Package ‘nonnest2’

May 6, 2024

Title Tests of Non-Nested Models
Version 0.5-7
Date 2024-05-05
Description Testing non-nested models via theory supplied by Vuong (1989) [DOI:10.2307/1912557]. Includes tests of model distinguishability and of model fit that can be applied to both nested and non-nested models. Also includes functionality to obtain confidence intervals associated with AIC and BIC. This material is partially based on work supported by the National Science Foundation under Grant Number SES-1061334.

Depends R (>= 3.0.0)
Imports CompQuadForm, mvtnorm, lavaan (>= 0.6-6), sandwich
License GPL-2 | GPL-3
Suggests mirt (>= 1.26.3), OpenMx, tidySEM, AER, MASS, faraway, mlogit, ordinal, pscl, knitr, rmarkdown, testthat

R topics documented:

icci ......................................................... 2
llcont ....................................................... 3
vuongtest .................................................. 4
Description

Calculate confidence intervals of AIC and BIC for non-nested models.

Usage

icci(object1, object2, conf.level = 0.95, ll1 = llcont, ll2 = llcont)

Arguments

object1: a model object
object2: a model object
conf.level: confidence level of the interval
ll1: an optional function for computing log-likelihood contributions of object1
ll2: an optional function for computing log-likelihood contributions of object2

Details

Functionality is currently available for models of classes `lm`, `glm`, `glm.nb`, `clm`, `hurdle`, `zeroinfl`, `mlogit`, `nls`, `polr`, `rlm`, and `lavaan`.

Users should take care to ensure that the two models have the same dependent variable (or, for lavaan objects, identical modeled variables), with observations ordered identically within each model object. Assuming the same data matrix is used to fit each model, observation ordering should generally be identical. There are currently no checks for this, however.

Note: if models are nested or if the "variance test" from `vuongtest()` indicates models are indistinguishable, then the intervals returned from `icci()` will be incorrect.

Value

an object of class `icci` containing test results.

### Examples

```r
## Not run:
## Count regression comparisons
require(MASS)
house1 <- glm(Freq ~ Infl + Type + Cont, family=poisson, data=housing)
house2 <- glm(Freq ~ Infl + Sat, family=poisson, data=housing)
## CI for BIC
icci(house2, house1)
## Further comparisons to hurdle, zero-inflated models
require(pscl)
bio1 <- glm(art ~ fem + mar + phd + ment, family=poisson, data=bioChemists)
bio2 <- hurdle(art ~ fem + mar + phd + ment, data=bioChemists)
bio3 <- zeroinfl(art ~ fem + mar + phd + ment, data=bioChemists)
icci(bio2, bio1)
icci(bio3, bio1)
icci(bio3, bio2)
## Latent variable model comparisons
require(lavaan)
HS.model <- \textquote{visual} \sim x1 + x2 + x3
\textquote{textual} \sim x4 + x5 + x6
\textquote{speed} \sim x7 + x8 + x9
fit1 <- cfa(HS.model, data=HolzingerSwineford1939, meanstructure=TRUE)
fit2 <- cfa(HS.model, data=HolzingerSwineford1939, group="school")
icci(fit1, fit2)
## End(Not run)
```

---

### llcont

**Individual Log-Likelihoods**

**Description**

Obtain log-likelihood values associated with individual observations, evaluated at the ML estimates.

**Usage**

```
llcont(x, ...)
```

**Arguments**

- `x` a model object
- `...` arguments passed to specific methods
Details

This is a S3 generic function. Currently, the method is defined for `lm`, `glm`, `glm.nb`, `clm`, `hurdle`, `zeroinfl`, `mlogit`, `nls`, `polr`, `rlm`, `lavaan`, `vglm`, `mirt`, and `OpenMx` objects.

Value

An object of class `numeric` containing individuals’ contributions to the log-likelihood. The sum of these contributions equals the model log-likelihood.

Author(s)

Ed Merkle, Dongjun You, Lennart Schneider, and Mauricio Garnier-Villarreal

Examples

```r
## Fit gamma glm, check that sum of llcont() equals
## the model loglikelihood:
clotting <- data.frame(u = c(5,10,15,20,30,40,60,80,100),
  lot1 = c(118,58,42,35,27,25,21,19,18),
  lot2 = c(69,35,26,21,18,16,13,12,12))
gam1 <- glm(lot1 ~ log(u), data = clotting, family = Gamma)
sum(llcont(gam1))
logLik(gam1)
```

---

**Vuong Tests for Model Comparison**

Description

Test pairs of models using Vuong’s (1989) <DOI:10.2307/1912557> theory. This includes a test of model distinguishability and a test of model fit.

Usage

```r
vuongtest(
  object1, object2,
  nested = FALSE, adj = "none",
  ll1 = llcont, ll2 = llcont,
  score1 = NULL, score2 = NULL,
  vc1 = vcov, vc2 = vcov
)
```
vuongtest

Arguments

object1  a model object
object2  a model object
nested   if TRUE, models are assumed to be nested
adj      Should an adjusted test statistic be calculated? Defaults to “none”, with possible
          adjustments being “aic” and “bic”
ll1      an optional function for computing log-likelihood contributions of object1
ll2      an optional function for computing log-likelihood contributions of object2
score1   an optional function for computing scores of object 1
score2   an optional function for computing scores of object 2
vc1      an optional function for computing the asymptotic covariance matrix of the ob-
          ject1 parameters
vc2      an optional function for computing the asymptotic covariance matrix of the ob-
          ject2 parameters

Details

For non-nested models, the test of distinguishability indicates whether or not the models can possibly be distinguished on the basis of the observed data. The LRT then indicates whether or not one model fits better than another.

For nested models (nested=TRUE), both tests serve as robust alternatives to the classical likelihood ratio tests. In this case, the adj argument is ignored.

Users should take care to ensure that the two models have the same dependent variable (or, for lavaan objects, identical modeled variables), with observations ordered identically within each model object. Assuming the same data matrix is used to fit each model, observation ordering should generally be identical. There are currently no checks for this, however.

Value

an object of class vuongtest containing test results.

Examples

## Not run:
## Count regression comparisons
require(MASS)
house1 <- glm(Freq ~ Infl + Type + Cont, family=poisson, data=housing)
house2 <- glm(Freq ~ Infl + Sat, family=poisson, data=housing)
house3 <- glm(Freq ~ Infl, family=poisson, data=housing)
## house3 is nested within house1 and house2
anova(house3, house1, test="Chisq")
anova(house3, house2, test="Chisq")

## house 2 is not nested in house1, so this test is invalid
anova(house2, house1, test="Chisq")

## Use vuongtest() instead
vuongtest(house2, house1)

## Application to models with different distributional assumptions
require(pscl)
bio1 <- glm(art ~ fem + mar + phd + ment, family=poisson, data=bioChemists)
bio2 <- hurdle(art ~ fem + mar + phd + ment, data=bioChemists)
bio3 <- zeroinfl(art ~ fem + mar + phd + ment, data=bioChemists)
 vuongtest(bio2, bio1)
 vuongtest(bio3, bio1)
 vuongtest(bio2, bio1)
 vuongtest(bio1, bio3)
 vuongtest(bio3, bio2)

## Application to latent variable models
require(lavaan)
HS.model <- 'visual =~ x1 + x2 + x3
textual =~ x4 + x5 + x6
speed =~ x7 + x8 + x9'
fit1 <- cfa(HS.model, data=HolzingerSwineford1939)
fit2 <- cfa(HS.model, data=HolzingerSwineford1939, group="school")
 vuongtest(fit1, fit2)

## Supplying custom vcov function
require(lme4)
require(merDeriv)
fm1 <- lmer(Reaction ~ Days + (Days | Subject), sleepstudy, REML=FALSE)
fm2 <- lmer(Reaction ~ Days + (Days || Subject), sleepstudy, REML=FALSE)
vc1 <- function(obj) vcov(obj, full=TRUE)
 vuongtest(fm1, fm2, vc1=vc1, vc2=vc1, nested=TRUE)

## End(Not run)
