Package ‘ormPlot’

June 21, 2019

Type Package

Title Advanced Plotting of Ordinal Regression Models

Version 0.3.2

Maintainer Richard Meitern <richard.meitern@ut.ee>

Description An extension to the Regression Modeling Strategies package that facilitates plotting ordinal regression model predictions together with confidence intervals for each dependent variable level. It also adds a functionality to plot the model summary as a modifiable object.

convert_arg

Function to convert any input to string vector

Description

Function to convert any input to string vector

Usage

convert_arg(x)

Arguments

x  string, object name or vector of these

Value

vector of strings

educ_data

Morfometrics of children

Description

A dataset containing the standardized residuals of Estonian schoolchildren.

Usage

educ_data
**join_ggplots**

**Format**

A data frame with 11032 rows and 10 variables:

- **educ_3** highest obtained educational level
- **Rural** location of school (rural or urban)
- **sex** gender of the child
- **max_SEP_3** highest parental profession
- **n_siblings** number of children in the family
- **cran_rzs** cranial volume (residuals to age an birth date)
- **height_rzs** height (residuals to age an birth date)
- **FW_rzs** face width (residuals to age an birth date)
- **YOB** year of birth
- **YOBc** centered but not scaled year of birth (YOB)

**Description**

Function to get aligned table of two ggplot objects

**Usage**

```r
join_ggplots(leftplot, rightplot, plot.widths = c(0.5, 0.5), title = "Odds Ratio")
```

**Arguments**

- **leftplot** the left side plot
- **rightplot** the plot on the right
- **plot.widths** the relative widths of the left and right plot should be a vector (c()) with 2 elements that sum to 1 defaults to equal widths
- **title** the tile row of the drawn plot

**Examples**

```r
set.seed(123)  #load the libraries
library(rms)
library(ormPlot)

#make the datadist
dd<-rm:::datadist(educ_data)
options(datadist="dd")
```
#create the model
cran_model <- orm(educ_3 ~ YOBc + sex + height_rzs + n_siblings + cran_rzs, data = educ_data)

#the antilog true produces odd ratios (default value for orm and lrm)
s <- summary(cran_model, antilog = TRUE)

#set the plotting default theme (optional)
theme_set(theme_classic())

#return modifiable ggplots
plots <- forestplot(s, return_ggplots = TRUE)

#modify like any ggplot2 object
table <- plots[[1]] + theme(axis.text = element_text(size = 12),
                           axis.line.x = element_line(color = "red", size = 1),
                           axis.text.y = element_blank())

graph <- plots[[2]] + theme(axis.line = element_line(color = "red", size = 1),
                           axis.text.y = element_text())

#join the graphs
join_ggplots(graph, table, title = "", plot.widths = c(0.6, 0.4))

---

oddstable  

Get row names from odd an values form even columns

Description

Get row names from odd an values form even columns

Usage

oddstable(x)

Arguments

x  

a matrix with even number of rows
oddstable_graph

Make a ggplot table

Description

Function to get a ggplot table from a matrix

Usage

oddstable_graph(x, digits = 3, theme = ggplot2::theme_get(),
  header = NULL, row.names.y = NULL)

Arguments

x a matrix or a data.frame
 digits the number of significant digits to display
 theme the desired ggplot2 theme
 header names of the table columns
 row.names.y new names for the variable rows

ormPlot

ormPlot: Plotting ordinal regression models from rms

Description

The package is an extension to the rms package that facilitates plotting the ordinal regression orm model objects. The aim is to get ggplot2 plots that are modifiable

Details

The ormPlot package provides two categories of important functions: forestplotting the summary and plotting the predictions

Summary plotting

The forestplot function facilitates plotting the summary.rms objects resulting from the orm or lrm model

See exported methods for more details:

- plot.summary.rms
- forestplot
- join_ggplots
Prediction plotting

The prediction plotting function facilitates plotting the `orm` objects using the results got from `predict` function. In particular it adds confidence intervals to orm prediction plots.

See exported methods for more details:

- `plot.orm`
- `predict_with_ci`

Data

`educ_data` data about morfometrics of schoolchildren born between 1937-1962 in Estonian territory. see also the citation("ormPlot") article

---

**orm_graph**

Make a ggplot figure

---

Description

Function to get a ggplot figure from a matrix x

Usage

```r
orm_graph(x, theme = ggplot2::theme_get(), header = NULL, 
row.names.y = NULL, shape = 19, limits = NULL, breaks = c(0.5, 1, 
1.5, 2, 3, 4))
```

Arguments

- `x` a matrix or a data.frame
- `theme` the desired ggplot2 theme
- `header` names of the table columns
- `row.names.y` new names for the variable rows
- `shape` point shape, see `aes_linetype_size_shape`
- `limits` the x axis limits as a vector, see also: `scale_continuous`
- `breaks` the x axis breaks as a vector, help see also: `scale_continuous`
plot.orm

Plot the prediction with confidence intervals

Description

This function plots the model predictions given that all variables that are not included in the plot are kept constant. Hence it requires at least one variable to produce a plot. returns a ggplot object that can be further customized like any other ggplot

Usage

```r
## S3 method for class 'orm'
plot(x, xval, plot_cols = c(), plot_rows = c(),
     label_with_colname = TRUE, facet_labels = NULL, xlab = NULL,
     ylab = NULL, np = 100, fun = stats::plogis, boot.type = "bca",
     conf.int = 0.95, . . .)
```

Arguments

- `x`: an rms fit object, or for print the result of Predict. options(datadist="d") must have been specified (where d was created by datadist), or it must have been in effect when the the model was fitted.
- `xval`: The model value plotted on the x axis
- `plot_cols`: A vector of strings with other model components that should be plotted. These are put on columns.
- `plot_rows`: A vector of strings with other model components that should be plotted. These are put on rows.
- `label_with_colname`: Should the variable name also be included on plot row and column names
- `facet_labels`: A named list of new names for variables on rows and columns
- `xlab`: A custom x-axis value (if specified)
- `ylab`: A custom y-axis value (if specified)
- `np`: the number of equally-spaced points computed for continuous predictors that vary, i.e., when the specified value is . or NA
- `fun`: an optional transformation of the linear predictor. Specify fun='mean' if the fit is a proportional odds model fit and you ran bootcov with coef.reps=TRUE. This will let the mean function be re-estimated for each bootstrap rep to properly account for all sources of uncertainty in estimating the mean response.
- `boot.type`: set to 'bca' to compute BCa confidence limits or 'basic' to use the basic bootstrap. The default is to compute percentile intervals
- `conf.int`: confidence level. Default is 0.95. Specify FALSE to suppress.
- `...`: additional parameters that will be passed to `Predict`
Value

a ggplot plot object

See Also

`Predict.datadist.orm`

Examples

```r
# load the libraries
library(rms)
library(ormPlot)

# make the datadist
dd <- datadist(educ_data)
options(datadist = 'dd')

# create the model
cran_model <- orm(educ_3 ~ Rural + sex + max_SEP_3 + cran_rzs, data = educ_data)

# plot the predictions of the model for varying one variable only
plot(cran_model, cran_rzs)

# customize the plotting varying all variables
plot(cran_model, cran_rzs,
     plot_cols = max_SEP_3,
     plot_rows = c(Rural, sex),
     xlab = "Cranial volume (residuals to age an birth date)",
     facet_labels = list(Rural = c("Urban", "Rural"),
                         sex = c("Boys", "Girls")))
```

---

**plot.summary.rms**

*Forest Plot of an rms model summary*

Description

Convenience function to create a plot of the `orm` model summary. For further customizing the plots use `return_ggplots = TRUE` This will create 2 `ggplot2` objects that can be joined with the `join_ggplots` commands.
plot.summary.rms

Usage

## S3 method for class 'summary.rms'
plot(x, ...)

forestplot(x, return_ggplots = FALSE, plot.widths = c(0.5, 0.5),
  title = "Odds ratio", digits = 3, shape = 19, header = NULL,
  limits = NULL, breaks = c(0.5, 1, 1.5, 2, 3, 4),
  theme = ggplot2::theme_get(), row.names.y = NULL)

forestplot.default(x, ...)
forestplot.summary.rms(x, ...)

Arguments

x             result of a summary command on orm or lrm model ie a summary.rms class object
...           see parameters of method forestplot
return_ggplots if TRUE the function returns 2 ggplot objects in a list instead of drawing a table-grid
plot.widths   the relative widths of the left and right plot should be a vector (c()) with 2 elements that sum to 1 defaults to equal widths
title         the tile row of the drawn plot
digits        the number of significant digits to display
shape          point shape, see aes_linetype_size_shape$header
                names of the table columns
limits         the x axis limits as a vector, see also: scale_continuous
breaks         the x axis breaks as a vector, help see also: scale_continuous
theme          the desired ggplot2 theme
row.names.y    new names for the variable rows

Examples

set.seed(123)
#load the libraries
library(rms)
library(ormPlot)

#make the datadist
dd<-rms::datadist(educ_data)
options(datadist="dd")

#create the model
cran_model <- orm(educ_3 ~ YOBc + sex + height_rzs + n_siblings + cran_rzs, data = educ_data)

#the antilog true produces odd ratios (default value for orm and lrm)
s<-summary(cran_model, antilog = TRUE)

#set the plotting default theme (optional)
theme_set(theme_classic())

#show simply the result
forestplot(s)

#return modifiable ggplots
forestplot(s, return_ggplots = TRUE )

#new row names and header
newnames <- c("Year of birth", "Height", "Number of children", "Cranial volume", "Sex")
newhead <- c("Odds ratio", "CI 5%", "CI 95%")

#adjust also the relative plot widths and change the color and shape
newtheme <- theme_classic() + theme(text = element_text(color = "red", size = 12),
  line = element_line(color = "red"),
  rect = element_rect(color="red"))

forestplot(s, row_names.y = newnames, header = newhead,
  plot.widths = c(0.6,0.4), shape = 17,
  theme = newtheme)

---

**predict_with_ci**

*Create a Prediction data.frame with confidence intervals*

**Description**

returns a data.frame object similar to the `predict` however it adds a column dependent that lists all factor levels with appropriate confidence intervals calculated for each level. It is similar to `predict.lrm` with type="fitted.ind" but also generates selected confidence intervals.

**Usage**

```r
predict_with_ci(x, ..., np = 100, fun = stats::plogis,
  conf.int = 0.95, boot.type = "bca")
```

**Arguments**

- **x**
  - an rms fit object, or for print the result of `Predict`. options(datadist="d") must have been specified (where d was created by datadist), or it must have been in effect when the the model was fitted.
- **...**
  - One or more variables to vary, or single-valued adjustment values. Specify a variable name without an equal sign to use the default display range, or any range you choose (e.g. seq(0,100,by=2),c(2,3,7,14)). The default list of values for which predictions are made is taken as the list of unique values of the variable if they number fewer than 11. For variables with > 10 unique values, np equally spaced values in the range are used for plotting if the range
predict_with_ci

is not specified. Variables not specified are set to the default adjustment value limits[2], i.e. the median for continuous variables and a reference category for non-continuous ones. Later variables define adjustment settings. For categorical variables, specify the class labels in quotes when specifying variable values. If the levels of a categorical variable are numeric, you may omit the quotes. For variables not described using datadist, you must specify explicit ranges and adjustment settings for predictors that were in the model. If no variables are specified in ..., predictions will be made by separately varying all predictors in the model over their default range, holding the other predictors at their adjustment values. This has the same effect as specifying name as a vector containing all the predictors. For rbind, ... represents a series of results from Predict. If you name the results, these names will be taken as the values of the new .set. variable added to the concatenated data frames. See an example below.

np the number of equally-spaced points computed for continuous predictors that vary, i.e., when the specified value is . or NA

fun an optional transformation of the linear predictor. Specify fun='mean' if the fit is a proportional odds model fit and you ran bootcov with coef.reps=TRUE. This will let the mean function be re-estimated for each bootstrap rep to properly account for all sources of uncertainty in estimating the mean response.

conf.int confidence level. Default is 0.95. Specify FALSE to suppress.

boot.type set to 'bca' to compute BCa confidence limits or 'basic' to use the basic bootstrap. The default is to compute percentile intervals

Value

da data.frame
