne(thisSamplerName, samplerFunction, targetOne, thisControlList, print)

For internal use only

getMonitors() Returns a character vector of the current monitors

Details: See the initialize() function

getMonitors2() Returns a character vector of the current monitors2

Details: See the initialize() function

getSamplerDefinition(ind, print = FALSE) Returns the nimbleFunction definition of an MCMC sampler.

Arguments:

ind: A numeric vector or character vector. A numeric vector may be used to specify the index of the sampler definition to return, or a character vector may be used to indicate a target node for which the sampler acting on this nodes will be printed. For example, getSamplerDefinition('x[2]') will return the definition of the sampler whose target is model node 'x[2]'. If more than one sampler function is specified, only the first is returned.
MCMCconf-class

Returns a list object, containing the setup function, run function, and additional member methods for the specified nimbleFunction sampler.

getSamplerExecutionOrder() Returns a numeric vector, specifying the ordering of sampler function execution.
The indices of execution specified in this numeric vector correspond to the enumeration of samplers printed by printSamplers(), or returned by getSamplers().

getSamplers(ind) Returns a list of samplerConf objects.
Arguments:
ind: A numeric vector or character vector. A numeric vector may be used to specify the indices of the samplerConf objects to return, or a character vector may be used to indicate a set of target nodes and/or variables, for which all samplers acting on these nodes will be returned. For example, getSamplers('x') will return all samplerConf objects whose target is model node 'x', or whose targets are contained (entirely or in part) in the model variable 'x'. If omitted, then all samplerConf objects in this MCMC configuration object are returned.

initialize( model, nodes, control = list(), monitors, thin = 1, monitors2 = character(), thin2 = 1, useConjugacy = ... enableWAIC = getNimbleOption("MCMCenableWAIC"), controlWAIC = list(), warnNoSamplerAssigned = TRUE, print = TRUE, ... )
Creates a MCMC configuration for a given model. The resulting object is suitable as an argument to buildMCMC.
Arguments:
model: A NIMBLE model object, created from nimbleModel(...) nodes: An optional character vector, specifying the nodes for which samplers should be created. Nodes may be specified in their indexed form, 'y[1, 3]', or nodes specified without indexing will be expanded fully, e.g., 'x' will be expanded to 'x[1]', 'x[2]', etc. If missing, the default value is all non-data stochastic nodes. If NULL, then no samplers are added.
control: An optional list of control arguments to sampler functions. If a control list is provided, the elements will be provided to all sampler functions which utilize the named elements given. For example, the standard Metropolis-Hastings random walk sampler (sampler_RW) utilizes control list elements 'adaptive', 'adaptInterval', 'scale'. The default values for control list arguments for samplers (if not otherwise provided as an argument to configureMCMC() or addSampler()) are contained in the setup code of each sampling algorithm.
monitors: A character vector of node names or variable names, to record during MCMC sampling. This set of monitors will be recorded with thinning interval 'thin', and the samples will be stored into the 'mvSamples' object. The default value is all top-level stochastic nodes of the model – those having no stochastic parent nodes.
monitors2: A character vector of node names or variable names, to record during MCMC sampling. This set of monitors will be recorded with thinning interval 'thin2', and the samples will be stored into the 'mvSamples2' object. The default value is an empty character vector, i.e. no values will be recorded.
thin: The thinning interval for 'monitors'. Default value is one.
thin2: The thinning interval for 'monitors2'. Default value is one.
useConjugacy: A logical argument, with default value TRUE. If specified as FALSE, then no conjugate samplers will be used, even when a node is determined to be in a conjugate relationship.
onlyRW: A logical argument, with default value FALSE. If specified as TRUE, then Metropolis-Hastings random walk samplers will be assigned for all non-terminal continuous-valued nodes. Discrete-valued nodes are assigned a slice sampler, and terminal nodes are assigned a posterior_predictive sampler.
onlySlice: A logical argument, with default value FALSE. If specified as TRUE, then a slice sampler is assigned for all non-terminal nodes. Terminal nodes are still assigned a posterior_predictive sampler.

multivariateNodesAsScalars: A logical argument, with default value FALSE. If specified as TRUE, then non-terminal multivariate stochastic nodes will have scalar samplers assigned to each of the scalar components of the multivariate node. The default value of FALSE results in a single block sampler assigned to the entire multivariate node. Note, multivariate nodes appearing in conjugate relationships will be assigned the corresponding conjugate sampler (provided useConjugacy == TRUE), regardless of the value of this argument.

enableWAIC: A logical argument, specifying whether to enable WAIC calculations for the resulting MCMC algorithm. Defaults to the value of nimbleOptions('MCMCenableWAIC'), which in turn defaults to FALSE. Setting nimbleOptions('MCMCenableWAIC' = TRUE) will ensure that WAIC is enabled for all calls to 'configureMCMC' and 'buildMCMC'.

controlWAIC A named list of inputs that control the behavior of the WAIC calculation, passed as the 'control' input to 'buildWAIC'. See 'help(waic)'.

warnNoSamplerAssigned: A logical argument specifying whether to issue a warning when no sampler is assigned to a node, meaning there is no matching sampler assignment rule. Default is TRUE.

print: A logical argument specifying whether to print the monitors and samplers. Default is TRUE.

...: Additional named control list elements for default samplers, or additional arguments to be passed to the autoBlock function when autoBlock = TRUE.

printMonitors() Prints all current monitors and monitors2
Details: See the initialize() function

printSamplers(..., ind, type, displayControlDefaults = FALSE, displayNonScalars = FALSE, displayConjugateDependencies = FALSE, executionOrder = FALSE, byType = FALSE)
Prints details of the MCMC samplers.
Arguments:
...: Character node or variable names, or numeric indices. Numeric indices may be used to specify the indices of the samplers to print, or character strings may be used to indicate a set of target nodes and/or variables, for which all samplers acting on these nodes will be printed. For example, printSamplers('x') will print all samplers whose target is model node 'x', or whose targets are contained (entirely or in part) in the model variable 'x'. If omitted, then all samplers are printed.

ind: A numeric vector or character vector. A numeric vector may be used to specify the indices of the samplers to print, or a character vector may be used to indicate a set of target nodes and/or variables, for which all samplers acting on these nodes will be printed. For example, printSamplers('x') will print all samplers whose target is model node 'x', or whose targets are contained (entirely or in part) in the model variable 'x'. If omitted, then all samplers are printed.

type: a character vector containing sampler type names. Only samplers with one of these specified types, as printed by this printSamplers method, will be displayed. Standard regular expression matching using is also applied.

displayConjugateDependencies: A logical argument, specifying whether to display the dependency lists of conjugate samplers (default FALSE).

displayNonScalars: A logical argument, specifying whether to display the values of non-scalar control list elements (default FALSE).
executionOrder: A logical argument, specifying whether to print the sampler functions in the (possibly modified) order of execution (default FALSE).

byType: A logical argument, specifying whether the nodes being sampled should be printed, sorted and organized according to the type of sampler (the sampling algorithm) which is acting on the nodes (default FALSE).

removeSampler(...) Alias for removeSamplers method

removeSamplers(..., ind, print = FALSE) Removes one or more samplers from an MCMC-conf object.

Arguments:
This function also has the side effect of resetting the sampler execution ordering so as to iterate over the remaining set of samplers, sequentially, executing each sampler once.

...: Character node names or numeric indices. Character node names specify the node names for samplers to remove, or numeric indices can provide the indices of samplers to remove.

ind: A numeric vector or character vector specifying the samplers to remove. A numeric vector may specify the indices of the samplers to be removed. Alternatively, a character vector may be used to specify a set of model nodes and/or variables, and all samplers whose 'target' is among these nodes will be removed. If omitted, then all samplers are removed.

print: A logical argument specifying whether to print the current list of samplers once the removal has been done (default FALSE).

resetMonitors() Resets the current monitors and monitors2 lists to nothing.

Details: See the initialize() function

setMonitors(..., ind = 1, print = TRUE) Sets new variables to the list of monitors.

Arguments:
...: One or more character vectors of indexed nodes, or variables, which are to be monitored. These replace the current monitors list.

print: A logical argument specifying whether to print all current monitors (default TRUE).

Details: See the initialize() function

setMonitors2(..., print = TRUE) Sets new variables to the list of monitors2.

Arguments:
...: One or more character vectors of indexed nodes, or variables, which are to be monitored. These replace the current monitors2 list.

print: A logical argument specifying whether to print all current monitors (default TRUE).

Details: See the initialize() function

setSampler(...) Alias for setSamplers method

setSamplerExecutionOrder(order, print = FALSE) Sets the ordering in which sampler functions will execute.

This allows some samplers to be "turned off", or others to execute multiple times in a single MCMC iteration. The ordering in which samplers execute can also be interleaved.

Arguments:
order: A numeric vector, specifying the ordering in which the sampler functions will execute. The indices of execution specified in this numeric vector correspond to the enumeration of samplers printed by printSamplers(), or returned by getSamplers(). If this argument is omitted, the sampler execution ordering is reset so as to sequentially execute each sampler once.

print: A logical argument specifying whether to print the current list of samplers in the modified order of execution (default FALSE).
setSamplers(..., ind, print = FALSE) Sets the ordering of the list of MCMC samplers.
This function also has the side effect of resetting the sampler execution ordering so as to iterate
over the specified set of samplers, sequentially, executing each sampler once.
Arguments:
...: Character strings or numeric indices. Character names may be used to specify the node
names for samplers to retain. Numeric indices may be used to specify the indices for the new
list of MCMC samplers, in terms of the current ordered list of samplers.
ind: A numeric vector or character vector. A numeric vector may be used to specify the
indices for the new list of MCMC samplers, in terms of the current ordered list of samplers.
For example, if the MCMCconf object currently has 3 samplers, then the ordering may be
reversed by calling MCMCconf$setSamplers(3:1), or all samplers may be removed by calling
MCMCconf$setSamplers(numeric(0)).
Alternatively, a character vector may be used to specify a set of model nodes and/or variables,
and the sampler list will modified to only those samplers acting on these target nodes.
As another alternative, a list of samplerConf objects may be used as the argument, in which
case this ordered list of samplerConf objects will define the samplers in this MCMC config-
uration object, completely over-writing the current list of samplers. No checking is done to
ensure the validity of the contents of these samplerConf objects; only that all elements of the
list argument are, in fact, samplerConf objects.
print: A logical argument specifying whether to print the new list of samplers (default FALSE).
setThin(thin, print = TRUE) Sets the value of thin.
Arguments:
thin: The new value for the thinning interval 'thin'.
print: A logical argument specifying whether to print all current monitors (default TRUE).
Details: See the initialize() function
setThin2(thin2, print = TRUE) Sets the value of thin2.
Arguments:
thin2: The new value for the thinning interval 'thin2'.
print: A logical argument specifying whether to print all current monitors (default TRUE).
Details: See the initialize() function

MCMC suite

Placeholder for MCMC suite

Description

This function has been moved to a separate package

Usage

MCMC suite(...)
checkConjugacy(nodeVector, restrictLink = NULL) Determines whether or not the input nodes appear in conjugate relationships
Arguments:
  nodeVector: A character vector specifying one or more node or variable names. If omitted, all stochastic non-data nodes are checked for conjugacy.
Details: The return value is a named list, with an element corresponding to each conjugate node. The list names are the conjugate node names, and list elements are the control list arguments required by the corresponding MCMC conjugate sampler functions. If no model nodes are conjugate, an empty list is returned.

expandNodeNames( nodes, env = parent.frame(), returnScalarComponents = FALSE, returnType = "names", sort = FALSE, unique = TRUE )
Takes a vector of names of nodes or variables and returns the unique and expanded names in the model, i.e. 'x' expands to 'x[1]', 'x[2]', ...
Arguments:
  nodes: a vector of names of nodes (or variables) to be expanded. Alternatively, can be a vector of integer graph IDs, but this use is intended only for advanced users
  returnScalarComponents: should multivariate nodes (i.e. dnorm or dmulti) be broken up into scalar components?
  returnType: return type. Options are 'names' (character vector) or 'ids' (graph IDs)
  sort: should names be topologically sorted before being returned?
  unique: should names be the unique names or should original ordering of nodes (after expansion of any variable names into node names) be preserved

getBound(node, bound)
See ‘help(getBound)’

getCode()
Return the code for a model after processing if-then-else statements, expanding macros, and replacing some keywords (e.g. nimStep for step) to avoid R ambiguity.

getConditionallyIndependentSets( nodes, givenNodes, omit = integer(), inputType = c("latent", "param", "data"), stochOnly = TRUE, returnType = "names", returnScalarComponents = FALSE )
Get a list of conditionally independent sets of nodes in a nimble model.
Conditionally independent sets of nodes are typically groups of latent states whose joint conditional probability (density) will not change even if any other non-fixed node is changed. Default fixed nodes are data nodes and parameter nodes (with no parent nodes), but this can be controlled.

model: A nimble model object (uncompiled or compiled).

nodes: A vector of node names or their graph IDs that are the starting nodes from which conditionally independent sets of nodes should be found. If omitted, the default will be all latent nodes, defined as stochastic nodes that are not data and have at least one stochastic parent node (possible with deterministic nodes in between). Note that this will omit latent states that have no hyperparameters. An example is the first latent state in some state-space (time-series) models, which is sometimes declared with known prior. See type because it relates to the interpretation of nodes.
givenNodes: A vector of node names or their graph IDs that should be considered as fixed and hence can be conditioned on. If omitted, the default will be all data nodes and all parameter nodes, the latter defined as nodes with no stochastic parent nodes (skipping over deterministic parent nodes).
omit: A vector of node names or their graph IDs that should be omitted and should block further graph exploration.
inputType: Type of input nodes provided in nodes argument. For 'latent', the input nodes are interpreted as latent states, from which both downstream and upstream exploration should be
done to find nodes in the same set (nodes that are not conditionally independent from each other). For 'param', the input nodes are interpreted as parameters, so graph exploration begins from the top (input) and proceeds downstream. For 'data', the input nodes are interpreted and data nodes, so graph exploration begins from the bottom (input) and proceeds upstream.

stochOnly: Logical for whether only stochastic nodes should be returned (default = TRUE). If FALSE, both deterministic and stochastic nodes are returned.

returnType: Either 'names' for returned nodes to be node names or 'ids' for returned nodes to be graph IDs.

returnScalarComponents: If FALSE (default), multivariate nodes are returned as full names (e.g. 'x[1:3]'). If TRUE, they are returned as scalar elements (e.g. 'x[1]', 'x[2]', 'x[3]').

Details: This function returns sets of conditionally independent nodes. Multiple input nodes might be in the same set or different sets, and other nodes (not in codes) will be included. By default, deterministic dependencies of givenNodes are also counted as given nodes. This is relevant only for parent nodes. This allows the givenNodes to include only stochastic nodes. Say we have A -> B -> C -> D. A and D are givenNodes. C is a latent node. B is a deterministic node. By default, B is considered given. Otherwise, other branches that depend on B would be grouped in the same output set as C, but this is usually not what is wanted. Any use of the resulting output must ensure that B is calculated when necessary, as usual with nimble's model-generic programming. To turn off this feature, set nimbleOptions(groupDetermWithGivenInCondIndSets = FALSE).

There is a non-exported function 'nimble:::testConditionallyIndependentSets(model, sets, initialize = TRUE)' that tests whether the conditional independence of sets is valid. It should be the case that 'nimble:::testConditionallyIndependentSets(model, getConditionallyIndependentSets(model), initialize = TRUE)' returns 'TRUE'.

Return value: List of nodes that are in conditionally independent sets. Within each set, nodes are returned in topologically sorted order. The sets themselves are returned in topologically sorted order of their first nodes.

getDependencies( nodes, omit = character(), self = TRUE, determOnly = FALSE, stochOnly = FALSE, includeData = TRUE, dataOnly = FALSE, includeRHSonly = FALSE, downstream = FALSE, returnType = "names", returnScalarComponents = FALSE )

Returns a character vector of the nodes dependent upon the input argument nodes, sorted topologically according to the model graph. In the genealogical metaphor for a graphical model, this function returns the "children" of the input nodes. In the river network metaphor, it returns downstream nodes. By default, the returned nodes include the input nodes, include both deterministic and stochastic nodes, and stop at stochastic nodes. Additional input arguments provide flexibility in the values returned.

Arguments:

nodes: Character vector of node names, with index blocks allowed, and/or variable names, the dependents of which will be returned.

omit: Character vector of node names, which will be omitted from the nodes returned. In addition, dependent nodes subsequent to these omitted nodes will not be returned. The omitted nodes argument serves to stop the downward search within the hierarchical model structure, and excludes the specified node.

self: Logical argument specifying whether to include the input argument nodes in the return vector of dependent nodes. Default is TRUE.

determOnly: Logical argument specifying whether to return only deterministic nodes. Default is FALSE.

stochOnly: Logical argument specifying whether to return only stochastic nodes. Default is FALSE. If both determOnly and stochOnly are TRUE, no nodes will be returned.
includeData: Logical argument specifying whether to include 'data' nodes (set via nimbleModel or the setData method). Default is TRUE.
dataOnly: Logical argument specifying whether to return only 'data' nodes. Default is FALSE.
includeRHSonly: Logical argument specifying whether to include right-hand-side-only nodes (model nodes which never appear on the left-hand-side of ~ or <- in the model code). These nodes are neither stochastic nor deterministic, but instead function as variable inputs to the model. Default is FALSE.
downstream: Logical argument specifying whether the downward search through the hierarchical model structure should continue beyond the first and subsequent stochastic nodes encountered, hence returning all nodes downstream of the input nodes. Default is FALSE.
returnType: Character argument specifying type of object returned. Options are 'names' (returns character vector) and 'ids' (returns numeric graph IDs for model).
returnScalarComponents: Logical argument specifying whether multivariate nodes should be returned as full node names (i.e. 'x[1:2]') or as scalar components (i.e. 'x[1]' and 'x[2]').

Details: The downward search for dependent nodes propagates through deterministic nodes, but by default will halt at the first level of stochastic nodes encountered. Use getDependenciesList for a list of one-step dependent nodes of each node in the model.

getDependenciesList(returnNames = TRUE, sort = TRUE) Returns a list of all dependent neighbor relationships. Each list element gives the one-step dependencies of one vertex, and the element name is the vertex label (integer ID or character node name)
Arguments:
returnNames: If TRUE (default), list names and element contents are returned as character node names, e.g. 'x[1]'. If FALSE, everything is returned using graph IDs, which are unique integer labels for each node.
sort: If TRUE (default), each list element is returned in topologically sorted order. If FALSE, they are returned in arbitrary order.
Details: This provides a fairly raw representation of the graph (model) structure that may be useful for inspecting what NIMBLE has created from model code.

getDimension(node, params = NULL, valueOnly = is.null(params) && !includeParams, includeParams = !is.null(params)) Determines the dimension of the value and/or parameters of the node
Arguments:
node: A character vector specifying a single node
params: an optional character vector of names of parameters for which dimensions are desired (possibly including 'value' and alternate parameters)
valueOnly: a logical indicating whether to only return the dimension of the value of the node
includeParams: a logical indicating whether to return dimensions of parameters. If TRUE and 'params' is NULL then dimensions of all parameters, including the dimension of the value of the node, are returned
Details: The return value is a numeric vector with an element for each parameter/value requested.

getDistribution(nodes) Returns the names of the distributions for the requested node or nodes
Arguments:
nodes: A character vector specifying one or more node or variable names.
Details: The return value is a character vector with an element for each node indicated in the input. Note that variable names are expanded to their constituent node names, so the length of the output may be longer than that of the input.
getDownstream(...) Identical to getDependencies(..., downstream = TRUE)

Details: See documentation for member method getDependencies.

getLogProb(nodes) See ‘help(getLogProb)

getNodeNames( determOnly = FALSE, stochOnly = FALSE, includeData = TRUE, dataOnly = FALSE, includeRHSonly = FALSE, topOnly = FALSE, latentOnly = FALSE, endOnly = FALSE, returnType = "names", returnScalarComponents = FALSE )

Returns a character vector of all node names in the model, in topologically sorted order. A variety of logical arguments allow for flexible subsetting of all model nodes.

Arguments:

determOnly: Logical argument specifying whether to return only deterministic nodes. Default is FALSE.

stochOnly: Logical argument specifying whether to return only stochastic nodes. Default is FALSE.

includeData: Logical argument specifying whether to include 'data' nodes (set via the member method setData). Default is TRUE.

dataOnly: Logical argument specifying whether to return only 'data' nodes. Default is FALSE.

includeRHSonly: Logical argument specifying whether to include right-hand-side-only nodes (model nodes which never appear on the left-hand-side of ~ or <- in the model code). Default is FALSE.

topOnly: Logical argument specifying whether to return only top-level nodes from the hierarchical model structure.

latentOnly: Logical argument specifying whether to return only latent (mid-level) nodes from the hierarchical model structure.

detOnly: Logical argument specifying whether to return only end nodes from the hierarchical model structure.

returnType: Character argument specific type object returned. Options are 'names' (returns character vector) and 'ids' (returns numeric graph IDs for model)

returnScalar Componenets: Logical argument specifying whether multivariate nodes should return full node name (i.e. 'x[1:2]') or should break down into scalar components (i.e. 'x[1]' and 'x[2]')

Details: Multiple logical input arguments may be used simultaneously. For example, ‘model$getNodeNames(endOnly = TRUE, dataOnly = TRUE)’ will return all end-level nodes from the model which are designated as 'data'.

getParam(node, param) See ‘help(getParam)

getParents( nodes, omit = character(), self = FALSE, determOnly = FALSE, stochOnly = FALSE, includeData = TRUE, dataOnly = FALSE, includeRHSonly = FALSE, upstream = FALSE, immediateOnly = FALSE, returnType = "names", returnScalarComponents = FALSE )

Returns a character vector of the nodes on which the input nodes depend, sorted topologically according to the model graph, by default recursing and stopping at stochastic parent nodes. In the genealogical metaphor for a graphical model, this function returns the "parents" of the input nodes. In the river network metaphor, it returns upstream nodes. By default, the returned nodes omit the input nodes. Additional input arguments provide flexibility in the values returned.

Arguments:

nodes: Character vector of node names, with index blocks allowed, and/or variable names, the parents of which will be returned.

omit: Character vector of node names, which will be omitted from the nodes returned. In addition, parent nodes beyond these omitted nodes will not be returned. The omitted nodes
argument serves to stop the upward search through the hierarchical model structure, and excludes the specified node.

self: Logical argument specifying whether to include the input argument nodes in the return vector of dependent nodes. Default is FALSE.

determOnly: Logical argument specifying whether to return only deterministic nodes. Default is FALSE.

stochOnly: Logical argument specifying whether to return only stochastic nodes. Default is FALSE. If both determOnly and stochOnly are TRUE, no nodes will be returned.

includeData: Logical argument specifying whether to include 'data' nodes (set via nimble::Model or the setData method). Default is TRUE.

dataOnly: Logical argument specifying whether to return only 'data' nodes. Default is FALSE.

includeRHSonly: Logical argument specifying whether to include right-hand-side-only nodes (model nodes which never appear on the left-hand-side of ~ or <- in the model code). These nodes are neither stochastic nor deterministic, but instead function as variable inputs to the model. Default is FALSE.

upstream: Logical argument specifying whether the upward search through the hierarchical model structure should continue beyond the first and subsequent stochastic nodes encountered, hence returning all nodes upstream of the input nodes. Default is FALSE.

immediateOnly: Logical argument specifying whether only the immediate parent nodes should be returned, even if they are deterministic. If FALSE, getParents recurses and stops at stochastic nodes. Default is FALSE.

returnType: Character argument specifying type of object returned. Options are 'names' (returns character vector) and 'ids' (returns numeric graph IDs for model).

returnScalarComponenets: Logical argument specifying whether multivariate nodes should be returned as full node names (i.e. 'x[1:2]') or as scalar componenets (i.e. 'x[1]' and 'x[2]').

Details: The upward search for dependent nodes propagates through deterministic nodes, but by default will halt at the first level of stochastic nodes encountered. Use getParentsList for a list of one-step parent nodes of each node in the model.

getParentsList(returnNames = TRUE, sort = TRUE) Returns a list of all parent neighbor relationships. Each list element gives the one-step parents of one vertex, and the element name is the vertex label (integer ID or character node name)

Arguments:

returnNames: If TRUE (default), list names and element contents are returns as character node names, e.g. ‘x[1]’’. If FALSE, everything is returned using graph IDs, which are unique integer labels for each node.

sort: If TRUE (default), each list element is returned in topologically sorted order. If FALSE, they are returned in arbitrary order.

Details: This provides a fairly raw representation of the graph (model) structure that may be useful for inspecting what NIMBLE has created from model code.

getVarNames(includeLogProb = FALSE, nodes) Returns the names of all variables in a model, optionally including the logProb variables

Arguments:

logProb: Logical argument specifying whether or not to include the logProb variables. Default is FALSE.

nodes: An optional character vector supplying a subset of nodes for which to extract the variable names and return the unique set of variable names
initializeInfo() Provides more detailed information on which model nodes are not initialized.

isBinary(nodes) Determines whether one or more nodes represent binary random variables

Arguments:
- nodes: A character vector specifying one or more node or variable names.
Details: The return value is a character vector with an element for each node indicated in the input. Note that variable names are expanded to their constituent node names, so the length of the output may be longer than that of the input.

isData(nodes) Returns a vector of logical TRUE / FALSE values, corresponding to the 'data' flags of the input node names.

Arguments:
- nodes: A character vector of node or variable names.
Details: The variable or node names specified is expanded into a vector of model node names. A logical vector is returned, indicating whether each model node has been flagged as containing 'data'. Multivariate nodes for which any elements are flagged as containing 'data' will be assigned a value of TRUE.

isDeterm(nodes) Determines whether one or more nodes are deterministic

Arguments:
- nodes: A character vector specifying one or more node or variable names.
Details: The return value is a character vector with an element for each node indicated in the input. Note that variable names are expanded to their constituent node names, so the length of the output may be longer than that of the input.

isDiscrete(nodes) Determines whether one or more nodes represent discrete random variables

Arguments:
- nodes: A character vector specifying one or more node or variable names.
Details: The return value is a character vector with an element for each node indicated in the input. Note that variable names are expanded to their constituent node names, so the length of the output may be longer than that of the input.

isEndNode(nodes) Determines whether one or more nodes are end nodes (nodes with no stochastic dependences)

Arguments:
- nodes: A character vector specifying one or more node or variable names.
Details: The return value is logical vector with an element for each node indicated in the input. Note that variable names are expanded to their constituent node names, so the length of the output may be longer than that of the input.

isMultivariate(nodes) Determines whether one or more nodes represent multivariate nodes

Arguments:
- nodes: A character vector specifying one or more node or variable names.
Details: The return value is a logical vector with an element for each node indicated in the input. Note that variable names are expanded to their constituent node names, so the length of the output may be longer than that of the input.

isStoch(nodes) Determines whether one or more nodes are stochastic

Arguments:
- nodes: A character vector specifying one or more node or variable names.
Details: The return value is a character vector with an element for each node indicated in the input. Note that variable names are expanded to their constituent node names, so the length of the output may be longer than that of the input.

isTruncated(nodes) Determines whether one or more nodes are truncated

Arguments:
- nodes: A character vector specifying one or more node or variable names.

Details: The return value is a character vector with an element for each node indicated in the input. Note that variable names are expanded to their constituent nodes names, so the length of the output may be longer than that of the input

isUnivariate(nodes) Determines whether one or more nodes represent univariate random variables

Arguments:
- nodes: A character vector specifying one or more node or variable names.

Details: The return value is a character vector with an element for each node indicated in the input. Note that variable names are expanded to their constituent nodes names, so the length of the output may be longer than that of the input

newModel(data = NULL, inits = NULL, modelName = character(), replicate = FALSE, check = getNimbleOption("checkModel"), calculate = TRUE)

Returns a new R model object, with the same model definition (as defined from the original model code) as the existing model object.

Arguments:
- data: A named list specifying data nodes and values, for use in the newly returned model. If not provided, the data argument from the creation of the original R model object will be used.
- inits: A named list specifying initial values, for use in the newly returned model. If not provided, the inits argument from the creation of the original R model object will be used.
- modelName: An optional character string, used to set the internal name of the model object. If provided, this name will propagate throughout the generated C++ code, serving to improve readability.
- replicate: Logical specifying whether to replicate all current values and data flags from the current model in the new model. If TRUE, then the data and inits arguments are not used. Default value is FALSE.
- check: A logical indicating whether to check the model object for missing or invalid values. Default is given by the NIMBLE option 'checkModel', see help on 'nimbleOptions' for details.
- calculate: A logical indicating whether to run 'calculate' on the model; this will calculate all deterministic nodes and logProbability values given the current state of all nodes. Default is TRUE. For large models, one might want to disable this, but note that deterministic nodes, including nodes introduced into the model by NIMBLE, may be NA.

Details: The newly created model object will be identical to the original model in terms of structure and functionality, but entirely distinct in terms of the internal values.

resetData() Resets the 'data' property of ALL model nodes to FALSE. Subsequent to this call, the model will have no nodes flagged as 'data'.

setData(..., warnAboutMissingNames = TRUE) Sets the 'data' flag for specified nodes to TRUE, and also sets the value of these nodes to the value provided. This is the exclusive method for specifying 'data' nodes in a model object. When a 'data' argument is provided to 'nimbleModel()', it uses this method to set the data nodes.
Arguments:

Arguments may be provided as named elements with numeric values or as character names of model variables. These may be provided in a single list, a single character vector, or as multiple arguments. When a named element with a numeric value is provided, the size and dimension must match the corresponding model variable. This value will be copied to the model variable and any non-NA elements will be marked as data. When a character name is provided, the value of that variable in the model is not changed but any currently non-NA values are marked as data. Examples: `setData('x', y = 1:10)` will mark both x and y as data and will set the value of y to 1:10. `setData(list('x', y = 1:10))` is equivalent. `setData(c('x','y'))` or `setData('x','y')` will mark both x and y as data.

Details: If a provided value (or the current value in the model when only a name is specified) contains some NA values, then the model nodes corresponding to these NAs will not have their value set, and will not be designated as 'data'. Only model nodes corresponding to numeric values in the argument list elements will be designated as data. Designating a deterministic model node as 'data' will result in an error. Designating part of a multivariate node as 'data' and part as non-data (NA) is allowed, but 'isData()' will report such a node as being 'data', calculations with the node will generally return NA, and MCMC samplers will not be assigned to such nodes.

`setInits(inits)` Sets initial values (or more generally, any named list of value elements) into the model

Arguments:

inits: A named list. The names of list elements must correspond to model variable names. The elements of the list must be of class numeric, with size and dimension each matching the corresponding model variable.

`simulate(nodes, includeData = FALSE)` See 'help(simulate)'

`topologicallySortNodes(nodes, returnType = "names")` Sorts the input list of node names according to the topological dependence ordering of the model structure.

Arguments:

nodes: A character vector of node or variable names, which is to be topologically sorted. Alternatively can be a numeric vector of graphIDs

returnType: character vector indicating return type. Choices are "names" or "ids"

Details: This function merely reorders its input argument. This may be important prior to calls such as model$simulate(nodes) or model$calculate(nodes), to enforce that the operation is performed in topological order.

`initializeModel`

**Examples**

code <- nimbleCode(
  mu ~ dnorm(0, 1)
x[1] ~ dnorm(mu, 1)
x[2] ~ dnorm(mu, 1)
})
Rmodel <- nimbleModel(code)
modelVars <- Rmodel$getVarNames()  ## returns 'mu' and 'x'
modelNodes <- Rmodel$getNodeNames()  ## returns 'mu', 'x[1]' and 'x[2]'
Rmodel$resetData()
Rmodel$setData(list(x = c(1.2, NA)))  ## flags only 'x[1]' node as data
Rmodel$isData(c('mu', 'x[1]', 'x[2]'))  ## returns c(FALSE, TRUE, FALSE)

---

modelNameDefClass-class  
Class for NIMBLE model definition

Description

Class for NIMBLE model definition that is not usually needed directly by a user.

Details

See modelNameBaseClass for information about creating NIMBLE BUGS models.

---

modelNameInitialization  
Information on initial values in a NIMBLE model

Description

Having uninitialized nodes in a NIMBLE model can potentially cause some algorithms to fail and can lead to poor performance in others. Here are some general guidelines on how non-initialized variables can affect performance:

- MCMC will auto-initialize but will do so from the prior distribution. This can cause slow convergence, especially in the case of diffuse priors.
- Likewise, particle filtering methods will initialize top-level parameters from their prior distributions, which can lead to errors or poor performance in these methods.
**modelValues**  

Create a NIMBLE modelValues Object

**Description**  
Builds modelValues object from a model values configuration object, which can include a NIMBLE model

**Usage**  

```r
modelValues(conf, m = 1)
```

**Arguments**

- `conf` An object which includes information for building modelValues. Can either be a NIMBLE model (see `help(modelBaseClass)`) or the object returned from `modelValuesConf`
- `m` The number of rows to create in the modelValues object. Can later be changed with `resize`

**Details**

See the User Manual or `help(modelValuesBaseClass)` for information about manipulating NIMBLE modelValues object returned by this function

**Author(s)**

NIMBLE development team

**Examples**

```r
#From model object:
code <- nimbleCode({
  a ~ dnorm(0,1)
  for(i in 1:3){
    for(j in 1:3)
      b[i,j] ~ dnorm(0,1)
  }
})
Rmodel <- nimbleModel(code)
Rmodel_mv <- modelValues(Rmodel, m = 2)

#Custom modelValues object:
mvConf <- modelValuesConf(vars = c('x', 'y'),
                          types = c('double', 'int'),
                          sizes = list(x = 3, y = c(2,2)))
custom_mv <- modelValues(mvConf, m = 2)
custom_mv['y',]
```
modelValues are NIMBLE containers built to store values from models. They can either be built directly from a model or be custom built via the modelValuesConf function. They consist of rows, where each row can be thought of as a set of values from a model. Like most nimble objects, and unlike most R objects, they are passed by reference instead of by value.

See the User Manual for more details.

Examples

```r
mvConf <- modelValuesConf(vars = c('a', 'b'),
types = c('double', 'double'),
sizes = list(a = 1, b = c(2,2)))
mv <- modelValues(mvConf)
as.matrix(mv)
resize(mv, 2)
as.matrix(mv)
mv['a',1] <- 1
mv['a',2] <- 2
mv['b',1] <- matrix(0, nrow = 2, ncol = 2)
mv['b',2] <- matrix(1, nrow = 2, ncol = 2)
mv['a',]

as.matrix(mv)

basicModelCode <- nimbleCode(
  a ~ dnorm(0,1)
  for(i in 1:4)
    b[i] ~ dnorm(0,1)
)
basicModel <- nimbleModel(basicModelCode)
basicMV <- modelValues(basicModel, m = 2) # m sets the number of rows
basicMV['b',]
```

Description

Builds an R-based modelValues conf object
modelValuesConf

Usage

modelValuesConf(
    symTab,  
    className,  
    vars,  
    types,  
    sizes,  
    modelDef = NA,  
    where = globalenv()
)

Arguments

symTab            For internal use only
className         For internal use only
vars              A vector of character strings naming each variable in the modelValues object
types             A vector of character strings describing the type of data for the modelValues object. Options include 'double' (for real-valued variables) and 'int'.
sizes             A list in which the named items of the list match the var arguments and each item is a numeric vector of the dimensions
modelDef          For internal use only
where             For internal use only

Details

See the User Manual or help(modelValuesBaseClass) and help(modelValues) for information

Clifford Anderson-Bergman

Examples

#Custom modelValues object:
mvConf <- modelValuesConf(vars = c('x', 'y'),
                          types = c('double', 'int'),
                          sizes = list(x = 3, y = c(2,2)))
custom_mv <- modelValues(mvConf, m = 2)
custom_mv['y',]
model_macro_builder  EXPERIMENTAL: Turn a function into a model macro builder A model macro expands one line of code in a nimbleModel into one or more new lines. This supports compact programming by defining re-usable modules. model_macro_builder takes as input a function that constructs new lines of model code from the original line of code. It returns a function suitable for internal use by nimbleModel that arranges arguments for input function. Macros are an experimental feature and are available only after setting nimbleOptions(enableModelMacros = TRUE).

Description

EXPERIMENTAL: Turn a function into a model macro builder A model macro expands one line of code in a nimbleModel into one or more new lines. This supports compact programming by defining re-usable modules. model_macro_builder takes as input a function that constructs new lines of model code from the original line of code. It returns a function suitable for internal use by nimbleModel that arranges arguments for input function. Macros are an experimental feature and are available only after setting nimbleOptions(enableModelMacros = TRUE).

Usage

model_macro_builder(fun, use3pieces = TRUE, unpackArgs = TRUE)

Arguments

fun  A function written to construct new lines of model code.

use3pieces  (TRUE or FALSE) Should the arguments from the input line be split into pieces for the LHS (left-hand side), RHS (right-hand side, possibly further split depending on unpackArgs), and stoch (TRUE if the line uses a ~, FALSE otherwise)? See details and examples.

unpackArgs  (TRUE or FALSE) Should arguments be passed as a list (FALSE) or as separate arguments (TRUE)? See details and examples.

Details

The arguments use3pieces and unpackArgs indicate how fun expects to have arguments arranged from an input line of code (processed by nimbleModel).

Consider the defaults use3pieces = TRUE and unpackArgs = TRUE, for a macro called macro1. In this case, the line of model code x ~ macro1(arg1 = z[1:10], arg2 = "hello") will be passed to fun as fun(stoch = TRUE, LHS = x, arg1 = z[1:10], arg2 = "hello").

If use3pieces = TRUE but unpackArgs = FALSE, then the RHS will be passed as is, without unpacking its arguments into separate arguments to fun. In this case, x ~ macro1(arg1 = z[1:10], arg2 = "hello") will be passed to fun as fun(stoch = TRUE, LHS = x, RHS = macro1(arg1 = z[1:10], arg2 = "hello")).
If `use3pieces = FALSE` and `unpackArgs = FALSE`, the entire line of code is passed as a single object. In this case, `x ~ macro1(arg1 = z[1:10], arg2 = "hello")` will be passed to `fun` as `fun(x ~ macro1(arg1 = z[1:10], arg2 = "hello")).` It is also possible in this case to pass a macro without using `~` or `<-`. For example, the line `macro1(arg1 = z[1:10], arg2 = "hello")` will be passed to `fun` as `fun(macro1(arg1 = z[1:10], arg2 = "hello")).`

If `use3pieces = FALSE` and `unpackArgs = TRUE`, it won't make sense to anticipate a declaration using `~` or `<-`. Instead, arguments from an arbitrary call will be passed as separate arguments. For example, the line `macro1(arg1 = z[1:10], arg2 = "hello")` will be passed to `fun` as `fun(arg1 = z[1:10], arg2 = "hello").`

It is extremely useful to be familiar with processing R code as an object to write `fun` correctly. Functions such as `substitute` and `as.name` (e.g. `as.name(~`) and `quote`, `parse` and `deparse` are particularly handy.

Multiple lines of new code should be contained in `{}`. Extra curly braces are not a problem. See example 2.

Macro expansion is done recursively: One macro can return code that invokes another macro.

### Value

A list with a named element `code` that contains the replacement code.

### Examples

```r
nimbleOptions(enableModelMacros = TRUE)
nimbleOptions(verbose = FALSE)

## Example 1: Say one is tired of writing "for" loops.
## This macro will generate a "for" loop with dnorm declarations
all_dnorm <- model_macro_builder(
  function(stoch, LHS, RHSvar, start, end, sd = 1) {
    newCode <- substitute(
      for(i in START:END) {
        LHS[i] ~ dnorm(RHSvar[i], SD)
      },
      list(START = start,
           END = end,
           LHS = LHS,
           RHSvar = RHSvar,
           SD = sd))
    list(code = newCode)
  },
  use3pieces = TRUE,
  unpackArgs = TRUE
)

model1 <- nimbleModel(
  nimbleCode(
    {
      ## Create a "for" loop of dnorm declarations by invoking the macro
      x ~ all_dnorm(mu, start = 1, end = 10)
    })
  )
```
The Multinomial Distribution
**Multinomial**

**Description**
Density and random generation for the multinomial distribution

**Usage**

```r
dmulti(x, size = sum(x), prob, log = FALSE)
rmulti(n = 1, size, prob)
```

**Arguments**
- `x`: vector of values.
- `size`: number of trials.
- `prob`: vector of probabilities, internally normalized to sum to one, of same length as `x`.
- `log`: logical; if TRUE, probability density is returned on the log scale.
- `n`: number of observations (only `n=1` is handled currently).

**Details**
See Gelman et al., Appendix A or the BUGS manual for mathematical details.

**Value**
`dmulti` gives the density and `rmulti` generates random deviates.

**Author(s)**
Christopher Paciorek

**References**

**See Also**
- Distributions for other standard distributions

**Examples**
```r
size <- 30
probs <- c(1/4, 1/10, 1 - 1/4 - 1/10)
x <- rmulti(1, size, probs)
dmulti(x, size, probs)
```
The Multivariate t Distribution

Description

Density and random generation for the multivariate t distribution, using the Cholesky factor of either the precision matrix (i.e., inverse scale matrix) or the scale matrix.

Usage

```r
dmvt_chol(x, mu, cholesky, df, prec_param = TRUE, log = FALSE)
```

```r
rmvt_chol(n = 1, mu, cholesky, df, prec_param = TRUE)
```

Arguments

- `x`: vector of values.
- `mu`: vector of values giving the location of the distribution.
- `cholesky`: upper-triangular Cholesky factor of either the precision matrix (i.e., inverse scale matrix) (when `prec_param` is TRUE) or scale matrix (otherwise).
- `df`: degrees of freedom.
- `prec_param`: logical; if TRUE the Cholesky factor is that of the precision matrix; otherwise, of the scale matrix.
- `log`: logical; if TRUE, probability density is returned on the log scale.
- `n`: number of observations (only n=1 is handled currently).

Details

See Gelman et al., Appendix A or the BUGS manual for mathematical details. The 'precision' matrix as used here is defined as the inverse of the scale matrix, $\Sigma^{-1}$, given in Gelman et al.

Value

`dmvt_chol` gives the density and `rmvt_chol` generates random deviates.

Examples

\[
\begin{align*}
\text{mu} & \leftarrow \text{c}(-10, 0, 10) \\
\text{scalemat} & \leftarrow \text{matrix(c(1, .9, .3, .9, 1, -0.1, .3, -0.1, 1), 3)} \\
\text{ch} & \leftarrow \text{chol(scalemat)} \\
x & \leftarrow \text{rmvt.chol}(1, \text{mu}, \text{ch}, \text{df} = 1, \text{prec.param} = \text{FALSE}) \\
x & \leftarrow \text{dmvt.chol}(x, \text{mu}, \text{ch}, \text{df} = 1, \text{prec.param} = \text{FALSE})
\end{align*}
\]

MultivariateNormal

The Multivariate Normal Distribution

Description

Density and random generation for the multivariate normal distribution, using the Cholesky factor of either the precision matrix or the covariance matrix.

Usage

\[
\begin{align*}
dmnorm.chol(x, \text{mean}, \text{cholesky}, \text{prec.param} = \text{TRUE}, \text{log} = \text{FALSE}) \\
rmnorm.chol(n = 1, \text{mean}, \text{cholesky}, \text{prec.param} = \text{TRUE})
\end{align*}
\]

Arguments

- \text{x} \quad \text{vector of values.}
- \text{mean} \quad \text{vector of values giving the mean of the distribution.}
- \text{cholesky} \quad \text{upper-triangular Cholesky factor of either the precision matrix (when \text{prec.param} is \text{TRUE}) or covariance matrix (otherwise).}
- \text{prec.param} \quad \text{logical; if \text{TRUE} the Cholesky factor is that of the precision matrix; otherwise, of the covariance matrix.}
- \text{log} \quad \text{logical; if \text{TRUE}, probability density is returned on the log scale.}
- \text{n} \quad \text{number of observations (only n=1 is handled currently).}

Details

See Gelman et al., Appendix A or the BUGS manual for mathematical details. The rate matrix as used here is defined as the inverse of the scale matrix, \( S^{-1} \), given in Gelman et al.

Value

\( \text{dmnorm.chol} \) gives the density and \( \text{rmnorm.chol} \) generates random deviates.

mean <- c(-10, 0, 10)
covmat <- matrix(c(1, .9, .3, .9, 1, -0.1, .3, -0.1, 1), 3)
ch <- chol(covmat)
x <- rmnorm_chol(1, mean, ch, prec_param = FALSE)
dmnorm_chol(x, mean, ch, prec_param = FALSE)
```

nfMethod

**access (call) a member function of a nimbleFunction**

Description

Internal function for accessing a member function (method) of a nimbleFunction. Normally a user will write `nf$method(x)` instead of `nfMethod(nf, method)(x)`.

Usage

```r
nfMethod(nf, methodName)
```

Arguments

- **nf**: a specialized nimbleFunction, i.e. one that has already had setup parameters processed
- **methodName**: a character string giving the name of the member function to call

Details

nimbleFunctions have a default member function called `run`, and may have other member functions provided via the `methods` argument to `nimbleFunction`. As an internal step, the NIMBLE compiler turns `nf$method(x)` into `nfMethod(nf, method)(x)`, but a NIMBLE user or programmer would not normally need to use `nfMethod` directly.

Value

a function that can be called.

Author(s)

NIMBLE development team
nfVar

Access or set a member variable of a nimbleFunction

Description

Access or set a member variable of a specialized nimbleFunction, i.e. a variable passed to or created during the setup function that is used in run code or preserved by setupOutputs. Works in R for any variable and in NIMBLE for numeric variables.

Usage

nfVar(nf, varName)

nfVar(nf, varName) <- value

Arguments

nf
  a specialized nimbleFunction, i.e. a function returned by executing a function returned from nimbleFunction with setup arguments

varName
  a character string naming a variable in the setup function.

value
  value to set the variable to.

Details

Internal way to access or set a member variable of a nimbleFunction created during setup. Normally in NIMBLE code you would use nf$var instead of nfVar(nf, var).

When nimbleFunction is called and a setup function is provided, then nimbleFunction returns a function. That function is a generator that should be called with arguments to the setup function and returns another function with run and possibly other member functions. The member functions can use objects created or passed to setup. During internal processing, the NIMBLE compiler turns some cases of nf$var into nfVar(nf, var). These provide direct access to setup variables (member data). nfVar is not typically called by a NIMBLE user or programmer.

For internal access to methods of nf, see nfMethod.

For more information, see ?nimbleFunction and the NIMBLE User Manual.

Value

whatever varName is in the nimbleFunction nf.

Author(s)

NIMBLE development team
Examples

```r
nfGen1 <- nimbleFunction(
  setup = function(A) {
    B <- matrix(rnorm(4), nrow = 2)
    setupOutputs(B) ## preserves B even though it is not used in run-code
  },
  run = function() {
    print('This is A', A, '\n')
  })

nfGen2 <- nimbleFunction(
  setup = function() {
    nf1 <- nfGen1(1000)
  },
  run = function() {
    print('accessing A:', nfVar(nf1, 'A'))
    nfVar(nf1, 'B')[2,2] <<- -1000
    print('accessing B:', nfVar(nf1, 'B'))
  })

nf2 <- nfGen2()
nf2$run()
```

Description

A system for writing hierarchical statistical models largely compatible with BUGS and JAGS, writing nimbleFunctions to operate models and do basic R-style math, and compiling both models and nimbleFunctions via custom-generated C++. NIMBLE includes default methods for MCMC, Monte Carlo Expectation Maximization, and some other tools. The nimbleFunction system makes it easy to do things like implement new MCMC samplers from R, customize the assignment of samplers to different parts of a model from R, and compile the new samplers automatically via C++ alongside the samplers NIMBLE provides. NIMBLE extends the BUGS/JAGS language by making it extensible: New distributions and functions can be added, including as calls to external compiled code. Although most people think of MCMC as the main goal of the BUGS/JAGS language for writing models, one can use NIMBLE for writing arbitrary other kinds of model-generic algorithms as well. A full User Manual is available at [https://r-nimble.org/html_manual/cha-welcome-nimble.html](https://r-nimble.org/html_manual/cha-welcome-nimble.html).
**Description**

Functions and classes used internally in NIMBLE and not expected to be called directly by users. Some functions and classes not intended for direct use are documented and/or exported because they are used within Reference Class methods for classes programmatically generated by NIMBLE.

nimble-math

*Mathematical functions for BUGS and nimbleFunction programming*

**Description**

Mathematical functions for use in BUGS code and in nimbleFunction programming (i.e., nimble-Function run code). See Chapter 5 of the User Manual for more details.

**Author(s)**

NIMBLE Development Team

---

nimble-R-functions

*NIMBLE language functions for R-like vector construction*

**Description**

The functions `c`, `rep`, `seq`, `which`, `diag`, `length`, `seq_along`, `is.na`, `is.nan`, `any`, and `all` can be used in nimbleFunctions and compiled using `compileNimble`.

**Usage**

```r
nimC(...)
nimRep(x, ...)
nimSeq(from, to, by, length.out)
```

**Arguments**

- `...` values to be concatenated.
- `x` vector of values to be replicated (`rep`), or logical array or vector (`which`), or object whose length is wanted (`length`), or input value (`diag`), or vector of values to be tested/checked (`is.na`, `is.nan`, `any`, `all`).
- `from` starting value of sequence.
- `to` end value of sequence.
- `by` increment of the sequence.
- `length.out` desired length of the sequence.
Details

For `c`, `rep`, `seq`, these functions are NIMBLE’s version of similar R functions, e.g., `nimRep` for `rep`. In a `nimbleFunction`, either the R name (e.g., `rep`) or the NIMBLE name (e.g., `nimRep`) can be used. If the R name is used, it will be converted to the NIMBLE name. For which, `length`, `diag`, `seq_along`, `is.na`, `is.nan`, `any`, `all`, all simply use the standard name without "nim". These functions largely mimic (see exceptions below) the behavior of their R counterparts, but they can be compiled in a `nimbleFunction` using `compileNimble`.

`nimC` is NIMBLE’s version of `c` and behaves identically.

`nimRep` is NIMBLE’s version of `rep`. It should behave identically to `rep`. There are no NIMBLE versions of `rep.int` or `rep_len`.

`nimSeq` is NIMBLE’s version of `seq`. It behaves like `seq` with support for `from`, `to`, `by` and `length.out` arguments. The `along.with` argument is not supported. There are no NIMBLE versions of `seq.int`, `seq_along` or `seq_len`, with the exception that `seq_along` can take a `nimbleFunctionList` as an argument to provide the index range of a for-loop (User Manual Ch. 13).

which behaves like the R version but without support for `arr.ind` or `useNames` arguments.

diag behaves like the R version but without support for the `nrow` and `ncol` arguments.

`length` behaves like the R version.

`seq_along` behaves like the R version.

`is.na` behaves like the R version but does not correctly handle NA values from R that are type 'logical', so convert these using `as.numeric()` before passing from R to NIMBLE.

`is.nan` behaves like the R version, but treats NA of type 'double' as being NaN and NA of type 'logical' as not being NaN.

any behaves like the R version but takes only one argument and treats NAs as FALSE.

all behaves like the R version but takes only one argument and treats NAs as FALSE.

nimbleCode  

Turn BUGS model code into an object for use in nimbleModel or readBUGSmodel

Description

Simply keeps model code as an R call object, the form needed by `nimbleModel` and optionally usable by `readBUGSmodel`.

Usage

```r
nimbleCode(code)
```

Arguments

code expression providing the code for the model
Details

It is equivalent to use the R function `quote`. `nimbleCode` is simply provided as a more readable alternative for NIMBLE users not familiar with `quote`.

Author(s)

Daniel Turek

Examples

```r
code <- nimbleCode({
  x ~ dnorm(mu, sd = 1)
  mu ~ dnorm(0, sd = prior_sd)
})
```

nimbleExternalCall

Create a `nimbleFunction` that wraps a call to external compiled code

Description

Given C header information, a function that takes scalars or pointers can be called from a compiled `nimbleFunction`. If non-scalar return values are needed, an argument can be selected to behave as the return value in `nimble`.

Usage

```r
nimbleExternalCall(
  prototype,
  returnType,
  Cfun,
  headerFile,
  oFile,
  where = getNimbleFunctionEnvironment()
)
```

Arguments

- `prototype`: Argument type information. This can be provided as an R function using `nimbleFunction` type declarations or as a list of `nimbleType` objects.
- `returnType`: Return object type information. This can be provided similarly to `prototype` as either a `nimbleFunction` type declaration or as a `nimbleType` object. In the latter case, the name will be ignored. If there is no return value, this should be `void()`.
- `Cfun`: Name of the external function (character).
- `headerFile`: Name (possibly including file path) of the header file where `Cfun` is declared.
nimbleExternalCall

**Details**

The only argument types allowed in Cfun are double, int, and bool, corresponding to `nimbleFunction` types double, integer, and logical, respectively.

If the dimensionality is greater than zero, the arguments in Cfun should be pointers. This means it will typically be necessary to pass additional integer arguments telling Cfun the size(s) of non-scalar arguments.

The return argument can only be a scalar or void. Since non-scalar arguments are passed by pointer, you can use an argument to return results from Cfun. If you wish to have a `nimbleFunction` that uses one argument of Cfun as a return object, you can wrap the result of `nimbleExternalCall` in another `nimbleFunction` that allocates the return object. This is useful for using Cfun in a `nimbleModel`. See example below.

Note that a `nimbleExternalCall` can only be executed in a compiled `nimbleFunction`, not an uncompiled one.

If you have problems with spaces in file paths (e.g. for `oFile`), try compiling everything locally by including `dirName = "."` as an argument to `compileNimble`.

**Value**

A `nimbleFunction` that takes the indicated input arguments, calls Cfun, and returns the result.

**Author(s)**

Perry de Valpine

**See Also**

`nimbleRcall` for calling arbitrary R code from compiled `nimbleFunctions`.

**Examples**

```r
## Not run:
sink("/quotesingle.Varadd1.h")
cat('extern "C" {
    void my_internal_function(double *p, double*ans, int n);
}
')
sink()
sink("/quotesingle.Varadd1.cpp")
cat('
#include <cstdio>
```
#include "add1.h"

void my_internal_function(double *p, double *ans, int n) {
    printf("In my_internal_function\n");
    /* cat reduces the double slash to single slash */
    for(int i = 0; i < n; i++)
        ans[i] = p[i] + 1.0;
}

Radd1 <- nimbleExternalCall(function(x = double(1), ans = double(1),
    n = integer()){}, Cfun = 'my_internal_function',
    headerFile = file.path(getwd(), 'add1.h'), returnType = void(),
    oFile = file.path(getwd(), 'add1.o'))

## If you need to use a function with non-scalar return object in model code,
## you can wrap it in another nimbleFunction like this:
model_add1 <- nimbleFunction(
    run = function(x = double(1)) {
        ans <- numeric(length(x))
        Radd1(x, ans, length(x))
        return(ans)
        returnType(double(1))
    })

demoCode <- nimbleCode(
    for(i in 1:4) {x[i] ~ dnorm(0,1)} ## just to get a vector
    y[1:4] <- model_add1(x[1:4])
)

demoModel <- nimbleModel(demoCode, inits = list(x = rnorm(4)),
    check = FALSE, calculate = FALSE)
CdemoModel <- compileNimble(demoModel, showCompilerOutput = TRUE)

## End(Not run)
name = NA,
    check = getNimbleOption("checkNimbleFunction"),
    where = getNimbleFunctionEnvironment()
)

Arguments

setup  An optional R function definition for setup processing.
run    An optional NIMBLE function definition that executes the primary job of the
       nimbleFunction
methods An optional named list of NIMBLE function definitions for other class methods.
globalSetup For internal use only
contains An optional object returned from nimbleFunctionVirtual that defines argu-
          ments and returnType for run and/or methods, to which the current nimble-
          Function must conform
enableDerivs EXPERIMENTAL A list of names of function methods to enable derivatives for.
            Currently only for developer use.
name    An optional name used internally, for example in generated C++ code. Usually
        this is left blank and NIMBLE provides a name.
check   Boolean indicating whether to check the run code for function calls that NIM-
        BLE cannot compile. Checking can be turned off for all calls to nimbleFunction
        using nimbleOptions(checkNimbleFunction = FALSE).
where   An optional where argument passed to setRefClass for where the reference
        class definition generated for this nimbleFunction will be stored. This is needed
        due to R package namespace issues but should never need to be provided by a
        user.

Details

This is the main function for defining nimbleFunctions. A lot of information is provided in the
NIMBLE User Manual, so only a brief summary will be given here.

If a setup function is provided, then nimbleFunction returns a generator: a function that when
called with arguments for the setup function will execute that function and return a specialized
nimbleFunction. The run and other methods can be called using $ like in other R classes, e.g.
in$run(). The methods can use objects that were created in or passed to the setup function.

If no setup function is provided, then nimbleFunction returns a function that executes the run
function. It is not a generator in this case, and no other methods can be provided.

If one wants a generator but does not need any setup arguments or code, setup = TRUE can be used.

See the NIMBLE User Manual for examples.

For more information about the contains argument, see the section on nimbleFunctionLists.

NIMBLE development team
Class nimbleFunctionBase

Description

Classes used internally in NIMBLE and not expected to be called directly by users.

Create a list of nimbleFunctions

Description

Create an empty list of nimbleFunctions that all will inherit from a base class.

Details

See the User Manual for information about creating and populating a nimbleFunctionList.

Author(s)

NIMBLE development team

create a virtual nimbleFunction, a base class for other nimbleFunctions

Description

define argument types and returnType for the run function and any methods, to be used in the contains argument of nimbleFunction

Usage

nimbleFunctionVirtual(
    contains = NULL,
    run = function() { },
    methods = list(),
    name = NA
)
Arguments

contains  Not yet functional
run  A NIMBLE function that will only be used to inspect its argument types and returnType.
methods  An optional named list of NIMBLE functions that will also only be used for inspecting argument types and returnTypes.
name  An optional name used internally by the NIMBLE compiled. This is usually omitted and NIMBLE provides one.

Details

See the NIMBLE User Manual section on nimbleFunctionLists for explanation of how to use a virtual nimbleFunction.

Value

An object that can be passed as the contains argument to nimbleFunction or as the argument to nimbleFunctionList

Author(s)

NIMBLE development team

See Also

nimbleFunction

nimbleList  create a nimbleList

Description

create a nimbleList from a nimbleList definition

Usage

nimbleList(
    ..., 
    name = NA, 
    predefined = FALSE, 
    where = getNimbleFunctionEnvironment()
)
Arguments

... arbitrary set of names and types for the elements of the list or a single R list of type `nimbleType`.

name optional character providing a name used internally, for example in generated C++ code. Usually this is left blank and NIMBLE provides a name.

predefined logical for internal use only.

where optional argument passed to `setRefClass` for where the reference class definition generated for this nimbleFunction will be stored. This is needed due to R package namespace issues but should never need to be provided by a user.

Details

This function creates a definition for a nimbleList. The `types` argument defines the names, types, and dimensions of the elements of the nimbleList. Elements of nimbleLists can be either basic types (e.g., `integer`, `double`) or other nimbleList definitions. The `types` argument can be either a series of expressions of the form `name = type(dim)`, or a list of `nimbleType` objects.

nimbleList returns a definition, which can be used to create instances of this type of nimbleList via the `new()` member function.

Definitions can be created in R’s general environment or in nimbleFunction setup code. Instances can be created using the `new()` function in R’s global environment, in nimbleFunction setup code, or in nimbleFunction run code.

Instances of `nimbleList` definitions can be used as arguments to run code of nimbleFunctions, and as the return type of nimbleFunctions.

Author(s)

NIMBLE development team

Examples

eexampleNimListDef <- nimbleList(x = integer(0), Y = double(2))
nimbleListTypes <- list(nimbleType(name = 'x', type = 'integer', dim = 0),
                       nimbleType(name = 'Y', type = 'double', dim = 2))

## this nimbleList definition is identical to the one created above
exampleNimListDef <- nimbleList(nimbleListTypes)

nimbleMCMC

Executes one or more chains of NIMBLE’s default MCMC algorithm, for a model specified using BUGS code
Description

nimbleMCMC is designed as the most straightforward entry point to using NIMBLE’s default MCMC algorithm. It provides capability for running multiple MCMC chains, specifying the number of MCMC iterations, thinning, and burn-in, and which model variables should be monitored. It also provides options to return the posterior samples, to return summary statistics calculated from the posterior samples, and to return a WAIC value.

Usage

nimbleMCMC(
  code,
  constants = list(),
  data = list(),
  inits,
  dimensions = list(),
  model,
  monitors,
  thin = 1,
  niter = 10000,
  nburnin = 0,
  nchains = 1,
  check = TRUE,
  setSeed = FALSE,
  progressBar = getNimbleOption("MCMCprogressBar"),
  samples = TRUE,
  samplesAsCodaMCMC = FALSE,
  summary = FALSE,
  WAIC = FALSE
)

Arguments

code: The quoted code expression representing the model, such as the return value from a call to nimbleCode). Not required if model is provided.

constants: Named list of constants in the model. Constants cannot be subsequently modified. For compatibility with JAGS and BUGS, one can include data values with constants and nimbleModel will automatically distinguish them based on what appears on the left-hand side of expressions in code.

data: Named list of values for the data nodes. Data values can be subsequently modified. Providing this argument also flags nodes as having data for purposes of algorithms that inspect model structure. Values that are NA will not be flagged as data.

inits: Argument to specify initial values for the model object, and for each MCMC chain. See details.

dimensions: Named list of dimensions for variables. Only needed for variables used with empty indices in model code that are not provided in constants or data.
model  A compiled or uncompiled NIMBLE model object. When provided, this model will be used to configure the MCMC algorithm to be executed, rather than using the code, constants, data and inits arguments to create a new model object. However, if also provided, the inits argument will still be used to initialize this model prior to running each MCMC chain.

monitors  A character vector giving the node names or variable names to monitor. The samples corresponding to these nodes will returned, and/or will have summary statistics calculated. Default value is all top-level stochastic nodes of the model.

thin  Thinning interval for collecting MCMC samples. Thinning occurs after the initial nburnin samples are discarded. Default value is 1.

niter  Number of MCMC iterations to run. Default value is 10000.

nburnin  Number of initial, pre-thinning, MCMC iterations to discard. Default value is 0.

nchains  Number of MCMC chains to run. Default value is 1.

check  Logical argument, specifying whether to check the model object for missing or invalid values. Default value is TRUE.

setSeed  Logical or numeric argument. If a single numeric value is provided, R’s random number seed will be set to this value at the onset of each MCMC chain. If a numeric vector of length nchains is provided, then each element of this vector is provided as R’s random number seed at the onset of the corresponding MCMC chain. Otherwise, in the case of a logical value, if TRUE, then R’s random number seed for the ith chain is set to be i, at the onset of each MCMC chain. Note that specifying the argument setSeed = 0 does not prevent setting the RNG seed, but rather sets the random number generation seed to 0 at the beginning of each MCMC chain. Default value is FALSE.

progressBar  Logical argument. If TRUE, an MCMC progress bar is displayed during execution of each MCMC chain. Default value is defined by the nimble package option MCMCprogressBar.

samples  Logical argument. If TRUE, then posterior samples are returned from each MCMC chain. These samples are optionally returned as coda mcmc objects, depending on the samplesAsCodaMCMC argument. Default value is TRUE. See details.

samplesAsCodaMCMC  Logical argument. If TRUE, then a coda mcmc object is returned instead of an R matrix of samples, or when nchains > 1 a coda mcmc.list object is returned containing nchains mcmc objects. This argument is only used when samples is TRUE. Default value is FALSE. See details.

summary  Logical argument. When TRUE, summary statistics for the posterior samples of each parameter are also returned, for each MCMC chain. This may be returned in addition to the posterior samples themselves. Default value is FALSE. See details.

WAIC  Logical argument. When TRUE, the WAIC (Watanabe, 2010) of the model is calculated and returned. If multiple chains are run, then a single WAIC value is calculated using the posterior samples from all chains. Default value is FALSE. Note that the version of WAIC used is the default WAIC conditional on random effects/latent states and without any grouping of data nodes. See help(waic) for more details. If a different version of WAIC is desired, use runMCMC instead of nimbleMCMC.
Details

The entry point for this function is providing the code, constants, data and inits arguments, to create a new NIMBLE model object, or alternatively providing an existing NIMBLE model object as the model argument.

At least one of samples, summary or WAIC must be TRUE, since otherwise, nothing will be returned. Any combination of these may be TRUE, including possibly all three, in which case posterior samples, summary statistics, and WAIC values are returned for each MCMC chain.

When samples = TRUE, the form of the posterior samples is determined by the samplesAsCodaMCMC argument, as either matrices of posterior samples, or coda mcmc and mcmc.list objects.

Posterior summary statistics are returned individually for each chain, and also as calculated from all chains combined (when nchains > 1).

The inits argument can be one of three things:

(1) a function to generate initial values, which will be executed once to initialize the model object, and once to generate initial values at the beginning of each MCMC chain, or
(2) a single named list of initial values which will be used to initialize the model object and for each MCMC chain, or
(3) a list of length nchains, each element being a named list of initial values. The first element will be used to initialize the model object, and once element of the list will be used for each MCMC chain.

The inits argument may also be omitted, in which case the model will not be provided with initial values. This is not recommended.

The niter argument specifies the number of pre-thinning MCMC iterations, and the nburnin argument specifies the number of pre-thinning MCMC samples to discard. After discarding these burn-in samples, thinning of the remaining samples will take place. The total number of posterior samples returned will be floor((niter-nburnin)/thin).

Value

A list is returned with named elements depending on the arguments passed to nimbleMCMC, unless only one among samples, summary, and WAIC are requested, in which case only that element is returned. These elements may include samples, summary, and WAIC. When nchains = 1, posterior samples are returned as a single matrix, and summary statistics as a single matrix. When nchains > 1, posterior samples are returned as a list of matrices, one matrix for each chain, and summary statistics are returned as a list containing nchains+1 matrices: one matrix corresponding to each chain, and the final element providing a summary of all chains, combined. If samplesAsCodaMCMC is TRUE, then posterior samples are provided as coda mcmc and mcmc.list objects. When WAIC is TRUE, a WAIC summary object is returned.

configureMCMC buildMCMC runMCMC
Examples

```r
## Not run:
code <- nimbleCode({
  mu ~ dnorm(0, sd = 1000)
  sigma ~ dunif(0, 1000)
  for(i in 1:10) {
    x[i] ~ dnorm(mu, sd = sigma)
  }
})
data <- list(x = c(2, 5, 3, 4, 1, 0, 1, 3, 5, 3))
inits <- function() list(mu = rnorm(1,0,1), sigma = runif(1,0,10))
mcmc.output <- nimbleMCMC(code, data = data, inits = inits,
  monitors = c("mu", "sigma"), thin = 10,
  niter = 20000, nburnin = 1000, nchains = 3,
  summary = TRUE, WAIC = TRUE)

## End(Not run)
```

### Description

processes BUGS model code and optional constants, data, and initial values. Returns a NIMBLE model (see `modelBaseClass`) or model definition.

### Usage

```r
nimbleModel(
  code,
  constants = list(),
  data = list(),
  inits = list(),
  dimensions = list(),
  returnDef = FALSE,
  where = globalenv(),
  debug = FALSE,
  check = getNimbleOption("checkModel"),
  calculate = TRUE,
  name = NULL,
  userEnv = parent.frame()
)
```
nimbleModel

Arguments

code  code for the model in the form returned by nimbleCode or (equivalently) quote

constants named list of constants in the model. For compatibility with JAGS and BUGS, one can include data values with constants and nimbleModel will automatically distinguish them based on what appears on the left-hand side of expressions in code.

data  named list of values for the data nodes. Data values can be subsequently modified. Providing this argument also flags nodes as having data for purposes of algorithms that inspect model structure. Values that are NA will not be flagged as data.

inits  named list of starting values for model variables. Unlike JAGS, should only be a single list, not a list of lists.

dimensions  named list of dimensions for variables. Only needed for variables used with empty indices in model code that are not provided in constants or data.

returnDef  logical indicating whether the model should be returned (FALSE) or just the model definition (TRUE).

where  argument passed to setRefClass, indicating the environment in which the reference class definitions generated for the model and its modelValues should be created. This is needed for managing package namespace issues during package loading and does not normally need to be provided by a user.

debug  logical indicating whether to put the user in a browser for debugging. Intended for developer use.

check  logical indicating whether to check the model object for missing or invalid values. Default is given by the NIMBLE option 'checkModel'. See nimbleOptions for details.

calculate  logical indicating whether to run calculate on the model after building it; this will calculate all deterministic nodes and logProbability values given the current state of all nodes. Default is TRUE. For large models, one might want to disable this, but note that deterministic nodes, including nodes introduced into the model by NIMBLE, may be NA.

name  optional character vector giving a name of the model for internal use. If omitted, a name will be provided.

userEnv  environment in which if-then-else statements in BUGS code will be evaluated if needed information not found in constants; intended primarily for internal use only

Details

See the User Manual or help(modelBaseClass) for information about manipulating NIMBLE models created by nimbleModel, including methods that operate on models, such as getDependencies.

The user may need to provide dimensions for certain variables as in some cases NIMBLE cannot automatically determine the dimensions and sizes of variables. See the User Manual for more information.
As noted above, one may lump together constants and data (as part of the constants argument (unlike R interfaces to JAGS and BUGS where they are provided as the data argument). One may not provide lumped constants and data as the data argument.

For variables that are a mixture of data nodes and non-data nodes, any values passed in via inits for components of the variable that are data will be ignored. All data values should be passed in through data (or constants as just discussed).

readBUGSmodel for creating models from BUGS-format model files

Examples

code <- nimbleCode({
  x ~ dnorm(mu, sd = 1)
  mu ~ dnorm(0, sd = prior_sd)
})
costants = list(prior_sd = 1)
data = list(x = 4)
Rmodel <- nimbleModel(code, constants = constants, data = data)

nimbleOptions

NIMBLE Options Settings

Description

Allow the user to set and examine a variety of global _options_ that affect the way in which NIMBLE operates. Call nimbleOptions() with no arguments to see a list of available options.

Usage

nimbleOptions(...)

Arguments

... any options to be defined as one or more name = value pairs or as a single list of name=value pairs.

Details

nimbleOptions mimics options. Invoking nimbleOptions() with no arguments returns a list with the current values of the options. To access the value of a single option, one should use getNimbleOption().
Value

When invoked with no arguments, returns a list with the current values of all options. When invoked with one or more arguments, returns a list of the the updated options with their updated values.

Author(s)

Christopher Paciorek

Examples

# Set one option:
nimbleOptions(verifyConjugatePosteriors = FALSE)

# Compactly print all options:
str(nimbleOptions(), max.level = 1)

# Save-and-restore options:
old <- nimbleOptions()  # Saves old options.
nimbleOptions(showCompilerOutput = TRUE,
               verboseErrors = TRUE)  # Sets temporary options.
# ...do stuff...
nimbleOptions(old)  # Restores old options.

---

nimbleRcall  Make an R function callable from compiled nimbleFunctions (including nimbleModels).

Description

Normally compiled nimbleFunctions call other compiled nimbleFunctions. nimbleRcall enables any R function (with viable argument types and return values) to be called (and evaluated in R) from compiled nimbleFunctions.

Usage

nimbleRcall(
  prototype,
  returnType,
  Rfun,
  where = getNimbleFunctionEnvironment()
)

Arguments

prototype  Argument type information for Rfun. This can be provided as an R function using nimbleFunction type declarations or as a list of nimbleType objects.
nimbleRcall

**ReturnType**   Return object type information. This can be provided similarly to prototype as either a nimbleFunction type declaration or as a nimbleType object. In the latter case, the name will be ignored. If there is no return value this should be void().

**Rfun**   The name of an R function to be called from compiled nimbleFunctions.

**where**   An optional where argument passed to setRefClass for where the reference class definition generated for this nimbleFunction will be stored. This is needed due to R package namespace issues but should never need to be provided by a user.

**Details**

The nimbleFunction returned by nimbleRcall can be used in other nimbleFunctions. When called from a compiled nimbleFunction (including from a model), arguments will be copied according to the declared types, the function named by Rfun will be called, and the returned object will be copied if necessary. The example below shows use of an R function in a compiled nimbleModel. A nimbleFunction returned by nimbleRcall can only be used in a compiled nimbleFunction. Rfun itself should work in an uncompiled nimbleFunction.

**Value**

A nimbleFunction that wraps a call to Rfun with type-declared arguments and return object.

**Author(s)**

Perry de Valpine

**See Also**

nimbleExternalCall for calling externally provided C (or other) compiled code.

**Examples**

```r
## Not run:
## Say we want an R function that adds 2 to every value in a vector
add2 <- function(x) {
  x + 2
}
Radd2 <- nimbleRcall(function(x = double(1)){}, Rfun = 'add2',
                      returnType = double(1))
demoCode <- nimbleCode(
  for(i in 1:4) {x[i] ~ dnorm(0,1)}
  z[1:4] <- Radd2(x[1:4])
)
demoModel <- nimbleModel(demoCode, inits = list(x = rnorm(4)),
                          check = FALSE, calculate = FALSE)
CdemoModel <- compileNimble(demoModel)
## End(Not run)
```
nimbleType-class  

create a nimbleType object

Description

Create a nimbleType object, with information on the name, type, and dimension of an object to be placed in a nimbleList.

Arguments

name  
The name of the object, given as a character string.
type  
The type of the object, given as a character string.
dim  
The dimension of the object, given as an integer. This can be left blank if the object is a nimbleList.

Details

This function creates nimbleType objects, which can be used to define the elements of a nimbleList. The type argument can be chosen from among character, double, integer, and logical, or can be the name of a previously created nimbleList definition. See the NIMBLE User Manual for additional examples.

Author(s)

NIMBLE development team

Examples

nimbleTypeList <- list()
nimbleTypeList[[1]] <- nimbleType(name = 'x', type = 'integer', dim = 0)
nimbleTypeList[[2]] <- nimbleType(name = 'Y', type = 'double', dim = 2)

nimCat  
cat function for use in nimbleFunctions

Description

cat function for use in nimbleFunctions

Usage

nimCat(...)
Arguments

... an arbitrary set of arguments that will be printed in sequence.

Details

`cat` in `nimbleFunction` run-code imitates the R function `cat`. It prints its arguments in order. No newline is inserted, so include "\n" if one is desired.

When an uncompiled `nimbleFunction` is executed, R’s `cat` is used. In a compiled `nimbleFunction`, a C++ output stream is used that will generally format output similarly to R’s `cat`. Non-scalar numeric objects can be included, although their output will be formatted slightly different in un-compiled and compiled `nimbleFunctions`.

In `nimbleFunction` run-time code, `cat` is identical to `print` except the latter appends a newline at the end.

`nimCat` is the same as `cat`, and the latter is converted to the former when a `nimbleFunction` is defined.

See Also

`print`

Examples

```r
ans <- matrix(1:4, nrow = 2)  ## R code, not NIMBLE code
nimCat('Answer is ', ans)  ## would work in R or NIMBLE
```

---

### nimCopy

**Copying function for NIMBLE**

**Description**

Copies values from a NIMBLE model or modelValues object to another NIMBLE model or modelValues. Work in R and NIMBLE. The NIMBLE keyword `copy` is identical to `nimCopy`.

**Usage**

```r
nimCopy(
  from,
  to,
  nodes = NULL,
  nodesTo = NULL,
  row = NA,
  rowTo = NA,
  logProb = FALSE,
  logProbOnly = FALSE
)
```
Arguments

from  Either a NIMBLE model or modelValues object

to   Either a NIMBLE model or modelValues object

nodes  Vector of one or more node names of object from that will be copied from

nodesTo  Vector of one or more node names of object to that will be copied to. If nodesTo is NULL, will automatically be set to nodes

row  If from is a modelValues, the row that will be copied from

rowTo  If to is a modelValues, the row which will be copied to. If rowTo is NA, will automatically be set to row

logProb  A logical value indicating whether the log probabilities of the given nodes should also be copied (i.e. if nodes = 'x' and logProb = TRUE, then both 'x' and 'logProb_x' will be copied)

logProbOnly  A logical value indicating whether only the log probabilities of the given nodes should be copied (i.e. if nodes = 'x' and logProbOnly = TRUE, then only 'logProb_x' will be copied)

Details

This function copies values from one or more nodes (possibly including log probabilities for nodes) between models and modelValues objects. For modelValues objects, the row must be specified. This function allows one to conveniently copy multiple nodes, avoiding having to write a loop.

Author(s)

Clifford Anderson-Bergman

Examples

# Building model and modelValues object
simpleModelCode <- nimbleCode({
  for(i in 1:100)
    x[i] ~ dnorm(0,1)
})
rModel <- nimbleModel(simpleModelCode)
rModelValues <- modelValues(rModel)

#Setting model nodes
rModel$x <- rnorm(100)
#Using nimCopy in R.
nimCopy(from = rModel, to = rModelValues, nodes = 'x', rowTo = 1)

#Use of nimCopy in a simple nimbleFunction
cCopyGen <- nimbleFunction(
  setup = function(model, modelValues, nodeNames){},
  run = function(){
    nimCopy(from = model, to = modelValues, nodes = nodeNames, rowTo = 1)
  }
)
rCopy <- cCopyGen(rModel, rModelValues, 'x')
## Not run:
cModel <- compileNimble(rModel)
cCopy <- compileNimble(rCopy, project = rModel)
cModel[['x']] <- rnorm(100)

cCopy$run() ## execute the copy with the compiled function

## End(Not run)
\nnimDerivs

Nimble Derivatives

Description

EXPERIMENTAL Computes the value, gradient, and Hessian of a given nimbleFunction method. The R version is currently unimplemented.

Usage

nimDerivs(nimFxn = NA, order = nimC(0, 1, 2))

Arguments

nimFxn a call to a nimbleFunction method with arguments included.
order an integer vector with values within the set 0, 1, 2, corresponding to whether the function value, gradient, and Hessian should be returned respectively.

nimDim

return sizes of an object whether it is a vector, matrix or array

Description

R’s regular dim function returns NULL for a vector. It is useful to have this function that treats a vector similarly to a matrix or array. Works in R and NIMBLE. In NIMBLE dim is identical to nimDim, not to R’s dim

Usage

nimDim(obj)

Arguments

obj objects for which the sizes are requested
Value

a vector of sizes in each dimension

Author(s)

NIMBLE development team

Examples

```r
x <- rnorm(4)
dim(x)
nimDim(x)
y <- matrix(x, nrow = 2)
dim(y)
nimDim(y)
```

---

nimEigen

Spectral Decomposition of a Matrix

Description

Computes eigenvalues and eigenvectors of a numeric matrix.

Usage

```r
nimEigen(x, symmetric = FALSE, only.values = FALSE)
```

Arguments

- **x**: a numeric matrix (double or integer) whose spectral decomposition is to be computed.
- **symmetric**: if TRUE, the matrix is guaranteed to be symmetric, and only its lower triangle (diagonal included) is used. Otherwise, the matrix is checked for symmetry. Default is FALSE.
- **only.values**: if TRUE, only the eigenvalues are computed, otherwise both eigenvalues and eigenvectors are computed. Setting only.values = TRUE can speed up eigendecompositions, especially for large matrices. Default is FALSE.

Details

Computes the spectral decomposition of a numeric matrix using the Eigen C++ template library. In a `nimbleFunction`, `eigen` is identical to `nimEigen`. If the matrix is symmetric, a faster and more accurate algorithm will be used to compute the eigendecomposition. Note that non-symmetric matrices can have complex eigenvalues, which are not supported by NIMBLE. If a complex eigenvalue or a complex element of an eigenvector is detected, a warning will be issued and that element will be returned as NaN.
Additionally, returnType(eigenNimbleList()) can be used within a link{nimbleFunction} to specify that the function will return a nimbleList generated by the nimEigen function. eigenNimbleList() can also be used to define a nested nimbleList element. See the User Manual for usage examples.

Value

The spectral decomposition of x is returned as a nimbleList with elements:

- values vector containing the eigenvalues of x, sorted in decreasing order. Since x is required to be symmetric, all eigenvalues will be real numbers.
- vectors. matrix with columns containing the eigenvectors of x, or an empty matrix if only.values is TRUE.

Author(s)

NIMBLE development team

See Also

nimSvd for singular value decompositions in NIMBLE.

Examples

eigenvaluesDemoFunction <- nimbleFunction(
  setup = function(){
    demoMatrix <- diag(4) + 2
  },
  run = function(){
    eigenvalues <- eigen(demoMatrix, symmetric = TRUE)$values
    returnType(double(1))
    return(eigenvalues)
  })

Description

In a nimbleFunction, matrix and array are identical to nimMatrix and nimArray, respectively.

Usage

nimMatrix(
  value = 0,
  nrow = NA,
  ncol = NA,
  init = TRUE,
  fillZeros = TRUE,
)
nimMatrix

recycle = TRUE,
type = "double"
)
nimArray(
  value = 0,
  dim = c(1, 1),
  init = TRUE,
  fillZeros = TRUE,
  recycle = TRUE,
  nDim,
  type = "double"
)

Arguments

- value: value(s) for initialization (default = 0). This can be a vector, matrix or array, but it will be used as a vector.
- nrow: the number of rows in a matrix (default = 1)
- ncol: the number of columns in a matrix (default = 1)
- init: logical, whether to initialize values (default = TRUE)
- fillZeros: logical, whether to initialize any elements not filled by (possibly recycled) value with 0 (or FALSE for nimLogical) (default = TRUE)
- recycle: logical, whether value should be recycled to fill the entire contents of the new object (default = TRUE)
- type: character representing the data type, i.e. 'double', 'integer', or 'logical' (default = 'double')
- dim: vector of dimension sizes in an array (default = c(1,1))
- nDim: number of dimensions in an array. This is only necessary for compileNimble if the length of dim cannot be determined during compilation.

Details

These functions are similar to R’s matrix and array functions, but they can be used in a nimbleFunction and compiled using compileNimble. Largely for compilation purposes, finer control is provided over initialization behavior, similarly to nimNumeric, nimInteger, and nimLogical. If init = FALSE, no initialization will be done, and value, fillZeros and recycle will be ignored. If init=TRUE and recycle=TRUE, then fillZeros will be ignored, and value will be repeated (according to R’s recycling rule) as much as necessary to fill the object. If init=TRUE and recycle=FALSE, then if fillZeros=TRUE, values of 0 (or FALSE for nimLogical) will be filled in after value. Compiled code will be more efficient if unnecessary initialization is not done, but this may or may not be noticeable depending on the situation.

When used in a nimbleFunction (in run or other member function), matrix and array are immediately converted to nimMatrix and nimArray, respectively.

The nDim argument is only necessary for a use like dim <-c(2,3,4); A <-nimArray(0,dim = dim,nDim = 3). It is necessary because the NIMBLE compiler must determine during compilation that A will
be a 3-dimensional numeric array. However, the compiler doesn’t know for sure what the length of \( \text{dim} \) will be at run time, only that it is a vector. On the other hand, \( A \leftarrow \text{nimArray}(0, \text{dim} = c(2, 3, 4)) \) is allowed because the compiler can directly determine that a vector of length three is constructed inline for the \( \text{dim} \) argument.

nimNumeric nimInteger nimLogical

nimNumeric

Creates numeric, integer or logical vectors for use in nimbleFunctions

Description

In a nimbleFunction, numeric, integer and logical are identical to nimNumeric, nimInteger and nimLogical, respectively.

Usage

\[
\begin{align*}
\text{nimNumeric}( & \\
& \text{length} = 0, \\
& \text{value} = 0, \\
& \text{init} = \text{TRUE}, \\
& \text{fillZeros} = \text{TRUE}, \\
& \text{recycle} = \text{TRUE} \\
& )
\end{align*}
\]

\[
\begin{align*}
\text{nimInteger}( & \\
& \text{length} = 0, \\
& \text{value} = 0, \\
& \text{init} = \text{TRUE}, \\
& \text{fillZeros} = \text{TRUE}, \\
& \text{recycle} = \text{TRUE} \\
& )
\end{align*}
\]

\[
\begin{align*}
\text{nimLogical}( & \\
& \text{length} = 0, \\
& \text{value} = 0, \\
& \text{init} = \text{TRUE}, \\
& \text{fillZeros} = \text{TRUE}, \\
& \text{recycle} = \text{TRUE} \\
& )
\end{align*}
\]
nimOptim

Arguments

- **length**: the length of the vector (default = 0)
- **value**: value(s) for initializing the vector (default = 0). This may be a vector, matrix or array but will be used as a vector.
- **init**: logical, whether to initialize elements of the vector (default = TRUE)
- **fillZeros**: logical, whether to initialize any elements not filled by (possibly recycled) value with 0 (or FALSE for nimLogical) (default = TRUE)
- **recycle**: logical, whether value should be recycled to fill the entire length of the new vector (default = TRUE)

Details

These functions are similar to R’s **numeric**, **integer**, **logical** functions, but they can be used in a nimbleFunction and then compiled using compileNimble. Largely for compilation purposes, finer control is provided over initialization behavior. If init = FALSE, no initialization will be done, and value, fillZeros and recycle will be ignored. If init=TRUE and recycle=TRUE, then fillZeros will be ignored, and value will be repeated (according to R’s recycling rule) as much as necessary to fill a vector of length length. If init=TRUE and recycle=FALSE, then if fillZeros=TRUE, values of 0 (or FALSE for nimLogical) will be filled in after value up to length length. Compiled code will be more efficient if unnecessary initialization is not done, but this may or may not be noticeable depending on the situation.

When used in a nimbleFunction (in run or other member function), numeric, integer and logical are immediately converted to nimNumeric, nimInteger and nimLogical, respectively.

nimOptim

Nimble wrapper around R’s builtin optim.

Description

Nimble wrapper around R’s builtin optim.
Usage

nimOptim(
  par,
  fn,
  gr = "NULL",
  ...,
  method = "Nelder-Mead",
  lower = -Inf,
  upper = Inf,
  control = nimOptimDefaultControl(),
  hessian = FALSE
)

Arguments

par  Initial values for the parameters to be optimized over.
fn   A function to be minimized (or maximized), with first argument the vector of parameters over which minimization is to take place. It should return a scalar result.
gr  A function to return the gradient for the "BFGS", "CG" and "L-BFGS-B" methods.
... IGNORED
method The method to be used. See ‘Details’ section of optim. One of: "Nelder-Mead", "BFGS", "CG", "L-BFGS-B". Note that the R methods "SANN", "Brent" are not supported.
lower Vector or scalar of lower bounds for parameters.
upper Vector or scalar of upper bounds for parameters.
control A list of control parameters. See Details section of optim.
hessian Logical. Should a Hessian matrix be returned?

Value

optimResultNimbleList

See Also

optim

Examples

## Not run:
objectiveFunction <- nimbleFunction(
  run = function(par = double(1)) {
    return(sum(par) * exp(-sum(par ^ 2) / 2))
  },
  returnType(double(0))
)
nimPrint

 optimizer <- nimbleFunction(
    run = function(method = character(0), fnscale = double(0)) {
      control <- optimDefaultControl()
      control$fnscale <- fnscale
      par <- c(0.1, -0.1)
      return(optim(par, objectiveFunction, method = method, control = control))
      returnType(optimResultNimbleList())
    }
  )
  cOptimizer <- compileNimble(optimizer)
cOptimizer(method = 'BFGS', fnscale = -1)

  ## End(Not run)

nimOptimDefaultControl

Creates a default control argument for nimOptim.

Description

Creates a default control argument for nimOptim.

Usage

nimOptimDefaultControl()

Value

optimControlNimbleList

nimOptim, optim

nimPrint

print function for use in nimbleFunctions

Description

print function for use in nimbleFunctions

Usage

nimPrint(...)

Arguments

... an arbitrary set of arguments that will be printed in sequence.
The keyword `print` in `nimbleFunction` run-time code will be automatically turned into `nimPrint`. This is a function that prints its arguments in order using `cat` in R, or using `std::cout` in C++ code generated by compiling `nimbleFunctions`. Non-scalar numeric objects can be included, although their output will be formatted slightly different in uncompiled and compiled `nimbleFunctions`.

#### See Also

`cat`

#### Examples

```r
ans <- matrix(1:4, nrow = 2)  ## R code, not NIMBLE code
nimPrint('Answer is ', ans)  ## would work in R or NIMBLE
```

---

### `nimStop`

_Halt execution of a `nimbleFunction` function method. Part of the NIMBLE language_

#### Description

Halt execution of a `nimbleFunction` function method. Part of the NIMBLE language

#### Usage

```r
nimStop(msg)
```

#### Arguments

- `msg`: Character object to be output as an error message

#### Details

The NIMBLE `stop` is similar to the native R `stop`, but it takes only one argument, the error message to be output. During uncompiled NIMBLE execution, `nimStop` simply calls R’s `stop` function. During compiled execution it calls the error function from the R headers. `stop` is an alias for `nimStop` in the NIMBLE language

#### Author(s)

Perry de Valpine
nimSvd

**Singular Value Decomposition of a Matrix**

**Description**

Computes singular values and, optionally, left and right singular vectors of a numeric matrix.

**Usage**

`nimSvd(x, vectors = "full")`

**Arguments**

- `x`: a symmetric numeric matrix (double or integer) whose spectral decomposition is to be computed.
- `vectors`: character that determines whether to calculate left and right singular vectors. Can take values 'none', 'thin' or 'full'. Defaults to 'full'. See 'Details'.

**Details**

Computes the singular value decomposition of a numeric matrix using the Eigen C++ template library.

The `vectors` character argument determines whether to compute no left and right singular vectors ('none'), thinned left and right singular vectors ('thin'), or full left and right singular vectors ('full'). For a matrix `x` with dimensions `n` and `p`, setting `vectors = 'thin'` will do the following (quoted from eigen website): In case of a rectangular `n`-by-`p` matrix, letting `m` be the smaller value among `n` and `p`, there are only `m` singular vectors; the remaining columns of `U` and `V` do not correspond to actual singular vectors. Asking for thin `U` or `V` means asking for only their `m` first columns to be formed. So `U` is then a `n`-by-`m` matrix, and `V` is then a `p`-by-`m` matrix. Notice that thin `U` and `V` are all you need for (least squares) solving.

Setting `vectors = 'full'` will compute full matrices for `U` and `V`, so that `U` will be of size `n`-by-`n`, and `V` will be of size `p`-by-`p`.

In a `nimbleFunction`, `svd` is identical to `nimSvd`.

`returnType(svdNimbleList())` can be used within a `link(nimbleFunction)` to specify that the function will return a `nimbleList` generated by the `nimSvd` function. `svdNimbleList()` can also be used to define a nested `nimbleList` element. See the User Manual for usage examples.

**Value**

The singular value decomposition of `x` is returned as a `nimbleList` with elements:

- `d` length `m` vector containing the singular values of `x`, sorted in decreasing order.
- `v` matrix with columns containing the left singular vectors of `x`, or an empty matrix if `vectors = 'none'`.
- `u` matrix with columns containing the right singular vectors of `x`, or an empty matrix if `vectors = 'none'`. 
Author(s)
NIMBLE development team

See Also
nimEigen for spectral decompositions.

Examples

```r
singularValuesDemoFunction <- nimbleFunction(
  setup = function()
    demoMatrix <- diag(4) + 2
  ),
  run = function()
    singularValues <- svd(demoMatrix)$d
    returnType(double(1))
    return(singularValues)
)
```

Description
calculate, calculateDiff, simulate, or get the current log probabilities (densities) of one or more nodes of a NIMBLE model and (for calculate and getLogProb) return the sum of their log probabilities (or densities). Part of R and NIMBLE.

Usage

```r
calculate(model, nodes, nodeFxnVector, nodeFunctionIndex)
calculateDiff(model, nodes, nodeFxnVector, nodeFunctionIndex)
getLogProb(model, nodes, nodeFxnVector, nodeFunctionIndex)
simulate(model, nodes, includeData = FALSE, nodeFxnVector, nodeFunctionIndex)
```

Arguments

- **model**: A NIMBLE model, either the compiled or uncompiled version
- **nodes**: A character vector of node names, with index blocks allowed, such as ‘x’, ‘y[2]’. or ‘z[1:3, 2:4]’
- **nodeFxnVector**: An optional vector of nodeFunctions on which to operate, in lieu of model and nodes
nodeFunctionIndex
   For internal NIMBLE use only
includeData    A logical argument specifying whether data nodes should be simulated into
   (only relevant for simulate)

Details

Standard usage is as a method of a model, in the form `model$calculate(nodes)`, but the usage as
a simple function with the model as the first argument as above is also allowed.

These functions expands the nodes and then process them in the model in the order provided. Ex-
panding nodes means turning `y[1:2]` into `c('y[1]','y[2]')` if `y` is a vector of scalar nodes. Calcu-
lation is defined for a stochastic node as executing the log probability (density) calculation and for
a deterministic node as calculating whatever function was provided on the right-hand side of the
model declaration.

Difference calculation (calculateDiff) executes the operation(s) on the model as calculate, but it
returns the sum of the difference between the new log probabilities and the previous ones.

Simulation is defined for a stochastic node as drawing a random value from its distribution, and for
deterministic node as equivalent to calculate.

getLogProb collects and returns the sum of the log probabilities of nodes, using the log probability
values currently stored in the model (as generated from the most recent call to calculate on each
node)

These functions can be used from R or in NIMBLE run-time functions that will be compiled. When
executed in R (including when an uncompiled nimbleFunction is executed), they can be slow be-
cause the nodes are expanded each time. When compiled in NIMBLE, the nodes are expanded only
once during compilation, so execution will be much faster.

It is common to want the nodes to be provided in topologically sorted order, so that they will be cal-
culated or simulated following the order of the model graph. Functions such as `model$getDependencies(nodes,
...) return nodes in topologically sorted order. They can be directly sorted by `model$topologicallySortNodes(nodes)
but if so it is a good idea to expand names first by `model$topologicallySortNodes(model$expandNodeNames(nodes))

Value

calculate and getLogProb return the sum of the log probabilities (densities) of the calculated nodes,
with a contribution of 0 from any deterministic nodes

calculateDiff returns the sum of the difference between the new and old log probabilities (densities)
of the calculated nodes, with a contribution of 0 from any deterministic nodes.

simulate returns NULL.

optimControlNimbleList

**EXPERIMENTAL** Data type for the control parameter of `nimOptim`

---

**Description**

`nimbleList` definition for the type of `nimbleList` input as the control parameter to `nimOptim`. See `optim` for details.

**Usage**

`optimControlNimbleList`

**Format**

An object of class `list` of length 1.

**See Also**

`optim`, `nimOptim`

---

`optimDefaultControl`  *Creates a default control argument for `optim` (just an empty list).*

---

**Description**

Creates a default control argument for `optim` (just an empty list).

**Usage**

`optimDefaultControl()`

**Value**

an empty list.

**See Also**

`nimOptim`, `optim`
printErrors

Description

Print error messages after failed compilation.

Usage

printErrors(excludeWarnings = TRUE)

printErrors

optimResultNimbleList   EXPERIMENTAL Data type for the return value of nimOptim

Description

nimbleList definition for the type of nimbleList returned by nimOptim.

Usage

optimResultNimbleList

Format

An object of class list of length 1.

Fields

par   The best set of parameters found.
value The value of fn corresponding to par.
counts A two-element integer vector giving the number of calls to fn and gr respectively.
convergence An integer code. 0 indicates successful completion. Possible error codes are 1 indicates that the iteration limit maxit had been reached. 10 indicates degeneracy of the Nelder-Mead simplex. 51 indicates a warning from the "L-BFGS-B" method; see component message for further details. 52 indicates an error from the "L-BFGS-B" method; see component message for further details.
message A character string giving any additional information returned by the optimizer, or NULL.
hessian Only if argument hessian is true. A symmetric matrix giving an estimate of the Hessian at the solution found.

See Also

optim, nimOptim
Arguments

excludeWarnings
logical indicating whether compiler warnings should be printed: generally such
warnings can be ignored.

rankSample
*Generates a weighted sample (with replacement) of ranks*

Description

Takes a set of non-negative weights (do not need to sum to 1) and returns a sample with size elements of the integers 1:length(weights), where the probability of being sampled is proportional to the value of weights. An important note is that the output vector will be sorted in ascending order. Also, right now it works slightly odd syntax (see example below). Later releases of NIMBLE will contain more natural syntax.

Usage

`rankSample(weights, size, output, silent = FALSE)`

Arguments

- `weights`: A vector of numeric weights. Does not need to sum to 1, but must be non-negative
- `size`: Size of sample
- `output`: An R object into which the values will be placed. See example below for proper use
- `silent`: Logical indicating whether to suppress logging information

Details

If invalid weights provided (i.e. negative weights or weights sum to 1), sets output = rep(1, size) and prints warning. `rankSample` can be used inside nimble functions.

`rankSample` first samples from the joint distribution size uniform(0,1) distributions by conditionally sampling from the rank statistics. This leads to a sorted sample of uniform(0,1)'s. Then, a cdf vector is constructed from weights. Because the sample of uniforms is sorted, `rankSample` walks down the cdf in linear time and fills out the sample.

Author(s)
Clifford Anderson-Bergman
Examples

```r
set.seed(1)
sampInts = NA # sampled integers will be placed in sampInts
rankSample(weights = c(1, 1, 2), size = 10, sampInts)
sampInts
# [1] 1 1 2 2 2 2 3 3 3
rankSample(weights = c(1, 1, 2), size = 10000, sampInts)
table(sampInts)
# sampInts
#  1  2  3
#2434 2492 5074

# Used in a nimbleFunction
sampGen <- nimbleFunction(setup = function()
  x = 1:2
),
run = function(weights = double(1), k = integer()){
  rankSample(weights, k, x)
  returnType(integer(1))
  return(x)
})
rSamp <- sampGen()
rSamp$run(1:4, 5)
# [1] 3 3 4 4 4
```

---

`readBUGSmodel`  
Create a NIMBLE BUGS model from a variety of input formats, including BUGS model files

**Description**

`readBUGSmodel` processes inputs providing the model and values for constants, data, initial values of the model in a variety of forms, returning a NIMBLE BUGS R model

**Usage**

```r
readBUGSmodel(
  model,
  data = NULL,
  inits = NULL,
  dir = NULL,
  useInits = TRUE,
  debug = FALSE,
  returnComponents = FALSE,
  check = getNimbleOption("checkModel"),
  calculate = TRUE
)
```
**readBUGSmodel**

**Arguments**

- **model**
  
  One of (1) a character string giving the file name containing the BUGS model code, with relative or absolute path, (2) an R function whose body is the BUGS model code, or (3) the output of `nimbleCode`. If a file name, the file can contain a ‘var’ block and ’data’ block in the manner of the JAGS versions of the BUGS examples but should not contain references to other input data files nor a const block. The `.bug` or `.txt` extension can be excluded.

- **data**
  
  (optional) (1) character string giving the file name for an R file providing the input constants and data as R code [assigning individual objects or as a named list], with relative or absolute path, or (2) a named list providing the input constants and data. If neither is provided, the function will look for a file named ‘name_of_model-data’ including extensions .R, .r, or .txt.

- **inits**
  
  (optional) (1) character string giving the file name for an R file providing starting values as R code [assigning individual objects or as a named list], with relative or absolute path, or (2) a named list providing the starting values. Unlike JAGS, this should provide a single set of starting values, and therefore if provided as a list should be a simple list and not a list of lists.

- **dir**
  
  (optional) character string giving the directory where the (optional) files are located

- **useInits**
  
  Boolean indicating whether to set the initial values, either based on `inits` or by finding the ‘-inits’ file corresponding to the input model file

- **debug**
  
  Logical indicating whether to put the user in a browser for debugging when `readBUGSmodel` calls `nimbleModel`. Intended for developer use.

- **returnComponents**
  
  Logical indicating whether to return pieces of model object without building the model. Default is FALSE.

- **check**
  
  Logical indicating whether to check the model object for missing or invalid values. Default is given by the NIMBLE option 'checkModel'. See `nimbleOptions` for details.

- **calculate**
  
  Logical indicating whether to run `calculate` on the model after building it; this will calculate all deterministic nodes and logProbability values given the current state of all nodes. Default is TRUE. For large models, one might want to disable this, but note that deterministic nodes, including nodes introduced into the model by NIMBLE, may be NA.

**Details**

Note that `readBUGSmodel` should handle most common ways of providing information on a model as used in BUGS and JAGS but does not handle input model files that refer to additional files containing data. Please see the BUGS examples provided with NIMBLE in the classic-bugs directory of the installed NIMBLE package or JAGS (https://sourceforge.net/projects/mcmc-jags/files/Examples/) for examples of supported formats. Also, `readBUGSmodel` takes both constants and data via the 'data' argument, unlike `nimbleModel`, in which these are distinguished. The reason for allowing both to be given via 'data' is for backwards compatibility with the BUGS examples, in which constants and data are not distinguished.
Value
returns a NIMBLE BUGS R model

pumpModel$x

registerDistributions  Add user-supplied distributions for use in NIMBLE BUGS models

Description
Register distributional information so that NIMBLE can process user-supplied distributions in BUGS model code

Usage

registerDistributions(
  distributionsInput,
  userEnv = parent.frame(),
  verbose = nimbleOptions("verbose")
)
Arguments

distributionsInput

either a list or character vector specifying the user-supplied distributions. If a
list, it should be a named list of lists in the form of that shown in nimble::distributionsInputList
with each list having required field BUGSdist and optional fields Rdist, altParams,
discrete, pqAvail, types, and with the name of the list the same as that of the
density function. Alternatively, simply a character vector providing the names
of the density functions for the user-supplied distributions.

userEnv

environment in which to look for the nimbleFunctions that provide the distribu-
tion; this will generally not need to be set by the user as it will default to the
environment from which this function was called.

verbose

logical indicating whether to print additional logging information

Details

When distributionsInput is a list of lists, see below for more information on the structure of the
list. When distributionsInput is a character vector, the distribution is assumed to be of standard
form, with parameters assumed to be the arguments provided in the density nimbleFunction, no
alternative parameterizations, and the distribution assumed to be continuous with range from minus
infinity to infinity. The availability of distribution and quantile functions is inferred from whether
appropriately-named functions exist in the global environment.

One usually does not need to explicitly call registerDistributions as it will be called automatic-
ically when the user-supplied distribution is used for the first time in BUGS code. However, if one
wishes to provide alternative parameterizations, to provide a range, or to indicate a distribution is
discrete, then one still must explicitly register the distribution using registerDistributions with
the argument in the list format.

Format of the component lists when distributionsInput is a list of lists:

- BUGSdist a character string in the form of the density name (starting with 'd') followed by
  the names of the parameters in parentheses. When alternative parameterizations are given
  in Rdist, this should be an exhaustive list of the unique parameter names from all possible
  parameterizations, with the default parameters specified first.

- Rdist an optional character vector with one or more alternative specifications of the density;
  each alternative specification can be an alternative name for the density, a different ordering
  of the parameters, different parameter name(s), or an alternative parameterization. In the latter
  case, the character string in parentheses should provide a given reparameterization as comma-
  separated name = value pairs, one for each default parameter, where name is the name of the
default parameter and value is a mathematical expression relating the default parameter to the
alternative parameters or other default parameters. The default parameters should correspond
  to the input arguments of the nimbleFunctions provided as the density and random generation
  functions. The mathematical expression can use any of the math functions allowed in NIM-
BLE (see the User Manual) as well as user-supplied nimbleFunctions (which must have no
setup code). The names of your nimbleFunctions for the distribution functions must match
the function name in the Rdist entry (or if missing, the function name in the BUGSdist entry

- discrete a optional logical indicating if the distribution is that of a discrete random variable.
  If not supplied, distribution is assumed to be for a continuous random variable.
• `pqAvail` an optional logical indicating if distribution (CDF) and quantile (inverse CDF) functions are provided as nimbleFunctions. These are required for one to be able to use truncated versions of the distribution. Only applicable for univariate distributions. If not supplied, assumed to be FALSE.

• `altParams` a character vector of comma-separated 'name = value' pairs that provide the mathematical expressions relating non-canonical parameters to canonical parameters (canonical parameters are those passed as arguments to your distribution functions). These inverse functions are used for MCMC conjugacy calculations when a conjugate relationship is expressed in terms of non-default parameters (such as the precision for normal-normal conjugacy). If not supplied, the system will still function but with a possible loss of efficiency in certain algorithms.

• `types` a character vector of comma-separated 'name = input' pairs indicating the type and dimension of the random variable and parameters (including default and alternative parameters). 'input' should take the form 'double(d)' or 'integer(d)', where 'd' is 0 for scalars, 1 for vectors, 2 for matrices. Note that since NIMBLE uses doubles for numerical calculations and the default type is `double(0)`, one should generally use 'double' and one need only specify the type for non-scalars. 'name' should be either 'value' to indicate the random variable itself or the parameter name to indicate a given parameter.

• `range` a vector of two values giving the range of the distribution for possible use in future algorithms (not used currently). When the lower or upper limit involves a strict inequality (e.g., $x>0$), you should simply treat it as a non-strict inequality ($x>=0$, and set the lower value to 0). Also we do not handle ranges that are functions of parameters, so simply use the smallest/largest possible values given the possible parameter values. If not supplied this is taken to be (-Inf,Inf).

**Examples**

dmyexp <- nimbleFunction(
  run = function(x = double(0), rate = double(0), log = integer(0)) {
    returnType(double(0))
    logProb <- log(rate) - x*rate
    if(log) {
      return(logProb)
    } else {
      return(exp(logProb))
    }
  }
)

rmyexp <- nimbleFunction(
  run = function(n = integer(0), rate = double(0)) {
    returnType(double(0))
    if(n != 1) nimPrint("rmyexp only allows n = 1; using n = 1.")
    dev <- runif(1, 0, 1)
    return(-log(1-dev) / rate)
  }
)

registerDistributions(list(}
dmyexp = list(
    BUGSdist = "dmyexp(rate, scale)",
    Rdist = "dmyexp(rate = 1/scale)",
    altParams = "scale = 1/rate",
    pqAvail = FALSE))

code <- nimbleCode(
    y ~ dmyexp(rate = r)
    r ~ dunif(0, 100)
)
m <- nimbleModel(code, inits = list(r = 1), data = list(y = 2))
m$calculate('y')
m$r <- 2
m$calculate('y')
m$resetData()
m$simulate('y')
m$y

# alternatively, simply specify a character vector with the
# name of one or more 'd' functions
deregisterDistributions('dmyexp')
registerDistributions('dmyexp')

# or simply use in BUGS code without registration
deregisterDistributions('dmyexp')
m <- nimbleModel(code, inits = list(r = 1), data = list(y = 2))

# example of Dirichlet-multinomial registration to illustrate
# use of 'types' (note that registration is not actually needed
# in this case)
ddirchmulti <- nimbleFunction(
    run = function(x = double(1), alpha = double(1), size = double(0),
                 log = integer(0, default = 0)) {
        returnType(double(0))
        logProb <- lgamma(size) - sum(lgamma(x)) + lgamma(sum(alpha)) -
                   sum(lgamma(alpha) + x) - lgamma(sum(alpha) + size)
        if(log) return(logProb)
        else return(exp(logProb))
    })

rdirchmulti <- nimbleFunction(
    run = function(n = integer(0), alpha = double(1), size = double(0)) {
        returnType(double(1))
        if(n != 1) print("rdirchmulti only allows n = 1; using n = 1."")
        p <- rdirch(1, alpha)
        return(rmulti(1, size = size, prob = p))
    })

registerDistributions(list(
    ddirchmulti = list(
        BUGSdist = "ddirchmulti(alpha, size)",
        types = c('value = double(1)', 'alpha = double(1)')
    )
)
## resize

### Description

Adds or removes rows to a modelValues object. If rows are added to a modelValues object, the default values are `NA`. Works in both R and NIMBLE.

### Usage

```
resize(container, k)
```

### Arguments

- **container**: modelValues object
- **k**: number of rows that modelValues is set to

### Details

See the User Manual or `help(modelValuesBaseClass)` for information about modelValues objects.

### Author(s)

Clifford Anderson-Bergman

### Examples

```r
mvConf <- modelValuesConf(vars = c('a', 'b'),
                          types = c('double', 'double'),
                          sizes = list(a = 1, b = c(2,2)))
mv <- modelValues(mvConf)
as.matrix(mv)
resize(mv, 3)
as.matrix(mv)
```
Rmatrix2mvOneVar

Set values of one variable of a modelValues object from an R matrix

Description

Normally a modelValues object is accessed one "row" at a time. This function allows all rows for one variable to set from a matrix with one dimension more than the variable to be set.

Usage

Rmatrix2mvOneVar(mat, mv, varName, k)

Arguments

mat Input matrix
mv modelValues object to be modified.
varName Character string giving the name of the variable on mv to be set
k Number of rows to use

Details

This function may be deprecated in the future when a more natural system for interacting with modelValues objects is developed.

RmodelBaseClass-class

Class RmodelBaseClass

Description

Classes used internally in NIMBLE and not expected to be called directly by users.

run.time

Time execution of NIMBLE code

Description

Time execution of NIMBLE code

Usage

run.time(code)
runCrossValidate

Arguments

code                  code to be timed

Details

Function for use in nimbleFunction run code; when nimbleFunctions are run in R, this simply wraps system.time.

Author(s)

NIMBLE Development Team

runCrossValidate

Perform k-fold cross-validation on a NIMBLE model fit by MCMC

Description

Takes a NIMBLE model MCMC configuration and conducts k-fold cross-validation of the MCMC fit, returning a measure of the model’s predictive performance.

Usage

runCrossValidate(
  MCMCconfiguration,  # a NIMBLE MCMC configuration object, returned by a call to configureMCMC.
  k,                   # number of folds that should be used for cross-validation.
  foldFunction = "random",  # one of (1) an R function taking a single integer argument i, and returning a character vector with the names of the data nodes to leave out of the model for fold i, or (2) the character string "random", indicating that data nodes will be randomly partitioned into k folds. Note that choosing "random" and setting k equal to the total number of data nodes in the model will perform leave-one-out cross-validation. Defaults to "random". See 'Details'.
  lossFunction = "MSE",  # a loss function to be used to evaluate predictive performance
  MCMCcontrol = list(),  # a list of MCMC control parameters
  returnSamples = FALSE,  # whether to return the samples from each fold
  nCores = 1,  # number of cores to use for parallel computation
  nBootReps = 200,  # number of bootstrap repetitions
  silent = FALSE  # whether to suppress output
)

Arguments

MCMCconfiguration
k
foldFunction
runCrossValidate

lossFunction one of (1) an R function taking a set of simulated data and a set of observed data, and calculating the loss from those, or (2) a character string naming one of NIMBLE's built-in loss functions. If a character string, must be one of "predictive" to use the log predictive density as a loss function or "MSE" to use the mean squared error as a loss function. Defaults to "MSE". See 'Details' for information on creating a user-defined loss function.

MCMCcontrol (optional) an R list with parameters governing the MCMC algorithm. See 'Details' for specific parameters.

returnSamples logical indicating whether to return all posterior samples from all MCMC runs. This can result in a very large returned object (there will be k sets of posterior samples returned). Defaults to FALSE.

nCores number of cpu cores to use in parallelizing the CV calculation. Only MacOS and Linux operating systems support multiple cores at this time. Defaults to 1.

nBootReps number of bootstrap samples to use when estimating the Monte Carlo error of the cross-validation metric. Defaults to 200. If no Monte Carlo error estimate is desired, nBootReps can be set to NA, which can potentially save significant computation time.

silent Boolean specifying whether to show output from the algorithm as it's running (default = FALSE).

Details

k-fold CV in NIMBLE proceeds by separating the data in a nimbleModel into k folds, as determined by the foldFunction argument. For each fold, the corresponding data are held out of the model, and MCMC is run to estimate the posterior distribution and simultaneously impute posterior predictive values for the held-out data. Then, the posterior predictive values are compared to the known, held-out data values via the specified lossFunction. The loss values are averaged over the posterior samples for each fold, and these averaged values for each fold are then averaged over all folds to produce a single out-of-sample loss estimate. Additionally, estimates of the Monte Carlo error for each fold are returned.

Value

an R list with four elements:

- CVvalue The CV value, measuring the model’s ability to predict new data. Smaller relative values indicate better model performance.

- CVstandardError The standard error of the CV value, giving an indication of the total Monte Carlo error in the CV estimate.

- foldCVInfo An list of fold CV values and standard errors for each fold.

- samples An R list, only returned when returnSamples = TRUE. The i’th element of this list will be a matrix of posterior samples from the model with the i’th fold of data left out. There will be k sets of samples.
The `foldFunction` Argument

If the default 'random' method is not used, the `foldFunction` argument must be an R function that takes a single integer-valued argument `i`. `i` is guaranteed to be within the range \([1, k]\). For each integer value `i`, the function should return a character vector of node names corresponding to the data nodes that will be left out of the model for that fold. The returned node names can be expanded, but don’t need to be. For example, if fold `i` is intended to leave out the model nodes `x[1]`, `x[2]` and `x[3]` then the function could return either `c('x[1]', 'x[2]', 'x[3]')` or `'x[1:3]'`.

The `lossFunction` Argument

If you don’t wish to use NIMBLE's built-in "MSE" or "predictive" loss functions, you may provide your own R function as the `lossFunction` argument to `runCrossValidate`. A user-supplied `lossFunction` must be an R function that takes two arguments: the first, named `simulatedDataValues`, will be a vector of simulated data values. The second, named `actualDataValues`, will be a vector of observed data values corresponding to the simulated data values in `simulatedDataValues`. The loss function should return a single scalar number. See 'Examples' for an example of a user-defined loss function.

The `MCMCcontrol` Argument

The `MCMCcontrol` argument is a list with the following elements:

- `niter` an integer argument determining how many MCMC iterations should be run for each loss value calculation. Defaults to 10000, but should probably be manually set.
- `nburnin` the number of samples from the start of the MCMC chain to discard as burn-in for each loss value calculation. Must be between 0 and `niter`. Defaults to 10

MCMCcontrol = list(niter = 5000,
  nburnin = 500))

## End(Not run)
runMCMC

Run one or more chains of an MCMC algorithm and return samples, summary and/or WAIC

Description

Takes as input an MCMC algorithm (ideally a compiled one for speed) and runs the MCMC with one or more chains, any returns any combination of posterior samples, posterior summary statistics, and a WAIC value.

Usage

runMCMC(
mcmc, niter = 10000, nburnin = 0, thin, thin2, nchains = 1, inits, setSeed = FALSE, progressBar = getNimbleOption("MCMCprogressBar"), samples = TRUE, samplesAsCodaMCMC = FALSE, summary = FALSE, WAIC = FALSE, perChainWAIC = FALSE)

Arguments

mcmc A NIMBLE MCMC algorithm. See details.
niter Number of iterations to run each MCMC chain. Default value is 10000.
nburnin Number of initial, pre-thinning, MCMC iterations to discard. Default value is 0.
thin Thinning interval for collecting MCMC samples, corresponding to monitors. Thinning occurs after the initial nburnin samples are discarded. Default value is 1.
thin2 Thinning interval for collecting MCMC samples, corresponding to the second, optional set of monitors2. Thinning occurs after the initial nburnin samples are discarded. Default value is 1.
nchains Number of MCMC chains to run. Default value is 1.
inits Optional argument to specify initial values for each chain. See details.
setSeed Logical or numeric argument. If a single numeric value is provided, R’s random number seed will be set to this value at the onset of each MCMC chain. If a numeric vector of length nchains is provided, then each element of this vector
is provided as R's random number seed at the onset of the corresponding MCMC chain. Otherwise, in the case of a logical value, if TRUE, then R's random number seed for the ith chain is set to be i, at the onset of each MCMC chain. Note that specifying the argument setSeed = 0 does not prevent setting the RNG seed, but rather sets the random number generation seed to 0 at the beginning of each MCMC chain. Default value is FALSE.

**progressBar**
Logical argument. If TRUE, an MCMC progress bar is displayed during execution of each MCMC chain. Default value is defined by the nimble package option MCMCprogressBar.

**samples**
Logical argument. If TRUE, then posterior samples are returned from each MCMC chain. These samples are optionally returned as coda mcmc objects, depending on the samplesAsCodaMCMC argument. Default value is TRUE. See details.

**samplesAsCodaMCMC**
Logical argument. If TRUE, then a coda mcmc object is returned instead of an R matrix of samples, or when nchains > 1 a coda mcmc.list object is returned containing nchains mcmc objects. This argument is only used when samples is TRUE. Default value is FALSE. See details.

**summary**
Logical argument. When TRUE, summary statistics for the posterior samples of each parameter are also returned, for each MCMC chain. This may be returned in addition to the posterior samples themselves. Default value is FALSE. See details.

**WAIC**
Logical argument. When TRUE, the WAIC (Watanabe, 2010) of the model is calculated and returned. Note that in order for the WAIC to be calculated, the mcmc object must have also been created with the argument 'enableWAIC = TRUE'. If multiple chains are run, then a single WAIC value is calculated using the posterior samples from all chains. Default value is FALSE. See help(waic).

**perChainWAIC**
Logical argument. When TRUE and multiple chains are run, the WAIC for each chain is returned as a means of helping assess the stability of the WAIC estimate. Default value is FALSE, corresponding to a single WAIC estimate based on all of the chains.

**Details**
At least one of samples, summary or WAIC must be TRUE, since otherwise, nothing will be returned. Any combination of these may be TRUE, including possibly all three, in which case posterior samples and summary statistics are returned for each MCMC chain, and an overall WAIC value is calculated and returned.

When samples = TRUE, the form of the posterior samples is determined by the samplesAsCodaMCMC argument, as either matrices of posterior samples, or coda mcmc and mcmc.list objects. Posterior summary statistics are returned individually for each chain, and also as calculated from all chains combined (when nchains > 1).

If provided, the inits argument can be one of three things:

(1) a function to generate initial values, which will be executed to generate initial values at the beginning of each MCMC chain, or (2) a single named list of initial values which, will be used for each chain, or (3) a list of length nchains, each element being a named list of initial values which be used for one MCMC chain.
The `inits` argument may also be omitted, in which case the current values in the `model` object will be used as the initial values of the first chain, and subsequent chains will begin using starting values where the previous chain ended.

Other aspects of the MCMC algorithm, such as the specific sampler assignments, must be specified in advance using the MCMC configuration object (created using `configureMCMC`), which is then used to build an MCMC algorithm (using `buildMCMC` argument).

The `niter` argument specifies the number of pre-thinning MCMC iterations, and the `nburnin` argument specifies the number of pre-thinning MCMC samples to discard. After discarding these burn-in samples, thinning of the remaining samples will take place. The total number of posterior samples returned will be `floor((niter-nburnin)/thin)`.

The MCMC option `mcmc$run(..., reset = FALSE)`, used to continue execution of an MCMC chain, is not available through `runMCMC()`.

Value

A list is returned with named elements depending on the arguments passed to `nimbleMCMC`, unless this list contains only a single element, in which case only that element is returned. These elements may include `samples`, `summary`, and `WAIC`, and when the MCMC is monitoring a second set of nodes using `monitors2`, also `samples2`. When `nchains = 1`, posterior samples are returned as a single matrix, and summary statistics as a single matrix. When `nchains > 1`, posterior samples are returned as a list of matrices, one matrix for each chain, and summary statistics are returned as a list containing `nchains+1` matrices: one matrix corresponding to each chain, and the final element providing a summary of all chains, combined. If `samplesAsCodaMCMC` is `TRUE`, then posterior samples are provided as `coda mcmc` and `mcmc.list` objects. When `WAIC` is `TRUE`, a WAIC summary object is returned.

sampler_BASE  MCMC Sampling Algorithms

**Description**

Details of the MCMC sampling algorithms provided with the NIMBLE MCMC engine

**Usage**

    sampler_BASE()
    sampler_posterior_predictive(model, mvSaved, target, control)
    sampler_posterior_predictive_branch(model, mvSaved, target, control)
    sampler_binary(model, mvSaved, target, control)
    sampler_categorical(model, mvSaved, target, control)
    sampler_RW(model, mvSaved, target, control)
    sampler_RW_block(model, mvSaved, target, control)
    sampler_RW_llFunction(model, mvSaved, target, control)
    sampler_slice(model, mvSaved, target, control)
    sampler_ess(model, mvSaved, target, control)
    sampler_AF_slice(model, mvSaved, target, control)
    sampler_crossLevel(model, mvSaved, target, control)
    sampler_RW_llFunction_block(model, mvSaved, target, control)
    sampler_RW_multinomial(model, mvSaved, target, control)
    sampler_RW_dirichlet(model, mvSaved, target, control)
    sampler_RW_wishart(model, mvSaved, target, control)
    sampler_RW_lkj_corr_cholesky(model, mvSaved, target, control)
sampler_RW_block_lkj_corr_cholesky(model, mvSaved, target, control)
sampler_CAR_normal(model, mvSaved, target, control)
sampler_CAR_proper(model, mvSaved, target, control)
sampler_RJ_fixed_prior(model, mvSaved, target, control)
sampler_RJ_indicator(model, mvSaved, target, control)
sampler_RJ_toggled(model, mvSaved, target, control)
sampler_CRP_concentration(model, mvSaved, target, control)
sampler_CRP(model, mvSaved, target, control)
sampler_slice_CRP_base_param(model, mvSaved, target, control)

**Arguments**

- **model** (uncompiled) model on which the MCMC is to be run
- **mvSaved** modelValues object to be used to store MCMC samples
- **target** node(s) on which the sampler will be used
- **control** named list that controls the precise behavior of the sampler, with elements specific to sampler type. The default values for control list are specified in the setup code of each sampling algorithm. Descriptions of each sampling algorithm, and the possible customizations for each sampler (using the control argument) appear below.

**sampler_base**

base class for new samplers

When you write a new sampler for use in a NIMBLE MCMC (see User Manual), you must include contains = sampler_BASE.

**binary sampler**

The binary sampler performs Gibbs sampling for binary-valued (discrete 0/1) nodes. This can only be used for nodes following either a dbern(p) or dbinom(p, size=1) distribution.

The binary sampler accepts no control list arguments.

**categorical sampler**

The categorical sampler performs Gibbs sampling for a single node, which must follow a categorical (dcat) distribution.

The categorical sampler accepts no control list arguments.
**RW sampler**

The RW sampler executes adaptive Metropolis-Hastings sampling with a normal proposal distribution (Metropolis, 1953), implementing the adaptation routine given in Shaby and Wells, 2011. This sampler can be applied to any scalar continuous-valued stochastic node, and can optionally sample on a log scale.

The RW sampler accepts the following control list elements:

- **log.** A logical argument, specifying whether the sampler should operate on the log scale. (default = FALSE)
- **reflective.** A logical argument, specifying whether the normal proposal distribution should reflect to stay within the range of the target distribution. (default = FALSE)
- **adaptive.** A logical argument, specifying whether the sampler should adapt the scale (proposal standard deviation) throughout the course of MCMC execution to achieve a theoretically desirable acceptance rate. (default = TRUE)
- **adaptInterval.** The interval on which to perform adaptation. Every adaptInterval MCMC iterations (prior to thinning), the RW sampler will perform its adaptation procedure. This updates the scale variable, based upon the sampler’s achieved acceptance rate over the past adaptInterval iterations. (default = 200)
- **adaptFactorExponent.** Exponent controlling the rate of decay of the scale adaptation factor. See Shaby and Wells, 2011, for details. (default = 0.8)
- **scale.** The initial value of the normal proposal standard deviation. If adaptive = FALSE, scale will never change. (default = 1)

The RW sampler cannot be used with options log=TRUE and reflective=TRUE, i.e. it cannot do reflective sampling on a log scale.

**RW_block sampler**

The RW_block sampler performs a simultaneous update of one or more model nodes, using an adaptive Metropolis-Hastings algorithm with a multivariate normal proposal distribution (Roberts and Sahu, 1997), implementing the adaptation routine given in Shaby and Wells, 2011. This sampler may be applied to any set of continuous-valued model nodes, to any single continuous-valued multivariate model node, or to any combination thereof.

The RW_block sampler accepts the following control list elements:

- **adaptive.** A logical argument, specifying whether the sampler should adapt the scale (a coefficient for the entire proposal covariance matrix) and propCov (the multivariate normal proposal covariance matrix) throughout the course of MCMC execution. If only the scale should undergo adaptation, this argument should be specified as TRUE. (default = TRUE)
- **adaptScaleOnly.** A logical argument, specifying whether adaptation should be done only for scale (TRUE) or also for propCov (FALSE). This argument is only relevant when adaptive = TRUE. When adaptScaleOnly = FALSE, both scale and propCov undergo adaptation; the sampler tunes the scaling to achieve a theoretically good acceptance rate, and the proposal covariance to mimic that of the empirical samples. When adaptScaleOnly = TRUE, only the proposal scale is adapted. (default = FALSE)
• adaptInterval. The interval on which to perform adaptation. Every adaptInterval MCMC iterations (prior to thinning), the RW_block sampler will perform its adaptation procedure, based on the past adaptInterval iterations. (default = 200)

• adaptFactorExponent. Exponent controlling the rate of decay of the scale adaptation factor. See Shaby and Wells, 2011, for details. (default = 0.8)

• scale. The initial value of the scalar multiplier for propCov. If adaptive = FALSE, scale will never change. (default = 1)

• propCov. The initial covariance matrix for the multivariate normal proposal distribution. This element may be equal to the character string 'identity', in which case the identity matrix of the appropriate dimension will be used for the initial proposal covariance matrix. (default = 'identity')

• tries. The number of times this sampler will repeatedly operate on each MCMC iteration. Each try consists of a new proposed transition and an accept/reject decision of this proposal. Specifying tries > 1 can help increase the overall sampler acceptance rate and therefore chain mixing. (default = 1)

Note that modifying elements of the control list may greatly affect the performance of this sampler. In particular, the sampler can take a long time to find a good proposal covariance when the elements being sampled are not on the same scale. We recommend providing an informed value for propCov in this case (possibly simply a diagonal matrix that approximates the relative scales), as well as possibly providing a value of scale that errs on the side of being too small. You may also consider decreasing adaptFactorExponent and/or adaptInterval, as doing so has greatly improved performance in some cases.

**RW_llFunction sampler**

Sometimes it is useful to control the log likelihood calculations used for an MCMC updater instead of simply using the model. For example, one could use a sampler with a log likelihood that analytically (or numerically) integrates over latent model nodes. Or one could use a sampler with a log likelihood that comes from a stochastic approximation such as a particle filter, allowing composition of a particle MCMC (PMCMC) algorithm (Andrieu et al., 2010). The RW_llFunction sampler handles this by using a Metropolis-Hastings algorithm with a normal proposal distribution and a user-provided log-likelihood function. To allow compiled execution, the log-likelihood function must be provided as a specialized instance of a nimbleFunction. The log-likelihood function may use the same model as the MCMC as a setup argument, but if so the state of the model should be unchanged during execution of the function (or you must understand the implications otherwise).

The RW_llFunction sampler accepts the following control list elements:

• adaptive. A logical argument, specifying whether the sampler should adapt the scale (proposal standard deviation) throughout the course of MCMC execution. (default = TRUE)

• adaptInterval. The interval on which to perform adaptation. (default = 200)

• scale. The initial value of the normal proposal standard deviation. (default = 1)

• llFunction. A specialized nimbleFunction that accepts no arguments and returns a scalar double number. The return value must be the total log-likelihood of all stochastic dependents of the target nodes – and, if includesTarget = TRUE, of the target node(s) themselves – or whatever surrogate is being used for the total log-likelihood. This is a required element with no default.
• includesTarget. Logical variable indicating whether the return value of llFunction includes the log-likelihood associated with target. This is a required element with no default.

slice sampler

The slice sampler performs slice sampling of the scalar node to which it is applied (Neal, 2003). This sampler can operate on either continuous-valued or discrete-valued scalar nodes. The slice sampler performs a ’stepping out’ procedure, in which the slice is iteratively expanded to the left or right by an amount sliceWidth. This sampler is optionally adaptive, governed by a control list element, whereby the value of sliceWidth is adapted towards the observed absolute difference between successive samples.

The slice sampler accepts the following control list elements:

• adaptive. A logical argument, specifying whether the sampler will adapt the value of sliceWidth throughout the course of MCMC execution. (default = TRUE)
• adaptInterval. The interval on which to perform adaptation. (default = 200)
• sliceWidth. The initial value of the width of each slice, and also the width of the expansion during the iterative ’stepping out’ procedure. (default = 1)
• sliceMaxSteps. The maximum number of expansions which may occur during the ’stepping out’ procedure. (default = 100)
• maxContractions. The maximum number of contractions of the interval that may occur during sampling (this prevents infinite looping in unusual situations). (default = 100)
• maxContractionsWarning. A logical argument specifying whether to warn when the maximum number of contractions is reached. (default = TRUE)

ess sampler

The ess sampler performs elliptical slice sampling of a single node, which must follow either a univariate or multivariate normal distribution (Murray, 2010). The algorithm is an extension of slice sampling (Neal, 2003), generalized to context of the Gaussian distribution. An auxiliary variable is used to identify points on an ellipse (which passes through the current node value) as candidate samples, which are accepted contingent upon a likelihood evaluation at that point. This algorithm requires no tuning parameters and therefore no period of adaptation, and may result in very efficient sampling from Gaussian distributions.

The ess sampler accepts the following control list arguments.

• maxContractions. The maximum number of contractions of the interval that may occur during sampling (this prevents infinite looping in unusual situations). (default = 100)
• maxContractionsWarning. A logical argument specifying whether to warn when the maximum number of contractions is reached. (default = TRUE)

AF_slice sampler

The automated factor slice sampler conducts a slice sampling algorithm on one or more model nodes. The sampler uses the eigenvectors of the posterior covariance between these nodes as an orthogonal basis on which to perform its ’stepping Out’ procedure. The sampler is adaptive in updating both the width of the slices and the values of the eigenvectors. The sampler can be applied
to any set of continuous or discrete-valued model nodes, to any single continuous or discrete-valued multivariate model node, or to any combination thereof. The automated factor slice sampler accepts the following control list elements:

- **sliceWidths.** A numeric vector of initial slice widths. The length of the vector must be equal to the sum of the lengths of all nodes being used by the automated factor slice sampler. Defaults to a vector of 1’s.
- **sliceAdaptFactorMaxIter.** The number of iterations for which the factors (eigenvectors) will continue to adapt to the posterior correlation. (default = 15000)
- **sliceAdaptFactorInterval.** The interval on which to perform factor adaptation. (default = 1000)
- **sliceAdaptWidthMaxIter.** The maximum number of iterations for which to adapt the widths for a given set of factors. (default = 512)
- **sliceAdaptWidthTolerance.** The tolerance for when widths no longer need to adapt, between 0 and 0.5. (default = 0.1)
- **sliceMaxSteps.** The maximum number of expansions which may occur during the ’stepping out’ procedure. (default = 100)
- **maxContractions.** The maximum number of contractions of the interval that may occur during sampling (this prevents infinite looping in unusual situations). (default = 100)
- **maxContractionsWarning.** A logical argument specifying whether to warn when the maximum number of contractions is reached. (default = TRUE)

**crossLevel sampler**

This sampler is constructed to perform simultaneous updates across two levels of stochastic dependence in the model structure. This is possible when all stochastic descendents of node(s) at one level have conjugate relationships with their own stochastic descendents. In this situation, a Metropolis-Hastings algorithm may be used, in which a multivariate normal proposal distribution is used for the higher-level nodes, and the corresponding proposals for the lower-level nodes undergo Gibbs (conjugate) sampling. The joint proposal is either accepted or rejected for all nodes involved based upon the Metropolis-Hastings ratio. This sampler is a conjugate version of Scheme 3 in Knorr-Held and Rue (2002). It can also be seen as a Metropolis-based version of collapsed Gibbs sampling (in particular Sampler 3 of van Dyk and Park (2008)).

The requirement that all stochastic descendents of the target nodes must themselves have only conjugate descendents will be checked when the MCMC algorithm is built. This sampler is useful when there is strong dependence across the levels of a model that causes problems with convergence or mixing.

The crossLevel sampler accepts the following control list elements:

- **adaptive.** Logical argument, specifying whether the multivariate normal proposal distribution for the target nodes should be adapted. (default = TRUE)
- **adaptInterval.** The interval on which to perform adaptation. (default = 200)
- **scale.** The initial value of the scalar multiplier for propCov. (default = 1)
- **propCov.** The initial covariance matrix for the multivariate normal proposal distribution. This element may be equal to the character string ’identity’ or any positive definite matrix of the appropriate dimensions. (default = ’identity’)
RW_llFunction_block sampler

Sometimes it is useful to control the log likelihood calculations used for an MCMC updater instead of simply using the model. For example, one could use a sampler with a log likelihood that analytically (or numerically) integrates over latent model nodes. Or one could use a sampler with a log likelihood that comes from a stochastic approximation such as a particle filter, allowing composition of a particle MCMC (PMCMC) algorithm (Andrieu et al., 2010) (but see samplers listed below for NIMBLE’s direct implementation of PMCMC). The RW_llFunction_block sampler handles this by using a Metropolis-Hastings algorithm with a multivariate normal proposal distribution and a user-provided log-likelihood function. To allow compiled execution, the log-likelihood function must be provided as a specialized instance of a nimbleFunction. The log-likelihood function may use the same model as the MCMC as a setup argument, but if so the state of the model should be unchanged during execution of the function (or you must understand the implications otherwise).

The RW_llFunction_block sampler accepts the following control list elements:

- **adaptive.** A logical argument, specifying whether the sampler should adapt the proposal covariance throughout the course of MCMC execution. (default is TRUE)
- **adaptScaleOnly.** A logical argument, specifying whether adaption should be done only for scale (TRUE) or also for propCov (FALSE). This argument is only relevant when adaptive = TRUE. When adaptScaleOnly = FALSE, both scale and propCov undergo adaptation; the sampler tunes the scaling to achieve a theoretically good acceptance rate, and the proposal covariance to mimic that of the empirical samples. When adaptScaleOnly = TRUE, only the proposal scale is adapted. (default = FALSE)
- **adaptInterval.** The interval on which to perform adaptation. (default = 200)
- **adaptFactorExponent.** Exponent controlling the rate of decay of the scale adaptation factor. See Shaby and Wells, 2011, for details. (default = 0.8)
- **scale.** The initial value of the scalar multiplier for propCov. If adaptive = FALSE, scale will never change. (default = 1)
- **propCov.** The initial covariance matrix for the multivariate normal proposal distribution. This element may be equal to the character string ’identity’, in which case the identity matrix of the appropriate dimension will be used for the initial proposal covariance matrix. (default = ′identity′)
- **llFunction.** A specialized nimbleFunction that accepts no arguments and returns a scalar double number. The return value must be the total log-likelihood of all stochastic dependents of the target nodes – and, if includesTarget = TRUE, of the target node(s) themselves – or whatever surrogate is being used for the total log-likelihood. This is a required element with no default.
- **includesTarget.** Logical variable indicating whether the return value of llFunction includes the log-likelihood associated with target. This is a required element with no default.

RW_multinomial sampler

This sampler is designed for sampling multinomial target distributions. The sampler performs a series of Metropolis-Hastings steps between pairs of groups. Proposals are generated via a draw from a binomial distribution, whereafter the proposed number density is moved from one group to another group. The acceptance or rejection of these proposals follows a standard Metropolis-Hastings
The RW_multinomial sampler accepts the following control list elements:

- adaptive. A logical argument, specifying whether the sampler should adapt the binomial proposal probabilities throughout the course of MCMC execution. (default = TRUE)
- adaptInterval. The interval on which to perform adaptation. A minimum value of 100 is required. (default = 200)

**RW_dirichlet sampler**

This sampler is designed for sampling non-conjugate Dirichlet distributions. The sampler performs a series of Metropolis-Hastings updates (on the log scale) to each component of a gamma-reparameterization of the target Dirichlet distribution. The acceptance or rejection of these proposals follows a standard Metropolis-Hastings procedure.

The RW_dirichlet sampler accepts the following control list elements:

- adaptive. A logical argument, specifying whether the sampler should independently adapt the scale (proposal standard deviation, on the log scale) for each componentwise Metropolis-Hasting update, to achieve a theoretically desirable acceptance rate for each. (default = TRUE)
- adaptInterval. The interval on which to perform adaptation. Every adaptInterval MCMC iterations (prior to thinning), the sampler will perform its adaptation procedure. (default = 200)
- adaptFactorExponent. Exponent controlling the rate of decay of the scale adaptation factor. See Shaby and Wells, 2011, for details. (default = 0.8)
- scale. The initial value of the proposal standard deviation (on the log scale) for each component of the reparameterized Dirichlet distribution. If adaptive = FALSE, the proposal standard deviations will never change. (default = 1)

**RW_wishart sampler**

This sampler is designed for sampling non-conjugate Wishart and inverse-Wishart distributions. More generally, it can update any symmetric positive-definite matrix (for example, scaled covariance or precision matrices). The sampler performs block Metropolis-Hastings updates following a transformation to an unconstrained scale (Cholesky factorization of the original matrix, then taking the log of the main diagonal elements.

The RW_wishart sampler accepts the following control list elements:

- adaptive. A logical argument, specifying whether the sampler should adapt the scale and proposal covariance for the multivariate normal Metropolis-Hasting proposals, to achieve a theoretically desirable acceptance rate for each. (default = TRUE)
- adaptInterval. The interval on which to perform adaptation. Every adaptInterval MCMC iterations (prior to thinning), the sampler will perform its adaptation procedure. (default = 200)
- adaptFactorExponent. Exponent controlling the rate of decay of the scale adaptation factor. See Shaby and Wells, 2011, for details. (default = 0.8)
- scale. The initial value of the scalar multiplier for the multivariate normal Metropolis-Hastings proposal covariance. If adaptive = FALSE, scale will never change. (default = 1)
RW_block_lkj_corr_cholesky sampler

This sampler is designed for sampling non-conjugate LKJ correlation Cholesky factor distributions. The sampler performs a blocked Metropolis-Hastings update following a transformation to an unconstrained scale (using the signed stickbreaking approach documented in Section 10.12 of the Stan Language Reference Manual, version 2.27).

The RW_block_lkj_corr_cholesky sampler accepts the following control list elements:

- **adaptive.** A logical argument, specifying whether the sampler should adapt the scale (a coefficient for the entire proposal covariance matrix) and propCov (the multivariate normal proposal covariance matrix) throughout the course of MCMC execution. If only the scale should undergo adaptation, this argument should be specified as TRUE. (default = TRUE)
- **adaptScaleOnly.** A logical argument, specifying whether adaption should be done only for scale (TRUE) or also for propCov (FALSE). This argument is only relevant when adaptive = TRUE. When adaptScaleOnly = FALSE, both scale and propCov undergo adaptation; the sampler tunes the scaling to achieve a theoretically good acceptance rate, and the proposal covariance to mimic that of the empirical samples. When adaptScaleOnly = TRUE, only the proposal scale is adapted. (default = FALSE)
- **adaptInterval.** The interval on which to perform adaptation. Every adaptInterval MCMC iterations (prior to thinning), the RW_block sampler will perform its adaptation procedure, based on the past adaptInterval iterations. (default = 200)
- **adaptFactorExponent.** Exponent controlling the rate of decay of the scale adaptation factor. See Shaby and Wells, 2011, for details. (default = 0.8)
- **scale.** The initial value of the scalar multiplier for propCov. If adaptive = FALSE, scale will never change. (default = 1)
- **propCov.** The initial covariance matrix for the multivariate normal proposal distribution. This element may be equal to the character string 'identity', in which case the identity matrix of the appropriate dimension will be used for the initial proposal covariance matrix. (default = 'identity')

This is the default sampler for the LKJ distribution. However, blocked samplers may perform poorly if the adaptation configuration is poorly chosen. See the comments in the RW_block section of this documentation.

RW_lkj_corr_cholesky sampler

This sampler is designed for sampling non-conjugate LKJ correlation Cholesky factor distributions. The sampler performs individual Metropolis-Hastings updates following a transformation to an unconstrained scale (using the signed stickbreaking approach documented in Section 10.12 of the Stan Language Reference Manual, version 2.27).

The RW_lkj_corr_cholesky sampler accepts the following control list elements:

- **adaptive.** A logical argument, specifying whether the sampler should adapt the scales of the univariate normal Metropolis-Hastings proposals, to achieve a theoretically desirable acceptance rate for each. (default = TRUE)
- **adaptInterval.** The interval on which to perform adaptation. Every adaptInterval MCMC iterations (prior to thinning), the sampler will perform its adaptation procedure. (default = 200)
• adaptFactorExponent. Exponent controlling the rate of decay of the scale adaptation factor. See Shaby and Wells, 2011, for details. (default = 0.8)

• scale. The initial value of the scalar multiplier for the multivariate normal Metropolis-Hastings proposal covariance. If adaptive = FALSE, scale will never change. (default = 1)

Note that this sampler is likely run much more slowly than the blocked sampler for the LKJ distribution, as updating each single element will generally incur the full cost of updating all dependencies of the entire matrix.

**CAR_normal sampler**

The CAR_normal sampler operates uniquely on improper (intrinsic) Gaussian conditional autoregressive (CAR) nodes, those with a dcar_normal prior distribution. It internally assigns one of three univariate samplers to each dimension of the target node: a posterior predictive, conjugate, or RW sampler; however these component samplers are specialized to operate on dimensions of a dcar_normal distribution.

The CAR_normal sampler accepts the following control list elements:

• carUseConjugacy. A logical argument, specifying whether to assign conjugate samplers for conjugate components of the target node. If FALSE, a RW sampler would be assigned instead. (default = TRUE)

• adaptive. A logical argument, specifying whether any component RW samplers should adapt the scale (proposal standard deviation), to achieve a theoretically desirable acceptance rate. (default = TRUE)

• adaptInterval. The interval on which to perform adaptation for any component RW samplers. Every adaptInterval MCMC iterations (prior to thinning), component RW samplers will perform an adaptation procedure. This updates the scale variable, based upon the sampler's achieved acceptance rate over the past adaptInterval iterations. (default = 200)

• scale. The initial value of the normal proposal standard deviation for any component RW samplers. If adaptive = FALSE, scale will never change. (default = 1)

**CAR_proper sampler**

The CAR_proper sampler operates uniquely on proper Gaussian conditional autoregressive (CAR) nodes, those with a dcar_proper prior distribution. It internally assigns one of three univariate samplers to each dimension of the target node: a posterior predictive, conjugate, or RW sampler, however these component samplers are specialized to operate on dimensions of a dcar_proper distribution.

The CAR_proper sampler accepts the following control list elements:

• carUseConjugacy. A logical argument, specifying whether to assign conjugate samplers for conjugate components of the target node. If FALSE, a RW sampler would be assigned instead. (default = TRUE)

• adaptive. A logical argument, specifying whether any component RW samplers should adapt the scale (proposal standard deviation), to achieve a theoretically desirable acceptance rate. (default = TRUE)
• adaptInterval. The interval on which to perform adaptation for any component RW samplers. Every adaptInterval MCMC iterations (prior to thinning), component RW samplers will perform an adaptation procedure. This updates the scale variable, based upon the sampler’s achieved acceptance rate over the past adaptInterval iterations. (default = 200)

• scale. The initial value of the normal proposal standard deviation for any component RW samplers. If adaptive = FALSE, scale will never change. (default = 1)

CRP sampler

The CRP sampler is designed for fitting models involving Dirichlet process mixtures. It is exclusively assigned by NIMBLE’s default MCMC configuration to nodes having the Chinese Restaurant Process distribution, dCRP. It executes sequential sampling of each component of the node (i.e., the cluster membership of each element being clustered). Internally, either of two samplers can be assigned, depending on conjugate or non-conjugate structures within the model. For conjugate and non-conjugate model structures, updates are based on Algorithm 2 and Algorithm 8 in Neal (2000), respectively.

• checkConjugacy. A logical argument, specifying whether to assign conjugate samplers if valid. (default = TRUE)

• printTruncation. A logical argument, specifying whether to print a warning when the MCMC attempts to use more clusters than the maximum number specified in the model. Only relevant where the user has specified the maximum number of clusters to be less than the number of observations. (default = TRUE)

CRP_concentration sampler

The CRP_concentration sampler is designed for Bayesian nonparametric mixture modeling. It is exclusively assigned to the concentration parameter of the Dirichlet process when the model is specified using the Chinese Restaurant Process distribution, dCRP. This sampler is assigned by default by NIMBLE’s default MCMC configuration and can only be used when the prior for the concentration parameter is a gamma distribution. The assigned sampler is an augmented beta-gamma sampler as discussed in Section 6 in Escobar and West (1995).

posterior_predictive and posterior_predictive_branch samplers

The posterior_predictive sampler is only appropriate for use on terminal stochastic nodes. Note that such nodes play no role in inference but have often been included in BUGS models to accomplish posterior predictive checks. NIMBLE allows posterior predictive values to be simulated independently of running MCMC, for example by writing a nimbleFunction to do so. This means that in many cases where terminal stochastic nodes have been included in BUGS models, they are not needed when using NIMBLE.

The posterior_predictive sampler functions by calling the simulate() method of relevant node, then updating model probabilities and deterministic dependent nodes. The application of a posterior_predictive sampler to any non-terminal node will result in invalid posterior inferences. The posterior_predictive sampler will automatically be assigned to all terminal, non-data stochastic nodes in a model by the default MCMC configuration, so it is uncommon to manually assign this sampler.

Closely related, the posterior_predictive_branch is only appropriate for nodes for which all downstream (dependent) nodes are non-data; that is, the branch beginning from that node is a jointly
posterior predictive network of nodes. This sampler operates by calling the simulate method of all nodes in this downstream (non-data) network, which serves to improve MCMC mixing of the posterior predictive branch.

The posterior_predictive and posterior_predictive_branch samplers accept no control list arguments.

RJ_fixed_prior sampler

This sampler proposes addition/removal for variable of interest in the framework of variable selection using reversible jump MCMC, with a specified prior probability of inclusion. A normal proposal distribution is used to generate proposals for the addition of the variable. This is a specialized sampler used by configureRJ function, when the model code is written without using indicator variables. See help(configureRJ) for details. It is not intended for direct assignment.

RJ_indicator sampler

This sampler proposes transitions of a binary indicator variable, corresponding to a variable of interest, in the framework of variable selection using reversible jump MCMC. This is a specialized sampler used by configureRJ function, when the model code is written using indicator variables. See help(configureRJ) for details. It is not intended for direct assignment.

RJ_toggled sampler

This sampler operates in the framework of variable selection using reversible jump MCMC. Specifically, it conditionally performs updates of the target variable of interest using the originally-specified sampling configuration, when variable is "in the model". This is a specialized sampler used by configureRJ when adding a reversible jump MCMC. See help(configureRJ) for details. It is not intended for direct assignment.

Particle filter samplers

As of Version 0.10.0 of NIMBLE, the RW_PF and RW_PF_block samplers live in the ‘nimbleSMC’ package. Please load that package in order to use the samplers.

```

setAndCalculate

Creates a nimbleFunction for setting the values of one or more model nodes, calculating the associated deterministic dependents and log-Prob values, and returning the total sum log-probability.

Description

This nimbleFunction generator must be specialized to any model object and one or more model nodes. A specialized instance of this nimbleFunction will set the values of the target nodes in the specified model, calculate the associated logProbs, calculate the values of any deterministic dependents, calculate the logProbs of any stochastic dependents, and return the sum log-probability associated with the target nodes and all stochastic dependent nodes.

Usage

setAndCalculate(model, targetNodes)

setAndCalculateDiff(model, targetNodes)

Arguments

model An uncompiled or compiled NIMBLE model. This argument is required.

targetNodes A character vector containing the names of one or more nodes or variables in the model. This argument is required.

Details

Calling setAndCalculate(model, targetNodes) or setAndCalculate(model, targetNodes) will return a nimbleFunction object whose run function takes a single, required argument:

targetValues: A vector of numeric values which will be put into the target nodes in the specified model object. The length of this numeric vector much exactly match the number of target nodes.

The difference between setAndCalculate and setAndCalculateDiff is the return value of their run functions. In the former, run returns the sum of the log probabilities of the targetNodes with the provided targetValues, while the latter returns the difference between that sum with the new targetValues and the previous values in the model.

Author(s)

Daniel Turek
Examples

code <- nimbleCode({ for(i in 1:3) { x[i] ~ dnorm(0, 1); y[i] ~ dnorm(0, 1) }})
Rmodel <- nimbleModel(code)
my_setAndCalc <- setAndCalculate(Rmodel, c('x[1]', 'x[2]', 'y[1]', 'y[2]'))
lp <- my_setAndCalc$run(c(1.2, 1.4, 7.6, 8.9))

setAndCalculateOne

Creating a nimbleFunction for setting the value of a scalar model node, calculating the associated deterministic dependents and logProb values, and returning the total sum log-probability.

Description

This nimbleFunction generator must be specialized to any model object and any scalar model node. A specialized instance of this nimbleFunction will set the value of the target node in the specified model, calculate the associated logProb, calculate the values of any deterministic dependents, calculate the logProbs of any stochastic dependents, and return the sum log-probability associated with the target node and all stochastic dependent nodes.

Usage

setAndCalculateOne(model, targetNode)

Arguments

model An uncompiled or compiled NIMBLE model. This argument is required.
targetNode The character name of any scalar node in the model object. This argument is required.

Details

Calling setAndCalculateOne(model, targetNode) will return a function with a single, required argument:
targetValue: The numeric value which will be put into the target node, in the specified model object.

Author(s)

Daniel Turek

Examples

code <- nimbleCode({ for(i in 1:3) { x[i] ~ dnorm(0, 1) }})
Rmodel <- nimbleModel(code)
my_setAndCalc <- setAndCalculateOne(Rmodel, 'x[1]')
lp <- my_setAndCalc$run(2)
Description

set the size of a numeric variable in NIMBLE. This works in R and NIMBLE, but in R it usually has no effect.

Usage

setSize(numObj, ..., copy = TRUE, fillZeros = TRUE)

Arguments

numObj This is the object to be resized
... sizes, provided as scalars, in order, or as a single vector
copy logical indicating whether values should be preserved (in column-major order)
fillZeros logical indicating whether newly allocated space should be initialized with zeros (in compiled code)

Details

Note that assigning the result of numeric, integer, logical, matrix, or array is often as good or better than using setSize. For example, ‘x <- matrix(nrow = 5, ncol = 5)’ is equivalent to ‘setSize(x, 5, 5)’ but the former allows more control over initialization.

This function is part of the NIMBLE language. Its purpose is to explicitly resize a multivariate object (vector, matrix or array), currently up to 4 dimensions. Explicit resizing is not needed when an entire object is assigned to. For example, in Y <- A %*% B, where A and B are matrices, Y will be resized automatically. Explicit resizing is necessary when assignment will be by indexed elements or blocks, if the object is not already an appropriate size for the assignment. E.g. prior to Y[5:10] <- A %*% B, one can use setSize to ensure that Y has a size (length) of at least 10.

This does work in uncompiled (R) and well as compiled execution, but in some cases it is only necessary for compiled execution. During uncompiled execution, it may not catch bugs due to resizing because some R objects will be dynamically resized during assignments anyway.

If preserving values in the resized object and/or initializing new values with 0 is not necessary, then setting these arguments to FALSE will yield slightly more efficient compiled code.

NIMBLE development team
setupOutputs

Explicitly declare objects created in setup code to be preserved and compiled as member data

Description

Normally a nimbleFunction determines what objects from setup code need to be preserved for run code or other member functions. setupOutputs allows explicit declaration for cases when an object created in setup code is not used in member functions.

Arguments

... An arbitrary set of names

Details

Normally any object created in setup whose name appears in run or another member function is included in the saved results of setup code. When the nimbleFunction is compiled, such objects will become member data of the resulting C++ class. If it is desired to force an object to become member data even if it does not appear in a member function, declare it using setupOutputs. E.g., setupOutputs(a,b) declares that a and b should be preserved.

The setupOutputs line will be removed from the setup code. It is really a marker during nimble-Function creation of what should be preserved.

simNodes

Basic nimbleFunctions for calculate, simulate, and getLogProb with a set of nodes

Description

simulate, calculate, or get existing log probabilities for the current values in a NIMBLE model

Usage

simNodes(model, nodes)
calcNodes(model, nodes)
getLogProbNodes(model, nodes)

Arguments

model A NIMBLE model
nodes A set of nodes. If none are provided, default is all model$getNodeNames()
Details

These are basic nimbleFunctions that take a model and set of nodes and return a function that will call calculate, simulate, or getLogProb on those nodes. Each is equivalent to a direct call from R, but in nimbleFunction form they can be be compiled and can be put into a nimbleFunction-List. For example, myCalc <-calcNodes(model,nodes); ans <-myCalc() is equivalent to ans <-model$calculate(nodes), but one can also do CmyCalc <-compileNimble(myCalc) to get a faster version.

In nimbleFunctions, for only one set of nodes, it is equivalent or slightly better to simply use model$calculate(nodes) in the run-time code. The compiler will process the model-nodes combination in the same way as would occur by creating a specialized calcNodes in the setup code. However, if there are multiple sets of nodes, one can do the following:

Setup code: myCalcs <-nimbleFunctionList(calcNodes); myCalcs[[1]] <-calcNodes(model,nodes[[1]]); myCalcs[[2]] <-calcNodes[[2]]

Run code: for(i in seq_along(myCalcs)) {ans[i] <-myCalcs[[i]]()}

| simNodesMV | Basic nimbleFunctions for using a NIMBLE model with sets of stored values |

Description

simulate, calculate, or get the existing log probabilities for values in a modelValues object using a NIMBLE model

Usage

simNodesMV(model, mv, nodes)
calcNodesMV(model, mv, nodes)
getLogProbNodesMV(model, mv, nodes)

Arguments

model A nimble model.
mv A modelValues object in which multiple sets of model variables and their corresponding logProb values are or will be saved. mv must include the nodes provided
nodes A set of nodes. If none are provided, default is all model$getNodeNames()
**Details**

*simNodesMV* simulates values in the given nodes and saves them in *mv*. *calcNodesMV* calculates these nodes for each row of *mv* and returns a vector of the total log probabilities (densities) for each row. *getLogProbNodesMV* is like *calcNodesMV* without actually doing the calculations.

Each of these will expand variables or index blocks and topologically sort them so that each node’s parent nodes are processed before itself.

*getLogProbMV* should be used carefully. It is generally for situations where the logProb values are guaranteed to have already been calculated, and all that is needed is to query them. The risk is that a program may have changed the values in the nodes, in which case *getLogProbMV* would collect logProb values that are out of date with the node values.

**Value**

from *simNodesMV*: NULL. from *calcNodesMV* and *getLogProbMV*: a vector of the sum of log probabilities (densities) from any stochastic nodes in nodes.

**Run time arguments**

- **m**
  
  (*simNodesMV* only). Number of simulations requested.

- **saveLP**
  
  (*calcNodesMV* only). Whether to save the logProb values in *mv*. Should be given as TRUE unless there is a good reason not to.

**Author(s)**

Clifford Anderson-Bergman

**Examples**

```r
code <- nimbleCode({
  for(i in 1:5)
    x[i] ~ dnorm(0,1)
})

myModel <- nimbleModel(code)
myMV <- modelValues(myModel)

Rsim <- simNodesMV(myModel, myMV)
Rcalc <- calcNodesMV(myModel, myMV)
Rglp <- getLogProbNodesMV(myModel, myMV)

## Not run:
cModel <- compileNimble(myModel)
Csim <- compileNimble(Rsim, project = myModel)
Ccalc <- compileNimble(Rcalc, project = myModel)
Cglp <- compileNimble(Rglp, project = myModel)

Csim$run(10)
Ccalc$run(saveLP = TRUE)
Cglp$run() # Gives identical answers to Ccalc because logProbs were saved
```
Csim$run(10)
Ccalc$run(saveLP = FALSE)
Cglp$run()  # Gives wrong answers because logProbs were not saved
result <- as.matrix(Csim$mv)

## End(Not run)

---

**singleVarAccessClass-class**

*Class: singleVarAccessClass*

**Description**

Classes used internally in NIMBLE and not expected to be called directly by users.

---

**StickBreakingFunction**  *The Stick Breaking Function*

**Description**

Computes probabilities based on stick breaking construction.

**Usage**

```r
stick_breaking(z, log = 0)
```

**Arguments**

- `z`  
  vector argument.

- `log`  
  logical; if TRUE, weights are returned on the log scale.

**Details**

The stick breaking function produces a vector of probabilities that add up to one, based on a series of individual probabilities in `z`, which define the breaking points relative to the remaining stick length. The first element of `z` determines the first probability based on breaking a proportion `z[1]` from a stick of length one. The second element of `z` determines the second probability based on breaking a proportion `z[2]` from the remaining stick (of length `1-z[1]`), and so forth. Each element of `z` should be in `(0, 1)`. The returned vector has length equal to the length of `z` plus 1. If `z[k]` is equal to 1 for any `k`, then the returned vector has length smaller than `z`. If one of the components is smaller than 0 or greater than 1, NaNs are returned.

**Author(s)**

Claudia Wehrhahn
References

Examples

```r
z <- rbeta(5, 1, 1)
stick_breaking(z)

## Not run:
cstick_breaking <- compileNimble(stick_breaking)
cstick_breaking(z)

## End(Not run)
```

#### svdNimbleList

**svdNimbleList definition**

**Description**

nimbleList definition for the type of nimbleList returned by `nimSvd`.

**Usage**

```r
svdNimbleList
```

**Format**

An object of class list of length 1.

`nimSvd`
The t Distribution

Description

Density, distribution function, quantile function and random generation for the t distribution with df degrees of freedom, allowing non-zero location, mu, and non-unit scale, sigma.

Usage

dt_nonstandard(x, df = 1, mu = 0, sigma = 1, log = FALSE)

rt_nonstandard(n, df = 1, mu = 0, sigma = 1)

pt_nonstandard(q, df = 1, mu = 0, sigma = 1, lower.tail = TRUE, log.p = FALSE)

qt_nonstandard(p, df = 1, mu = 0, sigma = 1, lower.tail = TRUE, log.p = FALSE)

Arguments

x vector of values.
df vector of degrees of freedom values.
mu vector of location values.
sigma vector of scale values.
log logical; if TRUE, probability density is returned on the log scale.
n number of observations.
q vector of quantiles.
lower.tail logical; if TRUE (default) probabilities are \( P[X \leq x] \); otherwise, \( P[X > x] \).
log.p logical; if TRUE, probabilities p are given by user as \( \log(p) \).
p vector of probabilities.

Details

See Gelman et al., Appendix A or the BUGS manual for mathematical details.

Value

dt_nonstandard gives the density, pt_nonstandard gives the distribution function, qt_nonstandard gives the quantile function, and rt_nonstandard generates random deviates.

*Distributions* for other standard distributions

Examples

```r
x <- rt_nonstandard(50, df = 1, mu = 5, sigma = 1)
dt_nonstandard(x, 3, 5, 1)
```

Description

testBUGSmodel builds a BUGS model in the NIMBLE system and simulates from the model, comparing the values of the nodes and their log probabilities in the uncompiled and compiled versions of the model

Usage

```r
testBUGSmodel(
  example = NULL,
  dir = NULL,
  model = NULL,
  data = NULL,
  inits = NULL,
  useInits = TRUE,
  expectModelWarning = FALSE,
  debug = FALSE,
  verbose = nimbleOptions("verbose")
)
```

Arguments

- `example` (optional) example character vector indicating name of BUGS example to test; can be null if `model` is provided
- `dir` (optional) character vector indicating directory in which files are contained, by default the classic-bugs directory if the installed package is used; to use the current working directory, set this to ""

---

**testBUGSmodel**

Tests BUGS examples in the NIMBLE system

Description

testBUGSmodel builds a BUGS model in the NIMBLE system and simulates from the model, comparing the values of the nodes and their log probabilities in the uncompiled and compiled versions of the model

Usage

```r
testBUGSmodel(
  example = NULL,
  dir = NULL,
  model = NULL,
  data = NULL,
  inits = NULL,
  useInits = TRUE,
  expectModelWarning = FALSE,
  debug = FALSE,
  verbose = nimbleOptions("verbose")
)
```

Arguments

- `example` (optional) example character vector indicating name of BUGS example to test; can be null if `model` is provided
- `dir` (optional) character vector indicating directory in which files are contained, by default the classic-bugs directory if the installed package is used; to use the current working directory, set this to ""
model (optional) one of (1) a character string giving the file name containing the BUGS model code, (2) an R function whose body is the BUGS model code, or (3) the output of `nimbleCode`. If a file name, the file can contain a `var` block and `data` block in the manner of the JAGS versions of the BUGS examples but should not contain references to other input data files nor a const block. The `.bug` or `.txt` extension can be excluded.

data (optional) one of (1) character string giving the file name for an R file providing the input constants and data as R code [assigning individual objects or as a named list] or (2) a named list providing the input constants and data. If neither is provided, the function will look for a file named `example-data` including extensions `.R`, `.r`, or `.txt`.

inits (optional) (1) character string giving the file name for an R file providing the initial values for parameters as R code [assigning individual objects or as a named list] or (2) a named list providing the values. If neither is provided, the function will look for a file named `example-init` or `example-inits` including extensions `.R`, `.r`, or `.txt`.

useInits boolean indicating whether to test model with initial values provided via `inits`.

expectModelWarning boolean indicating whether `nimbleModel` is expected to produce a warning or character string giving part of expected warning.

dead logical indicating whether to put the user in a browser for debugging when `testBUGSmodel` calls `readBUGSmodel`. Intended for developer use.

verbose logical indicating whether to print additional logging information

Details

Note that testing without initial values may cause warnings when parameters are sampled from improper or fat-tailed distributions

Author(s)

Christopher Paciorek

Examples

```r
## Not run:
testBUGSmodel('pump')
## End(Not run)
```
Description

Most nimbleFunctions written for direct user interaction allow standard R-object-like access to member data using $ or \texttt{\[]\texttt{\]}\texttt{\[]}. However, sometimes compiled nimbleFunctions contained within other compiled nimbleFunctions are interfaced with a light-weight system called a multi-interface. \texttt{valueInCompiledNimbleFunction} provides a way to get or set values in such cases.

Usage

\texttt{valueInCompiledNimbleFunction(cnf, name, value)}

Arguments

\begin{itemize}
  \item \texttt{cnf} Compiled nimbleFunction object
  \item \texttt{name} Name of the member data
  \item \texttt{value} If provided, the value to assign to the member data. If omitted, the value of the member data is returned.
\end{itemize}

Details

The member data of a nimbleFunction are the objects created in \texttt{setup} code that are used in \texttt{run} code or other member functions.

Whether multi-interfaces are used for nested nimbleFunctions is controlled by the \texttt{buildInterfacesForCompiledNestedNimbleFunctions} option in \texttt{nimbleOptions}.

To see an example of a multi-interface, see \texttt{samplerFunctions} in a compiled MCMC interface object.

Perry de Valpine

values

\textit{Access or set values for a set of nodes in a model}

Description

Get or set values for a set of nodes in a model

Usage

\texttt{\texttt{values(model, nodes, accessorIndex)}}

\texttt{\texttt{values(model, nodes, accessorIndex) <- value}}
Arguments

- **model**
  a NIMBLE model object, either compiled or uncompiled
- **nodes**
  a vector of node names, allowing index blocks that will be expanded
- **accessorIndex**
  For internal NIMBLE use only
- **value**
  value to set the node(s) to

Details

Access or set values for a set of nodes in a NIMBLE model.

Calling `values(model, nodes)` returns a vector of the concatenation of values from the nodes requested. `P <- values(model, nodes)` is a newer syntax for `getValues(P, model, values)`, which still works and modifies `P` in the calling environment.

Calling `values(model, nodes) <- P` sets the value of the nodes in the model, in sequential order from the vector `P`.

In both uses, when requested nodes are from matrices or arrays, the values will be handled following column-wise order.

The older function `getValues(P, model, nodes)` is equivalent to `P <- values(model, nodes)`, and the older function `setValues(P, model, nodes)` is equivalent to `values(model, nodes) <- P`.

These functions work in R and in NIMBLE run-time code that can be compiled.

Value

A vector of values concatenated from the provided nodes in the model

Author(s)

NIMBLE development team

**waic**

Using WAIC

Description

Details of the WAIC measure for comparing models. NIMBLE implements an online WAIC algorithm, computed during the course of the MCMC iterations.

Details

To use WAIC, set `enableWAIC = TRUE` when configuring or (if not using `configureMCMC` building an MCMC) and set `WAIC = TRUE` when calling `nimbleMCMC` and optionally when calling `runMCMC`.

By default, NIMBLE calculates WAIC using an online algorithm that updates required summary statistics at each post-burnin iteration of the MCMC.

One can also use `calculateWAIC` to run an offline version of the WAIC algorithm after all MCMC sampling has been done. This allows calculation of WAIC from a matrix (or dataframe) of posterior
samples and also retains compatibility with WAIC in versions of NIMBLE before 0.12.0. However, the offline algorithm is less flexible than the online algorithm and only provides conditional WAIC without the ability to group data points. See `help(calculateWAIC)` for details.

**controlWAIC list**

The `controlWAIC` argument is a list that controls the behavior of the WAIC algorithm and is passed to either `configureMCMC` or (if not using `configureMCMC`) `buildMCMC`. One can supply any of the following optional components:

- **online**: Logical value indicating whether to calculate WAIC during the course of the MCMC. Default is `TRUE` and setting to `FALSE` is primarily for backwards compatibility to allow use of the old `calculateWAIC` method that calculates WAIC from monitored values after the MCMC finishes.

- **dataGroups**: Optional list specifying grouping of data nodes, one element per group, with each list element containing the node names for the data nodes in that group. If provided, the predictive density values computed will be the joint density values, one joint density per group. Defaults to one data node per ‘group’. See details.

- **marginalizeNodes**: Optional set of nodes (presumably latent nodes) over which to marginalize to compute marginal WAIC (i.e., WAIC based on a marginal likelihood), rather than the default conditional WAIC (i.e., WAIC conditioning on all parent nodes of the data nodes). See details.

- **niterMarginal**: Number of Monte Carlo iterations to use when marginalizing (default is 1000).

- **convergenceSet**: Optional vector of numbers between 0 and 1 that specify a set of shorter Monte Carlo simulations for marginal WAIC calculation as fractions of the full (`niterMarginal`) Monte Carlo simulation. If not provided, NIMBLE will use 0.25, 0.50, and 0.75. NIMBLE will report the WAIC, lppd, and pWAIC that would have been obtained for these smaller Monte Carlo simulations, allowing assessment of the number of Monte Carlo samples needed for stable calculation of WAIC.

- **thin**: Logical value for specifying whether to do WAIC calculations only on thinned samples (default is `FALSE`). Likely only useful for reducing computation when using marginal WAIC.

**Extracting WAIC**

The calculated WAIC and related quantities can be obtained in various ways depending on how the MCMC is run. If using `nimbleMCMC` and setting `WAIC = TRUE`, see the `WAIC` component of the output list. If using `runMCMC` and setting `WAIC = TRUE`, either see the `WAIC` component of the output list or use the `getWAIC` method of the MCMC object (in the latter case `WAIC = TRUE` is not required). If using the `run` method of the MCMC object, use the `getWAIC` method of the MCMC object.

The output of running `WAIC` (unless one sets `online = FALSE`) is a list containing the following components:

- **WAIC**: The computed WAIC, on the deviance scale. Smaller values are better when comparing WAIC for two models.

- **lppd**: The log predictive density component of WAIC.

- **pWAIC**: The pWAIC estimate of the effective number of parameters, computed using the pWAIC2 method of Gelman et al. (2014).

To get further information, one can use the `getWAICdetails` method of the MCMC object. The result of running `getWAICdetails` is a list containing the following components:
marginal: Logical value indicating whether marginal (TRUE) or conditional (FALSE) WAIC was calculated.

niterMarginal: Number of Monte Carlo iterations used in computing marginal likelihoods if using marginal WAIC.

thin: Whether WAIC was calculated based only on thinned samples.

online: Whether WAIC was calculated during MCMC sampling.

WAIC_partialMC, lppd_partialMC, pWAIC_partialMC: The computed marginal WAIC, lppd, and pWAIC based on fewer Monte Carlo simulations, for use in assessing the sensitivity of the WAIC calculation to the number of Monte Carlo iterations.

niterMarginal_partialMC: Number of Monte Carlo iterations used for the values in WAIC_partialMC, lppd_partialMC, pWAIC_partialMC.

WAIC_elements, lppd_elements, pWAIC_elements: Vectors of individual WAIC, lppd, and pWAIC values, one element per data node (or group of nodes in the case of specifying dataGroups). Of use in computing the standard error of the difference in WAIC between two models, following Vehtari et al. (2017).

**Online WAIC**

As of version 0.12.0, NIMBLE provides enhanced WAIC functionality, with user control over whether to use conditional or marginal versions of WAIC and whether to group data nodes. In addition, users are no longer required to carefully choose MCMC monitors. WAIC by default is now calculated in an online manner (updating the required summary statistics at each MCMC iteration), using all post-burnin samples. The WAIC (Watanabe, 2010) is calculated from Equations 5, 12, and 13 in Gelman et al. (2014) (i.e., using "pWAIC2").

Note that there is not a unique value of WAIC for a model. By default, WAIC is calculated conditional on the parent nodes of the data nodes, and the density values used are the individual density values of the data nodes. However, by modifying the marginalizeNodes and dataGroups elements of the control list, users can request a marginal WAIC (using a marginal likelihood that integrates over user-specified latent nodes) and/or a WAIC based on grouping observations (e.g., all observations in a cluster) to use joint density values. See the MCMC Chapter of the NIMBLE User Manual for more details.

For more detail on the use of different predictive distributions, see Section 2.5 from Gelman et al. (2014) or Ariyo et al. (2019).

Note that based on a limited set of simulation experiments in Hug and Paciorek (2021) our tentative recommendation is that users only use marginal WAIC if also using grouping.

Examples

code <- nimbleCode({
  for(j in 1:J) {
    for(i in 1:n)
      y[j, i] ~ dnorm(mu[j], sd = sigma)
    mu[j] ~ dnorm(mu0, sd = tau)
  }
  sigma ~ dunif(0, 10)
  tau ~ dunif(0, 10)
})
J <- 5
n <- 10
groups <- paste0('y', 1:J, ', ', 1:J, n)
y <- matrix(rnorm(J*n), J, n)
Rmodel <- nimbleModel(code, constants = list(J = J, n = n), data = list(y = y),
inits = list(tau = 1, sigma = 1))

## Various versions of WAIC available via online calculation.
## Conditional WAIC without data grouping:
conf <- configureMCMC(Rmodel, enableWAIC = TRUE)
## Conditional WAIC with data grouping
conf <- configureMCMC(Rmodel, enableWAIC = TRUE, controlWAIC = list(dataGroups = groups))
## Marginal WAIC with data grouping:
conf <- configureMCMC(Rmodel, enableWAIC = TRUE, controlWAIC = list(dataGroups = groups, marginalizeNodes = 'mu'))

## Not run:
Rmcmc <- buildMCMC(conf)
Cmodel <- compileNimble(Rmodel)
Cmcmc <- compileNimble(Rmcmc, project = Rmodel)
output <- runMCMC(Cmcmc, niter = 1000, WAIC = TRUE)
output$WAIC # direct access
## Alternatively call via the 'getWAIC' method; this doesn't require setting
## 'waic=TRUE' in 'runMCMC'
Cmcmc$getWAIC()
Cmcmc$getWAICdetails()

## End(Not run)
### waicDetailsList

**Description**

waicDetailsList definition for the nimbleList type returned by WAIC computation.

**Usage**

waicDetailsList

**Format**

An object of class list of length 1.

**Details**

See help(waic) for details on the elements of the list.

**Author(s)**

The Wishart Distribution

Description
Density and random generation for the Wishart distribution, using the Cholesky factor of either the scale matrix or the rate matrix.

Usage

dwish_chol(x, cholesky, df, scale_param = TRUE, log = FALSE)

rwish_chol(n = 1, cholesky, df, scale_param = TRUE)

Arguments

x
vector of values.

cholesky
upper-triangular Cholesky factor of either the scale matrix (when scale_param is TRUE) or rate matrix (otherwise).

df
degrees of freedom.

scale_param
logical; if TRUE the Cholesky factor is that of the scale matrix; otherwise, of the rate matrix.

log
logical; if TRUE, probability density is returned on the log scale.

n
number of observations (only n=1 is handled currently).

Details
See Gelman et al., Appendix A or the BUGS manual for mathematical details. The rate matrix as used here is defined as the inverse of the scale matrix, $S^{-1}$, given in Gelman et al.

Value
dwish_chol gives the density and rwish_chol generates random deviates.

Author(s)
Christopher Paciorek

References

Distributions for other standard distributions
Examples

```r
df <- 40
ch <- chol(matrix(c(1, .7, .7, 1), 2))
x <- rwish_chol(1, ch, df = df)
dwish_chol(x, ch, df = df)
```

### Description

Temporarily set some NIMBLE options.

### Usage

```r
withNimbleOptions(options, expr)
```

### Arguments

- **options**: a list of options suitable for `nimbleOptions`.
- **expr**: an expression or statement to evaluate.

### Value

expr as evaluated with given options.

### Examples

```r
## Not run:
if (!(getNimbleOption('showCompilerOutput') == FALSE)) stop()
nf <- nimbleFunction(run = function(){ return(0); returnType(double()) })
cnf <- withNimbleOptions(list(showCompilerOutput = TRUE), {
  if (!(getNimbleOption('showCompilerOutput') == TRUE)) stop()
  compileNimble(nf)
})
if (!(getNimbleOption('showCompilerOutput') == FALSE)) stop()

## End(Not run)
```
