# Package ‘npregfast’

November 30, 2017

**Type**  Package  
**Title**  Nonparametric Estimation of Regression Models with Factor-by-Curve Interactions  
**Version**  1.5.1  
**Date**  2017-11-30  
**Maintainer**  Marta Sestelo <sestelo@uvigo.es>  
**Description**  A method for obtaining nonparametric estimates of regression models with or without factor-by-curve interactions using local polynomial kernel smoothers or splines. Additionally, a parametric model (allometric model) can be estimated.  
**BugReports**  [http://github.com/sestelo/npregfast/issues](http://github.com/sestelo/npregfast/issues)  
**Depends**  R (>= 3.2.0)  
**Suggests**  gridExtra  
**License**  MIT + file LICENSE  
**LazyData**  true  
**Imports**  graphics, stats, utils, shiny, doParallel, foreach, mgcv, sfsmisc, shinyjs, wesanderson, ggplot2  
**RoxygenNote**  6.0.1  
**NeedsCompilation**  yes  
**Author**  Marta Sestelo [aut, cre] (0000-0003-4284-6509), Nora M. Villanueva [aut], Javier Roca-Pardinas [aut]  
**Repository**  CRAN  
**Date/Publication**  2017-11-30 18:05:23 UTC

allotest

Bootstrap based test for testing an allometric model

Description

Bootstrap-based procedure that tests whether the data can be modelled by an allometric model.

Usage

allotest(formula, data, na.action = "na.omit", nboot = 500, seed = NULL, cluster = TRUE, ncores = NULL, test = "res", ...)

Arguments

- **formula**: An object of class `formula`: a symbolic description of the model to be fitted.
- **data**: An optional data frame, matrix or list required by the formula. If not found in data, the variables are taken from `environment(formula)`, typically the environment from which `allotest` is called.
- **na.action**: A function which indicates what should happen when the data contain 'NA's. The default is 'na.omit'.
- **nboot**: Number of bootstrap repeats.
- **seed**: Seed to be used in the bootstrap procedure.
- **cluster**: A logical value. If `TRUE` (default), the bootstrap procedure is parallelized (only for `smooth = "splines"`). Note that there are cases (e.g., a low number of bootstrap repetitions) that it will gain in performance through serial computation. It takes time to distribute tasks across the processors also it will need time for binding them all together later on. Therefore, if the time for distributing and gathering pieces together is greater than the time need for single-thread computing, it does not worth parallelize.
- **ncores**: An integer value specifying the number of cores to be used in the parallelized procedure. If `NULL` (default), the number of cores to be used is equal to the number of cores of the machine - 1.
- **test**: Statistic test to be used, based on residuals on the null model (`res`) or based on the likelihood ratio test using `rss0` and `rss1lrt`.
- **...**: Other options.
Details

In order to facilitate the choice of a model appropriate to the data while at the same time endeavouring to minimise the loss of information, a bootstrap-based procedure, that test whether the data can be modelled by an allometric model, was developed. Therefore, allotest tests the null hypothesis of an allometric model taking into account the logarithm of the original variable ($X^* = \log(X)$ and $Y^* = \log(Y)$).

Based on a general model of the type

$$Y^* = m(X^*) + \varepsilon$$

the aim here is to test the null hypothesis of an allometric model

$$H_0 = m(x^*) = a^* + b^* x^*$$

vs. the general hypothesis $H_1$, with $m$ being an unknown nonparametric function; or analogously,

$$H_1 : m(x^*) = a^* + b^* x^* + g(x^*)$$

with $g(x^*)$ being an unknown function not equal to zero.

To implement this test we have used the wild bootstrap.

Value

An object is returned with the following elements:

- **statistic**: the value of the test statistic.
- **value**: the p-value of the test.

Author(s)

Marta Sestelo, Nora M. Villanueva and Javier Roca-Pardinas.

References

Examples

```R
library(npregfast)
data(barnacle)
allotest(DW ~ RC, data = barnacle, nboot = 50, seed = 130853, cluster = FALSE)
```
autoplot.frfast

Visualization of frfast objects with ggplot2 graphics

Description

Useful for drawing the estimated regression function, first and second derivative (for each factor’s level) using ggplot2 graphics. Additionally, with the diffwith argument it is possible to draw the differences between two factor’s levels.

Usage

```r
## S3 method for class 'frfast'
autoplot(object = model, fac = NULL, der = 0,
         diffwith = NULL, points = TRUE, xlab = model$name[2],
         ylab = model$name[1], ylim = NULL, main = NULL, col = "black",
         CIcol = "black", CIIlinecol = "transparent", pcol = "grey80",
         abline = TRUE, ablinecol = "red", lty = 1, CIIty = 2, lwd = 1,
         CIlwd = 1, cex = 1.4, alpha = 0.2, ...)
```

Arguments

- **object**: frfast object.
- **fac**: Factor’s level to be taken into account in the plot. By default is NULL.
- **der**: Number which determines any inference process. By default der is 0. If this term is 0, the plot shows the initial estimate. If it is 1 or 2, it is designed for the first or second derivative, respectively.
- **diffwith**: Factor’s level used for drawing the differences respect to the level specified in the fac argument. By default, NULL. The differences are computed for the r-th derivative specified in the der argument.
- **points**: Draw the original data into the plot. By default it is TRUE.
- **xlab**: A title for the x axis.
- **ylab**: A title for the y axis.
- **ylim**: The y limits of the plot.
- **main**: An overall title for the plot.
- **col**: A specification for the default plotting color.
- **CIcol**: A specification for the default confidence intervals plotting color (for the fill).
- **CIIlinecol**: A specification for the default confidence intervals plotting color (for the edge).
- **pcol**: A specification for the points color.
- **abline**: Draw an horizontal line into the plot of the second derivative of the model.
- **ablinecol**: The color to be used for abline.
- **lty**: The line type. Line types can either be specified as an integer (0 = blank, 1 = solid (default), 2 = dashed, 3 = dotted, 4 = dotdash, 5 = longdash, 6 = twodash). See details in `par`.
autplot.frfast

CILty The line type for confidence intervals. Line types can either be specified as an integer (0 = blank, 1 = solid (default), 2 = dashed, 3 = dotted, 4 = dotdash, 5 = longdash, 6 = twodash).
lwd The line width, a positive number, defaulting to 1. See details in \code{par}.
CILwd The line width for confidence intervals, a positive number, defaulting to 1.
cex A numerical value giving the amount by which plotting symbols should be magnified relative to the default. See details in \code{par}.
alpha Alpha transparency for overlapping elements expressed as a fraction between 0 (complete transparency) and 1 (complete opacity).
...

Value

A \code{ggplot} object, so you can use common features from \code{ggplot2} package to manipulate the plot.

Author(s)

Marta Sestelo, Nora M. Villanueva and Javier Roca-Pardinas.

Examples

library(npregfast)
library(ggplot2)
data(barnacle)

# Nonparametric regression without interactions
fit <- frfast(DW ~ RC, data = barnacle, nboot = 50)
autplot(fit)
autplot(fit, points = FALSE) + ggtitle("Title")
autplot(fit, der = 1) + xlim(4, 20)
#autplot(fit, der = 1, col = "red", CICol = "blue")

# Nonparametric regression with interactions
fit2 <- frfast(DW ~ RC : F, data = barnacle, nboot = 50)
autplot(fit2, fac = "barca")
# autplot(fit2, der = 1, fac = "lens")

# Visualization of the differences between two factor’s levels
autplot(fit2, fac = "barca", diffwith = "lens")
# autplot(fit2, der = 1, fac = "barca", diffwith = "lens")

# Plotting in the same graphics device
## Not run:
if (requireNamespace("gridExtra", quietly = TRUE)) {

...
# For plotting two derivatives in the same graphic windows
ders <- lapply(0:1, function(x) autoplot(fit, der = x))
ggridExtra::grid.arrange(grobs = ders, ncol = 2, nrow = 1)

# For plotting two levels in the same graphic windows
facs <- lapply(c("barca", "lens"), function(x) autoplot(fit2, der = 0, fac = x))
ggridExtra::grid.arrange(grobs = facs, ncol = 2, nrow = 1)

}  
## End(Not run)

### barnacle

**Barnacle dataset.**

#### Description
This barnacle data set gives the measurements of the variables dry weight (in g.) and rostro-carinal length (in mm) for 2000 barnacles collected along the intertidal zone from two sites of the Atlantic coast of Galicia (Spain).

#### Usage
barnacle

#### Format
barnacle is a data frame with 2000 cases (rows) and 3 variables (columns).

- **DW**: Dry weight (in g.)
- **RC**: Rostro-carinal length (in mm).
- **F**: Factor indicating the sites of harvest: barca and lens.

#### References

#### Examples
```r
data(barnacle)
head(barnacle)
```
**children**

*Children dataset.*

**Description**

This children data set contains the age and height measurements of 2500 children aged 5 to 19 years, splitted by sex (1292 females and 1208 males).

**Usage**

`children`

**Format**

`children` is a data frame with 2500 cases (rows) and 3 variables (columns).

- **sex**: Individual’s gender (female or male).
- **height**: Height measured in centimeters.
- **age**: Age in years.

**Note**

Other data sets of this type can be obtained from [http://www.who.int/childgrowth/en/](http://www.who.int/childgrowth/en/).

**Examples**

```r
data(children)
head(children)
```

**critical**

*Critical points of the regression function*

**Description**

This function draws inference about some critical point in the support of \( X \) which is associated with some features of the regression function (e.g., minimum, maximum or inflection points which indicate changes in the sign of curvature). Returns the value of the covariate \( x \) which maximizes the estimate of the function, the value of the covariate \( x \) which maximizes the first derivative and the value of the covariate \( x \) which equals the second derivative to zero, for each level of the factor.

**Usage**

`critical(model, der = NULL)`
Arguments

model  Parametric or nonparametric regression out obtained by \texttt{frfast} function.
der  Number which determines any inference process. By default \texttt{der} is NULL. If this term is 0, the calculation is for the point which maximize the estimate. If it is 1 it is designed for the first derivative and if it is 2, it returns the point which equals the second derivative to zero.

Value

An object is returned with the following elements:

Estimation  x value which maximize the regression function with their 95\% confidence intervals (for each level).

First\_der  x value which maximize the first derivative with their 95\% confidence intervals (for each level).

Second\_der  x value which equals the second derivative to zero with their 95\% confidence intervals (for each level).

criticaldiff

Differences between the critical points for two factor’s levels

Description

Differences between the estimation of critical for two factor’s levels.

Usage

criticaldiff(model, level1 = NULL, level2 = NULL, der = NULL)

Arguments

model Parametric or nonparametric regression model obtained by frfast function.
level1 First factor’s level at which to perform the differences between critical points.
level2 Second factor’s level at which to perform the differences between critical points.
der Number which determines any inference process. By default der is NULL. If this term is 0, the calculate of the differences for the critical point is for the estimate. If it is 1 or 2, it is designed for the first or second derivative, respectively.

Details

Differences are calculated by subtracting a factor relative to another (level2 − level1). By default level2 and level1 are NULL, so the differences calculated are for all possible combinations between two factors. Additionally, it is obtained the 95% confidence interval for this difference which let us to make inference about them.

Value

An object is returned with the following elements:

critical.diff a table with a couple of factor’s level where it is used to calculate the differences between the critical points, and their 95% confidence interval (for the estimation, first and second derivative).

Author(s)

Marta Sestelo, Nora M. Villanueva and Javier Roca-Pardinas.

criticaldiff(fit2, der = 1)
criticaldiff(fit2, der = 1, level1 = "lens", level2 = "barca")
```

---

**frfast**  
*Fitting nonparametric models*

**Description**

This function is used to fit nonparametric models by using local polynomial kernel smoothers or splines. These models can include or not factor-by-curve interactions. Additionally, a parametric model (allometric model) can be estimated (or not).

**Usage**

```r
frfast(formula, data, na.action = "na.omit", model = "np",
       smooth = "kernel", h0 = -1, h = -1, nh = 30, weights = NULL,
       kernel = "epanech", p = 3, kbin = 100, nboot = 500, rankl = NULL,
       ranku = NULL, seed = NULL, cluster = TRUE, ncores = NULL, ...)
```

**Arguments**

- `formula`: An object of class `formula`: a symbolic description of the model to be fitted. The details of model specification are given under 'Details'.
- `data`: An optional data frame, matrix or list required by the formula. If not found in data, the variables are taken from `environment(formula)` typically the environment from which `frfast` is called.
- `na.action`: A function which indicates what should happen when the data contain 'NA's. The default is 'na.omit'.
- `model`: Type model used: model = "np" for a nonparametric regression model, model = "allo" for an allometric model. See details.
- `smooth`: Type smoother used: smooth = "kernel" for local polynomial kernel smoothers and smooth = "splines" for splines using the mgcv package.
- `h0`: The kernel bandwidth smoothing parameter for the global effect (see references for more details at the estimation). Large values of the bandwidth lead to smoothed estimates; smaller values of the bandwidth lead to undersmoothed estimates. By default, cross validation is used to obtain the bandwidth.
- `h`: The kernel bandwidth smoothing parameter for the partial effects.
- `nh`: Integer number of equally-spaced bandwidth in which the h is discretised, to speed up computation in the kernel-based regression.
weights
A character string specifying the desired kernel. Defaults to kernel = "epanech", where the Epanechnikov density function kernel will be used. Also, several types of kernel functions can be used: triangular and Gaussian density function, with "triang" and "gaussian" term, respectively.

kernel
Polynomial degree to be used in the kernel-based regression. Its value must be the value of derivative + 1. The default value is 3, returning the estimation, first and second derivative.

p
Number of binning nodes over which the function is to be estimated.

kbin
Number of bootstrap repeats. Defaults to 500 bootstrap repeats. The wild bootstrap is used when model = "np" and the simple bootstrap when model = "allo".

nboot
Number or vector specifying the minimum value for the interval at which to search the x value which maximizes the estimate, first or second derivative (for each level). The default is the minimum data value.

rankl
Number or vector specifying the maximum value for the interval at which to search the x value which maximizes the estimate, first or second derivative (for each level). The default is the maximum data value.

ranku
Seed to be used in the bootstrap procedure.

seed
A logical value. If TRUE (default), the bootstrap procedure is parallelized (only for smooth = "splines"). Note that there are cases (e.g., a low number of bootstrap repetitions) that R will gain in performance through serial computation. R takes time to distribute tasks across the processors also it will need time for binding them all together later on. Therefore, if the time for distributing and gathering pieces together is greater than the time need for single-thread computing, it does not worth parallelize.

ncores
An integer value specifying the number of cores to be used in the parallelized procedure. If NULL (default), the number of cores to be used is equal to the number of cores of the machine - 1.

... Other options.

Details
The models fitted by frfast function are specified in a compact symbolic form. The \sim operator is basic in the formation of such models. An expression of the form y \sim model is interpreted as a specification that the response y is modelled by a predictor specified symbolically by model. The possible terms consist of a variable name or a variable name and a factor name separated by : operator. Such a term is interpreted as the interaction of the continuous variable and the factor. However, if smooth = "splines", the formula is based on the function formula.gam of the mgcv package.

According with the model argument, if model = "np" the estimated regression model will be of the type

\[ Y = m(X) + e \]

being m an smooth and unknown function and e the regression error with zero mean. If model = "allo", users could estimate the classical allometric model (Huxley, 1924) with a regression curve
\[ m(X) = aX^b \]

being \( a \) and \( b \) the parameters of the model.

**Value**

An object is returned with the following elements:

- **x** Vector of values of the grid points at which model is to be estimate.
- **p** Matrix of values of the grid points at which to compute the estimate, their first and second derivative.
- **pl** Lower values of 95% confidence interval for the estimate, their first and second derivative.
- **pu** Upper values of 95% confidence interval for the estimate, their first and second derivative.
- **diff** Differences between the estimation values of a couple of levels (i.e. level 2 - level 1). The same procedure for their first and second derivative.
- **diffu** Upper values of 95% confidence interval for the differences between the estimation values of a couple of levels. It is performed for their first and second derivative.
- **diffmax** Differences between the estimation of \( \text{max} \) for a couple of levels (i.e. level 2 - level 1). The same procedure for their first and second derivative.
- **diffmaxu** Upper value of 95% confidence interval for the value \( \text{diffmax} \).
- **nboot** Number of bootstrap repeats.
- **n** Sample size.
- **dp** Degree of polynomial to be used.
- **h0** The kernel bandwidth smoothing parameter for the global effect.
- **h** The kernel bandwidth smoothing parameter for the partial effects.
- **fmod** Factor’s level for each data.
- **xdata** Original x values.
- **ydata** Original y values.
- **w** Weights on the data.
- **kbin** Number of binning nodes over which the function is to be estimated.
- **nf** Number of levels.
- **max** Value of covariate \( x \) which maximizes the estimate, first or second derivative.
- **maxu** Upper value of 95% confidence interval for the value max.
- **maxl** Lower value of 95% confidence interval for the value max.
- **diffmax** Differences between the estimation of max for a couple of levels (i.e. level 2 - level 1). The same procedure for their first and second derivative.
diffmax1  Lower value of 95% confidence interval for the value diffmax.
repboot  Matrix of values of the grid points at which to compute the estimate, their first and second derivative for each bootstrap repeat.
rankl  Maximum value for the interval at which to search the x value which maximizes the estimate, first or second derivative (for each level). The default is the maximum data value.
ranku  Minimum value for the interval at which to search the x value which maximizes the estimate, first or second derivative (for each level). The default is the minimum data value.
nmodel  Type model used: nmodel = 1 the nonparametric model, nmodel = 2 the allometric model.
label  Labels of the variables in the model.
numlabel  Number of labels.
kernl  A character specifying the derised kernel.
a  Estimated coefficient in the case of fitting an allometric model.
al  Lower value of 95% confidence interval for the value of a.
au  Upper value of 95% confidence interval for the value of a.
b  Estimated coefficient in the case of fitting an allometric model.
bl  Lower value of 95% confidence interval for the value of b.
bu  Upper value of 95% confidence interval for the value of b.
name  Name of the variables in the model.
formula  A symbolic description of the model to be fitted.

**globaltest**

*Testing the equality of the M curves specific to each level*

**Description**

This function can be used to test the equality of the M curves specific to each level.
Arguments

- **formula**: An object of class `formula`: a symbolic description of the model to be fitted. The details of model specification are given under 'Details'.
- **data**: An optional data frame, matrix or list required by the formula. If not found in data, the variables are taken from `environment(formula)`, typically the environment from which `globaltest` is called.
- **na.action**: A function which indicates what should happen when the data contain 'NA's. The default is 'na.omit'.
- **der**: Number which determines any inference process. By default der is `NULL`. If this term is 0, the testing procedures is applied for the estimate. If it is 1 or 2, it is designed for the first or second derivative, respectively.
- **smooth**: Type smoother used: smooth = "kernel" for local polynomial kernel smoothers and smooth = "splines" for splines using the mgcv package.
- **weights**: Prior weights on the data.
- **nboot**: Number of bootstrap repeats.
- **h0**: The kernel bandwidth smoothing parameter for the global effect (see references for more details at the estimation). Large values of the bandwidth lead to smoothed estimates; smaller values of the bandwidth lead to undersmoothed estimates. By default, cross validation is used to obtain the bandwidth.
- **h**: The kernel bandwidth smoothing parameter for the partial effects.
- **nh**: Integer number of equally-spaced bandwidth on which the h is discretised, to speed up computation.
- **kernel**: A character string specifying the desired kernel. Defaults to kernel = "epanech", where the Epanechnikov density function kernel will be used. Also, several types of kernel functions can be used: triangular and Gaussian density function, with "triang" and "gaussian" term, respectively.
- **p**: Degree of polynomial to be used. Its value must be the value of derivative + 1. The default value is 3 due to the function returns the estimation, first and second derivative.
- **kbin**: Number of binning nodes over which the function is to be estimated.
- **seed**: Seed to be used in the bootstrap procedure.
- **cluster**: A logical value. If TRUE (default), the bootstrap procedure is parallelized (only for smooth = "splines". Note that there are cases (e.g., a low number of bootstrap repetitions) that R will gain in performance through serial computation. R takes time to distribute tasks across the processors also it will need time for binding them all together later on. Therefore, if the time for distributing and gathering pieces together is greater than the time need for single-thread computing, it does not worth parallelize.
ncores

An integer value specifying the number of cores to be used in the parallelized procedure. If NULL (default), the number of cores to be used is equal to the number of cores of the machine - 1.

Details

globaltest can be used to test the equality of the \( M \) curves specific to each level. This bootstrap based test assumes the following null hypothesis:

\[
H_0^r : m_1^r(\cdot) = \ldots = m_M^r(\cdot)
\]

versus the general alternative

\[
H_1^r : m_i^r(\cdot) \neq m_j^r(\cdot) \quad \text{for some } i, j \in \{1, \ldots, M\}.
\]

Note that, if \( H_0 \) is not rejected, then the equality of critical points will also be accepted.

To test the null hypothesis, it is used a test statistic, \( T \), based on direct nonparametric estimates of the curves.

If the null hypothesis is true, the \( T \) value should be close to zero but is generally greater. The test rule based on \( T \) consists of rejecting the null hypothesis if \( T > T^{1-\alpha} \), where \( T^p \) is the empirical \( p \)-percentile of \( T \) under the null hypothesis. To obtain this percentile, we have used bootstrap techniques. See details in references.

Note that the models fitted by globaltest function are specified in a compact symbolic form. The \( \sim \) operator is basic in the formation of such models. An expression of the form \( y \sim \text{model} \) is interpreted as a specification that the response \( y \) is modelled by a predictor specified symbolically by \text{model}. The possible terms consist of a variable name or a variable name and a factor name separated by \( \sim \) operator. Such a term is interpreted as the interaction of the continuous variable and the factor. However, if \text{smooth} = "splines", the formula is based on the function formula.gam of the mgcv package.

Value

The \( T \) value and the \( p \)-value are returned. Additionally, it is shown the decision, accepted or rejected, of the global test. The null hypothesis is rejected if the \( p \)-value < 0.05.

Marta Sestelo, Nora M. Villanueva and Javier Roca-Pardinas.

References

Examples

```r
library(npregfast)
data(barnacle)
globaltest(DW ~ RC : F, data = barnacle, der = 1, seed = 130853, nboot = 100)

# globaltest(height ~ s(age, by = sex), data = children,
# seed = 130853, der = 0, smooth = "splines")
```

---

**localthest**  
*Testing the equality of critical points*

**Description**

This function can be used to test the equality of the $M$ critical points estimated from the respective level-specific curves.

**Usage**

```r
localthest(formula, data = data, na.action = "na.omit", der,
smooth = "kernel", weights = NULL, nboot = 500, h0 = -1, h = -1,
nh = 30, kernel = "epanech", p = 3, kbin = 100, rankl = NULL,
ranku = NULL, seed = NULL, cluster = TRUE, ncores = NULL,
ci.level = 0.95, ...)
```

**Arguments**

- `formula`: An object of class `formula`: a symbolic description of the model to be fitted. The details of model specification are given under 'Details'.
- `data`: An optional data frame, matrix or list required by the formula. If not found in data, the variables are taken from `environment(formula)`, typically the environment from which `localthest` is called.
- `na.action`: A function which indicates what should happen when the data contain 'NA's. The default is 'na.omit'.
- `der`: Number which determines any inference process. By default `der` is `NULL`. If this term is 0, the testing procedures is applied for the estimate. If it is 1 or 2, it is designed for the first or second derivative, respectively.
- `smooth`: Type smoother used: `smooth = "kernel"` for local polynomial kernel smoothers and `smooth = "splines"` for splines using the mgcv package.
- `weights`: Prior weights on the data.
- `nboot`: Number of bootstrap repeats.
- `h0`: The kernel bandwidth smoothing parameter for the global effect (see references for more details at the estimation). Large values of the bandwidth lead to smoothed estimates; smaller values of the bandwidth lead to undersmoothed estimates. By default, cross validation is used to obtain the bandwidth.
**Details**

`localtest` can be used to test the equality of the $M$ critical points estimated from the respective level-specific curves. Note that, even if the curves and/or their derivatives are different, it is possible for these points to be equal.

For instance, taking the maxima of the first derivatives into account, interest lies in testing the following null hypothesis

$$H_0 : x_{01} = \ldots = x_{0M}$$

versus the general alternative

$$H_1 : x_{0i} \neq x_{0j} \text{ for some } i, j \in \{1, \ldots, M\}.$$
The above hypothesis is true if \( d = x_{0j} - x_{0k} = 0 \) where
\[
(j, k) = \argmax_{(l, m) \in \{1 \leq l < m \leq M\}} |\hat{x}_{0l} - \hat{x}_{0m}|,
\]
on otherwise \( H_0 \) is false. It is important to highlight that, in practice, the true \( x_{0j} \) are not known, and consequently neither is \( d \), so an estimate \( \hat{d} = \hat{x}_{0j} - \hat{x}_{0k} \) is used, where, in general, \( \hat{x}_{0l} \) are the estimates of \( x_{0l} \) based on the estimated curves \( \hat{m}_l \) with \( l = 1, \ldots, M \).

Needless to say, since \( \hat{d} \) is only an estimate of the true \( d \), the sampling uncertainty of these estimates needs to be acknowledged. Hence, a confidence interval \((a, b)\) is created for \( d \) for a specific level of confidence (95%). Based on this, the null hypothesis is rejected if zero is not contained in the interval.

Note that if this hypothesis is rejected (and the factor has more than two levels), one option could be to use the \texttt{maxp.diff} function in order to obtain the differences between each pair of factor’s levels.

Note that the models fitted by \texttt{localtest} function are specified in a compact symbolic form. The \texttt{\~} operator is basic in the formation of such models. An expression of the form \texttt{y \~ model} is interpreted as a specification that the response \( y \) is modelled by a predictor specified symbolically by \texttt{model}. The possible terms consist of a variable name or a variable name and a factor name separated by \texttt{:} operator. Such a term is interpreted as the interaction of the continuous variable and the factor. However, if \texttt{smooth = "splines"}, the formula is based on the function \texttt{formula.gam} of the \texttt{mgcv} package.

**Value**

The estimate of \( d \) value is returned and its confidence interval for a specific-level of confidence, i.e. 95%. Additionally, it is shown the decision, accepted or rejected, of the local test. Based on the null hypothesis is rejected if a zero value is not within the interval.

Marta Sestelo, Nora M. Villanueva and Javier Roca-Pardinas.

**References**

**Examples**

```R
library(npregfast)
data(barnacle)
localtest(DW ~ RC : F, data = barnacle, der = 1, seed = 130853, nboot = 100)
```

# localtest(height ~ s(age, by = sex), data = children, seed = 130853,
# der = 1, smooth = "splines")
Description

Useful for drawing the estimated regression function, first and second derivative (for each factor's level). Additionally, with the `diffwith` argument it is possible to draw the differences between two factor's levels.

Usage

```r
## S3 method for class 'frfast'
plot(x = model, y = NULL, der = NULL, diffwith = NULL, points = TRUE, xlab = model$name[2],
ylab = model$name[1], ylim = NULL, main = NULL, col = "black",
CIcol = "black", pcol = "grey80", ablinecol = "red", abline = TRUE,
type = "l", CIttype = "l", lwd = 2, CIlwd = 1, lty = 1, CItly = 2,
cex = 0.6, ...)
```

Arguments

- `x`: `frfast` object.
- `y`: `NULL`.
- `fac`: Vector which determines the level to take into account in the plot. By default is `NULL`.
- `der`: Number or vector which determines any inference process. By default `der` is `NULL`. If this term is 0, the plot shows the initial estimate. If it is 1 or 2, it is designed for the first or second derivative, respectively.
- `diffwith`: Factor's level used for drawing the differences respect to the level specified in the `fac` argument. By default, `NULL`. The differences are computed for the r-th derivative specified in the `der` argument.
- `points`: Draw the original data into the plot. By default it is `TRUE`.
- `xlab`: A title for the x axis.
- `ylab`: A title for the y axis.
- `ylim`: The y limits of the plot.
- `main`: An overall title for the plot.
- `col`: A specification for the default plotting color.
- `CIcol`: A specification for the default confidence intervals plotting color.
- `pcol`: A specification for the points color.
- `ablinecol`: The color to be used for `abline`.
- `abline`: Draw an horizontal line into the plot of the second derivative of the model.
- `type`: What type of plot should be drawn. Possible types are, p for points, 1 for lines, o for overplotted, etc. See details in `par`. 
What type of plot should be drawn for confidence intervals. Possible types are, p for points, l for lines, o for overplotted.

The line width, a positive number, defaulting to 1. See details in `par`.

The line width for confidence intervals, a positive number, defaulting to 1.

The line type. Line types can either be specified as an integer (0 = blank, 1 = solid (default), 2 = dashed, 3 = dotted, 4 = dotdash, 5 = longdash, 6 = twodash). See details in `par`.

The line type for confidence intervals. Line types can either be specified as an integer (0 = blank, 1 = solid (default), 2 = dashed, 3 = dotted, 4 = dotdash, 5 = longdash, 6 = twodash).

A numerical value giving the amount by which plotting symbols should be magnified relative to the default. See details in `par`.

Other options.

Simply produce a plot.

Marta Sestelo, Nora M. Villanueva and Javier Roca-Pardinas.

library(npregfast)
data(barnacle)

# Nonparametric regression without interactions
fit <- frfast(DW ~ RC, data = barnacle, nboot = 100)
plot(fit)
plot(fit, der = 0)
plot(fit, der = 0, points = FALSE)
plot(fit, der = 1, col = "red", CIcol = "blue")

# Nonparametric regression with interactions
fit2 <- frfast(DW ~ RC : F, data = barnacle, nboot = 100)
plot(fit2)
plot(fit2, der = 0, fac = "lens")
plot(fit2, der = 1, col = "grey", CIcol = "red")
plot(fit2, der = c(0,1), fac = c("barca","lens"))

# Visualization of the differences between two factor's levels
plot(fit2, fac = "barca", diffwith = "lens")
plot(fit2, fac = "barca", diffwith = "lens", der = 1)
**predict.frfast**

*Prediction from fitted frfast model*

**Description**

Takes a fitted `frfast` object and produces predictions (with their 95% confidence intervals) from a fitted model with interactions or without interactions.

**Usage**

```r
## S3 method for class 'frfast'
predict(object = model, newdata, fac = NULL, der = NULL, 
        seed = NULL, ...)
```

**Arguments**

- `object` A fitted `frfast` object as produced by `frfast()`.
- `newdata` A data frame containing the values of the model covariates at which predictions are required. If `newdata` is provided, then it should contain all the variables needed for prediction: a warning is generated if not.
- `fac` Factor’s level to take into account. By default is `NULL`.
- `der` Number which determines any inference process. By default `der` is `NULL`. If this term is 0, the function returns the initial estimate. If it is 1 or 2, it is designed for the first or second derivative, respectively.
- `seed` Seed to be used in the bootstrap procedure.
- `...` Other options.

**Value**

`predict.frfast` computes and returns a list containing predictions of the estimates, first and second derivative, with their 95% confidence intervals.

**Author(s)**

Marta Sestelo, Nora M. Villanueva and Javier Roca-Pardinas.

**Examples**

```r
library(npregfast)
data(barnacle)

# Nonparametric regression without interactions
fit <- frfast(DW ~ RC, data = barnacle, nboot = 100)
nd <- data.frame(RC = c(10, 14, 18))
predict(fit, newdata = nd)

# Nonparametric regression with interactions
```
runExample

Description
Launch a Shiny app that shows a demo of what can be done with the package.

Usage
runExample()

Details
This example is also available online.

Examples

```r
## Only run this example in interactive R sessions
if (interactive()) {
  runExample()
}
```

summary.frfast

Summarizing fits of frfast class

Description
Takes a fitted frfast object produced by frfast() and produces various useful summaries from it.

Usage

```r
## S3 method for class 'frfast'
summary(object = model, ...)
```

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object</td>
<td>a fitted frfast object as produced by frfast().</td>
</tr>
<tr>
<td>...</td>
<td>additional arguments affecting the predictions produced.</td>
</tr>
</tbody>
</table>
summary.frfast

Details

print.frfast tries to be smart about summary.frfast.

Value

summary.frfast computes and returns a list of summary information for a fitted frfast object.

- `model`: type of model: nonparametric or allometric.
- `smooth`: type of smoother: kernel or splines.
- `h`: the kernel bandwidth smoothing parameter.
- `dp`: degree of the polynomial.
- `nboot`: number of bootstrap repeats.
- `kbin`: number of binning nodes over which the function is to be estimated.
- `n`: sample size.
- `fmod`: factor's levels.
- `coef`: if `model = "allo"`, coefficients of the model.
