Package ‘nloptr’

October 3, 2018

Type Package
Title R Interface to NLopt
Version 1.2.1
Date 2018-10-02
Author Jelmer Ypma <uctpjyy@ucl.ac.uk>, with contributions by
Hans W. Borchers <hwborchers@googlemail.com> and
Dirk Eddelbuettel <edd@debian.org>
Maintainer Jelmer Ypma <uctpjyy@ucl.ac.uk>
Description Solve optimization problems using an R interface to NLopt. NLopt is a
free/open-source library for nonlinear optimization, providing a common
interface for a number of different free optimization routines available
online as well as original implementations of various other algorithms.
See <http://ab-initio.mit.edu/wiki/index.php/NLopt_Introduction> for more
information on the available algorithms. During installation of nloptr on
Unix-based systems, the installer checks whether the NLopt library is
installed on the system. If the NLopt library cannot be found, the code
is compiled using the NLopt source included in the nloptr package.

nloptr-package

Description

nloptr is an R interface to NLopt, a free/open-source library for nonlinear optimization started by Steven G. Johnson, providing a common interface for a number of different free optimization routines available online as well as original implementations of various other algorithms. The NLopt library is available under the GNU Lesser General Public License (LGPL), and the copyrights are owned by a variety of authors. Most of the information here has been taken from the NLopt website, where more details are available.

Details

NLopt addresses general nonlinear optimization problems of the form:

\[ \min f(x) \text{ in } \mathbb{R}^n \]
\[ \text{s.t. } g(x) \leq 0 \quad h(x) = 0 \quad lb \leq x \leq ub \]

where \( f \) is the objective function to be minimized and \( x \) represents the \( n \) optimization parameters. This problem may optionally be subject to the bound constraints (also called box constraints), \( lb \) and \( ub \). For partially or totally unconstrained problems the bounds can take -Inf or Inf. One may also optionally have \( m \) nonlinear inequality constraints (sometimes called a nonlinear programming
An optimization problem can be solved with the general nloptr interface, or using one of the wrapper functions for the separate algorithms: auglag, bobyqa, cobyla, crs2lm, direct, lbfgs, mls, mma, neldermead, newuoa, sbplx, slsqp, stogo, tnewton, varmetric.

Note

See ?nloptr for more examples.

auglag  Augmented Lagrangian Algorithm

Description
The Augmented Lagrangian method adds additional terms to the unconstrained objective function,
designed to emulate a Lagrangian multiplier.

Usage
auglag(x0, fn, gr = NULL, lower = NULL, upper = NULL, hin = NULL,
    hinjac = NULL, heq = NULL, heqjac = NULL, localsolver = c("COBYLA"),
    localtol = 1e-06, ineq2local = FALSE, nl.info = FALSE,
    control = list(), ...) 

Arguments
  x0  starting point for searching the optimum.
  fn  objective function that is to be minimized.
  gr  gradient of the objective function; will be provided provided is NULL and the
      solver requires derivatives.
  lower, upper  lower and upper bound constraints.
  hin, hinjac  defines the inequality constraints, hin(x) >= 0
  heq, heqjac  defines the equality constraints, heq(x) = 0.
  localsolver  available local solvers: COBYLA, LBFGS, MMA, or SLSQP.
  localtol  tolerance applied in the selected local solver.
  ineq2local  logical; shall the inequality constraints be treated by the local solver?; not pos-
               sible at the moment.
  nl.info  logical; shall the original NLopt info been shown.
  control  list of options, see nl.opts for help.
  ...  additional arguments passed to the function.
Details

This method combines the objective function and the nonlinear inequality/equality constraints (if any) into a single function: essentially, the objective plus a ‘penalty’ for any violated constraints.

This modified objective function is then passed to another optimization algorithm with no nonlinear constraints. If the constraints are violated by the solution of this sub-problem, then the size of the penalties is increased and the process is repeated; eventually, the process must converge to the desired solution (if it exists).

Since all of the actual optimization is performed in this subsidiary optimizer, the subsidiary algorithm that you specify determines whether the optimization is gradient-based or derivative-free.

The local solvers available at the moment are “COBYLA” (for the derivative-free approach) and “LBFGS”, “MMA”, or “SLSQP” (for smooth functions). The tolerance for the local solver has to be provided.

There is a variant that only uses penalty functions for equality constraints while inequality constraints are passed through to the subsidiary algorithm to be handled directly; in this case, the subsidiary algorithm must handle inequality constraints. (At the moment, this variant has been turned off because of problems with the NLOPT library.)

Value

List with components:

- `par` the optimal solution found so far.
- `value` the function value corresponding to `par`.
- `iter` number of (outer) iterations, see `maxeval`.
- `global_solver` the global NLOPT solver used.
- `local_solver` the local NLOPT solver used, LBFGS or COBYLA.
- `convergence` integer code indicating successful completion (> 0) or a possible error number (< 0).
- `message` character string produced by NLopt and giving additional information.

Note

Birgin and Martinez provide their own free implementation of the method as part of the TANGO project; other implementations can be found in semi-free packages like LANCELOT.

**bobyqa**

*Bound Optimization by Quadratic Approximation*
Description

BOBYQA performs derivative-free bound-constrained optimization using an iteratively constructed quadratic approximation for the objective function.

Usage

bobyqa(x0, fn, lower = NULL, upper = NULL, nl.info = FALSE, control = list(), ...)

Arguments

- **x0**: starting point for searching the optimum.
- **fn**: objective function that is to be minimized.
- **lower, upper**: lower and upper bound constraints.
- **nl.info**: logical; shall the original NLopt info been shown.
- **control**: list of options, see `nl.opts` for help.
- **...**: additional arguments passed to the function.

Details

This is an algorithm derived from the BOBYQA Fortran subroutine of Powell, converted to C and modified for the NLOPT stopping criteria.

Value

List with components:

- **par**: the optimal solution found so far.
- **value**: the function value corresponding to par.
- **iter**: number of (outer) iterations, see maxeval.
- **convergence**: integer code indicating successful completion (> 0) or a possible error number (< 0).
- **message**: character string produced by NLopt and giving additional information.

Note

Because BOBYQA constructs a quadratic approximation of the objective, it may perform poorly for objective functions that are not twice-differentiable.

cobyla, newuoa
check.derivatives

Examples

fr <- function(x) {
  ## Rosenbrock Banana function
  100 * (x[2] - x[1]^2)^2 + (1 - x[1])^2
}
(S <- bobyqa(c(0, 0, 0), fr, lower = c(0, 0, 0), upper = c(0.5, 0.5, 0.5)))

Description

This function compares the analytic gradients of a function with a finite difference approximation and prints the results of these checks.

Usage

check.derivatives(.x, func, func_grad, check_derivatives_tol = 1e-04,
  check_derivatives_print = "all", func_grad_name = "grad_f", ...)

Arguments

  .x  point at which the comparison is done.
  func function to be evaluated.
  func_grad function calculating the analytic gradients.
  check_derivatives_tol option determining when differences between the analytic gradient and its finite difference approximation are flagged as an error.
  check_derivatives_print option related to the amount of output. 'all' means that all comparisons are shown, 'errors' only shows comparisons that are flagged as an error, and 'none' shows the number of errors only.
  func_grad_name option to change the name of the gradient function that shows up in the output.
  ... further arguments passed to the functions func and func_grad.

Value

The return value contains a list with the analytic gradient, its finite difference approximation, the relative errors, and vector comparing the relative errors to the tolerance.

Examples

```r
library('nloptr')

# example with correct gradient
f <- function(x, a) {
  return( sum((x - a)^2) )
}

f.grad <- function(x, a) {
  return( 2*(x - a) )
}

check.derivatives(.x=1:10, func=f, func_grad=f.grad,
                  check_derivatives_print='none', a=runif(10))

# example with incorrect gradient
f.grad <- function(x, a) {
  return( 2*(x - a) + c(0,.1,rep(0,8)) )
}

check.derivatives(.x=1:10, func=f, func_grad=f.grad,
                  check_derivatives_print='errors', a=runif(10))

# example with incorrect gradient of vector-valued function
f <- function(x, a) {
  return( c(sum(x-a), sum((x-a)^2)) )
}

f.grad <- function(x, a) {
  return( rbind(rep(1,length(x)) + c(0,.01,rep(0,8)), 2*(x-a) + c(0,.1,rep(0,8))) )
}

check.derivatives(.x=1:10, func=f, func_grad=f.grad,
                  check_derivatives_print='all', a=runif(10))
```

Description

COBYLA is an algorithm for derivative-free optimization with nonlinear inequality and equality constraints (but see below).
**cobyla**

**Usage**

cobyla(x₀, fn, lower = NULL, upper = NULL, hin = NULL, nl.info = FALSE, control = list(), ...)

**Arguments**

- **x₀** starting point for searching the optimum.
- **fn** objective function that is to be minimized.
- **lower, upper** lower and upper bound constraints.
- **hin** function defining the inequality constraints, that is hin >= 0 for all components.
- **nl.info** logical; shall the original NLopt info been shown.
- **control** list of options, see nl.opts for help.
- **...** additional arguments passed to the function.

**Details**

It constructs successive linear approximations of the objective function and constraints via a simplex of n+1 points (in n dimensions), and optimizes these approximations in a trust region at each step. COBYLA supports equality constraints by transforming them into two inequality constraints. As this does not give full satisfaction with the implementation in NLOPT, it has not been made available here.

**Value**

List with components:

- **par** the optimal solution found so far.
- **value** the function value corresponding to par.
- **iter** number of (outer) iterations, see maxeval.
- **convergence** integer code indicating successful completion (> 0) or a possible error number (< 0).
- **message** character string produced by NLopt and giving additional information.

**Note**

The original code, written in Fortran by Powell, was converted in C for the Scipy project.

Examples

```r
# Example
x0 <- c(1, 2, 0, 4, -0.1, 1)
fn <- function(x) {
}
hin <- function(x) {
  h <- numeric(4)
  return(h)
}
S <- cobyla(x0, fn, hin = hin, nl.info = TRUE, control = list(xtol_rel = 1e-8, maxeval = 2000))
# Optimal value of objective function: 680.630057374431
```
xtol_rel  stopping criterion for relative change reached.
nl.info   logical; shall the original NLopt info been shown.
...       additional arguments passed to the function.

Details

The CRS algorithms are sometimes compared to genetic algorithms, in that they start with a random population of points, and randomly evolve these points by heuristic rules. In this case, the evolution somewhat resembles a randomized Nelder-Mead algorithm.

The published results for CRS seem to be largely empirical.

Value

List with components:

- par        the optimal solution found so far.
- value      the function value corresponding to par.
- iter       number of (outer) iterations, see maxeval.
- convergence integer code indicating successful completion (> 0) or a possible error number (< 0).
- message    character string produced by NLopt and giving additional information.

Note

The initial population size for CRS defaults to $10^n(n+1)$ in $n$ dimensions, but this can be changed; the initial population must be at least $n+1$.

direct 
Dividing RECTangles Algorithm for Global Optimization

Description

DIRECT is a deterministic search algorithm based on systematic division of the search domain into smaller and smaller hyperrectangles. The DIRECT_L makes the algorithm more biased towards local search (more efficient for functions without too many minima).

Usage

direct(fn, lower, upper, scaled = TRUE, original = FALSE, nl.info = FALSE,
  control = list(), ...)

directL(fn, lower, upper, randomized = FALSE, original = FALSE,
  nl.info = FALSE, control = list(), ...)

Arguments

fn 
objective function that is to be minimized.
lower, upper 
lower and upper bound constraints.
scaled 
logical; shall the hypercube be scaled before starting.
original 
logical; whether to use the original implementation by Gablonsky – the performance is mostly similar.
nl.info 
logical; shall the original NLopt info been shown.
control list of options, see nl.opts for help.

... additional arguments passed to the function.

randomized logical; shall some randomization be used to decide which dimension to halve next in the case of near-ties.

Details

The DIRECT and DIRECT-L algorithms start by rescaling the bound constraints to a hypercube, which gives all dimensions equal weight in the search procedure. If your dimensions do not have equal weight, e.g. if you have a “long and skinny” search space and your function varies at about the same speed in all directions, it may be better to use unscaled variant of the DIRECT algorithm.

The algorithms only handle finite bound constraints which must be provided. The original versions may include some support for arbitrary nonlinear inequality, but this has not been tested.

The original versions do not have randomized or unscaled variants, so these options will be disregarded for these versions.

Value

List with components:

par the optimal solution found so far.

value the function value corresponding to par.

iter number of (outer) iterations, see maxeval.

convergence integer code indicating successful completion (> 0) or a possible error number (< 0).

message character string produced by NLopt and giving additional information.

Note

The DIRECT_L algorithm should be tried first.

Author(s)

Hans W. Borchers

**isres**  
*Improved Stochastic Ranking Evolution Strategy*

**Description**

The Improved Stochastic Ranking Evolution Strategy (ISRES) algorithm for nonlinearly constrained global optimization (or at least semi-global: although it has heuristics to escape local optima.

**Usage**

```
isres(x0, fn, lower, upper, hin = NULL, heq = NULL, maxeval = 10000,  
pop.size = 20 * (length(x0) + 1), xtol_rel = 1e-06, nl.info = FALSE,  
...)```

**Arguments**

x0  initial point for searching the optimum.
fn  objective function that is to be minimized.
lower, upper  lower and upper bound constraints.
hin  function defining the inequality constraints, that is hin>=0 for all components.
heq  function defining the equality constraints, that is heq==0 for all components.
maxeval  maximum number of function evaluations.
pop.size  population size.
xtol_rel  stopping criterion for relative change reached.
nl.info  logical; shall the original NLopt info been shown.
...  additional arguments passed to the function.
Details

The evolution strategy is based on a combination of a mutation rule (with a log-normal step-size update and exponential smoothing) and differential variation (a Nelder-Mead-like update rule). The fitness ranking is simply via the objective function for problems without nonlinear constraints, but when nonlinear constraints are included the stochastic ranking proposed by Runarsson and Yao is employed.

This method supports arbitrary nonlinear inequality and equality constraints in addition to the bound constraints.

Value

List with components:

- par: the optimal solution found so far.
- value: the function value corresponding to par.
- iter: number of (outer) iterations, see maxeval.
- convergence: integer code indicating successful completion (> 0) or a possible error number (< 0).
- message: character string produced by NLopt and giving additional information.

Note

The initial population size for CRS defaults to $20n(n+1)$ in $n$ dimensions, but this can be changed; the initial population must be at least $n+1$.

Examples

```r
### Rosenbrock Banana objective function
fn <- function(x)
  return( 100 * (x[2] - x[1] * x[1])^2 + (1 - x[1])^2 )

x0 <- c(-1.2, 1)
lb <- c(-3, -3)
ub <- c(3, 3)

isres(x0 = x0, fn = fn, lower = lb, upper = ub)
```
**Description**

Low-storage version of the Broyden-Fletcher-Goldfarb-Shanno (BFGS) method.

**Usage**

```plaintext
lbfgs(x0, fn, gr = NULL, lower = NULL, upper = NULL, nl.info = FALSE,
      control = list(), ...)
```

**Arguments**

- `x0`: initial point for searching the optimum.
- `fn`: objective function to be minimized.
- `gr`: gradient of function `fn`; will be calculated numerically if not specified.
- `lower, upper`: lower and upper bound constraints.
- `nl.info`: logical; shall the original NLopt info been shown.
- `control`: list of control parameters, see `nl.opts` for help.
- `...`: further arguments to be passed to the function.

**Details**

The low-storage (or limited-memory) algorithm is a member of the class of quasi-Newton optimization methods. It is well suited for optimization problems with a large number of variables.

One parameter of this algorithm is the number `m` of gradients to remember from previous optimization steps. NLopt sets `m` to a heuristic value by default. It can be changed by the NLopt function `set_vector_storage`.

**Value**

List with components:

- `par`: the optimal solution found so far.
- `value`: the function value corresponding to `par`.
- `iter`: number of (outer) iterations, see maxeval.
- `convergence`: integer code indicating successful completion (> 0) or a possible error number (< 0).
- `message`: character string produced by NLopt and giving additional information.

**Note**

Based on a Fortran implementation of the low-storage BFGS algorithm written by L. Luksan, and posted under the GNU LGPL license.

mlsl

Multi-level Single-linkage

Description
The “Multi-Level Single-Linkage” (MLSL) algorithm for global optimization searches by a sequence of local optimizations from random starting points. A modification of MLSL is included using a low-discrepancy sequence (LDS) instead of pseudorandom numbers.

Usage

```r
mlsl(x0, fn, gr = NULL, lower, upper, local.method = "LBFGS",
     low.discrepancy = TRUE, nl.info = FALSE, control = list(), ...)
```
Arguments

- **x0**: initial point for searching the optimum.
- **fn**: objective function that is to be minimized.
- **gr**: gradient of function fn; will be calculated numerically if not specified.
- **lower, upper**: lower and upper bound constraints.
- **local.method**: only BFGS for the moment.
- **low.discrepancy**: logical; shall a low discrepancy variation be used.
- **nl.info**: logical; shall the original NLopt info been shown.
- **control**: list of options, see nl.opts for help.
- **...**: additional arguments passed to the function.

Details

MLSL is a ‘multistart’ algorithm: it works by doing a sequence of local optimizations (using some other local optimization algorithm) from random or low-discrepancy starting points. MLSL is distinguished, however, by a ‘clustering’ heuristic that helps it to avoid repeated searches of the same local optima, and has some theoretical guarantees of finding all local optima in a finite number of local minimizations.

The local-search portion of MLSL can use any of the other algorithms in NLopt, and in particular can use either gradient-based or derivative-free algorithms. For this wrapper only gradient-based L-BFGS is available as local method.

Value

List with components:

- **par**: the optimal solution found so far.
- **value**: the function value corresponding to par.
- **iter**: number of (outer) iterations, see maxeval.
- **convergence**: integer code indicating successful completion (> 0) or a possible error number (< 0).
- **message**: character string produced by NLopt and giving additional information.

Note

If you don’t set a stopping tolerance for your local-optimization algorithm, MLSL defaults to ftol_rel=1e-15 and xtol_rel=1e-7 for the local searches.

## Current value of objective function: -3.32236801141552
## Current value of controls: 0.2016895 0.1508107 0.476874 0.2753234 0.3116516 0.6573005
```
Method of Moving Asymptotes

Description

Globally-convergent method-of-moving-asymptotes (MMA) algorithm for gradient-based local optimization, including nonlinear inequality constraints (but not equality constraints).

Usage

```plaintext
mma(x0, fn, gr = NULL, lower = NULL, upper = NULL, hin = NULL,
    hinjac = NULL, nl.info = FALSE, control = list(), ...)
```

Arguments

- `x0`: starting point for searching the optimum.
- `fn`: objective function that is to be minimized.
- `gr`: gradient of function `fn`; will be calculated numerically if not specified.
- `lower`: lower and upper bound constraints.
- `upper`: upper bound constraints.
- `hin`: function defining the inequality constraints, that is `hin >= 0` for all components.
- `hinjac`: Jacobian of function `hin`; will be calculated numerically if not specified.
- `nl.info`: logical; shall the original NLopt info been shown.
- `control`: list of options, see `nl.opts` for help.
- `...`: additional arguments passed to the function.

Details

This is an improved CCSA ("conservative convex separable approximation") variant of the original MMA algorithm published by Svanberg in 1987, which has become popular for topology optimization. Note:

Value

List with components:

- `par`: the optimal solution found so far.
- `value`: the function value corresponding to `par`.
- `iter`: number of (outer) iterations, see `maxeval`.
- `convergence`: integer code indicating successful completion (> 1) or a possible error number (< 0).
- `message`: character string produced by NLopt and giving additional information.
Note

“Globally convergent” does not mean that this algorithm converges to the global optimum; it means that it is guaranteed to converge to some local minimum from any feasible starting point.

Examples

```r
# Solve the Hock-Schittkowski problem no. 100 with analytic gradients
x0.hs100 <- c(1, 2, 0, 4, 0, 1, 1)
fn.hs100 <- function(x) {
}
hin.hs100 <- function(x) {
  h <- numeric(4)
  return(h)
}
gr.hs100 <- function(x) {
} hinjac.hs100 <- function(x) {
  matrix(c(4*x[1], 12*x[2]^3, 1, 8*x[4], 5, 0, 0, 7, 3, 20*x[3], 1, -1, 0, 0, 23, 2*x[2], 0, 0, 0, 12*x[6], -8, 8*x[1]-3*x[2], 2*x[2]-3*x[1], 4*x[3], 0, 0, 5, -11), 4, 7, byrow=TRUE)
}

# Incorrect result with exact Jacobian
S <- mma(x0.hs100, fn.hs100, gr = gr.hs100, hin = hin.hs100, hinjac = hinjac.hs100,
```
neldermead

Description

An implementation of almost the original Nelder-Mead simplex algorithm.

Usage

neldermead(x0, fn, lower = NULL, upper = NULL, nl.info = FALSE,
         control = list(), ...)

Arguments

x0         starting point for searching the optimum.
fn          objective function that is to be minimized.
lower, upper lower and upper bound constraints.
nl.info    logical; shall the original NLopt info been shown.
control     list of options, see nl.opts for help.
...         additional arguments passed to the function.

Details

Provides explicit support for bound constraints, using essentially the method proposed in [Box]. Whenever a new point would lie outside the bound constraints the point is moved back exactly onto the constraint.
Value

List with components:

- **par**: the optimal solution found so far.
- **value**: the function value corresponding to **par**.
- **iter**: number of (outer) iterations, see `maxeval`.
- **convergence**: integer code indicating successful completion (> 0) or a possible error number (< 0).
- **message**: character string produced by NLopt and giving additional information.

Note

The author of NLopt would tend to recommend the Subplex method instead.

  100*(x[3] - 10*atan2(x[2], x[1])/(2*pi))^2 +
x0 <- c(-1, 0, 0)
neldermead(x0, fphv) # 1 0 0

# Powell's Singular Function (PSF)
psf <- function(x) (x[1] + 10*x[2])^2 + 5*(x[3] - x[4])^2 +
x0 <- c(3, -1, 0, 1)
neldermead(x0, psf) # 0 0 0 0, needs maximum number of function calls

## Not run:
# Bounded version of Nelder-Mead
lower <- c(-Inf, 0, 0)
upper <- c(Inf, 0.5, 1)
```
newuoa

New Unconstrained Optimization with quadratic Approximation

Description

NEWUOA solves quadratic subproblems in a spherical trust region via a truncated conjugate-gradient algorithm. For bound-constrained problems, BOBYQA should be used instead, as Powell developed it as an enhancement thereof for bound constraints.

Usage

newuoa(x0, fn, nl.info = FALSE, control = list(), ...)

Arguments

x0	starting point for searching the optimum.
fn	objective function that is to be minimized.
nl.info	logical; shall the original NLopt info been shown.
control	list of options, see nl.opts for help.
...��itional arguments passed to the function.

Details

This is an algorithm derived from the NEWUOA Fortran subroutine of Powell, converted to C and modified for the NLOPT stopping criteria.

Value

List with components:

par	the optimal solution found so far.
value	the function value corresponding to par.
iter	number of (outer) iterations, see maxeval.
convergence	integer code indicating successful completion (> 0) or a possible error number (< 0).
message	character string produced by NLopt and giving additional information.

Note

NEWUOA may be largely superseded by BOBYQA.

Examples

```r
fr <- function(x) {
  # Rosenbrock Banana function
  100 * ((x[2] - x[1]^2)^2 + (1 - x[1])^2)
}
(S <- newua(c(1, 2), fr))
```

Description

Provides numerical gradients and jacobians.

Usage

```r
nl.grad(x0, fn, heps = .Machine$double.eps^(1/3), ...)
```

Arguments

- `x0` point as a vector where the gradient is to be calculated.
- `fn` scalar function of one or several variables.
- `heps` step size to be used.
- `...` additional arguments passed to the function.

Details

Both functions apply the “central difference formula” with step size as recommended in the literature.

Value

`grad` returns the gradient as a vector; `jacobian` returns the Jacobian as a matrix of usual dimensions.
Author(s)

Hans W. Borchers

Examples

```r
fn1 <- function(x) sum(x^2)
nl.grad(seq(0, 1, by = 0.2), fn1)
## [1] 0.0 0.4 0.8 1.2 1.6 2.0
nl.grad(rep(1, 5), fn1)
## [1] 2 2 2 2 2

fn2 <- function(x) c(sin(x), cos(x))
x <- (0:1)*2*pi
nl.jacobian(x, fn2)
## [,1] [,2]
## [1,] 1 0
## [2,] 0 1
## [3,] 0 0
## [4,] 0 0
```

### Description

Sets and changes the NLOPT options.

### Usage

```r
nl.opts(optlist = NULL)
```

### Arguments

- `optlist` list of options, see below.

### Details

The following options can be set (here with default values):

- `stopval = -Inf`, # stop minimization at this value
- `xtol_rel = 1e-6`, # stop on small optimization step
- `maxeval = 1000`, # stop on this many function evaluations
- `ftol_rel = 0.0`, # stop on change times function value
- `ftol_abs = 0.0`, # stop on small change of function value
- `check_derivatives = FALSE`
Value
returns a list with default and changed options.

Note
There are more options that can be set for solvers in NLOPT. These cannot be set through their wrapper functions. To see the full list of options and algorithms, type \texttt{nloptr\_print\_options()}.

Hans W. Borchers

Examples
\begin{verbatim}
nloptr(NN, maxeval = 2000)
\end{verbatim}

\texttt{nloptr}
\textit{R interface to NLopt}

Description
\texttt{nloptr} is an \textit{R} interface to NLopt, a free/open-source library for nonlinear optimization started by Steven G. Johnson, providing a common interface for a number of different free optimization routines available online as well as original implementations of various other algorithms. The NLopt library is available under the GNU Lesser General Public License (LGPL), and the copyrights are owned by a variety of authors. Most of the information here has been taken from the \texttt{NLopt website}, where more details are available.

Usage
\begin{verbatim}
nloptr(x0, eval_f, eval_grad_f = NULL, lb = NULL, ub = NULL, 
\quad eval_g_ineq = NULL, eval jac_g_ineq = NULL, eval_g_eq = NULL, 
\quad eval jac_g_eq = NULL, opts = list(), ...)
\end{verbatim}

Arguments
\begin{itemize}
\item \texttt{x0} vector with starting values for the optimization.
\item \texttt{eval_f} function that returns the value of the objective function. It can also return gradient information at the same time in a list with elements "objective" and "gradient" (see below for an example).
\item \texttt{eval_grad_f} function that returns the value of the gradient of the objective function. Not all of the algorithms require a gradient.
\item \texttt{lb} vector with lower bounds of the controls (use -Inf for controls without lower bound), by default there are no lower bounds for any of the controls.
\end{itemize}
ub vector with upper bounds of the controls (use Inf for controls without upper bound), by default there are no upper bounds for any of the controls.

eval_g_ineq function to evaluate (non-)linear inequality constraints that should hold in the solution. It can also return gradient information at the same time in a list with elements "objective" and "jacobian" (see below for an example).

eval_jac_g_ineq function to evaluate the jacobian of the (non-)linear inequality constraints that should hold in the solution.

eval_g_eq function to evaluate (non-)linear equality constraints that should hold in the solution. It can also return gradient information at the same time in a list with elements "objective" and "jacobian" (see below for an example).

eval_jac_g_eq function to evaluate the jacobian of the (non-)linear equality constraints that should hold in the solution.

opts list with options. The option "algorithm" is required. Check the NLopt website for a full list of available algorithms. Other options control the termination conditions (minf_max, ftol_rel, ftol_abs, xtol_rel, xtol_abs, maxeval, maxtime). Default is xtol_rel = 1e-4. More information here. A full description of all options is shown by the function nloptr.print.options().

Some algorithms with equality constraints require the option local_opts, which contains a list with an algorithm and a termination condition for the local algorithm. See nloptr-package for an example.

The option print_level controls how much output is shown during the optimization process. Possible values:

0 (default) no output
1 show iteration number and value of objective function
2 1 + show value of (in)equalitys
3 2 + show value of controls

The option check_derivatives (default = FALSE) can be used to run to compare the analytic gradients with finite difference approximations. The option check_derivatives_print ("all" (default), "errors", "none") controls the output of the derivative checker, if it is run, showing all comparisons, only those that resulted in an error, or none. The option check_derivatives_tol (default = 1e-04), determines when a difference between an analytic gradient and its finite difference approximation is flagged as an error.

Arguments that will be passed to the user-defined objective and constraints functions.

Details

NLopt addresses general nonlinear optimization problems of the form:

\[
\min f(x) \quad \text{x in } \mathbb{R}^n \\
\text{s.t. } g(x) \leq 0 \quad h(x) = 0 \quad lb \leq x \leq ub
\]

where \( f \) is the objective function to be minimized and \( x \) represents the \( n \) optimization parameters. This problem may optionally be subject to the bound constraints (also called box constraints), \( lb \)
and ub. For partially or totally unconstrained problems the bounds can take -Inf or Inf. One may also optionally have m nonlinear inequality constraints (sometimes called a nonlinear programming problem), which can be specified in g(x), and equality constraints that can be specified in h(x). Note that not all of the algorithms in NLopt can handle constraints.

**Value**

The return value contains a list with the inputs, and additional elements:

- **call**: the call that was made to solve
- **status**: integer value with the status of the optimization (0 is success)
- **message**: more informative message with the status of the optimization
- **iterations**: number of iterations that were executed
- **objective**: value if the objective function in the solution
- **solution**: optimal value of the controls
- **version**: version of NLopt that was used

**Note**

See `nlpar-package` for an extended example.

nloptr.get.default.options

Return a data.frame with all the options that can be supplied to nloptr.

Description

This function returns a data.frame with all the options that can be supplied to nloptr. The data.frame contains the default values of the options and an explanation. A user-friendly way to show these options is by using the function nloptr.print.options.

Usage

nloptr.get.default.options()

Value

The return value contains a data.frame with the following elements:

- name: name of the option
- type: type (numeric, logical, integer, character)
- possible_values: string explaining the values the option can take
- default: default value of the option (as a string)
- is_termination_condition: is this option part of the termination conditions?
- description: description of the option (taken from NLopt website if it’s an option that is passed on to NLopt).

nloptr.print.options  
*Print description of nloptr options*

Description
This function prints a list of all the options that can be set when solving a minimization problem using nloptr.

Usage
nloptr.print.options(opts.show = NULL, opts.user = NULL)

Arguments
- opts.show  
  list or vector with names of options. A description will be shown for the options in this list. By default, a description of all options is shown.
- opts.user  
  object containing user supplied options. This argument is optional. It is used when nloptr.print.options is called from nloptr. In that case options are listed if print_options_doc is set to TRUE when passing a minimization problem to nloptr.

Author(s)
Jelmer Ypma

nloptr

Examples

```r
library('nloptr')
nloptr.print.options()

nloptr.print.options( opts.show = c("algorithm", "check_derivatives") )

opts <- list("algorithm"="NLOPT_LD_LBFGS",  
              "xtol_rel"=1.0e-8)
nloptr.print.options( opts.user = opts )
```
print.nloptr  

Print results after running nloptr

Description

This function prints the nloptr object that holds the results from a minimization using nloptr.

Usage

```r
## S3 method for class 'nloptr'
print(x, show.controls = TRUE, ...)
```

Arguments

- `x` object containing result from minimization.
- `show.controls` Logical or vector with indices. Should we show the value of the control variables in the solution? If `show.controls` is a vector with indices, it is used to select which control variables should be shown. This can be useful if the model contains a set of parameters of interest and a set of nuisance parameters that are not of immediate interest.
- `...` further arguments passed to or from other methods.

Author(s)

Jelmer Ypma

- `nloptr`

sbplx  

Subplex Algorithm

Description

Subplex is a variant of Nelder-Mead that uses Nelder-Mead on a sequence of subspaces.

Usage

```r
sbplx(x0, fn, lower = NULL, upper = NULL, nl.info = FALSE,
     control = list(), ...)
```
Arguments

- **x0**: starting point for searching the optimum.
- **fn**: objective function that is to be minimized.
- **lower, upper**: lower and upper bound constraints.
- **nl.info**: logical; shall the original NLopt info been shown.
- **control**: list of options, see `nl.opts` for help.
- **...**: additional arguments passed to the function.

Details

SUBPLEX is claimed to be much more efficient and robust than the original Nelder-Mead, while retaining the latter's facility with discontinuous objectives.

This implementation has explicit support for bound constraints (via the method in the Box paper as described on the `neldermead` help page).

Value

List with components:

- **par**: the optimal solution found so far.
- **value**: the function value corresponding to `par`.
- **iter**: number of (outer) iterations, see `maxeval`.
- **convergence**: integer code indicating successful completion (> 0) or a possible error number (< 0).
- **message**: character string produced by NLopt and giving additional information.

Note

It is the request of Tom Rowan that reimplementations of his algorithm shall not use the name ‘subplex’.

slsqp

Sequential Quadratic Programming (SQP)

Description

Sequential (least-squares) quadratic programming (SQP) algorithm for nonlinearly constrained, gradient-based optimization, supporting both equality and inequality constraints.

Usage

slsqp(x0, fn, gr = NULL, lower = NULL, upper = NULL, hin = NULL, hinjac = NULL, heq = NULL, heqjac = NULL, nl.info = FALSE, control = list(), ...)

Arguments

x0            starting point for searching the optimum.
fn            objective function that is to be minimized.
gr            gradient of function fn; will be calculated numerically if not specified.
lower, upper  lower and upper bound constraints.
hin           function defining the inequality constraints, that is hin>=0 for all components.
hinjac        Jacobian of function hin; will be calculated numerically if not specified.
heq           function defining the equality constraints, that is heq==0 for all components.
heqjac        Jacobian of function heq; will be calculated numerically if not specified.
nl.info       logical; shall the original NLopt info been shown.
control       list of options, see nl.opt for help.
...           additional arguments passed to the function.
Details

The algorithm optimizes successive second-order (quadratic/least-squares) approximations of the objective function (via BFGS updates), with first-order (affine) approximations of the constraints.

Value

List with components:

- **par**: the optimal solution found so far.
- **value**: the function value corresponding to par.
- **iter**: number of (outer) iterations, see maxeval.
- **convergence**: integer code indicating successful completion (> 1) or a possible error number (< 0).
- **message**: character string produced by NLopt and giving additional information.

Examples

```r
## Solve the Hock-Schittkowski problem no. 100
x0.hs100 <- c(1, 2, 0, 4, 0, 1, 1)
fn.hs100 <- function(x) {
}
h.in hs100 <- function(x) {
  h <- numeric(4)
  return(h)
}
```
stogo

Description

StoGO is a global optimization algorithm that works by systematically dividing the search space into smaller hyper-rectangles.

Usage

```r
stogo(x0, fn, gr = NULL, lower = NULL, upper = NULL, maxeval = 10000,
      xtol_rel = 1e-06, randomized = FALSE, nl.info = FALSE, ...)
```

Arguments

- `x0` initial point for searching the optimum.
- `fn` objective function that is to be minimized.
- `gr` optional gradient of the objective function.
- `lower, upper` lower and upper bound constraints.
- `maxeval` maximum number of function evaluations.
- `xtol_rel` stopping criterion for relative change reached.
- `randomized` logical; shall a randomizing variant be used?
- `nl.info` logical; shall the original NLopt info been shown.
- `...` additional arguments passed to the function.

Details

StoGO is a global optimization algorithm that works by systematically dividing the search space (which must be bound-constrained) into smaller hyper-rectangles via a branch-and-bound technique, and searching them by a gradient-based local-search algorithm (a BFGS variant), optionally including some randomness.
Value

List with components:

- **par**: the optimal solution found so far.
- **value**: the function value corresponding to **par**.
- **iter**: number of (outer) iterations, see **maxeval**.
- **convergence**: integer code indicating successful completion (> 0) or a possible error number (< 0).
- **message**: character string produced by NLopt and giving additional information.

Note

Only bound-constrained problems are supported by this algorithm.

Examples

```r
### Rosenbrock Banana objective function
fn <- function(x)
  return( 100 * (x[2] - x[1] * x[1])^2 + (1 - x[1])^2 )
x0 <- c(-1.2, 1)
lb <- c(-3, -3)
ub <- c(3, 3)
stogo(x0 = x0, fn = fn, lower = lb, upper = ub)
```

**tnewton**

*Preconditioned Truncated Newton*

Description

Truncated Newton methods, also called Newton-iterative methods, solve an approximating Newton system using a conjugate-gradient approach and are related to limited-memory BFGS.
Usage

tnewton(x0, fn, gr = NULL, lower = NULL, upper = NULL, precond = TRUE, 
restart = TRUE, nl.info = FALSE, control = list(), ...)

Arguments

x0     starting point for searching the optimum.
fn     objective function that is to be minimized.
gr     gradient of function fn; will be calculated numerically if not specified.
lower, upper  lower and upper bound constraints.
precond logical; preset L-BFGS with steepest descent.
restart logical; restarting L-BFGS with steepest descent.
nl.info logical; shall the original NLopt info been shown.
control list of options, see nl.opts for help.
...    additional arguments passed to the function.

Details

Truncated Newton methods are based on approximating the objective with a quadratic function and
applying an iterative scheme such as the linear conjugate-gradient algorithm.

Value

List with components:

par     the optimal solution found so far.
value   the function value corresponding to par.
iter    number of (outer) iterations, see maxeval.
convergence integer code indicating successful completion (> 1) or a possible error number
         (< 0).
message character string produced by NLopt and giving additional information.

Note

Less reliable than Newton’s method, but can handle very large problems.

Examples

```r
flb <- function(x) {
  p <- length(x)
  sum(c(1, rep(4, p-1)) * (x - c(1, x[-p])^2)^2)
}
# 25-dimensional box constrained: par[24] is *not* at boundary
S <- tnewton(rep(3, 25), flb, lower=rep(2, 25), upper=rep(4, 25),
             nl.info = TRUE, control = list(xtol_rel=1e-8))
## Optimal value of objective function: 368.105912874334
## Optimal value of controls: 2 ... 2 2.109093 4
```

---

**varmetric**

*Shifted Limited-memory Variable-metric*

**Description**

Shifted limited-memory variable-metric algorithm.

**Usage**

```r
varmetric(x0, fn, gr = NULL, rank2 = TRUE, lower = NULL, upper = NULL,
          nl.info = FALSE, control = list(), ...)
```

**Arguments**

- `x0`: initial point for searching the optimum.
- `fn`: objective function to be minimized.
- `gr`: gradient of function `fn`; will be calculated numerically if not specified.
- `rank2`: logical; if true uses a rank-2 update method, else rank-1.
- `lower`, `upper`: lower and upper bound constraints.
- `nl.info`: logical; shall the original NLopt info been shown.
- `control`: list of control parameters, see `nl.opts` for help.
- `...`: further arguments to be passed to the function.

**Details**

Variable-metric methods are a variant of the quasi-Newton methods, especially adapted to large-scale unconstrained (or bound constrained) minimization.
Value

List with components:

- `par` the optimal solution found so far.
- `value` the function value corresponding to `par`.
- `iter` number of (outer) iterations, see `maxeval`.
- `convergence` integer code indicating successful completion (> 0) or a possible error number (< 0).
- `message` character string produced by NLopt and giving additional information.

Note

Based on L. Luksan’s Fortran implementation of a shifted limited-memory variable-metric algorithm.
