Package ‘pROC’

July 22, 2019

Type Package

Title Display and Analyze ROC Curves

Version 1.15.3

Date 2019-07-21

Encoding UTF-8

Depends R (>= 2.14)

Imports methods, plyr, Rcpp (>= 0.11.1)

Suggests microbenchmark, tcltk, MASS, logcondens, doParallel, testthat, vdiffr, ggplot2

LinkingTo Rcpp

Description Tools for visualizing, smoothing and comparing receiver operating characteristic (ROC curves). (Partial) area under the curve (AUC) can be compared with statistical tests based on U-statistics or bootstrap. Confidence intervals can be computed for (p)AUC or ROC curves.

License GPL (>= 3)

**pROC-package**  
**pROC**

**Description**

Tools for visualizing, smoothing and comparing receiver operating characteristic (ROC curves). (Partial) area under the curve (AUC) can be compared with statistical tests based on U-statistics or bootstrap. Confidence intervals can be computed for (p)AUC or ROC curves. Sample size / power computation for one or two ROC curves are available.

**Details**

The basic unit of the pROC package is the `roc` function. It will build a ROC curve, smooth it if requested (if `smooth=TRUE`), compute the AUC (if `auc=TRUE`), the confidence interval (CI) if requested (if `ci=TRUE`) and plot the curve if requested (if `plot=TRUE`).

The `roc` function will call `smooth`, `auc`, `ci` and `plot` as necessary. See these individual functions for the arguments that can be passed to them through `roc`. These function can be called separately.
Two paired (that is roc objects with the same response) or unpaired (with different response) ROC curves can be compared with the roc.test function.

Citation

If you use pROC in published research, please cite the following paper:

Type citation("pROC") for a BibTeX entry.

The authors would be glad to hear how pROC is employed. You are kindly encouraged to notify Xavier Robin <pROC-cran@xavier.robin.name> about any work you publish.

Abbreviations

The following abbreviations are employed extensively in this package:

- ROC: receiver operating characteristic
- AUC: area under the ROC curve
- pAUC: partial area under the ROC curve
- CI: confidence interval
- SP: specificity
- SE: sensitivity

Functions

roc Build a ROC curve
are.paired Determine if two ROC curves are paired
auc Compute the area under the ROC curve
ci Compute confidence intervals of a ROC curve
ci.auc Compute the CI of the AUC
ci.coords Compute the CI of arbitrary coordinates
ci.se Compute the CI of sensitivities at given specificities
ci.sp Compute the CI of specificities at given sensitivities
ci.thresholds Compute the CI of specificity and sensitivity of thresholds
ci.coords Compute the CI of arbitrary coordinates
coords Coordinates of the ROC curve
cov Covariance between two AUCs
ggroc Plot a ROC curve with ggplot2
has.partial.auc Determine if the ROC curve have a partial AUC
lines roc Add a ROC line to a ROC plot
plot.ci Plot CIs
plot Plot a ROC curve
print Print a ROC curve object
roc.test Compare the AUC of two ROC curves
smooth Smooth a ROC curve
var Variance of the AUC

Dataset

This package comes with a dataset of 141 patients with aneurysmal subarachnoid hemorrhage: aSAH.

Installing and using

To install this package, make sure you are connected to the internet and issue the following command in the R prompt:

install.packages("pROC")

To load the package in R:

library(pROC)

Experimental: pipelines

Since version 1.15.0, the roc function can be used in pipelines, for instance with dplyr or magrittr. This is still a highly experimental feature and will change significantly in future versions (see issue 542). The roc.data.frame method supports both standard and non-standard evaluation (NSE), and the roc_ function supports standard evaluation only.

library(dplyr)
aSAH %>%
  filter(gender == "Female") %>%
  roc(outcome, s100b)

By default it returns the roc object, which can then be piped to the coords function to extract coordinates that can be used in further pipelines.

library(dplyr)
aSAH %>%
  filter(gender == "Female") %>%
  roc(outcome, s100b) %>%
  coords(transpose=FALSE) %>%
  filter(sensitivity > 0.6,
         specificity > 0.6)

More details and use cases are available in the roc help page.

2https://github.com/xrobin/pROC/issues/54
Bootstrap

All the bootstrap operations for significance testing, confidence interval, variance and covariance computation are performed with non-parametric stratified or non-stratified resampling (according to the `stratified` argument) and with the percentile method, as described in Carpenter and Bithell (2000) sections 2.1 and 3.3.

Stratification of bootstrap can be controlled with `boot.stratified`. In stratified bootstrap (the default), each replicate contains the same number of cases and controls than the original sample. Stratification is especially useful if one group has only little observations, or if groups are not balanced.

The number of bootstrap replicates is controlled by `boot.n`. Higher numbers will give a more precise estimate of the significance tests and confidence intervals but take more time to compute. 2000 is recommended by Carpenter and Bithell (2000) for confidence intervals. In our experience this is sufficient for a good estimation of the first significant digit only, so we recommend the use of 10000 bootstrap replicates to obtain a good estimate of the second significant digit whenever possible.

Progress bars: A progressbar shows the progress of bootstrap operations. It is handled by the `plyr` package (Wickham, 2011), and is created by the `progress_*` family of functions. Sensible defaults are guessed during the package loading:

- In non-interactive mode, no progressbar is displayed.
- In embedded GNU Emacs “ESS”, a `txtProgressBar`.
- In Windows, a `winProgressBar`.
- In other systems with or without a graphical display, a `txtProgressBar`.

The default can be changed with the option “pROCProgress”. The option must be a list with a `name` item setting the type of progress bar (“none”, “win”, “tk” or “text”). Optional items of the list are “width”, “char” and “style”, corresponding to the arguments to the underlying progressbar functions. For example, to force a text progress bar:

```r
options(pROCProgress = list(name = "text", width = NA, char = ",", style = 3))
```

To inhibit the progress bars completely:

```r
options(pROCProgress = list(name = "none"))
```

Handling large datasets

Algorithms: Over the years, a significant amount of time has been invested in making `pROC` run faster and faster. From the naive algorithm iterating over all thresholds implemented in the first version (`algorithm = 1`), we went to a C++ implementation (with `Rcpp`, `algorithm = 3`), and a different algorithm using cumulative sum of responses sorted by the predictor, which scales only with the number of data points, independently on the number of thresholds (`algorithm = 2`). The curves themselves are identical, but computation time has been decreased massively.

Since version 1.12, `pROC` was able to automatically select the fastest algorithm for your dataset based on the number of thresholds of the ROC curve. Initially this number was around 1500 thresholds, above which algorithm 3 was selected. But with `pROC` 1.15 additional code profiling enabled us implement additional speedups that brought this number down to less than 100 thresholds. As the detection of the number of thresholds itself can have a large impact comparatively (up
to 10% now), a new algorithm = 6 was implemented, which assumes that ordered datasets should have relatively few levels, and hence thresholds. These predictors are processed with algorithm = 3. Any numeric dataset is now assumed to have a sufficient number of thresholds to be processed with algorithm = 2 efficiently. In the off-chance that you have a very large numeric dataset with very few thresholds, algorithm = 3 can be selected manually (in the call to roc). For instance with 5 thresholds you can expect a speedup of around to 3 times. This effect disappears altogether as soon as the curve gets to 50-100 thresholds.

This simple selection should work in most cases. However if you are unsure or want to test it for yourself, use algorithm = 0 to run a quick benchmark between 2 and 3. Make sure microbenchmark is installed. Beware, this is very slow as it will repeat the computation 10 times to obtain a decent estimate of each algorithm speed.

```r
if (!requireNamespace("microbenchmark")) install.packages("microbenchmark")

# First a ROC curve with many thresholds. Algorithm 2 is much faster.
response <- rbinom(5E3, 1, .5)
predictor <- rnorm(5E3)
rocobj <- roc(response, predictor, algorithm = 0)

# Next a ROC curve with few thresholds but more data points
response <- rbinom(1E6, 1, .5)
predictor <- rpois(1E6, 1)
rocobj <- roc(response, predictor, algorithm = 0)
```

Other functions have been optimized too, and bottlenecks removed. In particular, the coords function is orders of magnitude faster in pROC 1.15. The DeLong algorithm has been improved in versions 1.6, 1.7 and 1.9.1, and currently uses a much more efficient algorithm, both in computation time and memory footprint. We will keep working on improvements to make pROC more suited to large datasets in the future.

**Bootstrap:** Bootstrap is typically slow because it involves repeatedly computing the ROC curve (or a part of it). Some bootstrap functions are faster than others. Typically, ci.thresholds is the fastest, and ci.coords the slowest. Use ci.coords only if the CI you need cannot be computed by the specialized CI functions ci.thresholds, ci.se and ci.sp. Note that ci.auc cannot be replaced anyway.

A naive way to speed-up the bootstrap is by removing the progress bar:

```r
rocobj <- roc(response, round(predictor))
system.time(ci(rocobj))
system.time(ci(rocobj, progress = "none"))
```

It is of course possible to reduce the number of bootstrap iterations. See the boot.n argument to ci. This will reduce the precision of the bootstrap estimate.

**Parallel processing:** Bootstrap operations can be performed in parallel. The backend provided by the plyr package is used, which in turn relies on the foreach package.
To enable parallel processing, you first need to load an adaptor for the `foreach` package (`doMC`, `doMPI`, `doParallel`, `doRedis`, `doRNG` or `doSNOW`), register the backend, and set `parallel=TRUE`.

```r
library(doParallel)
registerDoParallel(cl <- makeCluster(getOption("mc.cores", 2)))
ci(rocobj, method="bootstrap", parallel=TRUE)
stopCluster(cl)
```

Progress bars are not available when parallel processing is enabled.

Using DeLong instead of bootstrap: DeLong is an asymptotically exact method to evaluate the uncertainty of an AUC (DeLong et al. (1988)). Since version 1.9, pROC uses the algorithm proposed by Sun and Xu (2014) which has an O(N log N) complexity and is always faster than bootstrapping. By default, pROC will choose the DeLong method whenever possible.

```r
rocobj <- roc(response, round(predictor), algorithm=3)
system.time(ci(rocobj, method="delong"))
system.time(ci(rocobj, method="bootstrap", parallel = TRUE))
```

CRAN packages ROCR, verification or Bioconductor's roc for ROC curves. CRAN packages plyr, MASS and logcondens employed in this package.

Examples

data(aSAH)

# Build a ROC object and compute the AUC
roc(aSAH$outcome, aSAH$s100b)
roc(outcome ~ s100b, aSAH)

# Smooth ROC curve
roc(outcome ~ s100b, aSAH, smooth=TRUE)

# more options, CI and plotting
roc1 <- roc(aSAH$outcome,
    aSAH$s100b, percent=TRUE,
    # arguments for auc
    partial.auc=c(100, 90), partial.auc.correct=TRUE,
    partial.auc.focus="sens",
    # arguments for ci
    ci=TRUE, boot.n=100, ci.alpha=0.9, stratified=FALSE,
    # arguments for plot
    plot=TRUE, auc.polygon=TRUE, max.auc.polygon=TRUE, grid=TRUE,
    print.auc=TRUE, show.thres=TRUE)

# Add to an existing plot. Beware of 'percent' specification!
roc2 <- roc(aSAH$outcome, aSAH$wfns,
    plot=TRUE, add=TRUE, percent=roc1$percent)

## Coordinates of the curve ##
coords(roc1, "best", ret=c("threshold", "specificity", "1-npv"))
coords(roc2, "local maximas", ret=c("threshold", "sens", "spec", "ppv", "npv"))

## Confidence intervals ##

# CI of the AUC
ci(roc2)

## Not run:
# CI of the curve
sens.ci <- ci.se(roc1, specificities=seq(0, 100, 5))
plot(sens.ci, type="shape", col="lightblue")
plot(sens.ci, type="bars")

## End(Not run)

# need to re-add roc2 over the shape
plot(roc2, add=TRUE)

## Not run:
are.paired

Are two ROC curves paired?

Description

This function determines if two ROC curves can be paired.

Usage

are.paired(...)

## S3 method for class 'auc'
are.paired(roc1, roc2, ...)

## S3 method for class 'smooth.roc'
are.paired(roc1, roc2, ...)

## S3 method for class 'roc'
are.paired(roc1, roc2, return.paired.rocs=FALSE,
reuse.auc = TRUE, reuse.ci = FALSE, reuse.smooth=TRUE, ...)
are.paired

Arguments

roc1, roc2  the two ROC curves to compare. Either “roc”, “auc” or “smooth.roc” objects (types can be mixed).

return.paired.rocs  if TRUE and the ROC curves can be paired, the two paired ROC curves with NAs removed will be returned.

reuse.auc, reuse.ci, reuse.smooth  if return.paired.rocs=TRUE, determines if auc, ci and smooth should be re-computed (with the same parameters than the original ROC curves)

...  additionnal arguments for are.paired.roc. Ignored in are.paired.roc

Details

Two ROC curves are paired if they are built on two variables observed on the same sample. In practice, the paired status is granted if the response and levels vector of both ROC curves are identical. If the responses are different, this can be due to missing values differing between the curves. In this case, the function will strip all NAs in both curves and check for identity again. It can raise false positives if the responses are identical but correspond to different patients.

Value

TRUE if roc1 and roc2 are paired, FALSE otherwise.

In addition, if TRUE and return.paired.rocs=TRUE, the following attributes are defined:

roc1, roc2  the two ROC curve with all NAs values removed in both curves.

See Also

roc, roc.test

Examples

data(aSAH)
aSAH.copy <- aSAH

# artificially insert NAs for demonstration purposes
aSAH.copy$outcome[42] <- NA
aSAH.copy$s100b[24] <- NA
aSAH.copy$ndka[1:10] <- NA

# Call roc() on the whole data
roc1 <- roc(aSAH.copy$outcome, aSAH.copy$s100b)
roc2 <- roc(aSAH.copy$outcome, aSAH.copy$ndka)
# are.paired can still find that the curves were paired
are.paired(roc1, roc2) # TRUE

# Removing the NAs manually before passing to roc() un-pairs the ROC curves
nas <- is.na(aSAH.copy$outcome) | is.na(aSAH.copy$ndka)
roc2b <- roc(aSAH.copy$outcome[!nas], aSAH.copy$ndka[!nas])
are.paired(roc1, roc2b) # FALSE

# Getting the two paired ROC curves with additional smoothing and ci options
roc2$ci <- ci(roc2)
paired <- are.paired(smooth(roc1), roc2, return.paired.rocs=TRUE, reuse.ci=TRUE)
paired.roc1 <- attr(paired, "roc1")
paired.roc2 <- attr(paired, "roc2")

**aSAH**  
*Subarachnoid hemorrhage data*

**Description**

This dataset summarizes several clinical and one laboratory variable of 113 patients with an aneurysmal subarachnoid hemorrhage.

**Usage**

*aSAH*

**Format**

A data.frame containing 113 observations of 7 variables.

**Source**

**See Also**

Other examples can be found in all the documentation pages of this package: `roc`, `auc`, `ci`, `ci.auc`, `ci.se`, `ci.sp`, `ci.thresholds`, `coords`, `plot.ci`, `plot.roc`, `print.roc`, `roc.test` and `smooth`.

An example analysis with pROC is shown in:

**auc**

*Compute the area under the ROC curve*

**Description**

This function computes the numeric value of area under the ROC curve (AUC) with the trapezoidal rule. Two syntaxes are possible: one object of class “roc”, or either two vectors (response, predictor) or a formula (response~predictor) as in the `roc` function. By default, the total AUC is computed, but a portion of the ROC curve can be specified with `partial.auc`.

**Usage**

```r
auc(...)
## S3 method for class 'roc'
auc(roc, partial.auc=FALSE, partial.auc.focus=c("specificity", "sensitivity"), partial.auc.correct=FALSE, allow.invalid.partial.auc.correct = FALSE, ...)
## S3 method for class 'smooth.roc'
auc(smooth.roc, ...)
## S3 method for class 'multiclass.roc'
auc(multiclass.roc, ...)
## S3 method for class 'formula'
auc(formula, data, ...)
## Default S3 method:
auc(response, predictor, ...)
```

**Arguments**

- `roc`, `smooth.roc`, `multiclass.roc`
  
a “roc” object from the `roc` function, a “smooth.roc” object from the `smooth` function, or a “multiclass.roc” or “mv.multiclass.roc” from the `multiclass.roc` function.
response, predictor
arguments for the roc function.

formula, data
a formula (and possibly a data object) of type response~predictor for the roc function.

partial.auc either FALSE (default: consider total area) or a numeric vector of length 2: boundaries of the AUC to consider in [0,1] (or [0,100] if percent is TRUE).

partial.auc.focus
if partial.auc is not FALSE and a partial AUC is computed, specifies if partial.auc specifies the bounds in terms of specificity (default) or sensitivity. Can be shortened to spec/sens or even sp/se. Ignored if partial.auc=FALSE.

partial.auc.correct
logical indicating if the correction of AUC must be applied in order to have a maximal AUC of 1.0 and a non-discriminant AUC of 0.5 whatever the partial.auc defined. Ignored if partial.auc=FALSE. Default: FALSE.

allow.invalid.partial.auc.correct
logical indicating if the correction must return NA (with a warning) when attempting to correct a pAUC below the diagonal. Set to TRUE to return a (probably invalid) corrected AUC. This is useful especially to avoid introducing a bias against low pAUCs in bootstrap operations.

Details
This function is typically called from roc when auc=TRUE (default). It is also used by ci. When it is called with two vectors (response, predictor) or a formula (response~predictor) arguments, the roc function is called and only the AUC is returned.

By default the total area under the curve is computed, but a partial AUC (pAUC) can be specified with the partial.auc argument. It specifies the bounds of specificity or sensitivity (depending on partial.auc.focus) between which the AUC will be computed. As it specifies specificities or sensitivities, you must adapt it in relation to the 'percent' specification (see details in roc).

partial.auc.focus is ignored if partial.auc=FALSE (default). If a partial AUC is computed, partial.auc.focus specifies if the bounds specified in partial.auc must be interpreted as sensitivity or specificity. Any other value will produce an error. It is recommended to plot the ROC curve with auc.polygon=TRUE in order to make sure the specification is correct.

If a pAUC is defined, it can be standardized (corrected). This correction is controled by the partial.auc.correct argument. If partial.auc.correct=TRUE, the correction by McClish will be applied:

$$1 + \frac{\text{auc-min}}{\text{max-min}}$$

where auc is the uncorrected pAUC computed in the region defined by partial.auc, min is the value of the non-discriminant AUC (with an AUC of 0.5 or 50 in the region and max is the maximum
possible AUC in the region. With this correction, the AUC will be 0.5 if non discriminant and 1.0 if maximal, whatever the region defined. This correction is fully compatible with percent.

Note that this correction is undefined for curves below the diagonal (auc < min). Attempting to correct such an AUC will return NA with a warning.

**Value**

The numeric AUC value, of class c("auc", "numeric") (or c("multiclass.auc", "numeric") or c("mv.multiclass.auc", "numeric") if a “multiclass.roc” was supplied), in fraction of the area or in percent if percent=TRUE, with the following attributes:

- **partial.auc** if the AUC is full (FALSE) or partial (and in this case the bounds), as defined in argument.
- **partial.auc.focus** only for a partial AUC, if the bound specifies the sensitivity or specificity, as defined in argument.
- **partial.auc.correct** only for a partial AUC, was it corrected? As defined in argument.
- **percent** whether the AUC is given in percent or fraction.
- **roc** the original ROC curve, as a “roc”, “smooth.roc” or “multiclass.roc” object.

**Smoothed ROC curves**

There is no difference in the computation of the area under a smoothed ROC curve, except for curves smoothed with method="binomial". In this case and only if a full AUC is requested, the classical binormal AUC formula is applied:

$$\text{auc} = \Phi \frac{a}{\sqrt{1 + b^2}}.$$

If the ROC curve is smoothed with any other method or if a partial AUC is requested, the empirical AUC described in the previous section is applied.

**Multi-class AUCs**

With an object of class “multiclass.roc”, a multi-class AUC is computed as an average AUC as defined by Hand and Till (equation 7).

$$\text{auc} = \frac{2}{c(c-1)} \sum \text{aucs}$$

with auc all the pairwise roc curves.

# Full AUC:
auc(roccobj)
# Partial AUC:
auc(roccobj, partial.auc=c(1, .8), partial.auc.focus="se", partial.auc.correct=TRUE)

# Alternatively, you can get the AUC directly from roc():
roc(aSAH$outcome, aSAH$s100b)$auc
roc(aSAH$outcome, aSAH$s100b,
    partial.auc=c(1, .8), partial.auc.focus="se",
    partial.auc.correct=TRUE)$auc

---

**ci**

*Compute the confidence interval of a ROC curve*

Description

This function computes the confidence interval (CI) of a ROC curve. The `of` argument controls the type of CI that will be computed. By default, the 95% CI are computed with 2000 stratified bootstrap replicates.
Usage

```r
Usage
ci(...)
## S3 method for class 'roc'
ci(roc, of = c("auc", "thresholds", "sp", "se", "coords"), ...)
## S3 method for class 'smooth.roc'
ci(smooth.roc, of = c("auc", "sp", "se", "coords"), ...)
## S3 method for class 'multiclass.roc'
ci(multiclass.roc, of = "auc", ...)
## S3 method for class 'multiclass.auc'
ci(multiclass.auc, of = "auc", ...)
## S3 method for class 'formula'
ci(formula, data, ...)
## Default S3 method:
ci(response, predictor, ...)
```

Arguments

- `roc, smooth.roc`:
  a “roc” object from the `roc` function, or a “smooth.roc” object from the `smooth` function.

- `multiclass.roc, multiclass.auc`:
  not implemented.

- `response, predictor`:
  arguments for the `roc` function.

- `formula, data`:
  a formula (and possibly a data object) of type response~predictor for the `roc` function.

- `of`:
  The type of confidence interval. One of “auc”, “thresholds”, “sp”, “se” or “coords”. Note that confidence interval on “thresholds” are not available for smoothed ROC curves.

- `...`:
  further arguments passed to or from other methods, especially `auc`, `roc`, and the specific `ci` functions `ci.auc, ci.thresholds, ci.sp, ci.se` and `ci.coords`.

Details

`ci.formula` and `ci.default` are convenience methods that build the ROC curve (with the `roc` function) before calling `ci.roc`. You can pass them arguments for both `roc` and `ci.roc`. Simply use `ci` that will dispatch to the correct method.

This function is typically called from `roc` when `ci=TRUE` (not by default). Depending on the of argument, the specific `ci` functions `ci.auc, ci.thresholds, ci.sp, ci.se` or `ci.coords` are called.

When the ROC curve has an `auc` of 1 (or 100%), the confidence interval will always be null (there is no interval). This is true for both “delong” and “bootstrap” methods that can not properly assess the variance in this case. This result is misleading, as the variance is of course not null. A warning will be displayed to inform of this condition, and of the misleading output.

CI of multiclass ROC curves and AUC is not implemented yet. Attempting to call these methods returns an error.
Value

The return value of the specific `ci` functions `ci.auc`, `ci.thresholds`, `ci.sp`, `ci.se` or `ci.coords`, depending on the `of` argument.

ci.auc

Compute the confidence interval of the AUC

Description

This function computes the confidence interval (CI) of an area under the curve (AUC). By default, the 95% CI is computed with 2000 stratified bootstrap replicates.

Usage

# ci.auc(...)
## S3 method for class 'roc'
  ci.auc(roc, conf.level=0.95, method=c("delong", "bootstrap"), boot.n = 2000, boot.stratified = TRUE, reuse.auc=TRUE, progress = getOption("pROCProgress")$name, parallel=FALSE, ...)
## S3 method for class 'smooth.roc'
  ci.auc(smooth.roc, conf.level=0.95, boot.n=2000, boot.stratified=TRUE, reuse.auc=TRUE, progress=getOption("pROCProgress")$name, parallel=FALSE, ...)
## S3 method for class 'auc'
  ci.auc(auc, ...)
## S3 method for class 'multiclass.roc'
  ci.auc(multiclass.roc, ...)
## S3 method for class 'multiclass.auc'
  ci.auc(multiclass.auc, ...)
## S3 method for class 'auc'
  ci.auc(auc, ...)
## S3 method for class 'formula'
  ci.auc(formula, data, ...)
## Default S3 method:
  ci.auc(response, predictor, ...)

Arguments

roc, smooth.roc
  a “roc” object from the roc function, or a “smooth.roc” object from the smooth function.
auc
  an “auc” object from the auc function.
multiclass.roc, multiclass.auc
  not implemented.
response, predictor
  arguments for the roc function.
formula, data
  a formula (and possibly a data object) of type response~predictor for the roc function.
ci.auc

conf.level the width of the confidence interval as [0,1], never in percent. Default: 0.95, resulting in a 95% CI.

method the method to use, either “delong” or “bootstrap”. The first letter is sufficient. If omitted, the appropriate method is selected as explained in details.

boot.n the number of bootstrap replicates. Default: 2000.

boot.stratified should the bootstrap be stratified (default, same number of cases/controls in each replicate than in the original sample) or not.

reuse.auc if TRUE (default) and the “roc” object contains an “auc” field, re-use these specifications for the test. If false, use optional . . . arguments to auc. See details.

progress the name of progress bar to display. Typically “none”, “win”, “tk” or “text” (see the name argument to create_progress_bar for more information), but a list as returned by create_progress_bar is also accepted. See also the “Progress bars” section of this package’s documentation.

parallel if TRUE, the bootstrap is processed in parallel, using parallel backend provided by plyr (foreach).

... further arguments passed to or from other methods, especially arguments for roc and roc.test.roc when calling roc.test.default or roc.test.formula. Arguments for auc and txtProgressBar (only char and style) if applicable.

Details

This function computes the CI of an AUC. Two methods are available: “delong” and “bootstrap” with the parameters defined in “roc$auc” to compute a CI. When it is called with two vectors (response, predictor) or a formula (response~predictor) arguments, the roc function is called to build the ROC curve first.

The default is to use “delong” method except for comparison of partial AUC and smoothed curves, where bootstrap is used. Using “delong” for partial AUC and smoothed ROCs is not supported.

With method="bootstrap", the function calls auc boot.n times. For more details about the bootstrap, see the Bootstrap section in this package’s documentation.

For smoothed ROC curves, smoothing is performed again at each bootstrap replicate with the parameters originally provided. If a density smoothing was performed with user-provided density.cases or density.controls the bootstrap cannot be performed and an error is issued.

With method="delong", the variance of the AUC is computed as defined by DeLong et al. (1988) using the algorithm by Sun and Xu (2014) and the CI is deduced with qnorm.

CI of multiclass ROC curves and AUC is not implemented yet. Attempting to call these methods returns an error.

Value

A numeric vector of length 3 and class “ci.auc”, “ci” and “numeric” (in this order), with the lower bound, the median and the upper bound of the CI, and the following attributes:

conf.level the width of the CI, in fraction.
method
boot.n
boot.stratified
auc

method
the method employed.
boot.n
the number of bootstrap replicates.
boot.stratified
whether or not the bootstrapping was stratified.

The auc item is not included in this list since version 1.2 for consistency reasons.

AUC specification
The comparison of the CI needs a specification of the AUC. This allows to compute the CI for full or partial AUCs. The specification is defined by:

1. the “auc” field in the “roc” object if reuse.auc is set to TRUE (default). It is naturally inherited from any call to roc and fits most cases.
2. passing the specification to auc with ...(arguments partial.auc, partial.auc.correct and partial.auc.focus). In this case, you must ensure either that the roc object do not contain an auc field (if you called roc with auc=FALSE), or set reuse.auc=FALSE.

If reuse.auc=FALSE the auc function will always be called with ... to determine the specification, even if the “roc” object do contain an auc field.
As well if the “roc” object do not contain an auc field, the auc function will always be called with ... to determine the specification.

Warning: if the roc object passed to ci contains an auc field and reuse.auc=TRUE, auc is not called and arguments such as partial.auc are silently ignored.

Warnings
If method="delong" and the AUC specification specifies a partial AUC, the warning “Using DeLong’s test for partial AUC is not supported. Using bootstrap test instead.” is issued. The method argument is ignored and “bootstrap” is used instead.

If boot.stratified=FALSE and the sample has a large imbalance between cases and controls, it could happen that one or more of the replicates contains no case or control observation, or that there are not enough points for smoothing, producing a NA area. The warning “NA value(s) produced during bootstrap were ignored.” will be issued and the observation will be ignored. If you have a large imbalance in your sample, it could be safer to keep boot.stratified=TRUE.

Errors
If density.cases and density.controls were provided for smoothing, the error “Cannot compute the statistic on ROC curves smoothed with density.controls and density.cases.” is issued.

ci.coords

Compute the confidence interval of arbitrary coordinates

Description

This function computes the confidence interval (CI) of the coordinates of a ROC curves with the coords function. By default, the 95% CI are computed with 2000 stratified bootstrap replicates.

Usage

# ci.coords(...) # S3 method for class 'roc'
  ci.coords(roc, x, 
    input=c("threshold", "specificity", "sensitivity"), 
    ret=c("threshold", "specificity", "sensitivity"), 
    best.method=c("youden", "closest.topleft"), best.weights=c(1, 0.5), 
    best.policy = c("stop", "omit", "random"), 
    conf.level=0.95, boot.n=2000, 
    boot.stratified=TRUE, 
    progress=getOption("pROCProgress")$name, ...)

# S3 method for class 'formula'
  ci.coords(formula, data, ...)

# S3 method for class 'smooth.roc'
  ci.coords(smooth.roc, x, 
    input=c("specificity", "sensitivity"), ret=c("specificity", "sensitivity"), 
    best.method=c("youden", "closest.topleft"), best.weights=c(1, 0.5), 
    best.policy = c("stop", "omit", "random"), 
    conf.level=0.95, boot.n=2000, 
    boot.stratified=TRUE, 
    progress=getOption("pROCProgress")$name, ...)

# Default S3 method:
  ci.coords(response, predictor, ...)
Arguments

roc, smooth.roc

- a “roc” object from the roc function, or a “smooth.roc” object from the smooth function.

response, predictor

- arguments for the roc function.

formula, data

- a formula (and possibly a data object) of type response~predictor for the roc function.

x, input, ret, best.method, best.weights

- Arguments passed to coords. See there for more details. The only difference is on the x argument which cannot be “all” or “local maximas”.

best.policy

- The policy follow when multiple “best” thresholds are returned by coords. “stop” will abort the processing with stop (default), “omit” will ignore the sample (as in NA) and “random” will select one of the threshold randomly.

conf.level

- the width of the confidence interval as [0,1], never in percent. Default: 0.95, resulting in a 95% CI.

boot.n

boot.stratified

- should the bootstrap be stratified (default, same number of cases/controls in each replicate than in the original sample) or not.

progress

- the name of progress bar to display. Typically “none”, “win”, “tk” or “text” (see the name argument to create_progress_bar for more information), but a list as returned by create_progress_bar is also accepted. See also the “Progress bars” section of this package’s documentation.

... further arguments passed to or from other methods, especially arguments for roc and ci.coords.roc when calling ci.coords.default or ci.coords.formula. Arguments for txtProgressBar (only char and style) if applicable.

Details

- ci.coords.formula and ci.coords.default are convenience methods that build the ROC curve (with the roc function) before calling ci.coords.roc. You can pass them arguments for both roc and ci.coords.roc. Simply use ci.coords that will dispatch to the correct method.

- This function creates boot.n bootstrap replicate of the ROC curve, and evaluates the coordinates specified by the x, input, ret, best.method and best.weights arguments. Then it computes the confidence interval as the percentiles given by conf.level.

- For more details about the bootstrap, see the Bootstrap section in this package’s documentation.

Value

- A matrix of class “ci.coords”, “ci” and “matrix” (in this order), with the confidence intervals of the CI. The matrix has 3 columns (lower bound, median and upper bound) and as many rows as x * ret were requested. Rows are sorted by x and then by ret and named as “input x: return”.

- Additionally, the list has the following attributes:
ci.coords

conf.level  the width of the CI, in fraction.
boot.n  the number of bootstrap replicates.
boot.stratified  whether or not the bootstrapping was stratified.
roc  the object of class "roc" that was used to compute the CI.

Warnings

If `boot.stratified=FALSE` and the sample has a large imbalance between cases and controls, it could happen that one or more of the replicates contains no case or control observation, producing a `NA` area. The warning “NA value(s) produced during bootstrap were ignored.” will be issued and the observation will be ignored. If you have a large imbalance in your sample, it could be safer to keep `boot.stratified=TRUE`.

This warning will also be displayed if you chose `best.policy = "omit"` and a ROC curve with multiple “best” threshold was generated during at least one of the replicates.

## End(Not run)

---

**ci.se**

Compute the confidence interval of sensitivities at given specificities

---

### Description

This function computes the confidence interval (CI) of the sensitivity at the given specificity points. By default, the 95% CI are computed with 2000 stratified bootstrap replicates.

### Usage

```r
# ci.se(...)  
## S3 method for class 'roc'
.ci.se(roc, specificities = seq(0, 1, .1) * ifelse(roc$percent, 100, 1), conf.level=0.95, boot.n=2000, boot.stratified=TRUE, progress=getOption("pROCProgress")$name, parallel=FALSE, ...)

## S3 method for class 'smooth.roc'
.ci.se(smooth.roc, specificities = seq(0, 1, .1) * ifelse(smooth.roc$percent, 100, 1), conf.level=0.95, boot.n=2000, boot.stratified=TRUE, progress=getOption("pROCProgress")$name, parallel=FALSE, ...)

## S3 method for class 'formula'
.ci.se(formula, data, ...)

## Default S3 method:
.ci.se(response, predictor, ...)
```

### Arguments

- `roc`, `smooth.roc`
  
a “roc” object from the roc function, or a “smooth.roc” object from the smooth function.

- `response`, `predictor`
  
  arguments for the roc function.
formula, data

a formula (and possibly a data object) of type response-predictor for the roc function.

specificities

on which specificities to evaluate the CI.

conf.level

the width of the confidence interval as [0,1], never in percent. Default: 0.95, resulting in a 95% CI.

boot.n

the number of bootstrap replicates. Default: 2000.

boot.stratified

should the bootstrap be stratified (default, same number of cases/controls in each replicate than in the original sample) or not.

progress

the name of progress bar to display. Typically “none”, “win”, “tk” or “text” (see the name argument to create_progress_bar for more information), but a list as returned by create_progress_bar is also accepted. See also the “Progress bars” section of this package’s documentation.

parallel

if TRUE, the bootstrap is processed in parallel, using parallel backend provided by plyr (foreach).

...

further arguments passed to or from other methods, especially arguments for roc and ci.se.roc when calling ci.se.default or ci.se.formula. Arguments for txtProgressBar (only char and style) if applicable.

Details

ci.se.formula and ci.se.default are convenience methods that build the ROC curve (with the roc function) before calling ci.se.roc. You can pass them arguments for both roc and ci.se.roc. Simply use ci.se that will dispatch to the correct method.

The ci.se.roc function creates boot.n bootstrap replicate of the ROC curve, and evaluates the sensitivity at specificities given by the specificities argument. Then it computes the confidence interval as the percentiles given by conf.level.

For more details about the bootstrap, see the Bootstrap section in this package’s documentation.

For smoothed ROC curves, smoothing is performed again at each bootstrap replicate with the parameters originally provided. If a density smoothing was performed with user-provided density.cases or density.controls the bootstrap cannot be performed and an error is issued.

Value

A matrix of class “ci.se”, “ci” and “matrix” (in this order) containing the given sensitivities. Row (names) are the specificities, the first column the lower bound, the 2nd column the median and the 3rd column the upper bound.

Additionally, the list has the following attributes:

conf.level the width of the CI, in fraction.

boot.n the number of bootstrap replicates.

boot.stratified whether or not the bootstrapping was stratified.
specificities

the specificities as given in argument.

roc

the object of class "roc" that was used to compute the CI.

Warnings

If `boot.stratified=FALSE` and the sample has a large imbalance between cases and controls, it could happen that one or more of the replicates contains no case or control observation, or that there are not enough points for smoothing, producing a NA area. The warning “NA value(s) produced during bootstrap were ignored.” will be issued and the observation will be ignored. If you have a large imbalance in your sample, it could be safer to keep `boot.stratified=TRUE`.

Errors

If `density.cases` and `density-controls` were provided for smoothing, the error “Cannot compute the statistic on ROC curves smoothed with density.controls and density.cases.” is issued.

ci.sp

**ci.sp**

*Compute the confidence interval of specificities at given sensitivities*

**Description**

This function computes the confidence interval (CI) of the specificity at the given sensitivity points. By default, the 95% CI are computed with 2000 stratified bootstrap replicates.

**Usage**

# ci.sp(...)
## S3 method for class 'roc'
ci.sp(roc, sensitivities = seq(0, 1, .1) * ifelse(roc$percent,
                                           100, 1), conf.level=0.95, boot.n=2000, boot.stratified=TRUE,
                                           progress=getOption("pROCProgress")$name, parallel=FALSE, ...)
## S3 method for class 'smooth.roc'
 ci.sp(smooth.roc, sensitivities = seq(0, 1, .1) * 
                                     ifelse(smooth.roc$percent, 100, 1), conf.level=0.95, boot.n=2000,
                                     boot.stratified=TRUE, progress=getOption("pROCProgress")$name, parallel=FALSE, ...)
## S3 method for class 'formula'
  ci.sp(formula, data, ...)
## Default S3 method:
  ci.sp(response, predictor, ...)
Arguments

roc, smooth.roc
   a “roc” object from the roc function, or a “smooth.roc” object from the smooth function.
response, predictor
   arguments for the roc function.
formula, data
   a formula (and possibly a data object) of type response~predictor for the roc function.
sensitivities
   on which sensitivities to evaluate the CI.
conf.level
   the width of the confidence interval as [0,1], never in percent. Default: 0.95, resulting in a 95% CI.
boot.n
   the number of bootstrap replicates. Default: 2000.
boot.stratified
   should the bootstrap be stratified (default, same number of cases/controls in each replicate than in the original sample) or not.
progress
   the name of progress bar to display. Typically “none”, “win”, “tk” or “text” (see the name argument to create_progress_bar for more information), but a list as returned by create_progress_bar is also accepted. See also the “Progress bars” section of this package’s documentation.
parallel
   if TRUE, the bootstrap is processed in parallel, using parallel backend provided by plyr (foreach).
...
   further arguments passed to or from other methods, especially arguments for roc and ci.sp.roc when calling ci.sp.default or ci.sp.formula. Arguments for txtProgressBar (only char and style) if applicable.

Details

ci.sp.formula and ci.sp.default are convenience methods that build the ROC curve (with the roc function) before calling ci.sp.roc. You can pass them arguments for both roc and ci.sp.roc. Simply use ci.sp that will dispatch to the correct method.

The ci.sp.roc function creates boot.n bootstrap replicate of the ROC curve, and evaluates the specificity at sensitivities given by the sensitivities argument. Then it computes the confidence interval as the percentiles given by conf.level.

For more details about the bootstrap, see the Bootstrap section in this package’s documentation.

For smoothed ROC curves, smoothing is performed again at each bootstrap replicate with the parameters originally provided. If a density smoothing was performed with user-provided density.cases or density.controls the bootstrap cannot be performed and an error is issued.

Value

A matrix of class “ci.sp”, “ci” and “matrix” (in this order) containing the given specificities. Row (names) are the sensitivities, the first column the lower bound, the 2nd column the median and the 3rd column the upper bound.

Additionally, the list has the following attributes:
conf.level  the width of the CI, in fraction.
boot.n      the number of bootstrap replicates.
boot.stratified whether or not the bootstrapping was stratified.
sensitivities the sensitivities as given in argument.
roc          the object of class “roc” that was used to compute the CI.

Warnings

If boot.stratified=FALSE and the sample has a large imbalance between cases and controls, it could happen that one or more of the replicates contains no case or control observation, or that there are not enough points for smoothing, producing a NA area. The warning “NA value(s) produced during bootstrap were ignored.” will be issued and the observation will be ignored. If you have a large imbalance in your sample, it could be safer to keep boot.stratified=TRUE.

Errors

If density.cases and density.controls were provided for smoothing, the error “Cannot compute the statistic on ROC curves smoothed with density.controls and density.cases.” is issued.

**ci.thresholds**

*Compute the confidence interval of thresholds*

**Description**

This function computes the confidence interval (CI) of the sensitivity and specificity of the thresholds given in argument. By default, the 95% CI are computed with 2000 stratified bootstrap replicates.

**Usage**

```r
# ci.thresholds(...)  
## S3 method for class 'roc'
ci.thresholds(roc, conf.level=0.95, boot.n=2000,  
boot.stratified=TRUE, thresholds = "local maximas",  
progress=getOption("pROCProgress")$name, parallel=FALSE, ...)
```
## S3 method for class 'formula'

```r
ci.thresholds(formula, data, ...)
```

## S3 method for class 'smooth.roc'

```r
ci.thresholds(smooth.roc, ...)
```

## Default S3 method:

```r
ci.thresholds(response, predictor, ...)
```

### Arguments

- **roc**: a “roc” object from the `roc` function.
- **smooth.roc**: not available for smoothed ROC curves, available only to catch the error and provide a clear error message.
- **response, predictor**: arguments for the `roc` function.
- **formula, data**: a formula (and possibly a data object) of type response–predictor for the `roc` function.
- **conf.level**: the width of the confidence interval as [0,1], never in percent. Default: 0.95, resulting in a 95% CI.
- **boot.n**: the number of bootstrap replicates. Default: 2000.
- **boot.stratified**: should the bootstrap be stratified (default, same number of cases/controls in each replicate than in the original sample) or not.
- **thresholds**: on which thresholds to evaluate the CI. Either the numeric values of the thresholds, a logical vector (as index of `roc$thresholds`) or a character “all”, “local maximas” or “best” that will be used to determine the threshold(s) on the supplied curve with `coords` (not on the resampled curves).
- **progress**: the name of progress bar to display. Typically “none”, “win”, “tk” or “text” (see the `name` argument to `create_progress_bar` for more information), but a list as returned by `create_progress_bar` is also accepted. See also the “Progress bars” section of this package’s documentation.
- **parallel**: if TRUE, the bootstrap is processed in parallel, using parallel backend provided by plyr (foreach).
- **...**: further arguments passed to or from other methods, especially arguments for `roc` and `ci.thresholds.roc` when calling `ci.thresholds.default` or `ci.thresholds.formula`. Arguments for `txtProgressBar` (only `char` and `style`) if applicable. Arguments `best.method` and `best.weights` to `coords`.

### Details

`ci.thresholds.formula` and `ci.thresholds.default` are convenience methods that build the ROC curve (with the `roc` function) before calling `ci.thresholds.roc`. You can pass them arguments for both `roc` and `ci.thresholds.roc`. Simply use `ci.thresholds` that will dispatch to the correct method.
**ci.thresholds**

This function creates `boot.n` bootstrap replicate of the ROC curve, and evaluates the sensitivity and specificity at thresholds given by the `thresholds` argument. Then it computes the confidence interval as the percentiles given by `conf.level`.

A threshold given as a logical vector or character is converted to the corresponding numeric vector once using the supplied ROC curve, and not at each bootstrap iteration. See `ci.coords` for the latter behaviour.

For more details about the bootstrap, see the Bootstrap section in this package’s documentation.

**Value**

A list of length 2 and class “ci.thresholds”, “ci” and “list” (in this order), with the confidence intervals of the CI and the following items:

- `specificity` a matrix of CI for the specificity. Row (names) are the thresholds, the first column the lower bound, the 2nd column the median and the 3rd column the upper bound.
- `sensitivity` same than specificity.

Additionally, the list has the following attributes:

- `conf.level` the width of the CI, in fraction.
- `boot.n` the number of bootstrap replicates.
- `boot.stratified` whether or not the bootstrapping was stratified.
- `thresholds` the thresholds, as given in argument.
- `roc` the object of class “roc” that was used to compute the CI.

**Warnings**

If `boot.stratified=FALSE` and the sample has a large imbalance between cases and controls, it could happen that one or more of the replicates contains no case or control observation, producing a NA area. The warning “NA value(s) produced during bootstrap were ignored.” will be issued and the observation will be ignored. If you have a large imbalance in your sample, it could be safer to keep `boot.stratified=TRUE`.

Examples

data(aSAH)

## Not run:
# Syntax (response, predictor):
ci.thresholds(aSAH$outcome, aSAH$s100b)

# With a roc object:
rocobj <- roc(aSAH$outcome, aSAH$s100b)
ci.thresholds(rocobj)

# Customized bootstrap and specific thresholds:
ci.thresholds(aSAH$outcome, aSAH$s100b,
   boot.n=500, conf.level=0.9, stratified=FALSE,
   thresholds=c(0.5, 1, 2))

## End(Not run)

# Alternatively, you can get the CI directly from roc():
rocobj <- roc(aSAH$outcome,
   aSAH$s100b, ci=TRUE, of="thresholds")

rocobj$ci

# Plotting the CI
plot(rocobj)
plot(rocobj$ci)

coords

Coordinates of a ROC curve

Description

This function returns the coordinates of the ROC curve at the specified point.
Usage

cords(...)
## S3 method for class 'roc'
cords(roc, x, input=c("threshold", "specificity", "sensitivity"), ret=c("threshold", "specificity", "sensitivity"), as.list=FALSE, drop=TRUE, best.method=c("youden", "closest.topleft"), best.weights=c(1, 0.5), transpose = TRUE, ...)
## S3 method for class 'smooth.roc'
cords(smooth.roc, x, input=c("specificity", "sensitivity"), ret=c("specificity", "sensitivity"), as.list=FALSE, drop=TRUE, best.method=c("youden", "closest.topleft"), best.weights=c(1, 0.5), transpose = TRUE, ...)

Arguments

roc, smooth.roc
  a “roc” object from the roc function, or a “smooth.roc” object from the smooth function.

x
  the coordinates to look for. Numeric (if so, their meaning is defined by the input argument) or one of “all” (all the points of the ROC curve), “local maximas” (the local maximas of the ROC curve) or “best” (see best.method argument). If missing or NULL, defaults to “all”.

input
  If x is numeric, the kind of input coordinate (x). One of “threshold”, “specificity” or “sensitivity”. Can be shortenend (for example to “thr”, “sens” and “spec”, or even to “t”, “se” and “sp”). Note that “threshold” is not allowed in coords.smooth.roc, and that the argument is ignored when x is a character.

ret
  The coordinates to return. See "Valid ret arguments" section below. Alternatively, the single value “all” can be used to return every coordinate available.

as.list
  DEPRECATED. If the returned object must be a list. Will be removed in a future version.

drop
  If TRUE the result is coerced to the lowest possible dimension, as per Extract. With FALSE if either ret or x is of length 1, the object returned will have the same format than if x was of length > 1.

best.method
  if x=“best”, the method to determine the best threshold. See details in the 'Best thresholds’ section.

best.weights
  if x=“best”, the weights to determine the best threshold. See details in the ‘Best thresholds’ section.

transpose
  when returning a matrix (as.list=FALSE), whether to return of thresholds in columns (TRUE) or rows (FALSE). The current default is TRUE and has been so since the initial version. However an upcoming version will change the default to FALSE, and a warning is printed if the argument is not passed explicitly. See coords_transpose for more details about upcoming changes.

... further arguments passed from other methods. Ignored.
Details

This function takes a “roc” or “smooth.roc” object as first argument, on which the coordinates will be determined. The coordinates are defined by the \( x \) and \( \text{input} \) arguments. “threshold” coordinates cannot be determined in a smoothed ROC.

If \( \text{input} = \text{"threshold"} \), the coordinates for the threshold are reported, even if the exact threshold do not define the ROC curve. The following convenience characters are allowed: “all”, “local maximas” and “best”. They will return all the thresholds, only the thresholds defining local maximas (upper angles of the ROC curve), or only the threshold(s) corresponding to the best sum of sensitivity + specificity respectively. Note that “best” can return more than one threshold. If \( x \) is a character, the coordinates are limited to the thresholds within the partial AUC if it has been defined, and not necessarily to the whole curve.

For \( \text{input} = \text{"specificity"} \) and \( \text{input} = \text{"sensitivity"} \), the function checks if the specificity or sensitivity is one of the points of the ROC curve (in \( \text{roc$sensitivities} \) or \( \text{roc$specificities} \)). More than one point may match (in step curves), then only the upper-left-most point coordinates are returned. Otherwise, the specificity and specificity of the point is interpolated and NA is returned as threshold.

The coords function in this package is a generic, but it might be superseded by functions in other packages such as \texttt{colorspace} or \texttt{spatstat} if they are loaded after \texttt{pROC}. In this case, call the \texttt{coords.roc} or \texttt{coords.smooth.roc} functions directly.

**Best thresholds:** If \( x = \text{"best"} \), the \texttt{best.method} argument controls how the optimal threshold is determined.

- **youden** Youden’s J statistic (Youden, 1950) is employed. The optimal cut-off is the threshold that maximizes the distance to the identity (diagonal) line. Can be shortened to “y”.
  - The optimality criterion is:
    \[
    \max(sensitivities + specificities)
    \]

- **closest.topleft** The optimal threshold is the point closest to the top-left part of the plot with perfect sensitivity or specificity. Can be shortened to “c” or “t”.
  - The optimality criterion is:
    \[
    \min((1 - sensitivities)^2 + (1 - specificities)^2)
    \]

In addition, weights can be supplied if false positive and false negative predictions are not equivalent: a numeric vector of length 2 to the \texttt{best.weights} argument. The elements define

1. the relative cost of of a false negative classification (as compared with a false positive classification)
2. the prevalence, or the proportion of cases in the population (\( \frac{n_{cases}}{n_{controls} + n_{cases}} \)).

The optimality criteria are modified as proposed by Perkins and Schisterman:

- **youden**
  \[
  \max(sensitivities + r \times specificities)
  \]

- **closest.topleft**
  \[
  \min((1 - sensitivities)^2 + r \times (1 - specificities)^2)
  \]
with

\[ r = \frac{1 - \text{prevalence}}{\text{cost} \times \text{prevalence}} \]

By default, prevalence is 0.5 and cost is 1 so that no weight is applied in effect.
Note that several thresholds might be equally optimal.

**Valid `ret` arguments:**
The following table lists valid `ret` arguments.

<table>
<thead>

<td>-</td>
</tr>
</tbody>
</table>

The value “threshold” is not allowed in `coords.smooth.roc`.
Values can be shortened (for example to “thr”, “sens” and “spec”, or even to “se”, “sp” or “1-np”). In addition, some values can be prefixed with 1- to get their complement: 1-specificity, 1-sensitivity, 1-accuracy, 1-npv, 1-ppv (but they cannot be shortened).
The values npv and ppe are automatically replaced with 1-npv and 1-ppv, respectively (and will therefore not appear as is in the output, but as 1-npv and 1-ppv instead). These must be used verbatim in ROC curves with `percent=TRUE` (ie. “100-ppv” is never accepted).
The “youden” and “closest.topleft” are weighted with \( r \), according to the value of the `best.weights` argument. See the “Best thresholds” section above for more details.
The single value “all” can be used to return every coordinate available.

**Value**

Depending on the length of `x` and `as.list` argument.

\[ \text{length}(x) == 1 \text{ or length}(\text{ret}) == 1 \]
as.list=TRUE a list of the length of, in the order of, and named after, ret.
as.list=FALSE a numeric vector of the length of, in the order of, and named after, ret (if length(x) == 1) or a numeric matrix with one row for each ret and one column for each x.

In all cases if input="specificity" or input="sensitivity" and interpolation was required, threshold is returned as NA.

Note that if giving a character as x ("all", "local maxima" or "best"), you cannot predict the dimension of the return value unless drop=FALSE. Even "best" may return more than one value (for example if the ROC curve is below the identity line, both extreme points).

coords may also return NULL when there a partial area is defined but no point of the ROC curve falls within the region.

# (identical curve, only the axis change)
plot(tpr ~ fpr,
    coords(rocobj, "all", ret = c("tpr", "fpr"), transpose = FALSE),
    type="l")

coords_transpose  Transposing the output of coords

Description

This help page describes recent and upcoming changes in the return values of the coords function.

Background information

Since the initial release of pROC, the coords has been returning a matrix with thresholds in columns, and the coordinate variables in rows.

```r
data(aSAH)
rocobj <- roc(aSAH$outcome, aSAH$s100b)
coords(rocobj, c(0.05, 0.2, 0.5))
# 0.05 0.2 0.5
# threshold 0.05000000 0.2000000 0.5000000
# specificity 0.06944444 0.8055556 0.9722222
# sensitivity 0.97560976 0.6341463 0.2926829
```

This format doesn’t conform to the grammar of the tidyverse\(^{37}\) which has become prevalent in modern R language.

In addition, the dropping of dimensions by default makes it difficult to guess what type of data coords is going to return.

```r
coords(rocobj, "best")
# threshold specificity sensitivity
# 0.2050000 0.8055556 0.6341463
# A numeric vector
```

Although it is possible to pass drop = FALSE, the fact that it is not the default makes the behaviour unintuitive.

In an upcoming version of pROC, this will be changed and coords will return a data.frame with the thresholds in rows and measurement in columns by default.

\(^{37}\)https://www.tidyverse.org/
Changes in 1.15

1. Addition of the `transpose` argument.
2. Display a warning if `transpose` is missing. Pass `transpose` explicitly to silence the warning.
3. Deprecation of `as.list`.

With `transpose = FALSE`, the output is a data.frame looking like this:

```r
cords(rocobj, c(0.05, 0.2, 0.5), transpose = FALSE)
#     threshold specificity sensitivity
# 0.05 0.05 0.06944444 0.9756098
# 0.2 0.20 0.80555556 0.6341463
# 0.5 0.50 0.97222222 0.2926829
```

It is recommended that new developments set `transpose = FALSE` explicitly. These changes are neutral to the API and do not affect functionality outside of a warning.

Upcoming backward incompatible changes in future versions

The next version of pROC will change the default `transpose` to FALSE. This is a backward incompatible change that will break any script that did not previously set `transpose` and will initially come with a warning to make debugging easier. The warning will eventually be removed. Scripts that set `transpose` explicitly will be unaffected.

Recommendations

If you are writing a script calling the `coords` function, set `transpose = FALSE` to silence the warning and make sure your script keeps running smoothly once the default `transpose` is changed to `FALSE`.

**cov.roc**

*Covariance of two paired ROC curves*

**Description**

This function computes the covariance between the AUC of two correlated (or paired) ROC curves.

\(^{38}\)https://github.com/xrobin/pROC/issues/54
Usage

cov(...)
## Default S3 method:
cov(...)
## S3 method for class 'auc'
cov(roc1, roc2, ...)
## S3 method for class 'smooth.roc'
cov(roc1, roc2, ...)
## S3 method for class 'roc'
cov(roc1, roc2, method=c("delong", "bootstrap", "obuchowski"),
  reuse.auc=TRUE, boot.n=2000, boot.stratified=TRUE, boot.return=FALSE,
  progress=getOption("pROCProgress")$name, parallel=FALSE, ...)

Arguments

roc1, roc2 the two ROC curves on which to compute the covariance. Either “roc”, “auc” or “smooth.roc” objects (types can be mixed as long as the original ROC curve are paired).

method the method to use, either “delong” or “bootstrap”. The first letter is sufficient. If omitted, the appropriate method is selected as explained in details.

reuse.auc if TRUE (default) and the “roc” objects contain an “auc” field, re-use these specifications for the test. See details.

boot.n for method="bootstrap" only: the number of bootstrap replicates or permutations. Default: 2000.

boot.stratified for method="bootstrap" only: should the bootstrap be stratified (same number of cases/controls in each replicate than in the original sample) or not. Default: TRUE.

boot.return if TRUE and method="bootstrap", also return the bootstrapped values. See the “Value” section for more details.

progress the name of progress bar to display. Typically “none”, “win”, “tk” or “text” (see the name argument to create_progress_bar for more information), but a list as returned by create_progress_bar is also accepted. See also the “Progress bars” section of this package’s documentation.

parallel if TRUE, the bootstrap is processed in parallel, using parallel backend provided by plyr (foreach).

... further arguments passed to or from other methods, especially arguments for cov.roc when calling cov, cov.auc or cov.smooth.roc. Arguments for auc (if reuse.auc=FALSE) and txtProgressBar (only char and style) if applicable.

Details

This function computes the covariance between the AUC of two correlated (or paired, according to the detection of are.paired) ROC curves. It is typically called with the two roc objects of interest. Two methods are available: “delong” and “bootstrap” (see “Computational details” section below).
The default is to use "delong" method except with partial AUC and smoothed curves where "bootstrap" is employed. Using "delong" for partial AUC and smoothed ROCs is not supported.

For smoothed ROC curves, smoothing is performed again at each bootstrap replicate with the parameters originally provided. If a density smoothing was performed with user-provided `density.cases` or `density.controls` the bootstrap cannot be performed and an error is issued.

cov.default forces the usage of the `cov` function in the `stats` package, so that other code relying on `cov` should continue to function normally.

### Value

The numeric value of the covariance.

If `boot.return=TRUE` and `method="bootstrap"`, an attribute `resampled.values` is set with the resampled (bootstrapped) values. It contains a matrix with the columns representing the two ROC curves, and the rows the `boot.n` bootstrap replicates.

### AUC specification

To compute the covariance of the AUC of the ROC curves, `cov` needs a specification of the AUC. The specification is defined by:

1. the "auc" field in the "roc" objects if `reuse.auc` is set to `TRUE` (default)
2. passing the specification to `auc` with ...(arguments `partial.auc`, `partial.auc.correct` and `partial.auc.focus`). In this case, you must ensure either that the `roc` object do not contain an `auc` field (if you called `roc` with `auc=FALSE`), or set `reuse.auc=FALSE`.

If `reuse.auc=FALSE` the `auc` function will always be called with ... to determine the specification, even if the "roc" objects do contain an `auc` field.

As well if the "roc" objects do not contain an `auc` field, the `auc` function will always be called with ... to determine the specification.

Warning: if the `roc` object passed to `roc.test` contains an `auc` field and `reuse.auc=TRUE`, `auc` is not called and arguments such as `partial.auc` are silently ignored.

### Computation details

With `method="bootstrap"`, the processing is done as follow:

1. `boot.n` bootstrap replicates are drawn from the data. If `boot.stratified` is `TRUE`, each replicate contains exactly the same number of controls and cases than the original sample, otherwise if `FALSE` the numbers can vary.
2. for each bootstrap replicate, the AUC of the two ROC curves are computed and stored.
3. the variance (as per `var.roc`) of the resampled AUCs and their covariance are assessed in a single bootstrap pass.
4. The following formula is used to compute the final covariance: \[ \text{Var}[AUC_1] + \text{Var}[AUC_2] - 2\text{cov}[AUC_1, AUC_2] \]

With `method="delong"`, the processing is done as described in Hanley and Hajian-Tilaki (1997) using the algorithm by Sun and Xu (2014).
With `method="obuchowski"`, the processing is done as described in Obuchowski and McClish (1997), Table 1 and Equation 5, p. 1531. The computation of \( g \) for partial area under the ROC curve is modified as:

\[
expr1 \times (2 \times \pi \times expr2)^{(-1)} \times (-expr4) - A \times B \times expr1 \times (2 \times \pi \times expr2^3)^{(-1/2)} \times expr3
\]

**Binormality assumption**

The “obuchowski” method makes the assumption that the data is binormal. If the data shows a deviation from this assumption, it might help to normalize the data first (that is, before calling `roc`), for example with quantile normalization:

```r
cov <- cov(roc(response, rank(x)/(length(x)+1), ...
```

“delong” and “bootstrap” methods make no such assumption.

**Errors**

If `density.cases` and `density.controls` were provided for smoothing, the error “Cannot compute the covariance on ROC curves smoothed with density.controls and density.cases.” is issued.

**Warnings**

If “auc” specifications are different in both roc objects, the warning “Different AUC specifications in the ROC curves. Enforcing the inconsistency, but unexpected results may be produced.” is issued. Unexpected results may be produced.

If one or both ROC curves are “smooth.roc” objects with different smoothing specifications, the warning “Different smoothing parameters in the ROC curves. Enforcing the inconsistency, but unexpected results may be produced.” is issued. This warning can be benign, especially if ROC curves were generated with `roc (... , smooth=TRUE)` with different arguments to other functions (such as plot), or if you really want to compare two ROC curves smoothed differently.

If `method="delong"` and the AUC specification specifies a partial AUC, the warning “Using DeLong for partial AUC is not supported. Using bootstrap test instead.” is issued. The `method` argument is ignored and “bootstrap” is used instead.

If `method="delong"` and the ROC curve is smoothed, the warning “Using DeLong for smoothed ROCs is not supported. Using bootstrap instead.” is issued. The `method` argument is ignored and “bootstrap” is used instead.

DeLong ignores the direction of the ROC curve so that if two ROC curves have a different direction, the warning “DeLong should not be applied to ROC curves with a different direction.” is printed. However, the spurious computation is enforced.

If `boot.stratified=FALSE` and the sample has a large imbalance between cases and controls, it could happen that one or more of the replicates contains no case or control observation, or that
there are not enough points for smoothing, producing a NA area. The warning “NA value(s) produced during bootstrap were ignored.” will be issued and the observation will be ignored. If you have a large imbalance in your sample, it could be safer to keep boot.stratified=TRUE. When both ROC curves have an auc of 1 (or 100%), their covariance will always be null. This is true for both “delong” and “bootstrap” and methods. This result is misleading, as the covariance is of course not null. A warning will be displayed to inform of this condition, and of the misleading output.

Messages

The covariance can only be computed on paired data. This assumption is enforced by are.paired. If the ROC curves are not paired, the covariance is 0 and the message “ROC curves are unpaired.” is printed. If your ROC curves are paired, make sure they fit are.paired criteria.

**ggroc.roc**

*Plot a ROC curve with ggplot2*

**Description**

This function plots a ROC curve with ggplot2.

**Usage**

```r
## S3 method for class 'roc'
ggroc(data, legacy.axes = FALSE, ...)
## S3 method for class 'list'
ggroc(data, aes = c("colour", "alpha", "linetype", "size", "group"),
     legacy.axes = FALSE, ...)
```

**Arguments**

- `data`: a roc object from the roc function, or a list of roc objects.
- `aes`: the name(s) of the aesthetics for `geom_line` to map to the different ROC curves supplied. Use “group” if you want the curves to appear with the same aesthetic, for instance if you are faceting instead.
- `legacy.axes`: a logical indicating if the specificity axis (x axis) must be plotted as as decreasing “specificity” (FALSE, the default) or increasing “1 - specificity” (TRUE) as in most legacy software.
- `...`: additional aesthetics for `geom_line` to set: alpha, colour, linetype and size.

**Details**

This function initializes a ggplot object from a ROC curve (or multiple if a list is passed). It returns the ggplot with a line layer on it. You can print it directly or add your own layers and theme elements.
See Also

roc.plot, roc, ggplot2

Examples

# Create a basic roc object
data(aSAH)
rocobj <- roc(aSAH$outcome, aSAH$s100b)
rocobj2 <- roc(aSAH$outcome, aSAH$wfns)

library(ggplot2)
g <- ggroc(rocobj)
g
# with additional aesthetics:
ggroc(rocobj, alpha = 0.5, colour = "red", linetype = 2, size = 2)

# You can then your own theme, etc.
g + theme_minimal() + ggtitle("My ROC curve") +
   geom_segment(aes(x = 1, xend = 0, y = 0, yend = 1), color="grey", linetype="dashed")

# And change axis labels to FPR/FPR
g1 <- ggroc(rocobj, legacy.axes = TRUE)
g1
g1 + xlab("FPR") + ylab("TPR") +
   geom_segment(aes(x = 0, xend = 1, y = 0, yend = 1), color="darkgrey", linetype="dashed")

# Multiple curves:
g2 <- ggroc(list(s100b=rocobj, wfns=rocobj2, ndka=roc(aSAH$outcome, aSAH$ndka)))
g2

# This is equivalent to using roc.formula:
roc.list <- roc(outcome ~ s100b + ndka + wfns, data = aSAH)
g.list <- ggroc(roc.list)
g.list

# with additional aesthetics:
g3 <- ggroc(roc.list, linetype=2)
g3
g4 <- ggroc(roc.list, aes="linetype", color="red")
g4

# changing multiple aesthetics:
g5 <- ggroc(roc.list, aes="(linetype", "color")
g5

# OR faceting
g.list + facet_grid(.~name) + theme(legend.position="none")

# To have all the curves of the same color, use aes="group":
g.group <- ggroc(roc.list, aes="group")
g.group
g.group + facet_grid(.~name)
groupGeneric

pROC Group Generic Functions

Description

Redefine base groupGeneric functions to handle auc and ci objects properly on operations and mathematical operations. Attributes are dropped so that the AUC/CI behaves as a numeric value/matrix, respectively. In the case of AUC, all attributes are dropped, while in CI only the CI-specific attributes are, keeping those necessary for the matrices.

Usage

Math(x, 
Ops(e1, e2)

Arguments

x, e1, e2 auc objects, or mixed numerics and auc objects.

... further arguments passed to other Math methods.

See Also

groupGeneric, auc

Examples

data(aSAH)

# Create a roc object:
aucobj1 <- auc(roc(aSAH$outcome, aSAH$s100b))
aucobj2 <- auc(roc(aSAH$outcome, aSAH$wfns))

# Math
sqrt(aucobj1)
round(aucobj2, digits=1)

# Ops
aucobj1 * 2
2 * aucobj2
aucobj1 + aucobj2

# With CI
ciaucobj <- ci(aucobj1)
ciaucobj * 2
sqrt(ciaucobj)
has.partial.auc  

*Does the ROC curve have a partial AUC?*

**Description**

This function determines if the ROC curve has a partial AUC.

**Usage**

```r
has.partial.auc(roc)
```

## S3 method for class 'auc'
has.partial.auc(roc)

## S3 method for class 'smooth.roc'
has.partial.auc(roc)

## S3 method for class 'roc'
has.partial.auc(roc)

**Arguments**

- `roc`  
  the ROC curve to check.

**Value**

`TRUE` if the AUC is a partial AUC, `FALSE` otherwise.

If the AUC is not defined (i.e. if `roc` was called with `AUC=FALSE`), returns `NULL`.

**See Also**

- `auc`

**Examples**

```r
data(aSAH)

# Full AUC
roc1 <- roc(aSAH$outcome, aSAH$s100b)
has.partial.auc(roc1)
has.partial.auc(auc(roc1))
has.partial.auc(smooth(roc1))

# Partial AUC
roc2 <- roc(aSAH$outcome, aSAH$s100b, partial.auc = c(1, 0.9))
has.partial.auc(roc2)
has.partial.auc(smooth(roc2))

# No AUC
roc3 <- roc(aSAH$outcome, aSAH$s100b, auc = FALSE)
has.partial.auc(roc3)
```
Add a ROC line to a ROC plot

Description

This convenience function adds a ROC line to a ROC curve.

Usage

```r
## S3 method for class 'roc'
lines(x, ...)
## S3 method for class 'smooth.roc'
lines(x, ...)
## S3 method for class 'roc'
lines.roc(x, lwd=2, ...)
## S3 method for class 'formula'
lines.roc(x, data, subset, na.action, ...)
## Default S3 method:
lines.roc(x, predictor, ...)
## S3 method for class 'smooth.roc'
lines.roc(x, ...)
```

Arguments

- `x` a roc object from the roc function (for plot.roc), a formula (for plot.roc.formula) or a response vector (for plot.roc.default).
- `predictor`, `data` arguments for the roc function.
- `subset`, `na.action` arguments for model.frame
- `lwd` line width (see par).
- `...` graphical parameters for lines, and especially `type` (see `plot.default`) and arguments for `par` such as `col` (color), `lty` (line type) or line characteristics `lend`, `ljoin` and `lmitre`.

Value

This function returns a list of class “roc” invisibly. See roc for more details.

See Also

roc, plot.roc
Examples

```r
data(aSAH)

rocobj <- plot.roc(aSAH$outcome, aSAH$s100b, type="n")
lines(rocobj, type="b", pch=21, col="blue", bg="grey")

# Without using 'lines':
rocobj <- plot.roc(aSAH$outcome, aSAH$s100b, type="b", pch=21, col="blue", bg="grey")
```

multiclass.roc

### Multi-class AUC

Description

This function builds multiple ROC curve to compute the multi-class AUC as defined by Hand and Till.

Usage

```r
multiclass.roc(...)
## S3 method for class 'formula'
multiclass.roc(formula, data, ...)
## Default S3 method:
multiclass.roc(response, predictor,
levels=base::levels(as.factor(response)),
percent=FALSE, direction = c("auto", "<", ">"), ...)
```

Arguments

- **response**: a factor, numeric or character vector of responses, typically encoded with 0 (controls) and 1 (cases), as in `roc`.
- **predictor**: either a numeric vector, containing the value of each observation, as in `roc`, or, a matrix giving the decision value (e.g. probability) for each class.
- **formula**: a formula of the type `response~predictor`.
- **data**: a matrix or `data.frame` containing the variables in the formula. See `model.frame` for more details.
- **levels**: the value of the response for controls and cases respectively. In contrast with `levels` argument to `roc`, all the levels are used and combined to compute the multiclass AUC.
- **percent**: if the sensitivities, specificities and AUC must be given in percent (TRUE) or in fraction (FALSE, default).
direction

in which direction to make the comparison? “auto” (default for univariate curves): automatically define in which group the median is higher and take the direction accordingly. Not available for multivariate curves. “>” (default for multivariate curves): if the predictor values for the control group are higher than the values of the case group (controls > t >= cases). “<”: if the predictor values for the control group are lower or equal than the values of the case group (controls < t <= cases).

... further arguments passed to roc.

Details

This function performs multiclass AUC as defined by Hand and Till (2001). A multiclass AUC is a mean of several auc and cannot be plotted. Only AUCs can be computed for such curves. Confidence intervals, standard deviation, smoothing and comparison tests are not implemented.

The multiclass.roc function can handle two types of datasets: uni- and multi-variate. In the univariate case, a single predictor vector is passed and all the combinations of responses are assessed. In the multivariate case, a matrix or data.frame is passed as predictor. The columns must be named according to the levels of the response.

This function has been much less tested than the rest of the package and is more subject to bugs. Please report them if you find one.

Value

If predictor is a vector, a list of class “multiclass.roc” (univariate) or “mv.multiclass.roc” (multivariate), with the following fields:

- auc if called with auc=TRUE, a numeric of class “auc” as defined in auc. Note that this is not the standard AUC but the multi-class AUC as defined by Hand and Till.
- ci if called with ci=TRUE, a numeric of class “ci” as defined in ci.
- response the response vector as passed in argument. If NA values were removed, a na.action attribute similar to na.omit stores the row numbers.
- predictor the predictor vector as passed in argument. If NA values were removed, a na.action attribute similar to na.omit stores the row numbers.
- levels the levels of the response as defined in argument.
- percent if the sensitivities, specificities and AUC are reported in percent, as defined in argument.
- call how the function was called. See match.call for more details.

Warnings

If response is an ordered factor and one of the levels specified in levels is missing, a warning is issued and the level is ignored.

# Limit set of levels
multiclass.roc(responses, predictor, levels = c("X1", "X2"))
# Use with formula. Here we need a data.frame to store the responses as characters
data <- cbind(as.data.frame(predictor), "response" = responses)
multiclass.roc(response ~ X1+X3, data)

---

**plot.ci**

Plot confidence intervals

**Description**

This function adds confidence intervals to a ROC curve plot, either as bars or as a confidence shape.

**Usage**

```r
## S3 method for class 'ci.thresholds'
plot(x, length=.01*ifelse(attr(x, "roc")$percent, 100, 1), col=par("fg"), ...)
## S3 method for class 'ci.sp'
plot(x, type=c("bars", "shape"), length=.01*ifelse(attr(x, "roc")$percent, 100, 1), col=ifelse(type="bars", par("fg"), "gainsboro"), no.roc=FALSE, ...)
## S3 method for class 'ci.se'
plot(x, type=c("bars", "shape"), length=.01*ifelse(attr(x, "roc")$percent, 100, 1), col=ifelse(type="bars", par("fg"), "gainsboro"), no.roc=FALSE, ...)
```
Arguments

- **x**: a confidence interval object from the functions `ci.thresholds`, `ci.se` or `ci.sp`.
- **type**: type of plot, “bars” or “shape”. Can be shortened to “b” or “s”. “shape” is only available for `ci.se` and `ci.sp`, not for `ci.thresholds`.
- **length**: the length (as plot coordinates) of the bar ticks. Only if `type="bars"`.
- **no.roc**: if `FALSE`, the ROC line is re-added over the shape. Otherwise if `TRUE`, only the shape is plotted. Ignored if `type="bars"`.
- **col**: color of the bars or shape.
- **...**: further arguments for `segments` (if `type="bars"`) or `polygon` (if `type="shape"`).

Details

This function adds confidence intervals to a ROC curve plot, either as bars or as a confidence shape, depending on the state of the `type` argument. The shape is plotted over the ROC curve, so that the curve is re-plotted unless `no.roc=TRUE`.

Graphical functions are called with suppressWarnings.

Value

This function returns the confidence interval object invisibly.

Warnings

With `type="shape"`, the warning “Low definition shape” is issued when the shape is defined by less than 15 confidence intervals. In such a case, the shape is not well defined and the ROC curve could pass outside the shape. To get a better shape, increase the number of intervals, for example with:

```
plot(ci.sp(rocobj, sensitivities=seq(0, 1, .01)), type="shape")
```

References

See Also

`plot.roc`, `ci.thresholds`, `ci.sp`, `ci.se`

⁴⁴http://dx.doi.org/10.1186/1471-2105-12-77
Examples

```r
data(aSAH)
## Not run:
# Start a ROC plot
rocobj <- plot.roc(aSAH$outcome, aSAH$s100b)
plot(rocobj)
# Thresholds
ci.thresolds.obj <- ci.thresholds(rocobj)
plot(ci.thresolds.obj)
# Specificities
plot(rocobj) # restart a new plot
ci.sp.obj <- ci.sp(rocobj, boot.n=500)

plot(ci.se.obj)

# Plotting a shape. We need more
ci.sp.obj <- ci.sp(rocobj, sensitivities=seq(0, 1, .01), boot.n=100)
plot(rocobj) # restart a new plot
plot(ci.sp.obj, type="shape", col="blue")

# Direct syntax (response, predictor):
plot.roc(aSAH$outcome, aSAH$s100b,
        ci=TRUE, of="thresholds")
## End(Not run)
```

Description

This function plots a ROC curve. It can accept many arguments to tweak the appearance of the plot. Two syntaxes are possible: one object of class “roc”, or either two vectors (response, predictor) or a formula (response~predictor) as in the `roc` function.

Usage

```r
## S3 method for class 'roc'
plot(x, ...)
## S3 method for class 'smooth.roc'
plot(x, ...)
## S3 method for class 'roc'
plot.roc(x, add=FALSE, reuse.auc=TRUE,

)
## S3 method for class 'formula'
plot.roc(x, data, subset, na.action, ...)
## Default S3 method:
plot.roc(x, predictor, ...)
## S3 method for class 'smooth.roc'
plot.roc(x, ...)

Arguments

x
    a roc object from the roc function (for plot.roc.roc), a formula (for plot.roc.formula)
    or a response vector (for plot.roc.default).
predictor, data
    arguments for the roc function.
subset, na.action
    arguments for model.frame
add
    if TRUE, the ROC curve will be added to an existing plot. If FALSE (default),
    a new plot will be created.
reuse.auc
    if TRUE (default) and the “roc” object contains an “auc” field, re-use these specifi-
    cations for the plot (specifically print.auc, auc.polygon and max.auc.polygon
    arguments). See details.
axes
    a logical indicating if the plot axes must be drawn.
legacy.axes
    a logical indicating if the specificity axis (x axis) must be plotted as decreasing
    “specificity” (FALSE, the default) or increasing “1 - specificity” (TRUE) as in
    most legacy software. This affects only the axis, not the plot coordinates.
xlim, ylim, xlab, ylab, asp, mar, mgp
    Generic arguments for the plot. See plot and plot.window for more details. Only
    used if add=FALSE.
col, lty, lwd  color, line type and line width for the ROC curve. See par for more details.

type  type of plotting as in plot.

identity  logical: whether or not the identity line (no discrimination line) must be displayed. Default: only on new plots.

identity.col, identity.lty, identity.lwd  color, line type and line width for the identity line. Used only if identity=TRUE. See par for more details.

print.thres  Should a selected set of thresholds be displayed on the ROC curve? FALSE, NULL or “no”: no threshold is displayed. TRUE or “best”: the threshold with the highest sum sensitivity + specificity is plotted (this might be more than one threshold), “all”: all the points of the ROC curve. “local maximas”: all the local maximas. Numeric vector: direct definition of the thresholds to display. Note that on a smoothed ROC curve, only “best” is supported.

print.thres.pch, print.thres.adj, print.thres.col, print.thres.cex  the plotting character (pch), text string adjustment (adj), color (col) and character expansion factor (cex) parameters for the printing of the thresholds. See points and par for more details.

print.thres.pattern  the text pattern for the thresholds, as a sprintf format. Three numerics are passed to sprintf: threshold, specificity, sensitivity.

print.thres.pattern.cex  the character expansion factor (cex) for the threshold text pattern. See par for more details.

print.thres.best.method, print.thres.best.weights  if print.thres=”best” or print.thres=TRUE, what method must be used to determine which threshold is the best. See argument best.method and best.weights to coords for more details.

print.auc  boolean. Should the numeric value of AUC be printed on the plot?

print.auc.pattern  the text pattern for the AUC, as a sprintf format. If NULL, a reasonable value is computed that takes partial AUC, CI and percent into account. If the CI of the AUC was computed, three numerics are passed to sprintf: AUC, lower CI bound, higher CI bound. Otherwise, only AUC is passed.

print.auc.x, print.auc.y  x and y position for the printing of the AUC.

print.auc.adj, print.auc.cex, print.auc.col  the text adjustment, character expansion factor and color for the printing of the AUC. See par for more details.

grid  boolean or numeric vector of length 1 or 2. Should a background grid be added to the plot? Numeric: show a grid with the specified interval between each line; Logical: show the grid or not. Length 1: same values are taken for horizontal and vertical lines. Length 2: grid value for vertical (grid[1]) and horizontal (grid[2]). Note that these values are used to compute grid.v and grid.h. Therefore if you specify a grid.h and grid.v, it will be ignored.

grid.v, grid.h  numeric. The x and y values at which a vertical or horizontal line (respectively) must be drawn. NULL if no line must be added.
grid.lty, grid.lwd, grid.col
the line type (lty), line width (lwd) and color (col) of the lines of the grid. See par for more details. Note that you can pass vectors of length 2, in which case it specifies the vertical (1) and horizontal (2) lines.

auc.polygon boolean. Whether or not to display the area as a polygon.

auc.polygon.col, auc.polygon.lty, auc.polygon.density, auc.polygon.angle, auc.polygon.border
color (col), line type (lty), density, angle and border for the AUC polygon. See polygon and par for more details.

max.auc.polygon
boolean. Whether or not to display the maximal possible area as a polygon.

max.auc.polygon.col, max.auc.polygon.lty, max.auc.polygon.density, max.auc.polygon.angle, max.auc.polygon.border
color (col), line type (lty), density, angle and border for the maximum AUC polygon. See polygon and par for more details.

ci boolean. Should we plot the confidence intervals?
ci.type, ci.col
type and col arguments for plot.ci. The special value “no” disables the plotting of confidence intervals.

... further arguments passed to or from other methods, especially arguments for roc and plot.roc when calling plot.roc.default or plot.roc.formula. Note that the plot argument for roc is not allowed. Arguments for auc and graphical functions plot, abline, polygon, points, text and plot.ci if applicable.

Details
This function is typically called from roc when plot=TRUE (not by default). plot.roc.formula and plot.roc.default are convenience methods that build the ROC curve (with the roc function) before calling plot.roc roc. You can pass them arguments for both roc and plot.roc roc. Simply use plot.roc that will dispatch to the correct method.

The plotting is done in the following order:
1. A new plot is created if add=FALSE.
2. The grid is added if grid.v and grid.h are not NULL.
3. The maximal AUC polygon is added if max.auc.polygon=TRUE.
4. The CI shape is added if ci=TRUE, ci.type=“shape” and x$ci isn’t a “ci.auc”.
5. The AUC polygon is added if auc.polygon=TRUE.
6. The identity line if identity=TRUE.
7. The actual ROC line is added.
8. The CI bars are added if ci=TRUE, ci.type=“bars” and x$ci isn’t a “ci.auc”.
9. The selected thresholds are printed if print.thres is TRUE or numeric.
10. The AUC is printed if print.auc=TRUE.

Graphical functions are called with suppressWarnings.
plot.roc

Value

This function returns a list of class “roc” invisibly. See roc for more details.

AUC specification

For print.auc, auc.polygon and max.auc.polygon arguments, an AUC specification is required. By default, the total AUC is plotted, but you may want a partial AUCs. The specification is defined by:

1. the “auc” field in the “roc” object if reuse.auc is set to TRUE (default). It is naturally inherited from any call to roc and fits most cases.
2. passing the specification to auc with ...(arguments partial.auc, partial.auc.correct and partial.auc.focus). In this case, you must ensure either that the roc object do not contain an auc field (if you called roc with auc=FALSE), or set reuse.auc=FALSE.

If reuse.auc=FALSE the auc function will always be called with ... to determine the specification, even if the “roc” object do contain an auc field.

As well if the “roc” object do not contain an auc field, the auc function will always be called with ... to determine the specification.

Warning: if the roc object passed to plot.roc contains an auc field and reuse.auc=TRUE, auc is not called and arguments such as partial.auc are silently ignored.

45http://dx.doi.org/10.1186/1471-2105-12-77
Sample size and power computation for ROC curves

Description
Computes sample size, power, significance level or minimum AUC for ROC curves.

Usage

col=c(par("fg"), "blue"), lwd=2)

# With more options:
plot(rocobj, print.auc=TRUE, auc.polygon=TRUE, grid=c(0.1, 0.2),
     grid.col=c("green", "red"), max.auc.polygon=TRUE,
     auc.polygon.col="blue", print.thres=TRUE)

# To plot a different partial AUC, we need to ignore the existing value
# with reuse.auc=FALSE:
plot(rocobj, print.auc=TRUE, auc.polygon=TRUE, partial.auc=c(1, 0.8),
     partial.auc.focus="se", grid=c(0.1, 0.2), grid.col=c("green", "red"),
     max.auc.polygon=TRUE, auc.polygon.col="blue", print.thres=TRUE,
     reuse.auc=FALSE)

# Add a line to the previous plot:
plot(aSAH$outcome, aSAH$wfns, add=TRUE)

# Alternatively, you can get the plot directly from roc():
roc(aSAH$outcome, aSAH$s100b, plot=TRUE)

power.roc.test

# One or Two ROC curves test with roc objects:
## S3 method for class 'roc'
power.roc.test(roc1, roc2, sig.level = 0.05,
    power = NULL, alternative = c("two.sided", "one.sided"),
    reuse.auc=TRUE, method = c("delong", "bootstrap", "obuchowski"), ...)

# One ROC curve with a given AUC:
## S3 method for class 'numeric'
power.roc.test(auc = NULL, ncontrols = NULL,
    ncases = NULL, sig.level = 0.05, power = NULL, kappa = 1,
    alternative = c("two.sided", "one.sided"), ...)

# Two ROC curves with the given parameters:
## S3 method for class 'list'
power.roc.test(parslist, ncontrols = NULL,
    ncases = NULL, sig.level = 0.05, power = NULL, kappa = 1,
    alternative = c("two.sided", "one.sided"), ...)
### Arguments

- **roc1, roc2**: one or two “roc” object from the `roc` function.
- **auc**: expected AUC.
- **parslist**: a list of parameters for the two ROC curves test with Obuchowski variance when no empirical ROC curve is known:
  - **A1**: binormal A parameter for ROC curve 1
  - **B1**: binormal B parameter for ROC curve 1
  - **A2**: binormal A parameter for ROC curve 2
  - **B2**: binormal B parameter for ROC curve 2
  - **rn**: correlation between the variables in control patients
  - **ra**: correlation between the variables in case patients
  - **delta**: the difference between AUC between the two ROC curves

For a partial AUC, the following additional parameters must be set:

- **FPR11**: upper bound of FPR (1 - specificity) of ROC curve 1
- **FPR12**: lower bound of FPR (1 - specificity) of ROC curve 1
- **FPR21**: upper bound of FPR (1 - specificity) of ROC curve 2
- **FPR22**: lower bound of FPR (1 - specificity) of ROC curve 2
- **ncontrols, ncases**: number of controls and case observations available.
- **sig.level**: expected significance level (probability of type I error).
- **power**: expected power of the test (1 - probability of type II error).
- **kappa**: expected balance between control and case observations. Must be positive. Only for sample size determination, that is to determine `ncontrols` and `ncases`.
- **alternative**: whether a one or two-sided test is performed.
- **reuse.auc**: if TRUE (default) and the “roc” objects contain an “auc” field, re-use these specifications for the test. See the `AUC specification` section for more details.
- **method**: the method to compute variance and covariance, either “delong”, “bootstrap” or “obuchowski”. The first letter is sufficient. Only for Two ROC curves power calculation. See `var` and `cov` documentations for more details.
- **...**: further arguments passed to or from other methods, especially auc (with reuse.auc=FALSE or no AUC in the ROC curve), cov and var (especially arguments method, boot.n and boot.stratified). Ignored (with a warning) with a `parslist`.

### Value

An object of class `power.htest` (such as that given by `power.t.test`) with the supplied and computed values.

### One ROC curve power calculation

If one or no ROC curves are passed to `power.roc.test`, a one ROC curve power calculation is performed. The function expects either `power`, `sig.level` or `auc`, or both `ncontrols` and
ncases to be missing, so that the parameter is determined from the others with the formula by Obuchowski et al., 2004 (formulas 2 and 3, p. 1123).

For the sample size, ncases is computed directly from formulas 2 and 3 and ncontrols is deduced with kappa. AUC is optimized by uniroot while sig.level and power are solved as quadratic equations.

power.roc.test can also be passed a roc object from the roc function, but the empirical ROC will not be used, only the number of patients and the AUC.

Two paired ROC curves power calculation

If two ROC curves are passed to power.roc.test, the function will compute either the required sample size (if power is supplied), the significance level (if sig.level=NULL and power is supplied) or the power of a test of a difference between to AUCs according to the formula by Obuchowski and McClish, 1997 et al. (formulas 2 and 3, p. 1530–1531). The null hypothesis is that the AUC of roc1 is the same than the AUC of roc2, with roc1 taken as the reference ROC curve.

For the sample size, ncases is computed directly from formula 2 and ncontrols is deduced from the ratio observed in roc1 and roc2. sig.level and power are solved as quadratic equations.

The variance and covariance of the ROC curve are computed with the var and cov functions. By default, DeLong method using the algorithm by Sun and Xu (2014) is used for full AUCs and the bootstrap for partial AUCs. It is possible to force the use of Obuchowski’s variance by specifying method="obuchowski".

Alternatively when no empirical ROC curve is known, or if only one is available, a list can be passed to power.roc.test, with the contents defined in the “Arguments” section. The variance and covariance are computed from Table 1 and Equation 4 and 5 of Obuchowski and McClish (1997), p. 1530–1531.

Power calculation for unpaired ROC curves is not implemented.

AUC specification

The comparison of the AUC of the ROC curves needs a specification of the AUC. The specification is defined by:

1. the “auc” field in the “roc” objects if reuse.auc is set to TRUE (default)
2. passing the specification to auc with ...(arguments partial.auc, partial.auc.correct and partial.auc.focus). In this case, you must ensure either that the roc object do not contain an auc field (if you called roc with auc=FALSE), or set reuse.auc=FALSE.

If reuse.auc=FALSE the auc function will always be called with ... to determine the specification, even if the “roc” objects do contain an auc field.

As well if the “roc” objects do not contain an auc field, the auc function will always be called with ... to determine the specification.

Warning: if the roc object passed to roc.test contains an auc field and reuse.auc=TRUE, auc is not called and arguments such as partial.auc are silently ignored.
Acknowledgements

The authors would like to thank Christophe Combescure and Anne-Sophie Jannot for their help with the implementation of this section of the package.

**print**

Print a ROC curve object

### Description

This function prints a ROC curve, AUC or CI object and return it invisibly.

### Usage

```r
print(x, digits=max(3, getOption("digits") - 3), call=TRUE, ...)
```
print(x, digits=max(3, getOption("digits") - 3), ...) 
## S3 method for class 'ci.sp'
print(x, digits=max(3, getOption("digits") - 3), ...) 
## S3 method for class 'ci.coords'
print(x, digits=max(3, getOption("digits") - 3), ...) 

Arguments

- **x**
  a roc, auc or ci object, from the roc, auc or ci functions respectively.
- **call**
  if the call is printed.
- **digits**
  the number of significant figures to print. See signif for more details.
- **...**
  further arguments passed to or from other methods. In particular, print.roc calls print.auc and the print.ci variants internally, and a digits argument is propagated. Not used in print.auc and print.ci variants.

Value

These functions return the object they were passed invisibly.

# the dedicated function:
print(rocobj$auc)
print(ci(rocobj))
roc

Build a ROC curve

Description

This is the main function of the pROC package. It builds a ROC curve and returns a “roc” object, a list of class “roc”. This object can be printed, plotted, or passed to the functions auc, ci, smooth.roc and coords. Additionally, two roc objects can be compared with roc.test.

Usage

roc(...)  
## S3 method for class 'formula'
roc(formula, data, ...)  
## S3 method for class 'data.frame'
roc(data, response, predictor, ret = c("roc", "coords", "all_coords"), ...)  
## Default S3 method:
roc(response, predictor, controls, cases, density.controls, density.cases, levels=base::levels(as.factor(response)), percent=FALSE, na.rm=TRUE, direction=c("auto", ",", ",") algorithm=6, quiet = FALSE, smooth=FALSE, auc=TRUE, ci=FALSE, plot=FALSE, smooth.method="binormal", smooth.n=512, ci.method=NULL, density=NULL, ...)  
roc_(data, response, predictor, ret = c("roc", "coords", "all_coords"), ...)

Arguments

response  
a factor, numeric or character vector of responses, typically encoded with 0 (controls) and 1 (cases). Only two classes can be used in a ROC curve. If the vector contains more than two unique values, or if their order could be ambiguous, use levels to specify which values must be used as control and case value. If the first argument was a data.frame, response should be the name of the column in data containing the response, quoted for roc_ and optionally quoted for roc.data.frame (non-standard evaluation or NSE).

predictor  
a numeric or ordered vector of the same length than response, containing the predicted value of each observation. If the first argument was a data.frame, predictor should be the name of the column in data containing the predictor, quoted for roc_ and optionally quoted for roc.data.frame (non-standard evaluation or NSE).

controls, cases  
instead of response, predictor, the data can be supplied as two numeric or ordered vectors containing the predictor values for control and case observations.

density.controls, density.cases  
a smoothed ROC curve can be built directly from two densities on identical x points, as in smooth.
a formula of the type response~predictor. If multiple predictors are passed, a named list of roc objects will be returned. Additional arguments data, subset and na.action are supported, see model.frame for more details.

levels

the value of the response for controls and cases respectively. By default, the first two values of levels(as.factor(response)) are taken, and the remaining levels are ignored. It usually captures two-class factor data correctly, but will frequently fail for other data types (response factor with more than 2 levels, or for example if your response is coded “controls” and “cases”, the levels will be inverted) and must then be specified here. If your data is coded as 0 and 1 with 0 being the controls, you can safely omit this argument.

percent

if the sensitivities, specificities and AUC must be given in percent (TRUE) or in fraction (FALSE, default).

na.rm

if TRUE, the NA values will be removed (ignored by roc.formula).

direction

in which direction to make the comparison? “auto” (default): automatically define in which group the median is higher and take the direction accordingly. “>”: if the predictor values for the control group are higher than the values of the case group (controls > t >= cases). “<”: if the predictor values for the control group are lower or equal than the values of the case group (controls < t <= cases). You should set this explicitly to “>” or “<” whenever you are resampling or randomizing the data, otherwise the curves will be biased towards higher AUC values.

algorithm

the method used to compute sensitivity and specificity, an integer of length 1 between 0 and 6. 1: a safe, well-tested, pure-R code that is efficient when the number of thresholds is low. It goes with $O(T*N)$. 2: an alternative pure-R algorithm that goes in $O(N)$. Typically faster than 1 when the number of thresholds of the ROC curve is above 1000. Less tested than 1. 3: a C++ implementation of 1, about 3-5x faster. Typically the fastest with ROC curves with less than 50-100 thresholds, but has a very bad worst-case when that number increases. 4 (debug only, slow): runs algorithms 1 to 3 and makes sure they return the same values. 5: select 2 or 3 based on the number of thresholds. 6 (default): quickly select the algorithm on the class of the data: 2 for numeric and 3 for ordered. 0: use microbenchmark to choose between 2 and 3.

ret

for roc.data.frame only, whether to return the threshold sensitivity and specificity at all thresholds (“coords”), all the coordinates at all thresholds (“all.coords”) or the roc object (“roc”).

quiet

set to TRUE to turn off messages when direction and levels are auto-detected.

smooth

if TRUE, the ROC curve is passed to smooth to be smoothed.

auc

compute the area under the curve (AUC)? If TRUE (default), additional arguments can be passed to auc.

ci

compute the confidence interval (CI)? If set to TRUE, additional arguments can be passed to ci.

plot

plot the ROC curve? If TRUE, additional arguments can be passed to plot.roc.
smooth.method, smooth.n, ci.method

in roc.formula and roc.default, the method and n arguments to smooth (if smooth=TRUE) and of="auc") must be passed as smooth.method, smooth.n and ci.method to avoid confusions.

density argument passed to smooth.

... further arguments passed to or from other methods, and especially:

- auc: partial.auc, partial.auc.focus, partial.auc.correct.
- ci: of, conf.level, boot.n, boot.stratified, progress
- ci.auc: reuse.auc, method
- ci.thresholds: thresholds
- ci.sp: sensitivities
- ci.se: specificities
- plot.roc: add, col and most other arguments to the plot.roc function. See plot.roc directly for more details.
- smooth: method, n, and all other arguments. See smooth for more details.

Details

This function's main job is to build a ROC object. See the “Value” section to this page for more details. Before returning, it will call (in this order) the smooth, auc, ci and plot.roc functions if smooth auc, ci and plot.roc (respectively) arguments are set to TRUE. By default, only auc is called.

Data can be provided as response, predictor, where the predictor is the numeric (or ordered) level of the evaluated signal, and the response encodes the observation class (control or case). The level argument specifies which response level must be taken as controls (first value of level) or cases (second). It can safely be ignored when the response is encoded as 0 and 1, but it will frequently fail otherwise. By default, the first two values of levels(as.factor(response)) are taken, and the remaining levels are ignored. This means that if your response is coded “control” and “case”, the levels will be inverted.

In some cases, it is more convenient to pass the data as controls, cases, but both arguments are ignored if response, predictor was specified to non-NULL values. It is also possible to pass density data with density.controls, density.cases, which will result in a smoothed ROC curve even if smooth=FALSE, but are ignored if response, predictor or controls, cases are provided.

Specifications for auc, ci and plot.roc are not kept if auc, ci or plot are set to FALSE. Especially, in the following case:

```r
myRoc <- roc(..., auc.polygon=TRUE, grid=TRUE, plot=FALSE)
plot(myRoc)
```

the plot will not have the AUC polygon nor the grid. Similarly, when comparing “roc” objects, the following is not possible:
roc1 <- roc(..., partial.auc=c(1, 0.8), auc=FALSE)
roc2 <- roc(..., partial.auc=c(1, 0.8), auc=FALSE)
roc.test(roc1, roc2)

This will produce a test on the full AUC, not the partial AUC. To make a comparison on the partial AUC, you must repeat the specifications when calling roc.test:

roc.test(roc1, roc2, partial.auc=c(1, 0.8))

Note that if roc was called with auc=TRUE, the latter syntax will not allow redefining the AUC specifications. You must use reuse.auc=FALSE for that.

Value

If the data contained any NA value and na.rm=FALSE, NA is returned. Otherwise, if smooth=FALSE, a list of class “roc” with the following fields:

- **auc** if called with auc=TRUE, a numeric of class “auc” as defined in auc.
- **ci** if called with ci=TRUE, a numeric of class “ci” as defined in ci.
- **response** the response vector. Patients whose response is not %in% levels are discarded. If NA values were removed, na.action attribute similar to na.omit stores the row numbers.
- **predictor** the predictor vector converted to numeric as used to build the ROC curve. Patients whose response is not %in% levels are discarded. If NA values were removed, a na.action attribute similar to na.omit stores the row numbers.
- **original.predictor, original.response** the response and predictor vectors as passed in argument.
- **levels** the levels of the response as defined in argument.
- **controls** the predictor values for the control observations.
- **cases** the predictor values for the cases.
- **percent** if the sensitivities, specificities and AUC are reported in percent, as defined in argument.
- **direction** the direction of the comparison, as defined in argument.
- **fun.sesp** the function used to compute sensitivities and specificities. Will be re-used in bootstrap operations.
- **sensitivities** the sensitivities defining the ROC curve.
- **specificities** the specificities defining the ROC curve.
- **thresholds** the thresholds at which the sensitivities and specificities were computed.
- **call** how the function was called. See match.call for more details.

If smooth=TRUE a list of class “smooth.roc” as returned by smooth, with or without additional elements auc and ci (according to the call).
Experimental: pipelines

Since version 1.15.0, the roc function can be used in pipelines, for instance with dplyr or magrittr. This is still a highly experimental feature and will change significantly in future versions (see issue 54\(^{49}\)). The roc.data.frame method supports both standard and non-standard evaluation (NSE):

```r
library(dplyr)
# Standard evaluation:
aSAH %>%
  filter(gender == "Female") %>%
  roc("outcome", "s100b")
# Non-Standard Evaluation:
aSAH %>%
  filter(gender == "Female") %>%
  roc(outcome, s100b)
```

For tasks involving programming and variable column names, the roc_ function provides standard evaluation:

```r
# Standard evaluation:
aSAH %>%
  filter(gender == "Female") %>%
  roc_("outcome", "s100b")
```

By default it returns the roc object, which can then be piped to the coords function to extract coordinates that can be used in further pipelines.

```r
# Returns thresholds, sensitivities and specificities:
aSAH %>%
  roc(outcome, s100b) %>%
  coords(transpose = FALSE) %>%
  filter(sensitivity > 0.6,
         specificity > 0.6)
# Returns all existing coordinates, then select precision and recall:
aSAH %>
  roc(outcome, s100b) %>%
  coords(ret = "all", transpose = FALSE) %>%
  select(precision, recall)
```

Errors

If no control or case observation exist for the given levels of response, no ROC curve can be built and an error is triggered with message “No control observation” or “No case observation”.

\(^{49}\)https://github.com/xrobin/pROC/issues/54
If the predictor is not a numeric or ordered, as defined by `as.numeric` or `as.ordered`, the message “Predictor must be numeric or ordered” is returned.

The message “No valid data provided” is issued when the data wasn’t properly passed. Remember you need both response and predictor of the same (not null) length, or both controls and cases. Combinations such as predictor and cases are not valid and will trigger this error.

Infinite values of the predictor cannot always be thresholded by infinity and can cause ROC curves to not reach 0 or 100% specificity or sensitivity. Since version 1.13.0, pROC returns `NaN` with a warning message “Infinite value(s) in predictor” if `predictor` contains any infinite values.

Examples

data(aSAH)

# Basic example
roc(aSAH$outcome, aSAH$s100b,
   levels=c("Good", "Poor"))

# As levels aSAH$outcome == c("Good", "Poor"),
# this is equivalent to:
roc(aSAH$outcome, aSAH$s100b)

# In some cases, ignoring levels could lead to unexpected results
# Equivalent syntaxes:
roc(outcome ~ s100b, aSAH)
roc(aSAH$outcome ~ aSAH$s100b)
with(aSAH, roc(outcome, s100b))
with(aSAH, roc(outcome ~ s100b))

# With a formula:
roc(outcome ~ s100b, data=aSAH)

## Not run:
library(dplyr)
aSAH %>%
  filter(gender == "Female") %>%
  roc(outcome, s100b)

## End(Not run)

50http://dx.doi.org/10.1016/j.patrec.2005.10.010
51http://dx.doi.org/10.1186/1471-2105-12-77
# Using subset (only with formula)
roc(outcome ~ s100b, data=aSAH, subset=(gender == "Male"))
roc(outcome ~ s100b, data=aSAH, subset=(gender == "Female"))

# With numeric controls/cases
roc(controls=aSAH$s100b[aSAH$outcome=="Good"], cases=aSAH$s100b[aSAH$outcome=="Poor"])
# With ordered controls/cases
roc(controls=aSAH$wfns[aSAH$outcome=="Good"], cases=aSAH$wfns[aSAH$outcome=="Poor"])

# Inverted the levels: "Poor" are now controls and "Good" cases:
roc(aSAH$outcome, aSAH$s100b,
   levels=c("Poor", "Good"))

# The result was exactly the same because of direction="auto".
# The following will give an AUC < 0.5:
roc(aSAH$outcome, aSAH$s100b,
   levels=c("Poor", "Good"), direction="<")

# If we are sure about levels and direction auto-detection,
# we can turn off the messages:
roc(aSAH$outcome, aSAH$s100b, quiet = TRUE)

# If we prefer counting in percent:
roc(aSAH$outcome, aSAH$s100b, percent=TRUE)

# Plot and CI (see plot.roc and ci for more options):
roc(aSAH$outcome, aSAH$s100b,
   percent=TRUE, plot=TRUE, ci=TRUE)

# Smoothed ROC curve
roc(aSAH$outcome, aSAH$s100b, smooth=TRUE)
# this is not identical to
smooth(roc(aSAH$outcome, aSAH$s100b))
# because in the latter case, the returned object contains no AUC

roc.test

---

**Compare the AUC of two ROC curves**

**Description**

This function compares the AUC or partial AUC of two correlated (or paired) or uncorrelated (unpaired) ROC curves. Several syntaxes are available: two object of class roc (which can be AUC or smoothed ROC), or either three vectors (response, predictor1, predictor2) or a response vector and a matrix or data.frame with two columns (predictors).

**Usage**

```
roc.test(...)
```

## S3 method for class 'roc'
roc.test(roc1, roc2, method=c("delong", "bootstrap", "venkatraman", "sensitivity", "specificity"), sensitivity = NULL, specificity = NULL, alternative = c("two.sided", "less", "greater"), paired=NULL, reuse.auc=TRUE, boot.n=2000, boot.stratified=TRUE, ties.method="first", progress=getOption("pROCProgress")$name, parallel=FALSE, ...
## S3 method for class 'auc'
roc.test(roc1, roc2, ...)
## S3 method for class 'smooth.roc'
roc.test(roc1, roc2, ...)
## S3 method for class 'formula'
roc.test(formula, data, ...)
## Default S3 method:
roc.test(response, predictor1, predictor2=NULL, na.rm=TRUE, method=NULL, ...

Arguments

roc1, roc2 the two ROC curves to compare. Either “roc”, “auc” or “smooth.roc” objects (types can be mixed).
response a vector or factor, as for the roc function.
predictor1 a numeric or ordered vector as for the roc function, or a matrix or data.frame with predictors two columns.
predictor2 only if predictor1 was a vector, the second predictor as a numeric vector.
formula a formula of the type response~predictor1+predictor2. Additional arguments data, subset and na.action are supported, see model.frame for more details.
data a matrix or data.frame containing the variables in the formula. See model.frame for more details.
na.rm if TRUE, the observations with NA values will be removed.
method the method to use, either “delong”, “bootstrap” or “venkatraman”. The first letter is sufficient. If omitted, the appropriate method is selected as explained in details.
sensitivity, specificity if method="sensitivity" or method="specificity", the respective level where the test must be assessed as a numeric of length 1.
alternative specifies the alternative hypothesis. Either of “two.sided”, “less” or “greater”. The first letter is sufficient. Default: “two.sided”. Only “two.sided” is available with method="venkatraman".
paired a logical indicating whether you want a paired roc.test. If NULL, the paired status will be auto-detected by are.paired. If TRUE but the paired status cannot be assessed by are.paired will produce an error.
reuse.auc if TRUE (default) and the “roc” objects contain an “auc” field, re-use these specifications for the test. See the AUC specification section for more details.
boot.n for method="bootstrap" and method="venkatraman" only: the number of bootstrap replicates or permutations. Default: 2000.
boot.stratified

for method="bootstrap" only: should the bootstrap be stratified (same number of cases/controls in each replicate than in the original sample) or not. Ignored with method="venkatraman". Default: TRUE.

ties.method

for method="venkatraman" only: argument for rank specifying how ties are handled. Defaults to "first" as described in the paper.

progress

the name of progress bar to display. Typically “none”, “win”, “tk” or “text” (see the name argument to create_progress_bar for more information), but a list as returned by create_progress_bar is also accepted. See also the “Progress bars” section of this package’s documentation.

parallel

if TRUE, the bootstrap is processed in parallel, using parallel backend provided by plyr (foreach).

... further arguments passed to or from other methods, especially arguments for roc and roc.test.roc when calling roc.test.default or roc.test.formula. Arguments for auc, and txtProgressBar (only char and style) if applicable.

details

This function compares two ROC curves. It is typically called with the two roc objects to compare. roc.test.default is provided as a convenience method and creates two roc objects before calling roc.test.roc.

Three methods are available: “delong”, “bootstrap” and “venkatraman” (see “Computational details” section below). “delong” and “bootstrap” are tests over the AUC whereas “venkatraman” compares the ROC curves themselves.

Default is to use “delong” method except for comparison of partial AUC, smoothed curves and curves with different direction, where bootstrap is used. Using “delong” for partial AUC and smoothed ROCs is not supported in pROC and result in an error. It is spurious to use “delong” for roc with different direction (a warning is issued but the spurious comparison is enforced). “venkatraman”’s test cannot be employed to compare smoothed ROC curves, or curves with partial AUC specifications. In addition, and comparison of ROC curves with different direction should be used with care (a warning is produced as well).

If alternative="two.sided", a two-sided test for difference in AUC is performed. If alternative="less", the alternative is that the AUC of roc1 is smaller than the AUC of roc2. For method="venkatraman", only “two.sided” test is available.

If the paired argument is not provided, the are.paired function is employed to detect the paired status of the ROC curves. It will test if the original response is identical between the two ROC curves (this is always the case if the call is made with roc.test.default). This detection is unlikely to raise false positives, but this possibility cannot be excluded entirely. It would require equal sample sizes and response values and order in both ROC curves. If it happens to you, use paired=FALSE. If you know the ROC curves are paired you can pass paired=TRUE. However this is useless as it will be tested anyway.

For smoothed ROC curves, smoothing is performed again at each bootstrap replicate with the parameters originally provided. If a density smoothing was performed with user-provided density.cases or density.controls the bootstrap cannot be performed and an error is issued.
Value

A list of class "htest" with following content:

- **p.value**  
  the p-value of the test.

- **statistic**  
  the value of the Z (method="delong") or D (method="bootstrap") statistics.

- **alternative**  
  the alternative hypothesis.

- **method**  
  the character string “DeLong’s test for two correlated ROC curves” (if method="delong")  
  or “Bootstrap test for two correlated ROC curves” (if method="bootstrap").

- **null.value**  
  the expected value of the statistic under the null hypothesis, that is 0.

- **estimate**  
  the AUC in the two ROC curves.

- **data.name**  
  the names of the data that was used.

- **parameter**  
  for method="bootstrap" only: the values of the boot.n and boot.stratified arguments.

AUC specification

The comparison of the AUC of the ROC curves needs a specification of the AUC. The specification  

is defined by:

1. the “auc” field in the “roc” objects if reuse.auc is set to TRUE (default)
2. passing the specification to auc with ...(arguments partial.auc, partial.auc.correct and partial.auc.focus). In this case, you must ensure either that the roc object do not contain an auc field (if you called roc with auc=FALSE), or set reuse.auc=FALSE.

If reuse.auc=FALSE the auc function will always be called with ... to determine the specification, even if the “roc” objects do contain an auc field.

As well if the “roc” objects do not contain an auc field, the auc function will always be called with ... to determine the specification.

The AUC specification is ignored in the Venkatraman test.

Warning: if the roc object passed to roc.test contains an auc field and reuse.auc=TRUE, auc is not called and arguments such as partial.auc are silently ignored.

Computation details

With method="bootstrap", the processing is done as follow:

1. **boot.n** bootstrap replicates are drawn from the data. If boot.stratified is TRUE,  
   each replicate contains exactly the same number of controls and cases than the original sample,  
   otherwise if FALSE the numbers can vary.
2. for each bootstrap replicate, the AUC of the two ROC curves are computed and the difference  
   is stored.
3. The following formula is used:

\[ D = \frac{AUC1 - AUC2}{s} \]

where s is the standard deviation of the bootstrap differences and AUC1 and AUC2 the AUC  

of the two (original) ROC curves.
4. \( D \) is then compared to the normal distribution, according to the value of `alternative`.

See also the Bootstrap section in this package’s documentation.

With `method="delong"`, the processing is done as described in DeLong et al. (1988) for paired ROC curves, using the algorithm of Sun and Xu (2014). Only comparison of two ROC curves is implemented. The method has been extended for unpaired ROC curves where the p-value is computed with an unpaired \( t \)-test with unequal sample size and unequal variance, with

\[
D = \frac{V^r(\theta^r) - V^s(\theta^s)}{\sqrt{S^r + S^s}}
\]

With `method="venkatraman"`, the processing is done as described in Venkatraman and Begg (1996) (for paired ROC curves) and Venkatraman (2000) (for unpaired ROC curves) with `boot.n` permutation of sample ranks (with ties breaking). For consistency reasons, the same argument `boot.n` as in bootstrap defines the number of permutations to execute, even though no bootstrap is performed.

For `method="specificity"`, the test assesses if the sensitivity of the ROC curves are different at the level of specificity given by the `specificity` argument, which must be a numeric of length 1. Bootstrap is employed as with `method="bootstrap"` and `boot.n` and `boot.stratified` are available. This is identical to the test proposed by Pepe et al. (2009).

The `method="sensitivity"` is very similar, but assesses if the specificity of the ROC curves are different at the level of sensitivity given by the `sensitivity` argument.

**Warnings**

If “auc” specifications are different in both roc objects, the warning “Different AUC specifications in the ROC curves. Enforcing the inconsistency, but unexpected results may be produced.” is issued. Unexpected results may be produced.

If one or both ROC curves are “smooth.roc” objects with different smoothing specifications, the warning “Different smoothing parameters in the ROC curves. Enforcing the inconsistency, but unexpected results may be produced.” is issued. This warning can be benign, especially if ROC curves were generated with `roc(...,smooth=TRUE)` with different arguments to other functions (such as plot), or if you really want to compare two ROC curves smoothed differently.

If `method="venkatraman"`, and `alternative` is “less” or “greater”, the warning “Only two-sided tests are available for Venkatraman. Performing two-sided test instead.” is produced and a two tailed test is performed.

Both DeLong and Venkatraman’s test ignores the direction of the ROC curve so that if two ROC curves have a different differ in the value of `direction`, the warning “(DeLong/Venkatraman)’s test should not be applied to ROC curves with different directions.” is printed. However, the spurious test is enforced.

If `boot.stratified=FALSE` and the sample has a large imbalance between cases and controls, it could happen that one or more of the replicates contains no case or control observation, or that there are not enough points for smoothing, producing a NA area. The warning “NA value(s) produced during bootstrap were ignored.” will be issued and the observation will be ignored. If you have a large imbalance in your sample, it could be safer to keep `boot.stratified=TRUE`.

When both ROC curves have an auc of 1 (or 100%), their variances and covariance will always be null, and therefore the p-value will always be 1. This is true for both “delong”, “bootstrap” and
“venkatraman” methods. This result is misleading, as the variances and covariance are of course not null. A warning will be displayed to inform of this condition, and of the misleading output.

Errors

An error will also occur if you give a predictor2 when predictor1 is a matrix or a data.frame, if predictor1 has more than two columns, or if you do not give a predictor2 when predictor1 is a vector.

If density.cases and density.controls were provided for smoothing, the error “Cannot compute the statistic on ROC curves smoothed with density.controls and density.cases.” is issued.

If method="venkatraman" and one of the ROC curves is smoothed, the error “Using Venkatraman’s test for smoothed ROCs is not supported.” is produced.

With method="specificity", the error “Argument ’specificity’ must be numeric of length 1 for a specificity test.” is given unless the specificity argument is specified as a numeric of length 1. The “Argument ’sensitivity’ must be numeric of length 1 for a sensitivity test.” message is given for method="sensitivity" under similar conditions.

Acknowledgements

We would like to thank E. S. Venkatraman and Colin B. Begg for their support in the implementation of their test.

Smooth a ROC curve

This function smooths a ROC curve of numeric predictor. By default, a binormal smoothing is performed, but density or custom smoothings are supported.

Usage

\[
\text{\texttt{smooth(...)}}
\]

## Default S3 method:
smooth(...)  
## S3 method for class 'roc'  
smooth(roc,  
method=c("binormal", "density", "fitdistr", "logcondens",  
"logcondens.smooth"), n=512, bw = "nrd0", density=NULL,  
density.controls=density, density.cases=density,  
start=NULL, start.controls=start, start.cases=start,  
reuse.auc=TRUE, reuse.ci=FALSE, ...)  
## S3 method for class 'smooth.roc'  
smooth(smooth.roc, ...)  

Arguments

roc, smooth.roc

A “roc” object from the roc function, or a “smooth.roc” object from the smooth function.

method

“binormal”, “density”, “fitdistr”, “logcondens”, “logcondens.smooth”, or a function returning a list of smoothed sensitivities and specificities.

n

The number of equally spaced points where the smoothed curve will be calculated.

bw

If method="density" and density.controls and density.cases are not provided, bw is passed to density to determine the bandwidth of the density. Can be a character string (“nrd0”, “nrd”, “ucv”, “bcv” or “SJ”, but any name matching a function prefixed with “bw.” is supported) or a numeric value, as described in density. Defaults to “nrd0”.

density, density.controls, density.cases

If method="density", a numeric value of density (over the y axis) or a function returning a density (such as density. If method="fitdistr", a densfun argument for fitdistr. If the value is different for control and case observations, density.controls and density.cases can be employed instead, otherwise density will be propagated to both density.controls and density.cases.

start, start.controls, start.cases

If method="fitdistr", optionnal start arguments for start.controls and start.cases allows to specify different distributions for controls and cases.

reuse.auc, reuse.ci

If TRUE (default for reuse.auc) and the “roc” objects contain “auc” or “ci” fields, re-use these specifications to regenerate auc or ci on the smoothed ROC curve with the original parameters. If FALSE, the object returned will not contain “auc” or “ci” fields. It is currently not possible to redefine auc and ci options directly: you need to call auc or ci later for that.

...  

Further arguments passed to or from other methods, and especially to density (only cut, adjust, and kernel, plus window for compatibility with S+) and fitdistr. Also passed to to method if it is a function.
**Details**

If `method="binormal"`, a linear model is fitted to the quantiles of the sensitivities and specificities. Smoothed sensitivities and specificities are then generated from this model on \( n \) points. This simple approach was found to work well for most ROC curves, but it may produce hooked smooths in some situations (see in Hanley (1988)).

With `method="density"`, the density function is employed to generate a smooth kernel density of the control and case observations as described by Zhou *et al.* (1997), unless `density.controls` or `density.cases` are provided directly. `bw` can be given to specify a bandwidth to use with `density`. It can be a numeric value or a character string ("nrd0", "nrd", "ucv", "bcv" or "SJ", but any name matching a function prefixed with "bw." is supported). In the case of a character string, the whole predictor data is employed to determine the numeric value to use on both controls and cases. Depending on your data, it might be a good idea to specify the `kernel` argument for `density`. By default, "gaussian" is used, but "epanechnikov", "rectangular", "triangular", "biweight", "cosine" and "optcosine" are supported. As all the kernels are symmetrical, it might help to normalize the data first (that is, before calling `roc`), for example with quantile normalization:

```r
norm.x <- qnorm(rank(x)/(length(x)+1))
smooth(roc(response, norm.x, ...), ...)
```

Additionally, `density` can be a function which must return either a numeric vector of densities over the y axis or a list with a "y" item like the `density` function. It must accept the following input:

```r
density.fun(x, n, from, to, bw, kernel, ...)
```

It is important to honour \( n \), \( \text{from} \) and \( \text{to} \) in order to have the densities evaluated on the same points for controls and cases. Failing to do so and returning densities of different length will produce an error. It is also a good idea to use a constant smoothing parameter (such as `bw`) especially when controls and cases have a different number of observations, to avoid producing smoother or rougher densities.

If `method="fitdistr"`, the `fitdistr` function from the MASS package is employed to fit parameters for the density function `density` with optional start parameters `start`. The density function are fitted separately in control (`density.controls`, `start.controls`) and case observations (`density.cases`, `start.cases`). `density` can be one of the character values allowed by `fitdistr` or a density function (such as `dnorm`, `dweibull`, ...).

The `method="logcondens"` and `method="logcondens.smooth"` use the `logcondens` package to generate a non-smoothed or smoothed (respectively) log-concave density estimate of of the control and case observation with the logConROC function.

Finally, `method` can also be a function. It must return a list with exactly 2 elements named "sensitivities" and "specificities", which must be numeric vectors between 0 and 1 or 100 (depending on the `percent` argument to `roc`). It is passed all the arguments to the `smooth` function.

`smooth.default` forces the usage of the `smooth` function in the `stats` package, so that other code relying on `smooth` should continue to function normally.

Smoothed ROC curves can be passed to `smooth` again. In this case, the smoothing is not re-applied on the smoothed ROC curve but the original "roc" object will be re-used.

Note that a `smooth.roc` curve has no threshold.
Value

A list of class "smooth.roc" with the following fields:

- sensitivities
  the smoothed sensitivities defining the ROC curve.
- specificities
  the smoothed specificities defining the ROC curve.
- percent
  if the sensitivities, specificities and AUC are reported in percent, as defined in argument.
- direction
  the direction of the comparison, as defined in argument.
- call
  how the function was called. See match.call for more details.
- smoothing.args
  a list of the arguments used for the smoothing. Will serve to apply the smoothing again in further bootstrap operations.
- auc
  if the original ROC curve contained an AUC, it is computed again on the smoothed ROC.
- ci
  if the original ROC curve contained a CI, it is computed again on the smoothed ROC.
- fit.controls, fit.cases
  with method="fitdistr" only: the result of MASS's fitdistr function for controls and cases, with an additional "densfun" item indicating the density function, if possible as character.
- logcondens
  with method="logcondens" and method="logcondens.smooth" only: the result of logcondens's logConROC function.
- model
  with method="binormal" only: the linear model from lm used to smooth the ROC curve.

Attributes: Additionally, the original roc object is stored as a "roc" attribute.

Errors

If method is a function, the return values will be checked thoroughly for validity (list with two numeric elements of the same length named "sensitivities" and "specificities" with values in the range of possible values for sensitivities and specificities).

The message "The 'density' function must return a numeric vector or a list with a 'y' item." will be displayed if the density function did not return a valid output. The message "Length of 'density.controls' and 'density.cases' differ:" will be displayed if the returned value differ in length.

Binormal smoothing cannot smooth ROC curve defined by only one point. Any such attempt will fail with the error "ROC curve not smoothable (not enough points).".

If the smooth ROC curve was generated by roc with density.controls and density.cases numeric arguments, it cannot be smoothed and the error "Cannot smooth a ROC curve generated directly with numeric 'density.controls' and 'density.cases'." is produced.

fitdistr and density smoothing methods require a numeric predictor. If the ROC curve to smooth was generated with an ordered factor only binormal smoothing can be applied and the
message “ROC curves of ordered predictors can be smoothed only with binormal smoothing.” is displayed otherwise.

fitdistr, logcondens and logcondens.smooth methods require additional packages. If not available, the following message will be displayed with the required command to install the package: “Package ? not available, required with method='?'. Please install it with 'install.packages("?")'. “

## Not run:
# you can bootstrap a ROC curve smoothed with a density function:
cl(s, boot.n=100)
## End(Not run)
Description

These functions compute the variance of the AUC of a ROC curve.

Usage

var(...)
## Default S3 method:
var(...)
## S3 method for class 'auc'
var(auc, ...)
## S3 method for class 'roc'
var(roc, method=c("delong", "bootstrap", "obuchowski"),
   boot.n = 2000, boot.stratified = TRUE, reuse.auc=TRUE,
   progress = getOption("pROCProgress")$name, parallel=FALSE, ...)
## S3 method for class 'smooth.roc'
var(smooth.roc, ...)

Arguments

roc, smooth.roc, auc

   a “roc” object from the roc function, a “smooth.roc” object from the smooth function or an “auc” object from the auc function.
method

   the method to use, either “delong” or “bootstrap”. The first letter is sufficient. If omitted, the appropriate method is selected as explained in details.
reuse.auc

   if TRUE (default) and the “roc” objects contain an “auc” field, re-use these specifications for the test. See details.
boot.n

   for method="bootstrap" only: the number of bootstrap replicates or permutations. Default: 2000.
boot.stratified

   for method="bootstrap" only: should the bootstrap be stratified (same number of cases/controls in each replicate than in the original sample) or not. Default: TRUE.
progress

   the name of progress bar to display. Typically “none”, “win”, “tk” or “text” (see the name argument to create_progress_bar for more information), but a list as returned by create_progress_bar is also accepted. See also the “Progress bars” section of this package’s documentation.
parallel

   if TRUE, the bootstrap is processed in parallel, using parallel backend provided by plyr (foreach).
...

   further arguments passed to or from other methods, especially arguments for var.roc when calling var, var.auc and var.smooth.roc. Arguments for auc (if reuse.auc=FALSE) and txtProgressBar (only char and style) if applicable.

Details

The var function computes the variance of the AUC of a ROC curve. It is typically called with the roc object of interest. Two methods are available: “delong” and “bootstrap” (see “Computational details” section below).
The default is to use “delong” method except for with partial AUC and smoothed curves where “bootstrap” is employed. Using “delong” for partial AUC and smoothed ROCs is not supported.

For smoothed ROC curves, smoothing is performed again at each bootstrap replicate with the parameters originally provided. If a density smoothing was performed with user-provided \texttt{density.cases} or \texttt{density.controls} the bootstrap cannot be performed and an error is issued.

\texttt{var.default} forces the usage of the \texttt{var} function in the \texttt{stats} package, so that other code relying on \texttt{var} should continue to function normally.

**Value**

The numeric value of the variance.

**AUC specification**

\texttt{var} needs a specification of the AUC to compute the variance of the AUC of the ROC curve. The specification is defined by:

1. the “auc” field in the “roc” objects if \texttt{reuse.auc} is set to \texttt{TRUE} (default)
2. passing the specification to \texttt{auc} with \ldots (arguments \texttt{partial.auc}, \texttt{partial.auc.correct} and \texttt{partial.auc.focus}). In this case, you must ensure either that the \texttt{roc} object do not contain an \texttt{auc} field (if you called \texttt{roc} with \texttt{auc=FALSE}), or set \texttt{reuse.auc=FALSE}.

If \texttt{reuse.auc=FALSE} the \texttt{auc} function will always be called with \ldots to determine the specification, even if the “roc” objects do contain an \texttt{auc} field.

As well if the “roc” objects do not contain an \texttt{auc} field, the \texttt{auc} function will always be called with \ldots to determine the specification.

Warning: if the \texttt{roc} object passed to \texttt{roc.test} contains an \texttt{auc} field and \texttt{reuse.auc=TRUE}, \texttt{auc} is not called and arguments such as \texttt{partial.auc} are silently ignored.

**Computation details**

With \texttt{method="bootstrap"}, the processing is done as follow:

1. \texttt{boot.n} bootstrap replicates are drawn from the data. If \texttt{boot.stratified} is \texttt{TRUE}, each replicate contains exactly the same number of controls and cases than the original sample, otherwise if \texttt{FALSE} the numbers can vary.
2. for each bootstrap replicate, the AUC of the ROC curve is computed and stored.
3. the variance of the resampled AUCs are computed and returned.

With \texttt{method="delong"}, the processing is done as described in Hanley and Hajian-Tilaki (1997) using the algorithm by Sun and Xu (2014).

With \texttt{method="obuchowski"}, the processing is done as described in Obuchowski and McClish (1997), Table 1 and Equation 4, p. 1530–1531. The computation of \( g \) for partial area under the ROC curve is modified as:

\[
expr1 * (2 * pi * expr2)^{-1} * (-expr4) - A * B * expr1 * (2 * pi * expr2^3)^{-1/2} * expr3
\]
Binormality assumption

The “obuchowski” method makes the assumption that the data is binormal. If the data shows a deviation from this assumption, it might help to normalize the data first (that is, before calling \texttt{roc}), for example with quantile normalization:

\begin{verbatim}
  norm.x <- qnorm(rank(x)/(length(x)+1))
  var(roc(response, norm.x, ...), ...)
\end{verbatim}

“delong” and “bootstrap” methods make no such assumption.

Warnings

If \texttt{method="delong"} and the AUC specification specifies a partial AUC, the warning “Using DeLong for partial AUC is not supported. Using bootstrap test instead.” is issued. The \texttt{method} argument is ignored and “bootstrap” is used instead.

If \texttt{method="delong"} and the ROC curve is smoothed, the warning “Using DeLong for smoothed ROCs is not supported. Using bootstrap test instead.” is issued. The \texttt{method} argument is ignored and “bootstrap” is used instead.

If \texttt{boot.stratified=FALSE} and the sample has a large imbalance between cases and controls, it could happen that one or more of the replicates contains no case or control observation, or that there are not enough points for smoothing, producing a \texttt{NA} area. The warning “NA value(s) produced during bootstrap were ignored.” will be issued and the observation will be ignored. If you have a large imbalance in your sample, it could be safer to keep \texttt{boot.stratified=TRUE}.

When the ROC curve has an \texttt{auc} of 1 (or 100%), the variance will always be null. This is true for both “delong” and “bootstrap” methods that can not properly assess the variance in this case. This result is misleading, as the variance is of course not null. A warning will be displayed to inform of this condition, and of the misleading output.

Errors

If \texttt{density.cases} and \texttt{density.controls} were provided for smoothing, the error “Cannot compute the covariance on ROC curves smoothed with density.controls and density.cases.” is issued.

**Examples**

data(aSAH)

```r
## Basic example
roc1 <- roc(aSAH$outcome, aSAH$s100b)
roc2 <- roc(aSAH$outcome, aSAH$wfn)
var(roc1)
var(roc2)

# We could also write it in one line:
var(roc(aSAH$outcome, aSAH$s100b))

## Not run:
# The latter used Delong. To use bootstrap:
var(roc1, method="bootstrap")
# Decrease boot.n for a faster execution
var(roc1, method="bootstrap", boot.n=1000)

## End(Not run)

# To use obuchowski:
var(roc1, method="obuchowski")

## Not run:
# Variance of smoothed ROCs:
# Smoothing is re-done at each iteration, and execution is slow
var(smooth(roc1))

## End(Not run)

# or from an AUC (no smoothing)
var(auc(roc1))
```
