Package ‘pROC’

June 10, 2017

Type Package

Title Display and Analyze ROC Curves

Version 1.10.0

Date 2017-06-10

Encoding UTF-8

Depends R (>= 2.14)

Imports plyr, utils, methods, Rcpp (>= 0.11.1), ggplot2,

Suggests microbenchmark, tcltk, MASS, logcondens, doParallel, testthat

LinkingTo Rcpp

Description Tools for visualizing, smoothing and comparing receiver operating characteristic (ROC curves). (Partial) area under the curve (AUC) can be compared with statistical tests based on U-statistics or bootstrap. Confidence intervals can be computed for (p)AUC or ROC curves.

License GPL (>= 3)

## Description

Tools for visualizing, smoothing and comparing receiver operating characteristic (ROC curves). (Partial) area under the curve (AUC) can be compared with statistical tests based on U-statistics or bootstrap. Confidence intervals can be computed for (p)AUC or ROC curves. Sample size / power computation for one or two ROC curves are available.

## Details

The basic unit of the pROC package is the roc function. It will build a ROC curve, smooth it if requested (if smooth=TRUE), compute the AUC (if auc=TRUE), the confidence interval (CI) if requested (if ci=TRUE) and plot the curve if requested (if plot=TRUE).

The roc function will call smooth, auc, ci and plot as necessary. See these individual functions for the arguments that can be passed to them through roc. These function can be called separately.
Two paired (that is `roc` objects with the same `response`) or unpaired (with different `response`) ROC curves can be compared with the `roc.test` function.

**Citation**

If you use pROC in published research, please cite the following paper:

Type `citation("pROC")` for a BibTeX entry.

The authors would be glad to hear how pROC is employed. You are kindly encouraged to notify Xavier Robin <Xavier.Robin@unige.ch> about any work you publish.

**Abbreviations**

The following abbreviations are employed extensively in this package:

- ROC: receiver operating characteristic
- AUC: area under the ROC curve
- pAUC: partial area under the ROC curve
- CI: confidence interval
- SP: specificity
- SE: sensitivity

**Functions**

- `roc`: Build a ROC curve
- `are.paired`: Determine if two ROC curves are paired
- `auc`: Compute the area under the ROC curve
- `ci`: Compute confidence intervals of a ROC curve
- `ci.auc`: Compute the CI of the AUC
- `ci.coords`: Compute the CI of arbitrary coordinates
- `ci.se`: Compute the CI of sensitivities at given specificities
- `ci.sp`: Compute the CI of specificities at given sensitivities
- `ci.thresholds`: Compute the CI of specificity and sensitivity of thresholds
- `ci.coords`: Compute the CI of arbitrary coordinates
- `coords`: Coordinates of the ROC curve
- `cov`: Covariance between two AUCs
- `ggroc`: Plot a ROC curve with `ggplot2` (Experimental)
- `has.partial.auc`: Determine if the ROC curve have a partial AUC
- `lines.roc`: Add a ROC line to a ROC plot
- `plot.ci`: Plot CIs
- `plot`: Plot a ROC curve
- `print`: Print a ROC curve object
- `roc.test`: Compare the AUC of two ROC curves
- `smooth`: Smooth a ROC curve
- `var`: Variance of the AUC
Dataset

This package comes with a dataset of 141 patients with aneurysmal subarachnoid hemorrhage: aSAH.

Installing and using

To install this package, make sure you are connected to the internet and issue the following command in the R prompt:

```
install.packages("pROC")
```

To load the package in R:

```
library(pROC)
```

Bootstrap

All the bootstrap operations for significance testing, confidence interval, variance and covariance computation are performed with non-parametric stratified or non-stratified resampling (according to the stratified argument) and with the percentile method, as described in Carpenter and Bithell (2000) sections 2.1 and 3.3.

Stratification of bootstrap can be controlled with boot.stratified. In stratified bootstrap (the default), each replicate contains the same number of cases and controls than the original sample. Stratification is especially useful if one group has only little observations, or if groups are not balanced.

The number of bootstrap replicates is controlled by boot.n. Higher numbers will give a more precise estimate of the significance tests and confidence intervals but take more time to compute. 2000 is recommended by Carpenter and Bithell (2000) for confidence intervals. In our experience this is sufficient for a good estimation of the first significant digit only, so we recommend the use of 10000 bootstrap replicates to obtain a good estimate of the second significant digit whenever possible.

Progress bars: A progressbar shows the progress of bootstrap operations. It is handled by the plyr package (Wickham, 2011), and is created by the progress_* family of functions. Sensible defaults are guessed during the package loading:

- In non-interactive mode, no progressbar is displayed.
- In embedded GNU Emacs “ESS”, a txtProgressBar
- In Windows, a winProgressBar bar.
- In other systems with a graphical display, a tkProgressBar.
- In systems without a graphical display, a txtProgressBar.
The default can be changed with the option “pROCProgress”. The option must be a list with a name item setting the type of progress bar (“none”, “win”, “tk” or “text”). Optional items of the list are “width”, “char” and “style”, corresponding to the arguments to the underlying progressbar functions. For example, to force a text progress bar:

```R
options(pROCProgress = list(name = "text", width = NA, char = "="), style = 3)
```

To inhibit the progress bars completely:

```R
options(pROCProgress = list(name = "none"))
```

**Handling large datasets**

Versions 1.6 and 1.7 of pROC focused on execution speed to handle large datasets. Let’s say we have the following dataset with 100 thousands observations:

```R
response <- round(runif(1E5))
predictor <- rnorm(1E5)
system.time(rocobj <- roc(response, predictor)) # Very slow!
```

**Choosing an algorithm for roc:**

By default, pROC uses an algorithm that linearly depends on the number of thresholds. An naive optimization is to reduce the precision of the predictor by generating ties in the data:

```R
system.time(rocobj <- roc(response, round(predictor))) # Faster - but losing precision
```

Since version 1.6, pROC contains an alternative algorithm with an overhead growing linearly as a function of the number of observations. Use the `algorithm` arguments when calling `roc`.

```R
system.time(rocobj <- roc(response, predictor, algorithm = 2)) # Better
```

When unsure about the fastest algorithm, use `algorithm=0` to choose between 2 and 3. Make sure `microbenchmark` is installed. Beware, this is very slow as it will repeat the computation 10 times to obtain a decent estimate of each algorithm speed.

```R
if (!require(microbenchmark))
  install.packages("microbenchmark")
rocobj <- roc(response, round(predictor), algorithm = 0)
rocobj <- roc(response, predictor, algorithm = 0) # Very slow!
```

**Bootstrap:** Bootstrap is typically slow because it involves repeatedly computing the ROC curve (or a part of it).

Some bootstrap functions are faster than others. Typically, `ci.thresholds` is the fastest, and `ci.coords` the slowest. Use `ci.coords` only if the CI you need cannot be computed by the specialized CI functions `ci.thresholds`, `ci.se` and `ci.sp`. Note that `ci.auc` cannot be replaced anyway.

A naive way to speed-up the bootstrap is by removing the progress bar:
rocobj <- roc(response, round(predictor))
system.time(ci(rocobj))
system.time(ci(rocobj, progress = "none"))

It is of course possible to reduce the number of bootstrap iterations. See the boot.n argument to ci. This will reduce the precision of the bootstrap estimate.

Parallel processing: Bootstrap operations can be performed in parallel. The backend provided by the plyr package is used, which in turn relies on the foreach package. To enable parallel processing, you first need to load an adaptor for the foreach package (doMC, doMPI, doParallel, doRedis, doRNG or doSNOW), register the backend, and set parallel=TRUE.

library(doParallel)
registerDoParallel(cl <- makeCluster(getOption("mc.cores", 2)))
ci(rocobj, method="bootstrap", parallel=TRUE)
stopCluster(cl)

Progress bars are not available when parallel processing is enabled.

Using DeLong instead of bootstrap: DeLong is an asymptotically exact method to evaluate the uncertainty of an AUC (DeLong et al. (1988)). Since version 1.9, pROC uses the algorithm proposed by Sun and Xu (2014) which has an O(N log N) complexity and is always faster than bootstrapping. By default, pROC will choose the DeLong method whenever possible.

rocobj <- roc(response, round(predictor), algorithm=3)
system.time(ci(rocobj, method="delong"))
system.time(ci(rocobj, method="bootstrap", parallel = TRUE))

data(aSAH)

    # Build a ROC object and compute the AUC
    roc(aSAH$outcome, aSAH$s100b)
    roc(outcome ~ s100b, aSAH)

    # Smooth ROC curve
    roc(outcome ~ s100b, aSAH, smooth=TRUE)

    # more options, CI and plotting
    roc1 <- roc(aSAH$outcome,
                aSAH$s100b, percent=TRUE,
                # arguments for auc
                partial.auc=c(100, 90), partial.auc.correct=TRUE,
                partial.auc.focus="sens",
                # arguments for ci
                ci=TRUE, boot.n=100, ci.alpha=0.9, stratified=FALSE,
                # arguments for plot
                plot=TRUE, auc.polygon=TRUE, max.auc.polygon=TRUE, grid=TRUE,
                print.auc=TRUE, show.thres=TRUE)

    # Add to an existing plot. Beware of 'percent' specification!
    roc2 <- roc(aSAH$outcome, aSAH$wfns,
                plot=TRUE, add=TRUE, percent=roc1$percent)

    ## Coordinates of the curve ##
    coords(roc1, "best", ret=c("threshold", "specificity", "1-npv"))
    coords(roc2, "local maximas", ret=c("threshold", "sens", "spec", "ppv", "npv"))

    ## Confidence intervals ##

    # CI of the AUC
    ci(roc2)

    ## Not run:
    # CI of the curve
    sens.ci <- ci.se(roc1, specificities=seq(0, 100, 5))
    plot(sens.ci, type="shape", col="lightblue")
    plot(sens.ci, type="bars")
## Description

This function determines if two ROC curves can be paired.

## Usage

```r
are.paired(...)  
## S3 method for class 'auc'
are.paired(roc1, roc2, ...)  
## S3 method for class 'smooth.roc'
are.paired(roc1, roc2, ...)
```
are.paired

```r
# S3 method for class 'roc'
are.paired(roc1, roc2, return.paired.rocs=FALSE,
           reuse.auc = TRUE, reuse.ci = FALSE, reuse.smooth=TRUE, ...)
```

**Arguments**

- `roc1, roc2` the two ROC curves to compare. Either “roc”, “auc” or “smooth.roc” objects (types can be mixed).
- `return.paired.rocs` if TRUE and the ROC curves can be paired, the two paired ROC curves with NAs removed will be returned.
- `reuse.auc, reuse.ci, reuse.smooth` if `return.paired.rocs=TRUE`, determines if `auc, ci` and `smooth` should be re-computed (with the same parameters than the original ROC curves)

**Details**

Two ROC curves are paired if they are built on two variables observed on the same sample.

In practice, the paired status is granted if the `response` and `levels` vector of both ROC curves are identical. If the responses are different, this can be due to missing values differing between the curves. In this case, the function will strip all NAs in both curves and check for identity again.

It can raise false positives if the responses are identical but correspond to different patients.

**Value**

`TRUE` if `roc1` and `roc2` are paired, `FALSE` otherwise.

In addition, if `TRUE` and `return.paired.rocs=TRUE`, the following attributes are defined:

- `roc1, roc2` the two ROC curve with all NAs values removed in both curves.

**See Also**

- `roc, roc.test`

**Examples**

```r
data(aSAH)
aSAH.copy <- aSAH

# artificially insert NAs for demonstration purposes
aSAH.copy$outcome[42] <- NA
aSAH.copy$s100b[24] <- NA
aSAH.copy$ndka[1:10] <- NA

# Call roc() on the whole data
roc1 <- roc(aSAH.copy$outcome, aSAH.copy$s100b)
roc2 <- roc(aSAH.copy$outcome, aSAH.copy$ndka)

# are.paired can still find that the curves were paired
```
are.paired(roc1, roc2) # TRUE

# Removing the NAs manually before passing to roc() un-pairs the ROC curves
nas <- is.na(aSAH.copy$outcome) | is.na(aSAH.copy$ndka)
roc2b <- roc(aSAH.copy$outcome[!nas], aSAH.copy$ndka[!nas])
are.paired(roc1, roc2b) # FALSE

# Getting the two paired ROC curves with additional smoothing and ci options
roc2$ci <- ci(roc2)
paired <- are.paired(smooth(roc1), roc2, return.paired.rocs=TRUE, reuse.ci=TRUE)
paired.roc1 <- attr(paired, "roc1")
paired.roc2 <- attr(paired, "roc2")

---

**aSAH**

*Subarachnoid hemorrhage data*

**Description**

This dataset summarizes several clinical and one laboratory variable of 113 patients with an aneurysmal subarachnoid hemorrhage.

**Usage**

aSAH

**Format**

A data.frame containing 113 observations of 7 variables.

**Source**

**See Also**

Other examples can be found in all the documentation pages of this package: roc, auc, ci, ci.auc, ci.se, ci.sp, ci.thresholds, coords, plot.ci, plot.roc, print.roc, roc.test and smooth.

An example analysis with pROC is shown in:

Examples

```r
# load the dataset
data(aSAH)

# Gender, outcome and set
with(aSAH, table(gender, outcome))

# Age
with(aSAH, by(age, outcome, mean))
  function(x) sprintf("mean: %.1f +/- %.1f, median: %.1f (%i-%i)",
                  mean(x), sd(x), median(x), min(x), max(x)))

# WFNS score
with(aSAH, table(wfns=ifelse(wfns<=2, "1-2", "3-4-5"), outcome))
```

---

**auc**

*Compute the area under the ROC curve*

**Description**

This function computes the numeric value of area under the ROC curve (AUC) with the trapezoidal rule. Two syntaxes are possible: one object of class “roc”, or either two vectors (response, predictor) or a formula (response~predictor) as in the `roc` function. By default, the total AUC is computed, but a portion of the ROC curve can be specified with `partial.auc`.

**Usage**

```r
auc(...)  
## S3 method for class 'roc'
roc, smooth.roc=FALSE, partial.auc.focus=c("specificity", "sensitivity"), partial.auc.correct=FALSE,
allow.invalid.partial.auc.correct = FALSE, ...)
## S3 method for class 'smooth.roc'
smooth.roc, ...)
## S3 method for class 'multiclass.roc'
multiclass.roc, ...)
## S3 method for class 'formula'
formula, data, ...)
## Default S3 method:
response, predictor, ...)
```

**Arguments**

- `roc, smooth.roc, multiclass.roc`
  - a “roc” object from the `roc` function, a “smooth.roc” object from the `smooth` function, or a “multiclass.roc” from the `multiclass.roc` function.
response, predictor

arguments for the \texttt{roc} function.

\texttt{formula, data} a formula (and possibly a data object) of type \texttt{response-predictor} for the \texttt{roc} function.

\texttt{partial.auc} either \texttt{FALSE} (default: consider total area) or a numeric vector of length 2: boundaries of the AUC to consider in [0,1] (or [0,100] if \texttt{percent} is \texttt{TRUE}).

\texttt{partial.auc.focus}

if \texttt{partial.auc} is not \texttt{FALSE} and a partial AUC is computed, specifies if \texttt{partial.auc} specifies the bounds in terms of specificity (default) or sensitivity. Can be shortened to spec/sens or even sp/se. Ignored if \texttt{partial.auc=}FALSE.

\texttt{partial.auc.correct}

logical indicating if the correction of AUC must be applied in order to have a maximal AUC of 1.0 and a non-discriminant AUC of 0.5 whatever the \texttt{partial.auc} defined. Ignored if \texttt{partial.auc=}FALSE. Default: \texttt{FALSE}.

\texttt{allow.invalid.partial.auc.correct}

logical indicating if the correction must return \texttt{NA} (with a \texttt{warning}) when attempting to correct a pAUC below the diagonal. Set to \texttt{TRUE} to return a (probably invalid) corrected AUC. This is useful especially to avoid introducing a bias against low pAUCs in bootstrap operations.

\ldots further arguments passed to or from other methods, especially arguments for \texttt{roc} when calling \texttt{auc.default, auc.formula, auc.smooth roc}. Note that the \texttt{auc} argument of \texttt{roc} is not allowed. Unused in \texttt{auc.roc}.

\textbf{Details}

This function is typically called from \texttt{roc} when \texttt{auc=}TRUE (default). It is also used by \texttt{ci}. When it is called with two vectors (response, predictor) or a formula (response-predictor) arguments, the \texttt{roc} function is called and only the AUC is returned.

By default the total area under the curve is computed, but a partial AUC (pAUC) can be specified with the \texttt{partial.auc} argument. It specifies the bounds of specificity or sensitivity (depending on \texttt{partial.auc.focus}) between which the AUC will be computed. As it specifies specificities or sensitivities, you must adapt it in relation to the 'percent' specification (see details in \texttt{roc}).

\texttt{partial.auc.focus} is ignored if \texttt{partial.auc=}FALSE (default). If a partial AUC is computed, \texttt{partial.auc.focus} specifies if the bounds specified in \texttt{partial.auc} must be interpreted as sensitivity or specificity. Any other value will produce an error. It is recommended to \texttt{plot} the ROC curve with \texttt{auc.polygon=}TRUE in order to make sure the specification is correct.

If a pAUC is defined, it can be standardized (corrected). This correction is controled by the \texttt{partial.auc.correct} argument. If \texttt{partial.auc.correct=}TRUE, the correction by McClish will be applied:

\[
\frac{1 + \frac{\text{auc}-\text{min}}{\text{max}-\text{min}}}{2}
\]

where \texttt{auc} is the uncorrected pAUC computed in the region defined by \texttt{partial.auc}. \texttt{min} is the value of the non-discriminant AUC (with an AUC of 0.5 or 50 in the region and \texttt{max} is the maximum possible AUC in the region. With this correction, the AUC will be 0.5 if non discriminant and 1.0 if maximal, whatever the region defined. This correction is fully compatible with \texttt{percent}. 

Note that this correction is undefined for curves below the diagonal (auc < min). Attempting to correct such an AUC will return NA with a warning.

Value

The numeric AUC value, of class c("auc", "numeric") (or c("multiclass.auc", "numeric") if a “multiclass.roc” was supplied), in fraction of the area or in percent if percent=TRUE, with the following attributes:

- partial.auc: if the AUC is full (FALSE) or partial (and in this case the bounds), as defined in argument.
- partial.auc.focus: only for a partial AUC, if the bound specifies the sensitivity or specificity, as defined in argument.
- partial.auc.correct: only for a partial AUC, was it corrected? As defined in argument.
- percent: whether the AUC is given in percent or fraction.
- roc: the original ROC curve, as a “roc”, “smooth.roc” or “multiclass.roc” object.

Smoothed ROC curves

There is no difference in the computation of the area under a smoothed ROC curve, except for curves smoothed with method="binomial". In this case and only if a full AUC is requested, the classical binormal AUC formula is applied:

\[ auc = \phi \frac{a}{\sqrt{1 + b^2}}. \]

If the ROC curve is smoothed with any other method or if a partial AUC is requested, the empirical AUC described in the previous section is applied.

Multi-class AUCs

With an object of class “multiclass.roc”, a multi-class AUC is computed as an average AUC as defined by Hand and Till (equation 7).

\[ auc = \frac{2}{c(c-1)} \sum aucs \]

with auc all the pairwise roc curves.

References

ci

Compute the confidence interval of a ROC curve

Description

This function computes the confidence interval (CI) of a ROC curve. The of argument controls the type of CI that will be computed. By default, the 95% CI are computed with 2000 stratified bootstrap replicates.

Usage

```R
ci(...)  
## S3 method for class 'roc'
ci(roc, of = c("auc", "thresholds", "sp", "se", "coords"), ...)
## S3 method for class 'smooth.roc'
ci(smooth.roc, of = c("auc", "sp", "se", "coords"), ...)
## S3 method for class 'formula'
ci(formula, data, ...)  
## Default S3 method:
ci(response, predictor, ...)
```

See Also

roc, ci.auc

Examples

```R
data(aSAH)

# Syntax (response, predictor):
auc(aSAH$outcome, aSAH$s100b)

# With a roc object:
roco <- roc(aSAH$outcome, aSAH$s100b)
# Full AUC:
auc(roco)
# Partial AUC:
auc(roco, partial.auc=c(1, .8), partial.auc.focus="se", partial.auc.correct=TRUE)

# Alternatively, you can get the AUC directly from roc():
roc(aSAH$outcome, aSAH$s100b)$auc
roc(aSAH$outcome, aSAH$s100b,  
  partial.auc=c(1, .8), partial.auc.focus="se",  
  partial.auc.correct=TRUE)$auc
```

Arguments

- `roc, smooth.roc` a “roc” object from the `roc` function, or a “smooth.roc” object from the `smooth` function.
- `response, predictor` arguments for the `roc` function.
- `formula, data` a formula (and possibly a data object) of type `response~predictor` for the `roc` function.
- `of` The type of confidence interval. One of “auc”, “thresholds”, “sp”, “se” or “coords”. Note that confidence interval on “thresholds” are not available for smoothed ROC curves.
- `...` further arguments passed to or from other methods, especially `auc`, `roc`, and the specific `ci` functions `ci.auc`, `ci.thresholds`, `ci.sp`, `ci.se` and `ci.coords`.

Details

ci.formula and ci.default are convenience methods that build the ROC curve (with the `roc` function) before calling `ci.roc`. You can pass them arguments for both `roc` and `ci.roc`. Simply use `ci` that will dispatch to the correct method.

This function is typically called from `roc` when `ci=TRUE` (not by default). Depending on the of argument, the specific `ci` functions `ci.auc`, `ci.thresholds`, `ci.sp`, `ci.se` or `ci.coords` are called.

When the ROC curve has an `auc` of 1 (or 100%), the confidence interval will always be null (there is no interval). This is true for both “delong” and “bootstrap” methods that can not properly assess the variance in this case. This result is misleading, as the variance is of course not null. A warning will be displayed to inform of this condition, and of the misleading output.

Value

The return value of the specific `ci` functions `ci.auc`, `ci.thresholds`, `ci.sp`, `ci.se` or `ci.coords`, depending on the of argument.

`roc, auc, ci.auc, ci.thresholds, ci.sp, ci.se, ci.coords`

Examples

data(aSAH)

# Syntax (response, predictor):
`ci(aSAH$outcome, aSAH$s100b)`
ci.auc

Compute the confidence interval of the AUC

Description

This function computes the confidence interval (CI) of an area under the curve (AUC). By default, the 95% CI is computed with 2000 stratified bootstrap replicates.

Usage

# ci.auc(...)  
## S3 method for class 'roc'
ci.auc(roc, conf.level=0.95, method=c("delong", "bootstrap"), boot.n = 2000, boot.stratified = TRUE, reuse.auc=TRUE, progress = getOption("pROCProgress")$name, parallel=FALSE, ...)

## S3 method for class 'smooth.roc'
  ci.auc(smooth.roc, conf.level=0.95, boot.n=2000, boot.stratified=TRUE, reuse.auc=TRUE, progress=getOption("pROCProgress")$name, parallel=FALSE, ...)

## S3 method for class 'auc'
  ci.auc(auc, ...)

## S3 method for class 'formula'
  ci.auc(formula, data, ...)

## Default S3 method:
  ci.auc(response, predictor, ...)
Arguments

roc, smooth.roc

A "roc" object from the roc function, or a "smooth.roc" object from the smooth function.

auc

An "auc" object from the auc function.

response, predictor

Arguments for the roc function.

formula, data

A formula (and possibly a data object) of type response~predictor for the roc function.

cnf.level

The width of the confidence interval as [0,1], never in percent. Default: 0.95, resulting in a 95% CI.

method

The method to use, either "delong" or "bootstrap". The first letter is sufficient. If omitted, the appropriate method is selected as explained in details.

boot.n

boot.stratified

Should the bootstrap be stratified (default, same number of cases/controls in each replicate than in the original sample) or not.

reuse.auc

If TRUE (default) and the "roc" object contains an "auc" field, re-use these specifications for the test. If false, use optional ... arguments to auc. See details.

progress

The name of progress bar to display. Typically "none", "win", "tk" or "text" (see the name argument to create_progress_bar for more information), but a list as returned by create_progress_bar is also accepted. See also the "Progress bars" section of this package’s documentation.

parallel

If TRUE, the bootstrap is processed in parallel, using parallel backend provided by plyr (foreach).

... 

Further arguments passed to or from other methods, especially arguments for roc and roc.test.roc when calling roc.test.default or roc.test.formula. Arguments for auc and txtProgressBar (only char and style) if applicable.

Details

This function computes the CI of an AUC. Two methods are available: "delong" and "bootstrap" with the parameters defined in "roc$sauc" to compute a CI. When it is called with two vectors (response, predictor) or a formula (response~predictor) arguments, the roc function is called to build the ROC curve first.

Default is to use "delong" method except for comparison of partial AUC and smoothed curves, where bootstrap is used. Using "delong" for partial AUC and smoothed ROCs is not supported in pROC (with smoothed ROCs, method is ignored, otherwise for pAUC a warning is produced and "bootstrap" is employed instead).

With method="bootstrap", the function calls auc boot.n times. For more details about the bootstrap, see the Bootstrap section in this package’s documentation.

For smoothed ROC curves, smoothing is performed again at each bootstrap replicate with the parameters originally provided. If a density smoothing was performed with user-provided density.cases or density.controls the bootstrap cannot be performed and an error is issued.
With method="delong", the variance of the AUC is computed as defined by DeLong et al. (1988) using the algorithm by Sun and Xu (2014) and the CI is deduced with \texttt{qnorm}.

**Value**

A numeric vector of length 3 and class “ci.auc”, “ci” and “numeric” (in this order), with the lower bound, the median and the upper bound of the CI, and the following attributes:

- \texttt{conf.level} the width of the CI, in fraction.
- \texttt{method} the method employed.
- \texttt{boot.n} the number of bootstrap replicates.
- \texttt{boot.stratified} whether or not the bootstrapping was stratified.
- \texttt{auc} an object of class “auc” stored for reference about the computed AUC details (partial, percent, ...)

The \texttt{aucs} item is not included in this list since version 1.2 for consistency reasons.

**AUC specification**

The comparison of the CI needs a specification of the AUC. This allows to compute the CI for full or partial AUCs. The specification is defined by:

1. the “auc” field in the “roc” object if \texttt{reuse.auc} is set to \texttt{TRUE} (default). It is naturally inherited from any call to \texttt{roc} and fits most cases.

2. passing the specification to \texttt{auc} with \texttt{...} (arguments \texttt{partial.auc}, \texttt{partial.auc.correct} and \texttt{partial.auc.focus}). In this case, you must ensure either that the \texttt{roc} object do not contain an auc field (if you called \texttt{roc} with \texttt{auc=FALSE}), or set \texttt{reuse.auc=FALSE}.

If \texttt{reuse.auc=FALSE} the \texttt{auc} function will always be called with \texttt{...} to determine the specification, even if the “roc” object do contain an auc field.

As well if the “roc” object do not contain an auc field, the \texttt{auc} function will always be called with \texttt{...} to determine the specification.

Warning: if the roc object passed to \texttt{ci} contains an auc field and \texttt{reuse.auc=TRUE}, \texttt{auc} is not called and arguments such as \texttt{partial.auc} are silently ignored.

**Warnings**

If method="delong" and the AUC specification specifies a partial AUC, the warning “Using DeLong’s test for partial AUC is not supported. Using bootstrap test instead.” is issued. The method argument is ignored and “bootstrap” is used instead.

If \texttt{boot.stratified=FALSE} and the sample has a large imbalance between cases and controls, it could happen that one or more of the replicates contains no case or control observation, or that there are not enough points for smoothing, producing a \texttt{NA} area. The warning “NA value(s) produced during bootstrap were ignored.” will be issued and the observation will be ignored. If you have a large imbalance in your sample, it could be safer to keep \texttt{boot.stratified=TRUE}.
Errors

If density.cases and density.controls were provided for smoothing, the error “Cannot compute the statistic on ROC curves smoothed with density.controls and density.cases.” is issued.

roc, auc, ci

CRAN package plyr, employed in this function.

Examples

data(aSAH)

# Syntax (response, predictor):
ci.auc(aSAH$outcome, aSAH$s100b)

# With a roc object:
roccobj <- roc(aSAH$outcome, aSAH$s100b)
# default values
ci.auc(roccobj)
ci(roccobj)
ci(auc(roccobj))
ci(roccobj$auc)
ci(roccobj$auc, method="delong")

# Partial AUC and customized bootstrap:
ci.auc(aSAH$outcome, aSAH$s100b,
    boot.n=100, conf.level=0.9, stratified=FALSE, partial.auc=c(1,.8),
    partial.auc.focus="se", partial.auc.correct=TRUE)

# Note that the following will NOT give a CI of the partial AUC:
ci.auc(roccobj, boot.n=500, conf.level=0.9, stratified=FALSE,
ci.coords

**Description**

This function computes the confidence interval (CI) of the coordinates of a ROC curves with the coords function. By default, the 95% CI are computed with 2000 stratified bootstrap replicates.

**Usage**

```r
# S3 method for class 'roc'
_ci.coords(rc, x, input=c("threshold", "specificity", "sensitivity"),
ret=c("threshold", "specificity", "sensitivity"),
best.method=c("youden", "closest.topleft"), best.weights=c(1, .5),
best.policy = c("stop", "omit", "random"),
conf.level=0.95, boot.n=2000,
boot.stratified=TRUE,
progress=getOption("pROCPProgress")$name, ...)
# S3 method for class 'formula'
_ci.coords(formula, data, ...)
# S3 method for class 'smooth.roc'
_ci.coords(smooth.roc, x, input=c("specificity", "sensitivity"), ret=c("specificity", "sensitivity"),
best.method=c("youden", "closest.topleft"), best.weights=c(1, .5),
best.policy = c("stop", "omit", "random"),
```
ci.coords

conf.level=0.95, boot.n=2000,
boot.stratified=TRUE,
progress=getOption("pROCProgress")$name, ...
## Default S3 method:
ci.coords(response, predictor, ...)

Arguments

roc, smooth.roc
a “roc” object from the roc function, or a “smooth.roc” object from the smooth function.

response, predictor
arguments for the roc function.

formula, data
a formula (and possibly a data object) of type response~predictor for the roc function.

x, input, ret, best.method, best.weights
Arguments passed to coords. See there for more details. The only difference is on the x argument which cannot be “all” or “local maximas”.

best.policy
The policy follow when multiple “best” thresholds are returned by coords. “stop” will abort the processing with stop (default), “omit” will ignore the sample (as in NA) and “random” will select one of the threshold randomly.

conf.level
the width of the confidence interval as [0,1], never in percent. Default: 0.95, resulting in a 95% CI.

boot.n
the number of bootstrap replicates. Default: 2000.

boot.stratified
should the bootstrap be stratified (default, same number of cases/controls in each replicate than in the original sample) or not.

progress
the name of progress bar to display. Typically “none”, “win”, “tk” or “text” (see the name argument to create_progress_bar for more information), but a list as returned by create_progress_bar is also accepted. See also the “Progress bars” section of this package’s documentation.

...

further arguments passed to or from other methods, especially arguments for roc and ci.coords.roc when calling ci.coords.default or ci.coords.formula. Arguments for txtProgressBar (only char and style) if applicable.

Details
ci.coords.formula and ci.coords.default are convenience methods that build the ROC curve (with the roc function) before calling ci.coords.roc. You can pass them arguments for both roc and ci.coords.roc. Simply use ci.coords that will dispatch to the correct method.

This function creates boot.n bootstrap replicate of the ROC curve, and evaluates the coordinates specified by the x, input, ret, best.method and best.weights arguments. Then it computes the confidence interval as the percentiles given by conf.level.

For more details about the bootstrap, see the Bootstrap section in this package’s documentation.
Value

A matrix of class “ci.coords”, “ci” and “matrix” (in this order), with the confidence intervals of the CI. The matrix has 3 columns (lower bound, median and upper bound) and as many rows as \( x \times \text{ret} \) were requested. Rows are sorted by \( x \) and then by \( \text{ret} \) and named as “input x: return”.

Additionally, the list has the following attributes:

- `conf.level`: the width of the CI, in fraction.
- `boot.n`: the number of bootstrap replicates.
- `boot.stratified`: whether or not the bootstrapping was stratified.
- `roc`: the object of class “roc” that was used to compute the CI.

Warnings

If `boot.stratified` is FALSE and the sample has a large imbalance between cases and controls, it could happen that one or more of the replicates contains no case or control observation, producing a NA area. The warning “NA value(s) produced during bootstrap were ignored.” will be issued and the observation will be ignored. If you have a large imbalance in your sample, it could be safer to keep `boot.stratified`=TRUE.

This warning will also be displayed if you chose `best.policy = "omit"` and a ROC curve with multiple “best” threshold was generated during at least one of the replicates.

### ci.se

#### Compute the confidence interval of sensitivities at given specificities

**Description**

This function computes the confidence interval (CI) of the sensitivity at the given specificity points. By default, the 95% CI are computed with 2000 stratified bootstrap replicates.

**Usage**

```
# ci.se(...)
## S3 method for class 'roc'
ci.se(roc, specificities = seq(0, 1, .1) * ifelse(roc$percent, 100, 1), conf.level=.95, boot.n=2000, boot.stratified=TRUE, progress=getOption("pROCProcess")$name, parallel=FALSE, ...)
## S3 method for class 'smooth.roc'
ci.se(smooth.roc, specificities = seq(0, 1, .1) * ifelse(smooth.roc$percent, 100, 1), conf.level=.95, boot.n=2000, boot.stratified=TRUE, progress=getOption("pROCProcess")$name, parallel=FALSE, ...)
## S3 method for class 'formula'
ci.se(formula, data, ...)  
## Default S3 method:
ci.se(response, predictor, ...)
```

**Arguments**

- `roc, smooth.roc`
  
  a “roc” object from the **roc** function, or a “smooth.roc” object from the **smooth** function.
response, predictor

arguments for the roc function.

formula, data

a formula (and possibly a data object) of type response-predictor for the roc function.

specificities

on which specificities to evaluate the CI.

conf.level

the width of the confidence interval as [0,1], never in percent. Default: 0.95, resulting in a 95% CI.

boot.n

the number of bootstrap replicates. Default: 2000.

boot.stratified

should the bootstrap be stratified (default, same number of cases/controls in each replicate than in the original sample) or not.

progress

the name of progress bar to display. Typically “none”, “win”, “tk” or “text” (see the name argument to create_progress_bar for more information), but a list as returned by create_progress_bar is also accepted. See also the “Progress bars” section of this package’s documentation.

parallel

if TRUE, the bootstrap is processed in parallel, using parallel backend provided by plyr (foreach).

...

further arguments passed to or from other methods, especially arguments for roc and ci.se.roc when calling ci.se.default or ci.se.formula. Arguments for txtProgressBar (only char and style) if applicable.

Details

ci.se.formula and ci.se.default are convenience methods that build the ROC curve (with the roc function) before calling ci.se.roc. You can pass them arguments for both roc and ci.se.roc. Simply use ci.se that will dispatch to the correct method.

The ci.se.roc function creates boot.n bootstrap replicate of the ROC curve, and evaluates the sensitivity at specificities given by the specificities argument. Then it computes the confidence interval as the percentiles given by conf.level.

For more details about the bootstrap, see the Bootstrap section in this package’s documentation.

For smoothed ROC curves, smoothing is performed again at each bootstrap replicate with the parameters originally provided. If a density smoothing was performed with user-provided density.cases or density.controls the bootstrap cannot be performed and an error is issued.

Value

A matrix of class “ci.se”, “ci” and “matrix” (in this order) containing the given sensitivities. Row (names) are the specificities, the first column the lower bound, the 2nd column the median and the 3rd column the upper bound.

Additionally, the list has the following attributes:

conf.level

the width of the CI, in fraction.

boot.n

the number of bootstrap replicates.

boot.stratified

whether or not the bootstrapping was stratified.

specificities

the specificities as given in argument.

roc

the object of class “roc” that was used to compute the CI.
Warnings

If boot.stratified=FALSE and the sample has a large imbalance between cases and controls, it could happen that one or more of the replicates contains no case or control observation, or that there are not enough points for smoothing, producing a NA area. The warning “NA value(s) produced during bootstrap were ignored.” will be issued and the observation will be ignored. If you have a large imbalance in your sample, it could be safer to keep boot.stratified=TRUE.

Errors

If density.cases and density.controls were provided for smoothing, the error “Cannot compute the statistic on ROC curves smoothed with density.controls and density.cases.” is issued.

ci.se(rocobj, boot.n=100)

# Customized bootstrap and specific specificities:
ci.se(rocobj, c(.95, .9, .85), boot.n=500, conf.level=0.9, stratified=FALSE)

## End(Not run)

# Alternatively, you can get the CI directly from roc():
rocobj <- roc(aSAH$outcome,
Description

This function computes the confidence interval (CI) of the specificity at the given sensitivity points. By default, the 95% CI are computed with 2000 stratified bootstrap replicates.

Usage

```r
# ci.sp(...) # S3 method for class 'roc'
ci.sp(roc, sensitivities = seq(0, 1, .1) * ifelse(roc$percent, 100, 1), conf.level=0.95, boot.n=2000, boot.stratified=TRUE, progress=getOption("pROCPreadless")$name, parallel=FALSE, ...)
# S3 method for class 'smooth.roc'
ci.sp(smooth.roc, sensitivities = seq(0, 1, .1) * ifelse(smooth.roc$percent, 100, 1), conf.level=0.95, boot.n=2000, boot.stratified=TRUE, progress=getOption("pROCPreadless")$name, parallel=FALSE, ...)
# S3 method for class 'formula'
# Default S3 method:
# ci.sp(formula, data, ...)
```

Arguments

- `roc`, `smooth.roc`:
  - a “roc” object from the `roc` function, or a “smooth.roc” object from the `smooth` function.

- `response`, `predictor`:
  - arguments for the `roc` function.

- `formula`, `data`:
  - a formula (and possibly a data object) of type response-predictor for the `roc` function.
ci.sp

sensitivities on which sensitivities to evaluate the CI.
conf.level the width of the confidence interval as [0,1], never in percent. Default: 0.95, resulting in a 95% CI.
boot.n the number of bootstrap replicates. Default: 2000.
boot.stratified should the bootstrap be stratified (default, same number of cases/controls in each replicate than in the original sample) or not.

## End(Not run)
```

---

**ci.thresholds**

*Compute the confidence interval of thresholds*

**Description**

This function computes the confidence interval (CI) of the sensitivity and specificity of the thresholds given in argument. By default, the 95% CI are computed with 2000 stratified bootstrap replicates.

**Usage**

```r
# ci.thresholds(...)  
## S3 method for class 'roc'  
ci.thresholds(roc, conf.level=0.95, boot.n=2000,  
boot.stratified=TRUE, thresholds = "local maximas",  
progress=getOption("pROCProgress")$name, parallel=FALSE, ...)  
## S3 method for class 'formula'  
 ci.thresholds(formula, data, ...)  
## S3 method for class 'smooth.roc'  
 ci.thresholds(smooth.roc, ...)  
## Default S3 method:  
 ci.thresholds(response, predictor, ...)
```

**Arguments**

- `roc` a “roc” object from the `roc` function.
- `smooth.roc` not available for smoothed ROC curves, available only to catch the error and provide a clear error message.
- `response, predictor` arguments for the `roc` function.
- `formula, data` a formula (and possibly a data object) of type response-predictor for the `roc` function.
ci.thresholds

conf.level  the width of the confidence interval as [0,1], never in percent. Default: 0.95, resulting in a 95% CI.

boot.n  the number of bootstrap replicates. Default: 2000.

boot.stratified  should the bootstrap be stratified (default, same number of cases/controls in each replicate than in the original sample) or not.

thresholds  on which thresholds to evaluate the CI. Either the numeric values of the thresholds, a logical vector (as index of roc$thresholds) or a character “all”, “local maximas” or “best” that will be used to determine the threshold(s) on the supplied curve with coords (not on the resampled curves).

progress  the name of progress bar to display. Typically “none”, “win”, “tk” or “text” (see the name argument to create_progress_bar for more information), but a list as returned by create_progress_bar is also accepted. See also the “Progress bars” section of this package’s documentation.

parallel  if TRUE, the bootstrap is processed in parallel, using parallel backend provided by plyr (foreach).

...  further arguments passed to or from other methods, especially arguments for roc and ci.thresholds.roc when calling ci.thresholds.default or ci.thresholds.formula. Arguments for txtProgressBar (only char and style) if applicable. Arguments best.method and best.weights to coords.

Details

ci.thresholds.formula and ci.thresholds.default are convenience methods that build the ROC curve (with the roc function) before calling ci.thresholds.roc. You can pass them arguments for both roc and ci.thresholds.roc. Simply use ci.thresholds that will dispatch to the correct method.

This function creates boot.n bootstrap replicate of the ROC curve, and evaluates the sensitivity and specificity at thresholds given by the thresholds argument. Then it computes the confidence interval as the percentiles given by conf.level.

A threshold given as a logical vector or character is converted to the corresponding numeric vector once using the supplied ROC curve, and not at each bootstrap iteration. See ci.coords for the latter behaviour.

For more details about the bootstrap, see the Bootstrap section in this package’s documentation.

Value

A list of length 2 and class “ci.thresholds”, “ci” and “list” (in this order), with the confidence intervals of the CI and the following items:

specificity  a matrix of CI for the specificity. Row (names) are the thresholds, the first column the lower bound, the 2nd column the median and the 3rd column the upper bound.

sensitivity  same than specificity.

Additionally, the list has the following attributes:
ci.thresholds

    conf.level  the width of the CI, in fraction.
    boot.n      the number of bootstrap replicates.
    boot.stratified whether or not the bootstrapping was stratified.
    thresholds  the thresholds, as given in argument.
    roc         the object of class “roc” that was used to compute the CI.

Warnings

If boot.stratified=FALSE and the sample has a large imbalance between cases and controls, it could happen that one or more of the replicates contains no case or control observation, producing a NA area. The warning “NA value(s) produced during bootstrap were ignored.” will be issued and the observation will be ignored. If you have a large imbalance in your sample, it could be safer to keep boot.stratified=TRUE.

## coords

### Coordinates of a ROC curve

### Description

This function returns the coordinates of the ROC curve at the specified point.

### Usage

```r
coords(...)
```

### Arguments

- **roc, smooth.roc**
  - a “roc” object from the `roc` function, or a “smooth.roc” object from the `smooth` function.
- **x**
  - the coordinates to look for. Numeric (if so, their meaning is defined by the `input` argument) or one of “all” (all the points of the ROC curve), “local maximas” (the local maximas of the ROC curve) or “best” (the point with the best sum of sensitivity and specificity).
- **input**
  - If `x` is numeric, the kind of input coordinate (x). One of “threshold”, “specificity” or “sensitivity”. Can be shortenend (for example to “thr”, “sens” and “spec”, or even to “t”, “se” and “sp”). Note that “threshold” is not allowed in `coords.smooth.roc`, and that the argument is ignored when `x` is a character.
The coordinates to return. One or more of “threshold”, “specificity”, “sensitivity”, “accuracy”, “tn” (true negative count), “tp” (true positive count), “fn” (false negative count), “fp” (false positive count), “npv” (negative predictive value), “ppv” (positive predictive value), “precision”, “recall”. “1-specificity”, “1-sensitivity”, “1-accuracy”, “1-npv” and “1-ppv” are recognized as well, and must be used verbatim in ROC curves with percent=TRUE (for instance “100-ppv” is never accepted). Values can be shortenend (for example to “thr”, “sens” and “spec”, or even to “se”, “sp” or “1-np”). Note that “threshold” is not allowed in coords.smooth.roc. In addition, “npe” is replaced by “1-npv” and “ppe” by “1-ppv” (but they cannot be shortened).

If the returned object must be a list. If FALSE (default), a named numeric vector is returned.

If TRUE the result is coerced to the lowest possible dimension, as per Extract. With FALSE if x is of length 1, the object returned will have the same format than if x was of length > 1.

if x="best", the method to determine the best threshold. See details in the ‘Best thresholds’ section.

if x="best", the weights to determine the best threshold. See details in the ‘Best thresholds’ section.

further arguments passed to or from other methods. Ignored.

This function takes a “roc” or “smooth.roc” object as first argument, on which the coordinates will be determined. The coordinates are defined by the x and input arguments. “threshold” coordinates cannot be determined in a smoothed ROC.

If input="threshold", the coordinates for the threshold are reported, even if the exact threshold do not define the ROC curve. The following convenience characters are allowed: “all”, “local maximas” and “best”. They will return all the thresholds, only the thresholds defining local maximas (upper angles of the ROC curve), or only the threshold(s) corresponding to the best sum of sensitivity + specificity respectively. Note that “best” can return more than one threshold. If x is a character, the coordinates are limited to the thresholds within the partial AUC if it has been defined, and not necessarily to the whole curve.

For input="specificity" and input="sensitivity", the function checks if the specificity or sensitivity is one of the points of the ROC curve (in roc$sensitivities or roc$specificities). More than one point may match (in step curves), then only the upper-left-most point coordinates are returned. Otherwise, the specificity and specificity of the point is interpolated and NA is returned as threshold.

The coords function in this package is a generic, but it might be superseded by functions in other packages such as colorspace or spatstat if they are loaded after pROC. In this case, call the coords.roc or coords.smooth.roc functions directly.

Depending on the length of x and as.list argument.

length(x) == 1 length(x) > 1 or drop == FALSE
as.list=TRUE a list of the length of, in the order of, and named after, ret.
as.list=FALSE a numeric vector of the length of, in the order of, and named after, ret.
a numeric matrix with one row for each ret.

In all cases if input="specificity" or input="sensitivity" and interpolation was required, threshold is returned as NA.

Note that if giving a character as x ("all", "local maximas" or "best"), you cannot predict the dimension of the return value unless drop=FALSE. Even "best" may return more than one value (for example if the ROC curve is below the identity line, both extreme points).

coords may also return NULL when there a partial area is defined but no point of the ROC curve falls within the region.

Best thresholds

If x="best", the best.method argument controls how the optimal threshold is determined.

“youden” Youden’s J statistic (Youden, 1950) is employed. The optimal cut-off is the threshold that maximizes the distance to the identity (diagonal) line. Can be shortened to “y”.

The optimality criterion is:

\[ \text{max}(\text{sensitivities} + \text{specificities}) \]

“closest.topleft” The optimal threshold is the point closest to the top-left part of the plot with perfect sensitivity or specificity. Can be shortened to “c” or “t”.

The optimality criterion is:

\[ \text{min}((1 - \text{sensitivities})^2 + (1 - \text{specificities})^2) \]

In addition, weights can be supplied if false positive and false negative predictions are not equivalent: a numeric vector of length 2 to the best.weights argument. The elements define

1. the relative cost of of a false negative classification (as compared with a false positive classification)
2. the prevalence, or the proportion of cases in the population (\( \frac{n_{\text{cases}}}{n_{\text{controls}}+n_{\text{cases}}} \)).

The optimality criteria are modified as proposed by Perkins and Schisterman:

“youden”

\[ \text{max}(\text{sensitivities} + r \cdot \text{specificities}) \]

“closest.topleft”

\[ \text{min}((1 - \text{sensitivities})^2 + r \cdot (1 - \text{specificities})^2) \]

with

\[ r = \frac{1 - \text{prevalence}}{\text{cost} \times \text{prevalence}} \]

By default, prevalence is 0.5 and cost is 1 so that no weight is applied in effect.

Note that several thresholds might be equally optimal.

coords(smooth(rocobj), 90, "specificity", drop=FALSE)
coords(smooth(rocobj), 90, "specificity", as.list=TRUE)
coords(smooth(rocobj), 90, "specificity", as.list=TRUE, drop=FALSE)

# Get the sensitivities for all thresholds
sensitivities <- coords(rocobj, rocobj$thresholds, "thr", "se")
# This is equivalent to taking sensitivities from rocobj directly
stopifnot(all.equal(as.vector(rocobj$sensitivities), as.vector(sensitivities)))
# You could also write:
sensitivities <- coords(rocobj, "all", ret="se")
stopifnot(all.equal(as.vector(rocobj$sensitivities), as.vector(sensitivities)))
# Get the best threshold
covs <- coords(rocobj, "b", ret="t")

# Get the best threshold according to different methods
rocobj <- roc(aSAH$outcome, aSAH$ndka, percent=TRUE)
covs <- coords(rocobj, "b", ret="t", best.method="youden") # default
covs <- coords(rocobj, "b", ret="t", best.method="closest.topleft")
# and with different weights
covs <- coords(rocobj, "b", ret="t", best.method="youden", best.weights=c(50, 0.2))
covs <- coords(rocobj, "b", ret="t", best.method="closest.topleft", best.weights=c(5, 0.2))
# and plot them
plot(rocobj, print.thres="best", print.thres.best.method="youden")
plot(rocobj, print.thres="best", print.thres.best.method="closest.topleft")
plot(rocobj, print.thres="best", print.thres.best.method="youden", print.thres.best.weights=c(50, 0.2))
plot(rocobj, print.thres="best", print.thres.best.method="closest.topleft", print.thres.best.weights=c(5, 0.2))

# Return more values:

# You can use coords to plot for instance a sensitivity + specificity vs. cut-off diagram
plot(specificity + sensitivity ~ threshold, t(coords(rocobj, seq(0, 1, 0.01))), type = "l")

# Plot the Precision-Recall curve
plot(precision ~ recall, t(coords(rocobj, "all", ret = c("recall", "precision"))), type="l")

---

cov.roc

Covariance of two paired ROC curves

Description

This function computes the covariance between the AUC of two correlated (or paired) ROC curves.
cov.roc

Usage

```r
cov(...)
## Default S3 method:
cov(...)  
## S3 method for class 'auc'
cov(roc1, roc2, ...)
## S3 method for class 'smooth.roc'
cov(roc1, roc2, ...)
## S3 method for class 'roc'
cov(roc1, roc2, method=c("delong", "bootstrap", "obuchowski"),
    reuse.auc=TRUE, boot.n=2000, boot.stratified=TRUE, boot.return=FALSE,
    progress=getOption("pROCProgress")$name, parallel=FALSE, ...)
```

Arguments

- `roc1`, `roc2`: the two ROC curves on which to compute the covariance. Either “roc”, “auc” or “smooth.roc” objects (types can be mixed as long as the original ROC curve are paired).

- `method`: the method to use, either “delong” or “bootstrap”. The first letter is sufficient. If omitted, the appropriate method is selected as explained in details.

- `reuse.auc`: if `TRUE` (default) and the “roc” objects contain an “auc” field, re-use these specifications for the test. See details.

- `boot.stratified`: for method="bootstrap" only: should the bootstrap be stratified (same number of cases/controls in each replicate than in the original sample) or not. Default: `TRUE`.

- `boot.return`: if `TRUE` and method="bootstrap", also return the bootstrapped values. See the “Value” section for more details.

- `progress`: the name of progress bar to display. Typically “none”, “win”, “tk” or “text” (see the name argument to `create_progress_bar` for more information), but a list as returned by `create_progress_bar` is also accepted. See also the “Progress bars” section of this package’s documentation.

- `parallel`: if `TRUE`, the bootstrap is processed in parallel, using parallel backend provided by plyr (foreach).

- `...`: further arguments passed to or from other methods, especially arguments for cov.roc when calling cov, cov.auc or cov.smooth.roc. Arguments for auc (if reuse.auc=FALSE) and txtProgressBar (only char and style) if applicable.

Details

This function computes the covariance between the AUC of two correlated (or paired, according to the detection of are.paired) ROC curves. It is typically called with the two roc objects of interest. Two methods are available: “delong” and “bootstrap” (see “Computational details” section below).
The default is to use “delong” method except with partial AUC and smoothed curves where “bootstrap” is employed. Using “delong” for partial AUC and smoothed ROCs is not supported (a warning is produced and “bootstrap” is employed instead).

For smoothed ROC curves, smoothing is performed again at each bootstrap replicate with the parameters originally provided. If a density smoothing was performed with user-provided density.cases or density.controls the bootstrap cannot be performed and an error is issued.

cov.default forces the usage of the cov function in the stats package, so that other code relying on cov should continue to function normally.

Value
The numeric value of the covariance.

If boot.return=TRUE and method="bootstrap", an attribute resampled.values is set with the resampled (bootstrapped) values. It contains a matrix with the columns representing the two ROC curves, and the rows the boot.n bootstrap replicates.

AUC specification
To compute the covariance of the AUC of the ROC curves, cov needs a specification of the AUC. The specification is defined by:

1. the “auc” field in the “roc” objects if reuse.auc is set to TRUE (default)
2. passing the specification to auc with ...(arguments partial.auc, partial.auc.correct and partial.auc.focus). In this case, you must ensure either that the roc object do not contain an auc field (if you called roc with auc=FALSE), or set reuse.auc=FALSE.

If reuse.auc=FALSE the auc function will always be called with ... to determine the specification, even if the “roc” objects do contain an auc field.

As well if the “roc” objects do not contain an auc field, the auc function will always be called with ... to determine the specification.

Warning: if the roc object passed to roc.test contains an auc field and reuse.auc=TRUE, auc is not called and arguments such as partial.auc are silently ignored.

Computation details
With method="bootstrap", the processing is done as follow:

1. boot.n bootstrap replicates are drawn from the data. If boot.stratified is TRUE, each replicate contains exactly the same number of controls and cases than the original sample, otherwise if FALSE the numbers can vary.
2. for each bootstrap replicate, the AUC of the two ROC curves are computed and stored.
3. the variance (as per var.roc) of the resampled AUCs and their covariance are assessed in a single bootstrap pass.
4. The following formula is used to compute the final covariance: 
   \[ \text{Var}[AUC1] + \text{Var}[AUC2] - 2 \text{cov}[AUC1, AUC2] \]
With method="delong", the processing is done as described in Hanley and Hajian-Tilaki (1997) using the algorithm by Sun and Xu (2014).

With method=“obuchowski”, the processing is done as described in Obuchowski and McClish (1997), Table 1 and Equation 5, p. 1531. The computation of \( g \) for partial area under the ROC curve is modified as:

\[
expr1 \times (2 \times \pi \times expr2)^{-1} \times (-expr4) - A \times B \times expr1 \times (2 \times \pi \times expr2^2)^{-1/2} \times expr3
\]

Binormality assumption

The “obuchowski” method makes the assumption that the data is binormal. If the data shows a deviation from this assumption, it might help to normalize the data first (that is, before calling \textit{roc}), for example with quantile normalization:

\[
\text{norm} = \text{qnorm}(\text{rank}(x)/(\text{length}(x)+1)) \\
\text{cov} = \text{roc}(\text{response, norm, ...})
\]

“delong” and “bootstrap” methods make no such assumption.

Errors

If \textit{density.cases} and \textit{density.controls} were provided for smoothing, the error “Cannot compute the covariance on ROC curves smoothed with density.controls and density.cases.” is issued.

Warnings

If “auc” specifications are different in both \textit{roc} objects, the warning “Different AUC specifications in the ROC curves. Enforcing the inconsistency, but unexpected results may be produced.” is issued. Unexpected results may be produced.

If one or both ROC curves are “smooth roc” objects with different smoothing specifications, the warning “Different smoothing parameters in the ROC curves. Enforcing the inconsistency, but unexpected results may be produced.” is issued. This warning can be benign, especially if ROC curves were generated with \textit{ roc(..., smooth=TRUE) } with different arguments to other functions (such as plot), or if you really want to compare two ROC curves smoothed differently.

If method=“delong” and the AUC specification specifies a partial AUC, the warning “Using DeLong for partial AUC is not supported. Using bootstrap test instead.” is issued. The method argument is ignored and “bootstrap” is used instead.

If method=“delong” and the ROC curve is smoothed, the warning “Using DeLong for smoothed ROCs is not supported. Using bootstrap instead.” is issued. The method argument is ignored and “bootstrap” is used instead.

DeLong ignores the direction of the ROC curve so that if two ROC curves have a different direction, the warning ““DeLong should not be applied to ROC curves with a different direction.”” is printed. However, the spurious computation is enforced.

If boot.stratified=FALSE and the sample has a large imbalance between cases and controls, it could happen that one or more of the replicates contains no case or control observation, or that there
are not enough points for smoothing, producing a NA area. The warning “NA value(s) produced during bootstrap were ignored.” will be issued and the observation will be ignored. If you have a large imbalance in your sample, it could be safer to keep boot.stratified=TRUE.

When both ROC curves have an auc of 1 (or 100%), their covariance will always be null. This is true for both “delong” and “bootstrap” and methods. This result is misleading, as the covariance is of course not null. A warning will be displayed to inform of this condition, and of the misleading output.

Messages

The covariance can only be computed on paired data. This assumption is enforced by are.paired. If the ROC curves are not paired, the covariance is 0 and the message “ROC curves are unpaired.” is printed. If your ROC curves are paired, make sure they fit are.paired criteria.

**ggroc**

*Plot a ROC curve with ggplot2 (Experimental)*

**Description**

This function plots a ROC curve with ggplot2.

**Usage**

```
## S3 method for class 'roc'
ggroc(data, ...)
## S3 method for class 'list'
ggroc(data, aes = c("colour", "alpha", "linetype", "size"), ...)
```

**Arguments**

- `data`  
  a roc object from the `roc` function, or a list of roc objects.
- `aes`  
  the name of the aesthetics for `geom_line` to map to the different ROC curves supplied
- `...`  
  additional aesthetics for `geom_line` to set: alpha, colour, linetype and size.

**Details**

This function initializes a ggplot object from a ROC curve (or multiple if a list is passed). It returns the ggplot with a line layer on it. You can print it directly or add your own layers and theme elements.

This function is experimental and may change in the future. Please report bugs and feedback on the GitHub issue tracker.

**See Also**

Examples

# Create a basic roc object
data(aSAH)
rocobj <- roc(aSAH$outcome, aSAH$s100b)
rocobj2 <- roc(aSAH$outcome, aSAH$wfns)

library(ggplot2)
g <- ggroc(rocobj)
g
# with additional aesthetics:
ggroc(rocobj, alpha = 0.5, colour = "red", linetype = 2, size = 2)

# You can then your own theme, etc.
g + theme_minimal() + ggtitle("My ROC curve")

# Multiple curves:
g2 <- ggroc(list(s100b=rocobj, wfns=rocobj2))
g2
# with additional aesthetics:
g2 <- ggroc(list(s100b=rocobj, wfns=rocobj2), linetype=2)
ggroc(list(s100b=rocobj, wfns=rocobj2), aes("linetype", color="red"))

---

groupGeneric pROC Group Generic Functions

Description

Redefine base groupGeneric functions to handle auc and ci objects properly on operations and mathematical operations. Attributes are dropped so that the AUC/CI behaves as a numeric value/matrix, respectively. In the case of AUC, all attributes are dropped, while in CI only the CI-specific attributes are, keeping those necessary for the matrices.

Usage

Math(x, ...)
Ops(e1, e2)

Arguments

x, e1, e2 auc objects, or mixed numerics and auc objects.
...

See Also

groupGeneric, auc
Examples

data(aSAH)

# Create a roc object:
aucobj1 <- auc(roc(aSAH$outcome, aSAH$s100b))
aucobj2 <- auc(roc(aSAH$outcome, aSAH$wfns))

# Math
sqrt(aucobj1)
round(aucobj2, digits=1)

# Ops
aucobj1 * 2
2 * aucobj2
aucobj1 + aucobj2

# With CI
ciaucobj <- ci(aucobj1)
ciaucobj * 2
sqrt(ciaucobj)

---

has.partial.auc  

Does the ROC curve have a partial AUC?

Description

This function determines if the ROC curve has a partial AUC.

Usage

has.partial.auc(roc)
## S3 method for class 'auc'
has.partial.auc(roc)
## S3 method for class 'smooth.roc'
has.partial.auc(roc)
## S3 method for class 'roc'
has.partial.auc(roc)

Arguments

roc  
the ROC curve to check.

Value

TRUE if the AUC is a partial AUC, FALSE otherwise.
If the AUC is not defined (i.e. if roc was called with AUC=FALSE), returns NULL.
lines.roc

auc

Examples

data(aSAH)

# Full AUC
roc1 <- roc(aSAH$outcome, aSAH$s100b)
has.partial.auc(roc1)
has.partial.auc(auc(roc1))
has.partial.auc(smooth(roc1))

# Partial AUC
roc2 <- roc(aSAH$outcome, aSAH$s100b, partial.auc = c(1, 0.9))
has.partial.auc(roc2)
has.partial.auc(smooth(roc2))

# No AUC
roc3 <- roc(aSAH$outcome, aSAH$s100b, auc = FALSE)
has.partial.auc(roc3)

lines.roc

Add a ROC line to a ROC plot

Description

This convenience function adds a ROC line to a ROC curve.

Usage

## S3 method for class 'roc'
lines(x, ...)
## S3 method for class 'smooth.roc'
lines(x, ...)
## S3 method for class 'roc'
lines.roc(x, lwd=2, ...)
## S3 method for class 'formula'
lines.roc(x, data, ...)
## Default S3 method:
lines.roc(x, predictor, ...)
## S3 method for class 'smooth.roc'
lines.roc(x, ...)
Arguments

- `x`: a `roc` object from the `roc` function (for `plot.roc.roc`), a formula (for `plot.roc.formula`) or a response vector (for `plot.roc.default`).
- `predictor`, `data`: arguments for the `roc` function.
- `lwd`: line width (see `par`).
- `...`: graphical parameters for `lines`, and especially `type` (see `plot.default`) and arguments for `par` such as `col` (color), `lty` (line type) or line characteristics `lend`, `ljoin` and `lmitre`.

Value

This function returns a list of class “roc” invisibly. See `roc` for more details.

See Also

`roc`, `plot.roc`

Examples

data(aSAH)

rocobj <- plot.roc(aSAH$outcome, aSAH$s100b, type="n")
lines(rocobj, type="b", pch=21, col="blue", bg="grey")

# Without using 'lines':
rocobj <- plot.roc(aSAH$outcome, aSAH$s100b, type="b", pch=21, col="blue", bg="grey")

---

### multiclass.roc

**Multi-class AUC**

**Description**

This function builds multiple ROC curve to compute the multi-class AUC as defined by Hand and Till.

**Usage**

```r
multiclass.roc(...)  
## S3 method for class 'formula'
multiclass.roc(formula, data, ...)  
## Default S3 method:
multiclass.roc(response, predictor, 
levels=base::levels(as.factor(response)), 
percent=FALSE, ...)
```
Arguments

response  a factor, numeric or character vector of responses, typically encoded with 0 (controls) and 1 (cases), as in `roc`.
predictor  a numeric vector, containing the value of each observation, as in `roc`.
formula   a formula of the type `response~predictor`.
data      a matrix or data.frame containing the variables in the formula. See `model.frame` for more details.
levels    the value of the response for controls and cases respectively. In contrast with the `levels` argument to `roc`, all the levels are used and combined to compute the multiclass AUC.
percent   if the sensitivities, specificities and AUC must be given in percent (`TRUE`) or in fraction (`FALSE`, default).
...       further arguments passed to `roc`.

Details

This function performs multiclass AUC as defined by Hand and Till (2001). A multiclass AUC is a mean of `auc` and cannot be plotted.

This function has been much less tested than the rest of the package and is more subject to bugs. Please report them if you find one. Confidence intervals and comparison tests are not implemented yet.

Value

A list of class “multiclass.roc” with the following fields:

- `auc` if called with `auc=TRUE`, a numeric of class “auc” as defined in `auc`. Note that this is not the standard AUC but the multi-class AUC as defined by Hand and Till.
- `ci` if called with `ci=TRUE`, a numeric of class “ci” as defined in `ci`.
- `response` the response vector as passed in argument. If NA values were removed, a `na.action` attribute similar to `na.omit` stores the row numbers.
- `predictor` the predictor vector as passed in argument. If NA values were removed, a `na.action` attribute similar to `na.omit` stores the row numbers.
- `levels` the levels of the response as defined in argument.
- `percent` if the sensitivities, specificities and AUC are reported in percent, as defined in argument.
- `call` how the function was called. See `match.call` for more details.

Warnings

If `response` is an ordered factor and one of the levels specified in `levels` is missing, a warning is issued and the level is ignored.
References

See Also

auc

Examples

data(aSAH)

# Basic example
multiclass.roc(aSAH$gos6, aSAH$s100b)
# Produces an innocuous warning because one level has no observation

# Select only 3 of the aSAH$gos6 levels:
multiclass.roc(aSAH$gos6, aSAH$s100b, levels=c(3, 4, 5))

# Give the result in percent
multiclass.roc(aSAH$gos6, aSAH$s100b, percent=TRUE)

Description

This function adds confidence intervals to a ROC curve plot, either as bars or as a confidence shape.

Usage

```r
# S3 method for class 'ci.thresholds'
plot(x, length=.01*ifelse(attr(x, "roc")$percent, 100, 1), col=par("fg"), ...)
# S3 method for class 'ci.sp'
plot(x, type=c("bars", "shape"), length=.01*ifelse(attr(x, "roc")$percent, 100, 1), col=ifelse(type="bars", par("fg"), "gainsboro"), no.roc=FALSE, ...)
# S3 method for class 'ci.se'
plot(x, type=c("bars", "shape"), length=.01*ifelse(attr(x, "roc")$percent, 100, 1), col=ifelse(type="bars", par("fg"), "gainsboro"), no.roc=FALSE, ...)
```
Arguments

- `x`: a confidence interval object from the functions `ci.thresholds`, `ci.se` or `ci.sp`.
- `type`: type of plot, “bars” or “shape”. Can be shortened to “b” or “s”. “shape” is only available for `ci.se` and `ci.sp`, not for `ci.thresholds`.
- `length`: the length (as plot coordinates) of the bar ticks. Only if type="bars".
- `no roc`: if FALSE, the ROC line is re-added over the shape. Otherwise if TRUE, only the shape is plotted. Ignored if type="bars".
- `col`: color of the bars or shape.
- `...`: further arguments for `segments` (if type="bars") or `polygon` (if type="shape").

Details

This function adds confidence intervals to a ROC curve plot, either as bars or as a confidence shape, depending on the state of the `type` argument. The shape is plotted over the ROC curve, so that the curve is re-plotted unless `no roc`=TRUE.

Graphical functions are called with `suppressWarnings`.

Value

This function returns the confidence interval object invisibly.

Warnings

With `type="shape"`, the warning "Low definition shape" is issued when the shape is defined by less than 15 confidence intervals. In such a case, the shape is not well defined and the ROC curve could pass outside the shape. To get a better shape, increase the number of intervals, for example with:

```r
plot(ci.sp(rocobj, sensitivities=seq(0, 1, .01)), type="shape")
```

References

See Also

- `plot.roc`
- `ci.thresholds`
- `ci.sp`
- `ci.se`

Examples

```r
data(aSAH)
## Not run:
# Start a ROC plot
rocobj <- plot.roc(aSAH$outcome, aSAH$s100b)
plot(rocobj)
# Thresholds
```
### Description

This function plots a ROC curve. It can accept many arguments to tweak the appearance of the plot. Two syntaxes are possible: one object of class "roc", or either two vectors (response, predictor) or a formula (response-predictor) as in the `roc` function.

### Usage

```r
## S3 method for class 'roc'
plot(x, ...)  
## S3 method for class 'smooth.roc'
plot(x, ...)  
## S3 method for class 'roc'
plot.roc(x, add=FALSE, reuse.auc=TRUE, axes=TRUE, legacy.axes=FALSE,  
          # Generic arguments for par:
xlim=if(x$percent){c(100, 0)} else{c(1, 0)},

Arguments

x a roc object from the roc function (for plot.roc.roc), a formula (for plot.roc.formula) or a response vector (for plot.roc.default).
predictor, data arguments for the roc function.
add if TRUE, the ROC curve will be added to an existing plot. If FALSE (default), a new plot will be created.
reuse.auc if TRUE (default) and the “roc” object contains an “auc” field, re-use these specifications for the plot (specifically print.auc, auc.polygon and max.auc.polygon arguments). See details.
axes a logical indicating if the plot axes must be drawn.
legacy.axes a logical indicating if the specificity axis (x axis) must be plotted as as decreasing “specificity” (FALSE, the default) or increasing “1 - specificity” (TRUE) as in most legacy software. This affects only the axis, not the plot coordinates.
xlim, ylim, xlab, ylab, asp, mar, mgp Generic arguments for the plot. See plot and plot.window for more details. Only used if add=FALSE.
col, lty, lwd color, line type and line width for the ROC curve. See par for more details.
type type of plotting as in plot.
identity logical: whether or not the identity line (no discrimination line) must be displayed. Default: only on new plots.
identity.col, identity.lty, identity.lwd color, line type and line width for the identity line. Used only if identity=TRUE. See par for more details.
Should a selected set of thresholds be displayed on the ROC curve? FALSE, NULL or “no”: no threshold is displayed. TRUE or “best”: the threshold with the highest sum sensitivity + specificity is plotted (this might be more than one threshold). “all”: all the points of the ROC curve. “local maximas”: all the local maximas. Numeric vector: direct definition of the thresholds to display. Note that on a smoothed ROC curve, only “best” is supported.

the plotting character (pch), text string adjustment (adj), color (col) and character expansion factor (cex) parameters for the printing of the thresholds. See `points` and `par` for more details.

the text pattern for the thresholds, as a `sprintf` format. Three numerics are passed to `sprintf`: threshold, specificity, sensitivity.

the character expansion factor (cex) for the threshold text pattern. See `par` for more details.

if `print.thres="best"` or `print.thres=TRUE`, what method must be used to determine which threshold is the best. See argument `best.method` and `best.weights` to `coords` for more details.

boolean. Should the numeric value of AUC be printed on the plot?

the text pattern for the AUC, as a `sprintf` format. If NULL, a reasonable value is computed that takes partial AUC, CI and percent into account. If the CI of the AUC was computed, three numerics are passed to `sprintf`: AUC, lower CI bound, higher CI bound. Otherwise, only AUC is passed.

x and y position for the printing of the AUC.

the text adjustment, character expansion factor and color for the printing of the AUC. See `par` for more details.

boolean or numeric vector of length 1 or 2. Should a background grid be added to the plot? Numeric: show a grid with the specified interval between each line; Logical: show the grid or not. Length 1: same values are taken for horizontal and vertical lines. Length 2: grid value for vertical (`grid[1]`) and horizontal (`grid[2]`). Note that these values are used to compute `grid.v` and `grid.h`. Therefore if you specify a `grid.h` and `grid.v`, it will be ignored.

numeric. The x and y values at which a vertical or horizontal line (respectively) must be drawn. NULL if no line must be added.

the line type (lty), line width (lwd) and color (col) of the lines of the grid. See `par` for more details. Note that you can pass vectors of length 2, in which case it specifies the vertical (1) and horizontal (2) lines.

boolean. Whether or not to display the area as a polygon.

color (col), line type (lty), density, angle and border for the AUC polygon. See `polygon` and `par` for more details.
max.auc.polygon
  boolean. Whether or not to display the maximal possible area as a polygon.

max.auc.polygon.col, max.auc.polygon.lty, max.auc.polygon.density, max.auc.polygon.angle, max.auc.polygon.border
  color (col), line type (lty), density, angle and border for the maximum AUC polygon. See polygon and par for more details.

ci
  boolean. Whether or not to display the confidence intervals.

ci.type, ci.col
  type and col arguments for plot.ci. The special value “no” disable the plotting of confidence intervals.

... further arguments passed to or from other methods, especially arguments for roc and plot.roc when calling plot.roc.default or plot.roc.formula. Note that the plot argument for roc is not allowed. Arguments for auc and graphical functions plot, abline, polygon, points, text and plot.ci if applicable.

Details

This function is typically called from roc when plot=TRUE (not by default). plot.roc.formula and plot.roc.default are convenience methods that build the ROC curve (with the roc function) before calling plot.roc.roc. You can pass them arguments for both roc and plot.roc.roc. Simply use plot.roc that will dispatch to the correct method.

The plotting is done in the following order:

  1. A new plot is created if add=FALSE.
  2. The grid is added if grid.v and grid.h are not NULL.
  3. The maximal AUC polygon is added if max.auc.polygon=TRUE.
  4. The CI shape is added if ci=TRUE, ci.type="shape" and x$ci isn’t a “ci.auc".
  5. The AUC polygon is added if auc.polygon=TRUE.
  6. The identity line if identity=TRUE.
  7. The actual ROC line is added.
  8. The CI bars are added if ci=TRUE, ci.type="bars" and x$ci isn’t a “ci.auc".
  9. The selected thresholds are printed if print.thres is TRUE or numeric.
 10. The AUC is printed if print.auc=TRUE.

Graphical functions are called with suppressWarnings.

Value

This function returns a list of class “roc” invisibly. See roc for more details.

AUC specification

For print.auc, auc.polygon and max.auc.polygon arguments, an AUC specification is required. By default, the total AUC is plotted, but you may want a partial AUCs. The specification is defined by:
1. the “auc” field in the “roc” object if `reuse.auc` is set to TRUE (default). It is naturally inherited from any call to `roc` and fits most cases.

2. passing the specification to `auc` with ... (arguments `partial.auc`, `partial.auc.correct` and `partial.auc.focus`). In this case, you must ensure either that the `roc` object do not contain an auc field (if you called `roc` with `auc=FALSE`), or set `reuse.auc=FALSE`.

If `reuse.auc=FALSE` the `auc` function will always be called with ... to determine the specification, even if the “roc” object do contain an auc field.

As well if the “roc” object do not contain an auc field, the `auc` function will always be called with ... to determine the specification.

Warning: if the roc object passed to plot.roc contains an auc field and `reuse.auc=TRUE`, `auc` is not called and arguments such as `partial.auc` are silently ignored.

# To plot a different partial AUC, we need to ignore the existing value
# with reuse.auc=FALSE:
plot(roco, print.auc=TRUE, auc.polygon=TRUE, partial.auc=c(1, 0.8),
     partial.auc.focus="se", grid=c(0.1, 0.2), grid.col=c("green", "red"),
     max.auc.polygon=TRUE, auc.polygon.col="blue", print.thres=TRUE,
power.roc.test

Sample size and power computation for ROC curves

Description

Computes sample size, power, significance level or minimum AUC for ROC curves.

Usage

power.roc.test(...)
# One or Two ROC curves test with roc objects:
## S3 method for class 'roc'
power.roc.test(roc1, roc2, sig.level = 0.05,
power = NULL, alternative = c("two.sided", "one.sided"),
reuse.auc=TRUE, method = c("delong", "bootstrap", "obuchowski"), ...)
# One ROC curve with a given AUC:
## S3 method for class 'numeric'
power.roc.test(roc = NULL, ncontrols = NULL,
ncases = NULL, sig.level = 0.05, power = NULL, kappa = 1,
alternative = c("two.sided", "one.sided"), ...)
# Two ROC curves with the given parameters:
## S3 method for class 'list'
power.roc.test(parslist, ncontrols = NULL,
ncases = NULL, sig.level = 0.05, power = NULL, kappa = 1,
alternative = c("two.sided", "one.sided"), ...)

Arguments

roc1, roc2 one or two "roc" object from the roc function.
auc expected AUC.
parslist a list of parameters for the two ROC curves test with Obuchowski variance when no empirical ROC curve is known:
A1 binormal A parameter for ROC curve 1
B1 binormal B parameter for ROC curve 1
A2 binormal A parameter for ROC curve 2
B2 binormal B parameter for ROC curve 2
rn correlation between the variables in control patients
ra correlation between the variables in case patients
delta  the difference of AUC between the two ROC curves
For a partial AUC, the following additional parameters must be set:
FPR11  Upper bound of FPR (1 - specificity) of ROC curve 1
FPR12  Lower bound of FPR (1 - specificity) of ROC curve 1
FPR21  Upper bound of FPR (1 - specificity) of ROC curve 2
FPR22  Lower bound of FPR (1 - specificity) of ROC curve 2
ncontrols, ncases
number of controls and case observations available.
sig.level  expected significance level (probability of type I error).
power  expected power of the test (1 - probability of type II error).
kappa  expected balance between control and case observations. Must be positive. Only
for sample size determination, that is to determine ncontrols and ncases.
alternative whether a one or two-sided test is performed.
reuse.auc  if TRUE (default) and the “roc” objects contain an “auc” field, re-use these spe-
cifications for the test. See the AUC specification section for more details.
method  the method to compute variance and covariance, either “delong”, “bootstrap” or
“obuchowski”. The first letter is sufficient. Only for Two ROC curves power
calculation. See var and cov documentations for more details.
...  further arguments passed to or from other methods, especially auc (with reuse.auc=FALSE
or no AUC in the ROC curve), cov and var (especially arguments method,
boot.n and boot.stratified). Ignored (with a warning) with a parslist.

Value
An object of class power.htest (such as that given by power.t.test) with the supplied and com-
puted values.

One ROC curve power calculation
If one or no ROC curves are passed to power.roc.test, a one ROC curve power calculation
is performed. The function expects either power, sig.level or auc, or both ncontrols and ncases
to be missing, so that the parameter is determined from the others with the formula by Obuchowski
et al., 2004 (formulas 2 and 3, p. 1123).
For the sample size, ncases is computed directly from formulas 2 and 3 and ncontrols is deduced
with kappa. AUC is optimized by uniroot while sig.level and power are solved as quadratic
equations.

power.roc.test can also be passed a roc object from the roc function, but the empirical ROC
will not be used, only the number of patients and the AUC.

Two paired ROC curves power calculation
If two ROC curves are passed to power.roc.test, the function will compute either the required
sample size (if power is supplied), the significance level (if sig.level=NULL and power is supplied)
or the power of a test of a difference between to AUCs according to the formula by Obuchowski
and McClish, 1997 et al. (formulas 2 and 3, p. 1530–1531). The null hypothesis is that the AUC of roc1 is the same than the AUC of roc2, with roc1 taken as the reference ROC curve.

For the sample size, ncases is computed directly from formula 2 and ncontrols is deduced from the ratio observed in roc1 and roc2. sig.level and power are solved as quadratic equations.

The variance and covariance of the ROC curve are computed with the var and cov functions. By default, DeLong method using the algorithm by Sun and Xu (2014) is used for full AUCs and the bootstrap for partial AUCs. It is possible to force the use of Obuchowski’s variance by specifying method="obuchowski".

Alternatively when no empirical ROC curve is known, or if only one is available, a list can be passed to power.roc.test, with the contents defined in the “Arguments” section. The variance and covariance are computed from Table 1 and Equation 4 and 5 of Obuchowski and McClish (1997), p. 1530–1531.

Power calculation for unpaired ROC curves is not implemented.

AUC specification

The comparison of the AUC of the ROC curves needs a specification of the AUC. The specification is defined by:

1. the “auc” field in the “roc” objects if reuse.auc is set to TRUE (default)
2. passing the specification to auc with ... (arguments partial.auc, partial.auc.correct and partial.auc.focus). In this case, you must ensure either that the roc object do not contain an auc field (if you called roc with auc=FALSE), or set reuse.auc=FALSE.

If reuse.auc=FALSE the auc function will always be called with ... to determine the specification, even if the “roc” objects do contain an auc field.

As well if the “roc” objects do not contain an auc field, the auc function will always be called with ... to determine the specification.

Warning: if the roc object passed to roc.test contains an auc field and reuse.auc=TRUE, auc is not called and arguments such as partial.auc are silently ignored.

Acknowledgements

The authors would like to thank Christophe Combescure and Anne-Sophie Jannot for their help with the implementation of this section of the package.

**Description**

This function prints a ROC curve, AUC or CI object and return it invisibly.

**Usage**

```r
## S3 method for class 'roc'
print(x, digits=max(3, getOption("digits") - 3), call=TRUE, ...)
## S3 method for class 'multiclass.roc'
print(x, digits=max(3, getOption("digits") - 3), call=TRUE, ...)
## S3 method for class 'smooth.roc'
print(x, digits=max(3, getOption("digits") - 3), call=TRUE, ...)
## S3 method for class 'smooth.roc'
print(x, digits=max(3, getOption("digits") - 3), call=TRUE, ...)
## S3 method for class 'multiclass.roc'
print(x, digits=max(3, getOption("digits") - 3), call=TRUE, ...)
## S3 method for class 'multiclass.roc'
print(x, digits=max(3, getOption("digits") - 3), call=TRUE, ...)
## S3 method for class 'multiclass.roc'
print(x, digits=max(3, getOption("digits") - 3), call=TRUE, ...)
## S3 method for class 'multiclass.roc'
print(x, digits=max(3, getOption("digits") - 3), call=TRUE, ...)
```  

**Arguments**

- `x` a roc, auc or ci object, from the `roc`, `auc` or `ci` functions respectively.
- `call` if the call is printed.
- `digits` the number of significant figures to print. See `signif` for more details.
- `...` further arguments passed to or from other methods. In particular, `print.roc` calls `print.auc` and the `print.ci` variants internally, and a `digits` argument is propagated. Not used in `print.auc` and `print.ci` variants.

**Value**

These functions return the object they were passed invisibly.

  # Print a smoothed roc object
  print(smooth(roccobj))

  # implicit printing
  roc(aSAH$outcome, aSAH$s100b)

  # Print an auc and a ci object, from the ROC object or calling
  # the dedicated function:
  print(roccobj$auc)
  print(ci(roccobj))

roc

Build a ROC curve

Description

This is the main function of the pROC package. It builds a ROC curve and returns a “roc” object, a list of class “roc”. This object can be printed, plotted, or passed to the functions auc, ci, smooth.roc and coords. Additionally, two roc objects can be compared with roc.test.

Usage

roc(...)  
## S3 method for class 'formula'
roc(formula, data, ...)
## Default S3 method:
roc(response, predictor, controls, cases,
    density.controls, density.cases,
    levels=base::levels(as.factor(response)), percent=FALSE, na.rm=TRUE,
    direction=c("auto", "<", ">"), algorithm = 1, quiet = TRUE,
    smooth=FALSE, auc=TRUE, ci=FALSE, plot=FALSE, smooth.method="binormal",
    ci.method=NULL, density=FALSE, density=FALSE, ...)

Arguments

response a factor, numeric or character vector of responses, typically encoded with 0 (controls) and 1 (cases). Only two classes can be used in a ROC curve. If the vector contains more than two unique values, or if their order could be ambiguous, use levels to specify which values must be used as control and case value.
predictor a numeric vector of the same length than response, containing the predicted value of each observation. An ordered factor is coerced to a numeric.

controls, cases instead of response, predictor, the data can be supplied as two numeric or ordered vectors containing the predictor values for control and case observations.

density.controls, density.cases a smoothed ROC curve can be built directly from two densities on identical x points, as in smooth.

formula, data a formula of the type response~predictor. If multiple predictors are passed, a named list of roc objects will be returned. Additional arguments data, subset and na.action are supported, see model.frame for more details.

levels the value of the response for controls and cases respectively. By default, the first two values of levels(as.factor(response)) are taken, and the remaining levels are ignored. It usually captures two-class factor data correctly, but will frequently fail for other data types (response factor with more than 2 levels, or for example if your response is coded “controls” and “cases”, the levels will be inverted) and must then be specified here. If your data is coded as 0 and 1 with 0 being the controls, you can safely omit this argument.

percent if the sensitivities, specificities and AUC must be given in percent (TRUE) or in fraction (FALSE, default).

na.rm if TRUE, the NA values will be removed (ignored by roc.formula).

direction in which direction to make the comparison? “auto” (default): automatically define in which group the median is higher and take the direction accordingly. “>”: if the predictor values for the control group are higher than the values of the case group (controls > t >= cases). “<”: if the predictor values for the control group are lower or equal than the values of the case group (controls < t <= cases).

algorithm the method used to compute sensitivity and specificity, an integer of length 1 between 0 and 4. 1 (default): a safe, well-tested, pure-R code that is efficient when the number of thresholds is low. It goes with O(T*N). 2: an alternative pure-R algorithm that goes in O(N). Typically faster than 1 when the number of thresholds of the ROC curve is above 1000. Less tested than 1. 3: a C++ implementation of 1, about 3-5x faster. Typically the fastest with ROC curves with less than 3000-5000 thresholds. 4 (debug only, slow): runs all 3 algorithms and makes sure they return the same values. 0: use microbenchmark to choose between 2 and 3.

quiet set to FALSE to turn on messages when direction and levels are auto-detected. This default will be changed to TRUE in the future.

smooth if TRUE, the ROC curve is passed to smooth to be smoothed.

auc compute the area under the curve (AUC)? If TRUE (default), additional arguments can be passed to auc.

ci compute the confidence interval (CI)? If set to TRUE, additional arguments can be passed to ci.

plot plot the ROC curve? If TRUE, additional arguments can be passed to plot.roc.
smooth.method, ci.method

in roc.formula and roc.default, the method arguments to smooth (if smooth=TRUE) and of="auc") must be passed as smooth.method and ci.method to avoid confusions.

density density argument passed to smooth.

... further arguments passed to or from other methods, and especially:

• auc: partial.auc, partial.auc.focus, partial.auc.correct.
• ci: of, conf.level, boot.n, boot.stratified, progress
• ci.auc; reuse.auc, method
• ci.thresholds: thresholds
• ci.sp: sensitivities
• ci.se: specificities
• plot.roc: add, col and most other arguments to the plot.roc function. See plot.roc directly for more details.
• smooth: method, n, and all other arguments. See smooth for more details.

Details

This function’s main job is to build a ROC object. See the “Value” section to this page for more details. Before returning, it will call (in this order) the smooth, auc, ci and plot.roc functions if smooth auc, ci and plot.roc (respectively) arguments are set to TRUE. By default, only auc is called.

Data can be provided as response, predictor, where the predictor is the numeric (or ordered) level of the evaluated signal, and the response encodes the observation class (control or case). The level argument specifies which response level must be taken as controls (first value of level) or cases (second). It can safely be ignored when the response is encoded as 0 and 1, but it will frequently fail otherwise. By default, the first two values of levels(as.factor(response)) are taken, and the remaining levels are ignored. This means that if your response is coded “control” and “case”, the levels will be inverted.

In some cases, it is more convenient to pass the data as controls, cases, but both arguments are ignored if response, predictor was specified to non-NULL values. It is also possible to pass density data with density.controls, density.cases, which will result in a smoothed ROC curve even if smooth=FALSE, but are ignored if response, predictor or controls, cases are provided.

Specifications for auc, ci and plot.roc are not kept if auc, ci or plot are set to FALSE. Especially, in the following case:

```r
myRoc <- roc(..., auc=TRUE, grid=TRUE, plot=FALSE)
plot(myRoc)
```

the plot will not have the AUC polygon nor the grid. Similarly, when comparing “roc” objects, the following is not possible:

```r
roc1 <- roc(..., partial.auc=c(1, 0.8), auc=FALSE)
roc2 <- roc(..., partial.auc=c(1, 0.8), auc=FALSE)
```
roc.test(roc1, roc2)

This will produce a test on the full AUC, not the partial AUC. To make a comparison on the partial AUC, you must repeat the specifications when calling `roc.test`:

roc.test(roc1, roc2, partial.auc=c(1, 0.8))

Note that if `roc` was called with `auc=TRUE`, the latter syntax will not allow redefining the AUC specifications. You must use `reuse.auc=FALSE` for that.

Value

If the data contained any `NA` value and `na.rm=FALSE`, `NA` is returned. Otherwise, if `smooth=FALSE`, a list of class “roc” with the following fields:

- **auc**: if called with `auc=TRUE`, a numeric of class “auc” as defined in `auc`.
- **ci**: if called with `ci=TRUE`, a numeric of class “ci” as defined in `ci`.
- **response**: the response vector. Patients whose response is not %in% levels are discarded. If NA values were removed, a `na.action` attribute similar to `na.omit` stores the row numbers.
- **predictor**: the predictor vector converted to numeric as used to build the ROC curve. Patients whose response is not %in% levels are discarded. If NA values were removed, a `na.action` attribute similar to `na.omit` stores the row numbers.
- **original.predictor**, **original.response**: the response and predictor vectors as passed in argument.
- **levels**: the levels of the response as defined in argument.
- **controls**: the predictor values for the control observations.
- **cases**: the predictor values for the cases.
- **percent**: if the sensitivities, specificities and AUC are reported in percent, as defined in argument.
- **direction**: the direction of the comparison, as defined in argument.
- **fun.sesp**: the function used to compute sensitivities and specificities. Will be re-used in bootstrap operations.
- **sensitivities**: the sensitivities defining the ROC curve.
- **specificities**: the specificities defining the ROC curve.
- **thresholds**: the thresholds at which the sensitivities and specificities were computed.
- **call**: how the function was called. See `match.call` for more details.

If `smooth=TRUE` a list of class “smooth.roc” as returned by `smooth`, with or without additional elements `auc` and `ci` (according to the call).
Errors

If no control or case observation exist for the given levels of response, no ROC curve can be built and an error is triggered with message “No control observation” or “No case observation”.

If the predictor is not a numeric or ordered, as defined by `as.numeric` or `as.ordered`, the message “Predictor must be numeric or ordered” is returned.

The message “No valid data provided” is issued when the data wasn’t properly passed. Remember you need both response and predictor of the same (not null) length, or both controls and cases. Combinations such as predictor and cases are not valid and will trigger this error.

Examples

data(aSAH)

# Basic example
roc(aSAH$outcome, aSAH$s100b,
   levels=c("Good", "Poor"))
# As levels aSAH$outcome == c("Good", "Poor"),
# this is equivalent to:
roc(aSAH$outcome, aSAH$s100b)
# In some cases, ignoring levels could lead to unexpected results
# Equivalent syntaxes:
roc(outcome ~ s100b, aSAH)
roc(aSAH$outcome ~ aSAH$s100b)
with(aSAH, roc(outcome, s100b))
with(aSAH, roc(outcome ~ s100b))

# With a formula:
roc(outcome ~ s100b, data=aSAH)

# Using subset (only with formula)
roc(outcome ~ s100b, data=aSAH, subset=(gender == "Male"))
roc(outcome ~ s100b, data=aSAH, subset=(gender == "Female"))

# With numeric controls/cases
roc(controls=aSAH$s100b[aSAH$outcome=="Good"], cases=aSAH$s100b[aSAH$outcome=="Poor"])
# With ordered controls/cases
roc(controls=aSAH$wfns[aSAH$outcome=="Good"], cases=aSAH$wfns[aSAH$outcome=="Poor"])
roc.test

# Inverted the levels: "Poor" are now controls and "Good" cases:
roc(aSAH$outcome, aSAH$s100b,
   levels=c("Poor", "Good"))

# The result was exactly the same because of direction="auto".
# The following will give an AUC < 0.5:
roc(aSAH$outcome, aSAH$s100b,
   levels=c("Poor", "Good"), direction="<")

# If we are sure about levels and direction auto-detection,
# we can turn off the messages:
roc(aSAH$outcome, aSAH$s100b, quiet = TRUE)

# If we prefer counting in percent:
roc(aSAH$outcome, aSAH$s100b, percent=TRUE)

# Test the different algorithms:
roc(aSAH$outcome, aSAH$s100b, algorithm = 1)
roc(aSAH$outcome, aSAH$s100b, algorithm = 2)
roc(aSAH$outcome, aSAH$s100b, algorithm = 3)
if (require(microbenchmark)) {
   roc(aSAH$outcome, aSAH$s100b, algorithm = 0)
}

# Plot and CI (see plot.roc and ci for more options):
roc(aSAH$outcome, aSAH$s100b,
   percent=TRUE, plot=TRUE, ci=TRUE)

# Smoothed ROC curve
roc(aSAH$outcome, aSAH$s100b, smooth=TRUE)
# this is not identical to
smooth(roc(aSAH$outcome, aSAH$s100b))
# because in the latter case, the returned object contains no AUC

---

roc.test

**Compare the AUC of two ROC curves**

**Description**

This function compares the AUC or partial AUC of two correlated (or paired) or uncorrelated (unpaired) ROC curves. Several syntaxes are available: two object of class roc (which can be AUC or smoothed ROC), or either three vectors (response, predictor1, predictor2) or a response vector and a matrix or data.frame with two columns (predictors).

**Usage**

# roc.test(...)
## S3 method for class 'roc'
roc.test(roc1, roc2, method=c("delong", "bootstrap",
   "venkatraman", "sensitivity", "specificity"), sensitivity = NULL,
specificity = NULL, alternative = c("two.sided", "less", "greater"),
paired=FALSE, reuse.auc=TRUE, boot.n=2000, boot.stratified=TRUE,
ties.method="first", progress=getOption("PRROCP/progress")$name,
parallel=FALSE, ...)  
## S3 method for class 'auc'
roc.test(roc1, roc2, ...)  
## S3 method for class 'smooth.roc'
roc.test(roc1, roc2, ...)  
## S3 method for class 'formula'
roc.test(formula, data, ...)  
## Default S3 method:
roc.test(response, predictor1, predictor2=NULL, na.rm=TRUE, method=NULL, ...)

Arguments

roc1, roc2 the two ROC curves to compare. Either “roc”, “auc” or “smooth.roc” objects (types can be mixed).
response a vector or factor, as for the roc function.
predictor1 a numeric or ordered vector as for the roc function, or a matrix or data.frame with predictors two columns.
predictor2 only if predictor1 was a vector, the second predictor as a numeric vector.
formula a formula of the type response~predictor1+predictor2. Additional arguments data, subset and na.action are supported, see model.frame for more details.
data a matrix or data.frame containing the variables in the formula. See model.frame for more details.
na.rm if TRUE, the observations with NA values will be removed.
method the method to use, either “delong”, “bootstrap” or “venkatraman”. The first letter is sufficient. If omitted, the appropriate method is selected as explained in details.
sensitivity, specificity if method="sensitivity" or method="specificity", the respective level where the test must be assessed as a numeric of length 1.
alternative specifies the alternative hypothesis. Either of “two.sided”, “less” or “greater”. The first letter is sufficient. Default: “two.sided”. Only “two.sided” is available with method="venkatraman".
paired a logical indicating whether you want a paired roc.test. If NULL, the paired status will be auto-detected by are.paired. If TRUE but the paired status cannot be assessed by are.paired will produce an error.
reuse.auc if TRUE (default) and the “roc” objects contain an “auc” field, re-use these specifications for the test. See the AUC specification section for more details.
boot.n for method="bootstrap" and method="venkatraman" only: the number of bootstrap replicates or permutations. Default: 2000.
boot.stratified for method="bootstrap" only: should the bootstrap be stratified (same number of cases/controls in each replicate than in the original sample) or not. Ignored with method="venkatraman". Default: TRUE.
ties.method for method="venkatraman" only: argument for rank specifying how ties are handled. Defaults to “first” as described in the paper.

progress the name of progress bar to display. Typically “none”, “win”, “tk” or “text” (see the name argument to create_progress_bar for more information), but a list as returned by create_progress_bar is also accepted. See also the “Progress bars” section of this package's documentation.

parallel if TRUE, the bootstrap is processed in parallel, using parallel backend provided by plyr (foreach).

... further arguments passed to or from other methods, especially arguments for roc and roc.test.roc when calling roc.test.default or roc.test.formula. Arguments for auc, and txtProgressbar (only char and style) if applicable.

Details

This function compares two ROC curves. It is typically called with the two roc objects to compare. roc.test.default is provided as a convenience method and creates two roc objects before calling roc.test.roc.

Three methods are available: “delong”, “bootstrap” and “venkatraman” (see “Computational details” section below). “delong” and “bootstrap” are tests over the AUC whereas “venkatraman” compares the ROC curves themselves.

Default is to use “delong” method except for comparison of partial AUC, smoothed curves and curves with different direction, where bootstrap is used. Using “delong” for partial AUC and smoothed ROCs is not supported in pROC (a warning is produced and “bootstrap” is employed instead). It is spurious to use “delong” for roc with different direction (a warning is issued but the spurious comparison is enforced). “venkatraman”’s test cannot be employed to compare smoothed ROC curves. Additionally, partial AUC specifications are ignored (with a warning), and comparison of ROC curves with different direction should be used with care (a warning is produced as well).

If alternative="two.sided", a two-sided test for difference in AUC is performed. If alternative="less", the alternative is that the AUC of roc1 is smaller than the AUC of roc2. For method="venkatraman", only “two.sided” test is available.

If the paired argument is not provided, the are.paired function is employed to detect the paired status of the ROC curves. It will test if the original response is identical between the two ROC curves (this is always the case if the call is made with roc.test.default). This detection is unlikely to raise false positives, but this possibility cannot be excluded entirely. It would require equal sample sizes and response values and order in both ROC curves. If it happens to you, use paired=FALSE. If you know the ROC curves are paired you can pass paired=TRUE. However this is useless as it will be tested anyway.

For smoothed ROC curves, smoothing is performed again at each bootstrap replicate with the parameters originally provided. If a density smoothing was performed with user-provided density.cases or density.controls the bootstrap cannot be performed and an error is issued.

Value

A list of class "htest" with following content:

p.value the p-value of the test.
statistic the value of the Z (method="delong") or D (method="bootstrap") statistics.
alternative the alternative hypothesis.

method the character string “DeLong’s test for two correlated ROC curves” (if method="deLong") or “Bootstrap test for two correlated ROC curves” (if method="bootstrap").

null.value the expected value of the statistic under the null hypothesis, that is 0.

estimate the AUC in the two ROC curves.

data.name the names of the data that was used.

parameter for method="bootstrap" only: the values of the boot.n and boot.stratified arguments.

AUC specification

The comparison of the AUC of the ROC curves needs a specification of the AUC. The specification is defined by:

1. the “auc” field in the “roc” objects if reuse.auc is set to TRUE (default)
2. passing the specification to auc with ... (arguments partial.auc, partial.auc.correct and partial.auc.focus). In this case, you must ensure either that the roc object do not contain an auc field (if you called roc with auc=FALSE), or set reuse.auc=FALSE.

If reuse.auc=FALSE the auc function will always be called with ... to determine the specification, even if the “roc” objects do contain an auc field.

As well if the “roc” objects do not contain an auc field, the auc function will always be called with ... to determine the specification.

The AUC specification is ignored in the Venkatraman test.

Warning: if the roc object passed to roc.test contains an auc field and reuse.auc=TRUE, auc is not called and arguments such as partial.auc are silently ignored.

Computation details

With method="bootstrap", the processing is done as follow:

1. boot.n bootstrap replicates are drawn from the data. If boot.stratified is TRUE, each replicate contains exactly the same number of controls and cases than the original sample, otherwise if FALSE the numbers can vary.
2. for each bootstrap replicate, the AUC of the two ROC curves are computed and the difference is stored.
3. The following formula is used:

\[ D = \frac{AUC1 - AUC2}{s} \]

where s is the standard deviation of the bootstrap differences and AUC1 and AUC2 the AUC of the two (original) ROC curves.
4. D is then compared to the normal distribution, according to the value of alternative.
See also the Bootstrap section in this package’s documentation.

With method="delong", the processing is done as described in DeLong et al. (1988) for paired ROC curves, using the algorithm of Sun and Xu (2014). Only comparison of two ROC curves is implemented. The method has been extended for unpaired ROC curves where the p-value is computed with an unpaired t-test with unequal sample size and unequal variance, with

$$D = \frac{V^r(\theta^r) - V^s(\theta^s)}{\sqrt{S^r + S^s}}$$

With method="venkatraman", the processing is done as described in Venkatraman and Begg (1996) (for paired ROC curves) and Venkatraman (2000) (for unpaired ROC curves) with boot.n permutation of sample ranks (with ties breaking). For consistency reasons, the same argument boot.n as in bootstrap defines the number of permutations to execute, even though no bootstrap is performed.

For method="specificity", the test assesses if the sensitivity of the ROC curves are different at the level of specificity given by the specificity argument, which must be a numeric of length 1. Bootstrap is employed as with method="bootstrap" and boot.n and boot.stratified are available. This is identical to the test proposed by Pepe et al. (2009). The method="sensitivity" is very similar, but assesses if the specificity of the ROC curves are different at the level of sensitivity given by the sensitivity argument.

Warnings

If “auc” specifications are different in both roc objects, the warning “Different AUC specifications in the ROC curves. Enforcing the inconsistency, but unexpected results may be produced.” is issued. Unexpected results may be produced.

If one or both ROC curves are “smooth.roc” objects with different smoothing specifications, the warning “Different smoothing parameters in the ROC curves. Enforcing the inconsistency, but unexpected results may be produced.” is issued. This warning can be benign, especially if ROC curves were generated with roc(..., smooth=TRUE) with different arguments to other functions (such as plot), or if you really want to compare two ROC curves smoothed differently.

If method="delong" and the AUC specification specifies a partial AUC, the warning “Using DeLong’s test for partial AUC is not supported. Using bootstrap test instead.” is issued. The method argument is ignored and “bootstrap” is used instead.

If method="delong" and the ROC curve is smoothed, the warning “Using DeLong’s test for smoothed ROCs is not supported. Using bootstrap test instead.” is issued. The method argument is ignored and “bootstrap” is used instead.

If method="venkatraman", and the AUC specification specifies a partial AUC, the AUC specification is ignored with the warning “Partial AUC is ignored in Venkatraman’s test.”.

If method="venkatraman", and alternative is “less” or “greater”, the warning “Only two-sided tests are available for Venkatraman. Performing two-sided test instead.” is produced and a two tailed test is performed.

Both DeLong and Venkatraman’s test ignores the direction of the ROC curve so that if two ROC curves have a different differ in the value of direction, the warning “(DeLong|Venkatraman)'s test should not be applied to ROC curves with different directions.” is printed. However, the spurious test is enforced.

If boot.stratified=FALSE and the sample has a large imbalance between cases and controls, it could happen that one or more of the replicates contains no case or control observation, or that there
are not enough points for smoothing, producing a NA area. The warning “NA value(s) produced during bootstrap were ignored.” will be issued and the observation will be ignored. If you have a large imbalance in your sample, it could be safer to keep boot.stratified=TRUE.

When both ROC curves have an auc of 1 (or 100%), their variances and covariance will always be null, and therefore the p-value will always be 1. This is true for both “delong”, “bootstrap” and “venkatraman” methods. This result is misleading, as the variances and covariance are of course not null. A warning will be displayed to inform of this condition, and of the misleading output.

Errors

An error will also occur if you give a predictor2 when predictor1 is a matrix or a data.frame, if predictor1 has more than two columns, or if you do not give a predictor2 when predictor1 is a vector.

If density.cases and density.controls were provided for smoothing, the error “Cannot compute the statistic on ROC curves smoothed with density.controls and density.cases.” is issued.

If method="venkatraman" and one of the ROC curves is smoothed, the error “Using Venkatraman’s test for smoothed ROCs is not supported.” is produced.

With method="specificity", the error ‘Argument ‘specificity’ must be numeric of length 1 for a specificity test.” is given unless the specificity argument is specified as a numeric of length 1. The “Argument ‘sensitivity’ must be numeric of length 1 for a sensitivity test.” message is given for method="sensitivity" under similar conditions.

Acknowledgements

We would like to thank E. S. Venkatraman and Colin B. Begg for their support in the implementation of their test.

smooth

Smooth a ROC curve

Description

This function smoothes a ROC curve of numeric predictor. By default, a binormal smoothing is performed, but density or custom smoothings are supported.

Usage

smooth(...)
smooth

## Default S3 method:
smooth(...)

## S3 method for class 'roc'
smooth(roc,  
method=c("binormal", "density", "fitdistr", "logcondens",  
"logcondens.smooth"), n=512, bw = "nrd0", density=NULL,  
density.controls=density, density.cases=density,  
start=NULL, start.controls=start, start.cases=start,  
reuse.auc=TRUE, reuse.ci=FALSE, ...)

## S3 method for class 'smooth.roc'
smooth(smooth.roc, ...)

### Arguments

roc, smooth.roc

a “roc” object from the roc function, or a “smooth.roc” object from the smooth function.

method

“binormal”, “density”, “fitdistr”, “logcondens”, “logcondens.smooth”, or a function returning a list of smoothed sensitivities and specificities.

n

the number of equally spaced points where the smoothed curve will be calculated.

bw

if method=“density” and density.controls and density.cases are not provided, bw is passed to density to determine the bandwidth of the density. Can be a character string ("nrd0", "nrd", "ucv", "bcv" or "SJ", but any name matching a function prefixed with "bw." is supported) or a numeric value, as described in density. Defaults to "nrd0".

density, density.controls, density.cases

if method=“density”, a numeric value of density (over the y axis) or a function returning a density (such as density). If method=“fitdistr”, a densfun argument for fitdistr. If the value is different for control and case observations, density.controls and density.cases can be employed instead, otherwise density will be propagated to both density.controls and density.cases.

start, start.controls, start.cases

if method=“fitdistr”, optionnal start arguments for start.controls and start.cases allows to specify different distributions for controls and cases.

reuse.auc, reuse.ci

if TRUE (default for reuse.auc) and the “roc” objects contain “auc” or “ci” fields, re-use these specifications to regenerate auc or ci on the smoothed ROC curve with the original parameters. If FALSE, the object returned will not contain “auc” or “ci” fields. It is currently not possible to redefine auc and ci options directly: you need to call auc or ci later for that.

... further arguments passed to or from other methods, and especially to density (only cut, adjust, and kernel, plus window for compatibility with S+) and fitdistr. Also passed to to method if it is a function.
Details

If method="binormal", a linear model is fitted to the quantiles of the sensitivities and specificities. Smoothed sensitivities and specificities are then generated from this model on n points. This simple approach was found to work well for most ROC curves, but it may produce hooked smooths in some situations (see in Hanley (1988)).

With method="density", the density function is employed to generate a smooth kernel density of the control and case observations as described by Zhou et al. (1997), unless density.controls or density.cases are provided directly. bw can be given to specify a bandwidth to use with density. It can be a numeric value or a character string ("nrd0", "nrd", "ucv", "bcv" or "SJ", but any name matching a function prefixed with "bw." is supported). In the case of a character string, the whole predictor data is employed to determine the numeric value to use on both controls and cases. Depending on your data, it might be a good idea to specify the kernel argument for density. By default, "gaussian" is used, but “epanechnikov”, “rectangular”, “triangular”, “biweight”, “cosine” and “optcosine” are supported. As all the kernels are symetrical, it might help to normalize the data first (that is, before calling roc), for example with quantile normalization:

```r
norm.x <- qnorm(rank(x)/(length(x)+1))
smooth(roc(response, norm.x, ...), ...)
```

Additionally, density can be a function which must return either a numeric vector of densities over the y axis or a list with a “y” item like the density function. It must accept the following input:

```r
density.fun(x, n, from, to, bw, kernel, ...)
```

It is important to honour n, from and to in order to have the densities evaluated on the same points for controls and cases. Failing to do so and returning densities of different length will produce an error. It is also a good idea to use a constant smoothing parameter (such as bw) especially when controls and cases have a different number of observations, to avoid producing smoother or rougher densities.

If method="fitdistr", the fitdistr function from the MASS package is employed to fit parameters for the density function density with optionnal start parameters start. The density function are fitted separately in control (density.controls, start.controls) and case observations (density.cases, start.cases). density can be one of the character values allowed by fitdistr or a density function (such as dnorm, dweibull, ...).

The method="logcondens" and method="logcondens.smooth" use the logcondens package to generate a non smoothed or smoothed (respectively) log-concave density estimate of of the control and case observation with the logConROC function.

Finally, method can also be a function. It must return a list with exactly 2 elements named “sensitivities” and “specificities”, which must be numeric vectors between 0 and 1 or 100 (depending on the percent argument to roc). It is passed all the arguments to the smooth function.

smooth.default forces the usage of the smooth function in the stats package, so that other code relying on smooth should continue to function normally.

Smoothed ROC curves can be passed to smooth again. In this case, the smoothing is not re-applied on the smoothed ROC curve but the original “roc” object will be re-used.

Note that a smooth.roc curve has no threshold.
Value

A list of class “smooth.roc” with the following fields:

- **sensitivities**: the smoothed sensitivities defining the ROC curve.
- **specificities**: the smoothed specificities defining the ROC curve.
- **percent**: if the sensitivities, specificities and AUC are reported in percent, as defined in argument.
- **direction**: the direction of the comparison, as defined in argument.
- **call**: how the function was called. See `match.call` for more details.
- **smoothing.args**: a list of the arguments used for the smoothing. Will serve to apply the smoothing again in further bootstrap operations.
- **auc**: if the original ROC curve contained an AUC, it is computed again on the smoothed ROC.
- **ci**: if the original ROC curve contained a CI, it is computed again on the smoothed ROC.
- **fit.controls, fit.cases**: with method="fitdistr" only: the result of MASS's `fitdistr` function for controls and cases, with an additional "densfun" item indicating the density function, if possible as character.
- **logcondens**: with method="logcondens" and method="logcondens.smooth" only: the result of `logcondens`'s logConROC function.
- **model**: with method="binormal" only: the linear model from `lm` used to smooth the ROC curve.

Attributes: Additionally, the original roc object is stored as a “roc” attribute.

Errors

If method is a function, the return values will be checked thoroughly for validity (list with two numeric elements of the same length named “sensitivities” and “specificities” with values in the range of possible values for sensitivities and specificities).

The message “The 'density' function must return a numeric vector or a list with a 'y' item.” will be displayed if the density function did not return a valid output. The message “Length of 'density.controls' and 'density.cases' differ.” will be displayed if the returned value differ in length.

Binormal smoothing cannot smooth ROC curve defined by only one point. Any such attempt will fail with the error “ROC curve not smoothable (not enough points).”.

If the smooth ROC curve was generated by roc with density.controls and density.cases numeric arguments, it cannot be smoothed and the error “Cannot smooth a ROC curve generated directly with numeric 'density.controls' and 'density.cases'." is produced.

fitdistr and density smoothing methods require a numeric predictor. If the ROC curve to smooth was generated with an ordered factor only binormal smoothing can be applied and the message “ROC curves of ordered predictors can be smoothed only with binormal smoothing.” is displayed otherwise.

fitdistr, logcondens and logcondens.smooth methods require additional packages. If not available, the following message will be displayed with the required command to install the package: “Package ? not available, required with method='?'. Please install it with 'install.packages("?")'. "

# you can bootstrap a ROC curve smoothed with a density function:
  ci(s, boot.n=100)

C End(Not run)

var.roc

Variance of a ROC curve

Description

These functions compute the variance of the AUC of a ROC curve.

Usage

var(...)
## Default S3 method:
var(...)
## S3 method for class 'auc'
var(auc, ...)
## S3 method for class 'roc'
var(roc, method=c("delong", "bootstrap", "obuchowski"),
    boot.n = 2000, boot.stratified = TRUE, reuse.auc=TRUE,
    ...)

## End(Not run)
progress = getOption("pROCProgress")[name, parallel=FALSE, ...]
## S3 method for class 'smooth.roc'
var(smooth.roc, ...)

**Arguments**

- `roc, smooth.roc, auc`:
  - A “roc” object from the `roc` function, a “smooth.roc” object from the `smooth` function or an “auc” object from the `auc` function.
- `method`:
  - The method to use, either “delong” or “bootstrap”. The first letter is sufficient. If omitted, the appropriate method is selected as explained in details.
- `reuse.auc`:
  - If TRUE (default) and the “roc” objects contain an “auc” field, re-use these specifications for the test. See details.
- `boot.n`:
  - For `method="bootstrap"` only: the number of bootstrap replicates or permutations. Default: 2000.
- `boot.stratified`:
  - For `method="bootstrap"` only: should the bootstrap be stratified (same number of cases/controls in each replicate than in the original sample) or not. Default: TRUE.
- `progress`:
  - The name of progress bar to display. Typically “none”, “win”, “tk” or “text” (see the name argument to `create_progress_bar` for more information), but a list as returned by `create_progress_bar` is also accepted. See also the “Progress bars” section of this package’s documentation.
- `parallel`:
  - If TRUE, the bootstrap is processed in parallel, using parallel backend provided by plyr (foreach).
- `...`:
  - Further arguments passed to or from other methods, especially arguments for `var.roc` when calling `var`, `var.auc` and `var.smooth.roc`. Arguments for `auc` (if `reuse.auc=FALSE`) and `txtProgressBar` (only char and style) if applicable.

**Details**

The `var` function computes the variance of the AUC of a ROC curve. It is typically called with the `roc` object of interest. Two methods are available: “delong” and “bootstrap” (see “Computational details” section below).

The default is to use “delong” method except for with partial AUC and smoothed curves where “bootstrap” is employed. Using “delong” for partial AUC and smoothed ROCs is not supported (a warning is produced and “bootstrap” is employed instead).

For **smoothed ROC curves**, smoothing is performed again at each bootstrap replicate with the parameters originally provided. If a density smoothing was performed with user-provided `density.cases` or `density.controls` the bootstrap cannot be performed and an error is issued.

`var.default` forces the usage of the `var` function in the `stats` package, so that other code relying on `var` should continue to function normally.

**Value**

The numeric value of the variance.
AUC specification

var needs a specification of the AUC to compute the variance of the AUC of the ROC curve. The specification is defined by:

1. the “auc” field in the “roc” objects if reuse.auc is set to TRUE (default)
2. passing the specification to auc with ...(arguments partial.auc, partial.auc.correct and partial.auc.focus). In this case, you must ensure either that the roc object do not contain an auc field (if you called roc with auc=FALSE), or set reuse.auc=FALSE.

If reuse.auc=FALSE the auc function will always be called with ... to determine the specification, even if the “roc” objects do contain an auc field.

As well if the “roc” objects do not contain an auc field, the auc function will always be called with ... to determine the specification.

Warning: if the roc object passed to roc.test contains an auc field and reuse.auc=TRUE, auc is not called and arguments such as partial.auc are silently ignored.

Computation details

With method="bootstrap", the processing is done as follow:

1. boot.n bootstrap replicates are drawn from the data. If boot.stratified is TRUE, each replicate contains exactly the same number of controls and cases than the original sample, otherwise if FALSE the numbers can vary.
2. for each bootstrap replicate, the AUC of the ROC curve is computed and stored.
3. the variance of the resampled AUCs are computed and returned.

With method="delong", the processing is done as described in Hanley and Hajian-Tilaki (1997) using the algorithm by Sun and Xu (2014).

With method="obuchowski", the processing is done as described in Obuchowski and McClish (1997), Table 1 and Equation 4, p. 1530–1531. The computation of g for partial area under the ROC curve is modified as:

\[ expr1 \times (2 \times pi \times expr2)^{-1} \times (-expr4) - A \times B \times expr1 \times (2 \times pi \times expr2^3)^{-1/2} \times expr3 \]

. Binormality assumption

The “obuchowski" method makes the assumption that the data is binormal. If the data shows a deviation from this assumption, it might help to normalize the data first (that is, before calling roc), for example with quantile normalization:

\[ \text{norm.x} \leftarrow \text{qnorm}(\text{rank(x)}/(\text{length(x)}+1)) \]
\[ \text{var}(\text{roc(response, norm.x, ...), ...}) \]

“delong” and “bootstrap" methods make no such assumption.
var.roc

83

Warnings

If `method="delong"` and the AUC specification specifies a partial AUC, the warning “Using DeLong for partial AUC is not supported. Using bootstrap test instead.” is issued. The method argument is ignored and “bootstrap” is used instead.

If `method="delong"` and the ROC curve is smoothed, the warning “Using DeLong for smoothed ROCs is not supported. Using bootstrap test instead.” is issued. The method argument is ignored and “bootstrap” is used instead.

If `boot.stratified=FALSE` and the sample has a large imbalance between cases and controls, it could happen that one or more of the replicates contains no case or control observation, or that there are not enough points for smoothing, producing a NA area. The warning “NA value(s) produced during bootstrap were ignored.” will be issued and the observation will be ignored. If you have a large imbalance in your sample, it could be safer to keep `boot.stratified=TRUE`.

When the ROC curve has an auc of 1 (or 100%), the variance will always be null. This is true for both “delong” and “bootstrap” methods that can not properly assess the variance in this case. This result is misleading, as the variance is of course not null. A warning will be displayed to inform of this condition, and of the misleading output.

Errors

If `density.cases` and `density.controls` were provided for smoothing, the error “Cannot compute the covariance on ROC curves smoothed with density.controls and density.cases.” is issued.
