Package ‘plumber’

March 23, 2024

Encoding UTF-8
Type Package
Title An API Generator for R
Version 1.2.2
Roxygen list(markdown = TRUE)
License MIT + file LICENSE

BugReports https://github.com/rstudio/plumber/issues

Description Gives the ability to automatically generate and serve an HTTP API
from R functions using the annotations in the R documentation around your
functions.

Depends R (>= 3.0.0)
Imports R6 (>= 2.0.0),
  stringi (>= 0.3.0),
  jsonlite (>= 0.9.16),
  webutils (>= 1.1),

as_attachment

Return an attachment response

Description

This will set the appropriate fields in the Content-Disposition header value. To make sure the attachment is used, be sure your serializer eventually calls serializer_headers.
Usage

```r
as_attachment(value, filename = NULL)
```

Arguments

- `value`  Response value to be saved
- `filename`  File name to use when saving the attachment. If no filename is provided, the value will be treated as a regular attachment

Value

Object with class "plumber_attachment"

Examples

```r
## Not run:
# plumber.R
#
# @get /data
# @serializer csv
function() {
  # will cause the file to be saved as `iris.csv`, not `data` or `data.csv`
  as_attachment(iris, "iris.csv")
}
## End(Not run)
```

---

**endpoint_serializer**  
**Endpoint Serializer with Hooks**

Description

This method allows serializers to return preexec, postexec, and aroundexec ([Experimental](https://en.wikipedia.org/wiki/Experimental_(software))) hooks in addition to a serializer. This is useful for graphics device serializers which need a preexec and postexec hook to capture the graphics output.

Usage

```r
depth_endpoint_serializer(
  serializer,
  preexec_hook = NULL,
  postexec_hook = NULL,
  aroundexec_hook = NULL
)
```

Arguments

- `serializer`  Serializer method to be used. This method should already have its initialization arguments applied.
- `preexec_hook`  Function to be run directly before a PlumberEndpoint calls its route method.
- `postexec_hook`  Function to be run directly after a PlumberEndpoint calls its route method.
forward

aroundexec_hook

Function to be run around a PlumberEndpoint call. Must handle a .next argument to continue execution. [Experimental]

Details

preexec and postexec hooks happened directly before and after a route is executed. These hooks are specific to a single PlumberEndpoint’s route calculation.

Examples

# The definition of `serializer_device` returns
# * a `serializer_content_type` serializer
# * `aroundexec` hook
print(serializer_device)

forward

Forward Request to The Next Handler

Description

This function is used when a filter is done processing a request and wishes to pass control off to the next handler in the chain. If this is not called by a filter, the assumption is that the filter fully handled the request itself and no other filters or endpoints should be evaluated for this request.

Usage

forward()

get_character_set

Request character set

Description

Request character set

Usage

get_character_set(content_type = NULL)

Arguments

content_type Request Content-Type header

Value

Default to UTF-8. Otherwise return charset defined in request header.
include_file  

Send File Contents as Response

Description

Returns the file at the given path as the response. If you want an endpoint to return a file as an attachment for user to download see `as_attachment()`.

Usage

```r
include_file(file, res, content_type = getContentType(tools::file_ext(file)))
include_html(file, res)
include_md(file, res, format = NULL)
include_rmd(file, res, format = NULL)
```

Arguments

- **file** The path to the file to return
- **res** The response object into which we’ll write
- **content_type** If provided, the given value will be sent as the Content-Type header in the response. Defaults to the contentType of the file extension. To disable the Content-Type header, set `content_type = NULL`.
- **format** Passed as the `output_format` to `rmarkdown::render`

Details

`include_html` will merely return the file with the proper `content_type` for HTML. `include_md` and `include_rmd` will process the given markdown file through `rmarkdown::render` and return the resultant HTML as a response.

is_plumber  

Determine if Plumber object

Description

Determine if Plumber object

Usage

```r
is_plumber(pr)
```

Arguments

- **pr** Hopefully a `Plumber` object
**options_plumber**  

Value  

Logical value if `pr` inherits from `Plumber`  

Examples  

```r  
is_plumber(Plumber$new()) # TRUE  
is_plumber(list()) # FALSE  
```

---  

**options_plumber**  

*Plumber options*  

Description  

There are a number of global options that affect Plumber’s behavior. These can be set globally with `options()` or with `options_plumber()`. Options set using `options_plumber()` should not include the `plumber.` prefix. Alternatively, environment variable can be used to set plumber options using uppercase and underscores (i.e. to set `plumber.apiHost` you can set environment variable `PLUMBER_APIHOST`).

Usage  

```r  
options_plumber(  
    ...,  
    port = getOption("plumber.port"),  
    docs = getOption("plumber.docs"),  
    docs.callback = getOption("plumber.docs.callback"),  
    trailingSlash = getOption("plumber.trailingSlash"),  
    methodNotAllowed = getOption("plumber.methodNotAllowed"),  
    apiURL = getOption("plumber.apiURL"),  
    apiScheme = getOption("plumber.apiScheme"),  
    apiHost = getOption("plumber.apiHost"),  
    apiPort = getOption("plumber.apiPort"),  
    apiPath = getOption("plumber.apiPath"),  
    maxRequestSize = getOption("plumber.maxRequestSize"),  
    sharedSecret = getOption("plumber.sharedSecret"),  
    legacyRedirects = getOption("plumber.legacyRedirects")  
  )  
```

```r  
get_option_or_env(x, default = NULL)  
```

Arguments  

```r  
...  
Ignored. Should be empty  
port, docs, docs.callback, trailingSlash, methodNotAllowed, apiScheme, apiHost, apiPort, apiPath, apiURL, maxRequestSize, sharedSecret, legacyRedirects  
See details  
x  
a character string holding an option name.  
default  
if the specified option is not set in the options list, this value is returned. This facilitates retrieving an option and checking whether it is set and setting it separately if not.
Details

**plumber.port** Port Plumber will attempt to use to start http server. If the port is already in use, server will not be able to start. Defaults to NULL.

**plumber.docs** Name of the visual documentation interface to use. Defaults to TRUE, which will use "swagger".

**plumber.docs.callback** A function. Called with a single parameter corresponding to the visual documentation url after Plumber server is ready. This can be used by RStudio to open the docs when then API is ran from the editor. Defaults to option NULL.

**plumber.trailingSlash** Logical value which allows the router to redirect any request that has a matching route with a trailing slash. For example, if set to TRUE and the GET route /test/ existed, then a GET request of /test?a=1 would redirect to /test/?a=1. Defaults to FALSE. This option will default to TRUE in a future release.

**plumber.methodNotAllowed** [Experimental] Logical value which allows the router to notify that an unavailable method was requested, but a different request method is allowed. For example, if set to TRUE and the GET route /test existed, then a POST request of /test would receive a 405 status and the allowed methods. Defaults to TRUE.

**plumber.apiURL** Server urls for OpenAPI Specification respecting pattern scheme://host:port/path. Other api* options will be ignored when set.

**plumber.apiScheme** Scheme used to build OpenAPI url and server url for OpenAPI Specification. Defaults to http, or an empty string when used outside a running router.

**plumber.apiHost** Host used to build docs url and server url for OpenAPI Specification. Defaults to host defined by run method, or an empty string when used outside a running router.

**plumber.apiPort** Port used to build OpenAPI url and server url for OpenAPI Specification. Defaults to port defined by run method, or an empty string when used outside a running router.

**plumber.apiPath** Path used to build OpenAPI url and server url for OpenAPI Specification. Defaults to an empty string.

**plumber.maxRequestSize** Maximum length in bytes of request body. Body larger than maximum are rejected with http error 413. 0 means unlimited size. Defaults to 0.

**plumber.sharedSecret** Shared secret used to filter incoming request. When NULL, secret is not validated. Otherwise, Plumber compares secret with http header PLUMBER_SHARED_SECRET. Failure to match results in http error 400. Defaults to NULL.

**plumber.legacyRedirects** Plumber will redirect legacy route /__swagger__/ and /__swagger__/index.html to ../__docs__/ and ../__docs__/index.html. You can disable this by setting this option to FALSE. Defaults to TRUE

Value

The complete, prior set of options() values. If a particular parameter is not supplied, it will return the current value. If no parameters are supplied, all returned values will be the current options() values.
Description

Parsers are used in Plumber to transform request body received by the API. Extra parameters may be provided to parser functions when enabling them on router. This will allow for non-default behavior.

Usage

parser_form()
parser_json(...)
parser_geojson(...)
parser_text(parse_fn = identity)
parser_yaml(...)
parser_csv(...)
parser_tsv(...)
parser_read_file(read_fn = readLines)
parser_rds(...)
parser_feather(...)
parser_parquet(...)
parser_octet()
parser_multi()
parser_none()

Arguments

... parameters supplied to the appropriate internal function
parse_fn function to further decode a text string into an object
read_fn function used to read a the content of a file. Ex: readRDS()

Details

Parsers are optional. When unspecified, only default endpoint parsers are enabled. You can use @parser NAME tag to enable parser on endpoint. Multiple parsers can be enabled on the same endpoint using multiple @parser NAME tags.
User should be aware that rds parsing should only be done from a trusted source. Do not accept rds files blindly.

See `registered_parsers()` for a list of registered parsers names.

**Functions**

- `parser_form()`: Form query string parser
- `parser_json()`: JSON parser. See `jsonlite::parse_json()` for more details. (Defaults to using `simplifyVectors = TRUE`)
- `parser_geojson()`: GeoJSON parser. See `geojsonsf::geojson_sf()` for more details.
- `parser_text()`: Helper parser to parse plain text
- `parser_yaml()`: YAML parser. See `yaml::yaml.load()` for more details.
- `parser_csv()`: CSV parser. See `readr::read_csv()` for more details.
- `parser_tsv()`: TSV parser. See `readr::read_tsv()` for more details.
- `parser_read_file()`: Helper parser that writes the binary body to a file and reads it back again using `read_fn`. This parser should be used when reading from a file is required.
- `parser_rds()`: RDS parser. See `readRDS()` for more details.
- `parser_feather()`: feather parser. See `arrow::read_feather()` for more details.
- `parser_parquet()`: parquet parser. See `arrow::read_parquet()` for more details.
- `parser_octet()`: Octet stream parser. Returns the raw content.
- `parser_multi()`: Multi part parser. This parser will then parse each individual body with its respective parser. When this parser is used, `req$body` will contain the updated output from `webutils::parse_multipart()` by adding the parsed output to each part. Each part may contain detailed information, such as `name` (required), `content_type`, `content_disposition`, `filename`, (raw, original) `value`, and `parsed` (parsed value). When performing Plumber route argument matching, each multipart part will match its name to the parsed content.
- `parser_none()`: No parser. Will not process the postBody.

**Examples**

```r
## Not run:
# Overwrite `text/json` parsing behavior to not allow JSON vectors to be simplified
#* @parser json list(simplifyVector = FALSE)
# Activate `rds` parser in a multipart request
#* @parser multi
#* @parser rds
pr <- Plumber$new()
pr$handle("GET", "/upload", function(rds) (rds), parsers = c("multi", "rds"))
```

## End(Not run)
process a Plumber API

```
plumb(file = NULL, dir = ".")
```

**Arguments**

- `file`: The file to parse as the plumber router definition.
- `dir`: The directory containing the `plumber.R` file to parse as the plumber router definition. Alternatively, if an `entrypoint.R` file is found, it will take precedence and be responsible for returning a runnable router.

**Details**

API routers are the core request handler in plumber. A router is responsible for taking an incoming request, submitting it through the appropriate filters and eventually to a corresponding endpoint, if one is found.

See the [Programmatic Usage](#) article for additional details on the methods available on this object.

---

**Description**

Package Plumber Router

**Details**

Routers are the core request handler in plumber. A router is responsible for taking an incoming request, submitting it through the appropriate filters and eventually to a corresponding endpoint, if one is found.

See the [Programmatic Usage](#) article for additional details on the methods available on this object.

**Super class**

`plumber::Hookable` -> `Plumber`

**Public fields**

- `flags` For internal use only
Active bindings

- endpoints: Plumber router endpoints read-only
- filters: Plumber router filters read-only
- mounts: Plumber router mounts read-only
- environment: Plumber router environment read-only
- routes: Plumber router routes read-only

Methods

**Public methods:**

- `Plumber$new()`
- `Plumber$run()`
- `Plumber$mount()`
- `Plumber$unmount()`
- `Plumber$registerHook()`
- `Plumber$handle()`
- `Plumber$removeHandle()`
- `Plumber$print()`
- `Plumber$serve()`
- `Plumber$route()`
- `Plumber$call()`
- `Plumber$onHeaders()`
- `Plumber$onWSOpen()`
- `Plumber$setSerializer()`
- `Plumber$setParsers()`
- `Plumber$set404Handler()`
- `Plumber$setErrorHandler()`
- `Plumber$setDocs()`
- `Plumber$setDocsCallback()`
- `Plumber$setDebug()`
- `Plumber$getDebug()`
- `Plumber$filter()`
- `Plumber$setApiSpec()`
- `Plumber$getApiSpec()`
- `Plumber$addEndpoint()`
- `Plumber$addAssets()`
- `Plumber$addFilter()`
- `Plumber$addGlobalProcessor()`
- `Plumber$openAPIFile()`
- `Plumber$swaggerFile()`
- `Plumber$clone()`

**Method new():** Create a new Plumber router

See also `plumb()`, `pr()`

Usage:

`Plumber$new(file = NULL, filters = defaultPlumberFilters, envir)`
Arguments:
- file path to file to plumb
- filters a list of Plumber filters
- envir an environment to be used as the enclosure for the routers execution

Returns: A new Plumber router

Method run(): Start a server using Plumber object.
See also: pr_run()

Usage:
Plumber$run(
  host = "127.0.0.1",
  port = get_option_or_env("plumber.port", NULL),
  swagger = deprecated(),
  debug = missing_arg(),
  swaggerCallback = missing_arg(),
  ...
  docs = missing_arg(),
  quiet = FALSE
)

Arguments:
- host a string that is a valid IPv4 or IPv6 address that is owned by this server, which the application will listen on. "0.0.0.0" represents all IPv4 addresses and "::/0" represents all IPv6 addresses.
- port a number or integer that indicates the server port that should be listened on. Note that on most Unix-like systems including Linux and Mac OS X, port numbers smaller than 1025 require root privileges. This value does not need to be explicitly assigned. To explicitly set it, see options_plumber().
- swagger Deprecated. Please use docs instead. See $setDocs(docs) or $setApiSpec() for more customization.
- debug If TRUE, it will provide more insight into your API errors. Using this value will only last for the duration of the run. If a $setDebug() has not been called, debug will default to interactive() at $run() time. See $setDebug() for more details.
- swaggerCallback An optional single-argument function that is called back with the URL to an OpenAPI user interface when one becomes ready. If missing, defaults to information previously set with $setDocsCallback(). This value will only be used while running the router.
- ... Should be empty.
- docs Visual documentation value to use while running the API. This value will only be used while running the router. If missing, defaults to information previously set with setDocs(). For more customization, see $setDocs() or pr_set_docs() for examples.
- quiet If TRUE, don't print routine startup messages.

Method mount(): Mount a Plumber router
Plumber routers can be “nested” by mounting one into another using the mount() method. This allows you to compartmentalize your API by paths which is a great technique for decomposing large APIs into smaller files.
See also: pr_mount()

Usage:
Plumber$mount(path, router)
Arguments:
path a character string. Where to mount router.
router a Plumber router. Router to be mounted.

Examples:
\dontrun{
  root <- pr()

  users <- Plumber$new("users.R")
  root$mount("/users", users)

  products <- Plumber$new("products.R")
  root$mount("/products", products)
}

Method unmount(): Unmount a Plumber router
Usage:
Plumber$unmount(path)
Arguments:
path a character string. Where to unmount router.

Method registerHook(): Register a hook
Plumber routers support the notion of "hooks" that can be registered to execute some code at a
particular point in the lifecycle of a request. Plumber routers currently support four hooks:
1. preroute(data, req, res)
2. postroute(data, req, res, value)
3. preserialize(data, req, res, value)
4. postserialize(data, req, res, value)
In all of the above you have access to a disposable environment in the data parameter that is
created as a temporary data store for each request. Hooks can store temporary data in these hooks
that can be reused by other hooks processing this same request.
One feature when defining hooks in Plumber routers is the ability to modify the returned value.
The convention for such hooks is: any function that accepts a parameter named value is expected
to return the new value. This could be an unmodified version of the value that was passed in, or
it could be a mutated value. But in either case, if your hook accepts a parameter named value,
whatever your hook returns will be used as the new value for the response.
You can add hooks using the registerHook method, or you can add multiple hooks at once using
the registerHooks method which takes a name list in which the names are the names of the
hooks, and the values are the handlers themselves.
See also: pr_hook(), pr_hooks()

Usage:
Plumber$registerHook(
  stage = c("preroute", "postroute", "preserialize", "postserialize", "exit"),
  handler
)
Arguments:
stage a character string. Point in the lifecycle of a request.
handler a hook function.
Examples:
\dontrun{
pr <- pr()
pr$registerHook("preroute", function(req){
  cat("Routing a request for", req$PATH_INFO, "...\n")
})
pr$registerHooks(list(
  preserialize=function(req, value){
    print("About to serialize this value:")
    print(value)
    # Must return the value since we took one in. Here we're not choosing
    # to mutate it, but we could.
    value
  },
  postserialize=function(res){
    print("We serialized the value as:")
    print(res$body)
  }
))
}

pr$handle("GET", "/", function(){ 123 })
}

Method handle(): Define endpoints

The "handler" functions that you define in these handle calls are identical to the code you would
have defined in your plumber.R file if you were using annotations to define your API. The handle() method takes additional arguments that allow you to control nuanced behavior of the endpoint like
which filter it might preempt or which serializer it should use.

See also: pr_handle(), pr_get(), pr_post(), pr_put(), pr_delete()

Usage:
Plumber$handle(
  methods,
  path,
  handler,
  preempt,
  serializer,
  parsers,
  endpoint,
  ...
)

Arguments:
methods  a character string. http method.
path a character string. Api endpoints
handler a handler function.
preempt a preempt function.
serializer a serializer function.
parsers a named list of parsers.
endpoint a PlumberEndpoint object.
... additional arguments for PlumberEndpoint new method (namely lines, params, comments,
  responses and tags. Excludes envir).
Examples:
\dontref{pr <- pr()
pr$handle("GET", "/", function(){
  "<html><h1>Programmatic Plumber!</h1></html>"
}, serializer=plumber::serializer_html())
}
Plumber$onHeaders(req)

Arguments:
req request object

Method onWSOpen(): httpuv interface onWSOpen function. (Required for httpuv)

Usage:
Plumber$onWSOpen(ws)

Arguments:
ws WebSocket object

Method setSerializer(): Sets the default serializer of the router.

See also: pr_set_serializer()

Usage:
Plumber$setSerializer(serializer)

Arguments:
serializer a serializer function

Examples:
\dontrun{
pr <- pr()
pr$setSerializer(serializer_unboxed_json())
}

Method setParsers(): Sets the default parsers of the router. Initialized to c("json", "form", "text", "octet", "multi")

Usage:
Plumber$setParsers(parsers)

Arguments:
parsers Can be one of:
  • A NULL value
  • A character vector of parser names
  • A named list() whose keys are parser names names and values are arguments to be applied with do.call()
  • A TRUE value, which will default to combining all parsers. This is great for seeing what is possible, but not great for security purposes

If the parser name “all” is found in any character value or list name, all remaining parsers will be added. When using a list, parser information already defined will maintain their existing argument values. All remaining parsers will use their default arguments.

Example:
# provide a character string
parsers = "json"

# provide a named list with no arguments
parsers = list(json = list())

# provide a named list with arguments; include `rds`
parsers = list(json = list(simplifyVector = FALSE), rds = list())

# default plumber parsers
parsers = c("json", "form", "text", "octet", "multi")
**Method** set404Handler(): Sets the handler that gets called if an incoming request can’t be served by any filter, endpoint, or sub-router.

See also: `pr_set_404()`

*Usage:*

```r
Plumber$set404Handler(fun)
```

*Arguments:*

- `fun` a handler function.

*Examples:*

```r
\dontrun{
pr <- pr()
pr$set404Handler(function(req, res) {cat(req$PATH_INFO))})
}
```

**Method** setErrorHandler(): Sets the error handler which gets invoked if any filter or endpoint generates an error.

See also: `pr_set_404()`

*Usage:*

```r
Plumber(setErrorHandler(fun)
```

*Arguments:*

- `fun` a handler function.

*Examples:*

```r
\dontrun{
pr <- pr()
pr$setErrorHandler(function(req, res, err) {
message("Found error: ")
str(err)
})
}
```

**Method** setDocs(): Set visual documentation to use for API

See also: `pr_set_docs()`, `register_docs()`, `registered_docs()`

*Usage:*

```r
Plumber$setDocs(docs = get_option_or_env("plumber.docs", TRUE), ...)
```

*Arguments:*

- `docs` a character value or a logical value. See `pr_set_docs()` for examples. If using `options_plumber()`, the value must be set before initializing your Plumber router.

... Arguments for the visual documentation. See each visual documentation package for further details.

**Method** setDocsCallback(): Set a callback to notify where the API’s visual documentation is located.

When set, it will be called with a character string corresponding to the API docs url. This allows RStudio to locate visual documentation.

If using `options_plumber()`, the value must be set before initializing your Plumber router.

See also: `pr_set_docs_callback()`

*Usage:*

```r
```
Plumber\$setDocsCallback(
    callback = get_option_or_env("plumber.docs.callback", NULL)
)

Arguments:
callback a callback function for taking action on the docs url. (Also accepts NULL values to
disable the callback.)

Method setDebug(): Set debug value to include error messages.
See also: $getDebug() and pr_set_debug()
Usage:
Plumber\$setDebug(debug = interactive())
Arguments:
default TRUE provides more insight into your API errors.

Method getDebug(): Retrieve the debug value. If it has never been set, the result of interactive() will be used.
See also: $getDebug() and pr_set_debug()
Usage:
Plumber\$getDebug()

Method filter(): Add a filter to plumber router
See also: pr_filter()
Usage:
Plumber\$filter(name, expr, serializer)
Arguments:
name a character string. Name of filter
expr an expr that resolve to a filter function or a filter function
serializer a serializer function

Method setApiSpec(): Allows to modify router autogenerated OpenAPI Specification
Note, the returned value will be sent through serializer_unboxed_json() which will turn all length 1 vectors into atomic values. To force a vector to serialize to an array of size 1, be sure to call as.list() on your value. list() objects are always serialized to an array value.
See also: pr_set_api_spec()
Usage:
Plumber\$setApiSpec(api = NULL)
Arguments:
api This can be
• an OpenAPI Specification formatted list object
• a function that accepts the OpenAPI Specification autogenerated by plumber and returns
  a OpenAPI Specification formatted list object.
• a path to an OpenAPI Specification
The value returned will not be validated for OAS compatibility.

Method getApiSpec(): Retrieve OpenAPI file
Usage:
Plumber\$getApiSpec()
Method `addEndpoint()`: `addEndpoint` has been deprecated in v0.4.0 and will be removed in a coming release. Please use `handle()` instead.

Usage:
```r
Plumber$addEndpoint(
  verbs,
  path,
  expr,
  serializer,
  processors,
  preempt = NULL,
  params = NULL,
  comments
)
```

Arguments:
- `verbs` verbs
- `path` path
- `expr` expr
- `serializer` serializer
- `processors` processors
- `preempt` preempt
- `params` params
- `comments` comments

Method `addAssets()`: `addAssets` has been deprecated in v0.4.0 and will be removed in a coming release. Please use `mount` and `PlumberStatic$new()` instead.

Usage:
```r
Plumber$addAssets(dir, path = "/public", options = list())
```

Arguments:
- `dir` dir
- `path` path
- `options` options

Method `addFilter()`: `$addFilter()` has been deprecated in v0.4.0 and will be removed in a coming release. Please use `$filter()` instead.

Usage:
```r
Plumber$addFilter(name, expr, serializer, processors)
```

Arguments:
- `name` name
- `expr` expr
- `serializer` serializer
- `processors` processors

Method `addGlobalProcessor()`: `$addGlobalProcessor()` has been deprecated in v0.4.0 and will be removed in a coming release. Please use `$registerHook()` instead.

Usage:
```r
Plumber$addGlobalProcessor(proc)
```

Arguments:
Method openAPIFile(): Deprecated. Retrieve OpenAPI file
Usage:
Plumber$openAPIFile()

Method swaggerFile(): Deprecated. Retrieve OpenAPI file
Usage:
Plumber$swaggerFile()

Method clone(): The objects of this class are cloneable with this method.
Usage:
Plumber$clone(deep = FALSE)
Arguments:
deepl Whether to make a deep clone.

## ------------------------------------------------
## Method `Plumber$mount`
## ------------------------------------------------
## Not run:
root <- pr()
users <- Plumber$new("users.R")
root$mount("/users", users)
products <- Plumber$new("products.R")
root$mount("/products", products)
## End(Not run)

## ------------------------------------------------
## Method `Plumber$registerHook`
## ------------------------------------------------
## Not run:
pr <- pr()
pr$registerHook("preroute", function(req){
  cat("Routing a request for", req$PATH_INFO, "...
")
})
pr$registerHooks(list(
  preserialize=function(req, value){
    print("About to serialize this value:")
    print(value)
  }
  # Must return the value since we took one in. Here we're not choosing
# to mutate it, but we could.
value
postserialize=function(res){
  print("We serialized the value as:")
  print(res$body)
}
}  
pr$handle("GET", "/", function(){ 123 })

## End(Not run)

## Method `Plumber$handle`

## Not run:
pr <- pr()
pr$handle("GET", "/", function(){
  "<html><h1>Programmatic Plumber!</h1><html>
}, serializer=plumber::serializer_html())

## End(Not run)

## Method `Plumber$setSerializer`

## Not run:
pr <- pr()
pr$setSerializer(serializer_unboxed_json())

## End(Not run)

## Method `Plumber$set404Handler`

## Not run:
pr <- pr()
pr$set404Handler(function(req, res) {cat(req$PATH_INFO)})

## End(Not run)

## Method `Plumber.setErrorHandler`

## Not run:
pr <- pr()
pr$setErrorHandler(function(req, res, err) {
  message("Found error: ")
  str(err)
})

## End(Not run)
**Description**

Plumber Endpoint

**Details**

Defines a terminal handler in a Plumber router.

Parameters values are obtained from parsing blocks of lines in a plumber file. They can also be provided manually for historical reasons.

**Super classes**

`plumber::Hookable` -> `plumber::PlumberStep` -> `PlumberEndpoint`

**Public fields**

- `verbs` a character vector. http methods. For historical reasons we have to accept multiple verbs for a single path. Now it's simpler to just parse each separate verb/path into its own endpoint, so we just do that.
- `path` a character string. endpoint path
- `comments` endpoint comments
- `description` endpoint description
- `responses` endpoint responses
- `params` endpoint parameters
- `tags` endpoint tags
- `parsers` step allowed parsers

**Methods**

**Public methods:**

- `PlumberEndpoint$getTypedParams()`  
- `PlumberEndpoint$canServe()`  
- `PlumberEndpoint$matchesPath()`  
- `PlumberEndpoint$new()`  
- `PlumberEndpoint$getPathParams()`  
- `PlumberEndpoint$getFunc()`  
- `PlumberEndpoint$getFuncParams()`  
- `PlumberEndpoint$getEndpointParams()`  
- `PlumberEndpoint$setPath()`  
- `PlumberEndpoint$clone()`

**Method** `getTypedParams()`: retrieve endpoint typed parameters

*Usage:*
Method `canServe()`: ability to serve request

Usage:
```
PlumberEndpoint$canServe(req)
```

Arguments:
- `req` a request object

Returns: a logical. TRUE when endpoint can serve request.

Method `matchesPath()`: determines if route matches requested path

Usage:
```
PlumberEndpoint$matchesPath(path)
```

Arguments:
- `path` a url path

Returns: a logical. TRUE when endpoint matches the requested path.

Method `new()`: Create a new `PlumberEndpoint` object

Usage:
```
PlumberEndpoint$new(
  verbs,
  path,
  expr,
  envir,
  serializer,
  parsers,
  lines,
  params,
  comments,
  description,
  responses,
  tags,
  srcref
)
```

Arguments:
- `verbs` Endpoint verb Ex: "GET", "POST"
- `path` Endpoint path. Ex: "/index.html", "/foo/bar/baz"
- `expr` Endpoint function or expression that evaluates to a function.
- `envir` Endpoint environment
- `serializer` Endpoint serializer. Ex: `serializer_json()`
- `parsers` Can be one of:
  - A NULL value
  - A character vector of parser names
  - A named `list()` whose keys are parser names names and values are arguments to be applied with `do.call()`
  - A TRUE value, which will default to combining all parsers. This is great for seeing what is possible, but not great for security purposes
If the parser name "all" is found in any character value or list name, all remaining parsers will be added. When using a list, parser information already defined will maintain their existing argument values. All remaining parsers will use their default arguments.

Example:

```r
# provide a character string
parsers = "json"

# provide a named list with no arguments
parsers = list(json = list())

# provide a named list with arguments; include `rds`
parsers = list(json = list(simplifyVector = FALSE), rds = list())
```

# default plumber parsers
parsers = c("json", "form", "text", "octet", "multi")

---

**Method** getPathParams(): retrieve endpoint path parameters

**Usage:**

`PlumberEndpoint$getPathParams(path)`

**Arguments:**

- `path`: endpoint path

**Method** getFunc(): retrieve endpoint function

**Usage:**

`PlumberEndpoint$getFunc()`

**Method** getFuncParams(): retrieve endpoint expression parameters

**Usage:**

`PlumberEndpoint$getFuncParams()`

**Method** getEndpointParams(): retrieve endpoint defined parameters

**Usage:**

`PlumberEndpoint$getEndpointParams()`

**Method** setPath(): Updates $path with a sanitized path and updates the internal path metadata

**Usage:**

`PlumberEndpoint$setPath(path)`

**Arguments:**

- `path`: Path to set $path. If missing a beginning slash, one will be added.

**Method** clone(): The objects of this class are cloneable with this method.

**Usage:**

`PlumberEndpoint$clone(deep = FALSE)`

**Arguments:**

- `deep`: Whether to make a deep clone.
PlumberStatic

Static file router

Description
Static file router
Static file router

Details
Creates a router that is backed by a directory of files on disk.

Super classes
plumber::Hookable -> plumber::Plumber -> PlumberStatic

Methods

Public methods:

• PlumberStatic$new()
• PlumberStatic$print()
• PlumberStatic$clone()

Method new(): Create a new PlumberStatic router

Usage:
PlumberStatic$new(direc, options)

Arguments:
direc a path to an asset directory.
options options to be evaluated in the PlumberStatic router environment

Returns: A new PlumberStatic router

Method print(): Print representation of PlumberStatic() router.

Usage:
PlumberStatic$print(prefix = "", topLevel = TRUE, ...)

Arguments:
prefix a character string. Prefix to append to representation.
topLevel a logical value. When method executed on top level router, set to TRUE.
... additional arguments for recursive calls

Returns: A terminal friendly representation of a PlumberStatic() router.

Method clone(): The objects of this class are cloneable with this method.

Usage:
PlumberStatic$clone(deep = FALSE)

Arguments:
deep Whether to make a deep clone.
PlumberStep

Description

an object representing a step in the lifecycle of the treatment of a request by a plumber router.

Super class

`plumber::Hookable` -> PlumberStep

Public fields

- `srcref` from step block
- `lines` lines from step block
- `serializer` step serializer function

Methods

Public methods:
- `PlumberStep$new()`
- `PlumberStep$exec()`
- `PlumberStep$registerHook()`
- `PlumberStep$clone()`

Method `new()`: Create a new `PlumberStep()` object

Usage:

```r
PlumberStep$new(expr, envir, lines, serializer, srcref)
```

Arguments:

- `expr` step expr
- `envir` step environment
- `lines` step block
- `serializer` step serializer
- `srcref` srcref attribute from block

Returns: A new PlumberStep object

Method `exec()`: step execution function

Usage:

```r
PlumberStep$exec(req, res)
```

Arguments:

- `req`, `res` Request and response objects created by a Plumber request

Method `registerHook()`: step hook registration method

Usage:

```r
PlumberStep$registerHook(
    stage = c("preexec", "postexec", "aroundexec"),
    handler
)
```
plumb_api

Arguments:
stage  a character string.
handler  a step handler function.

Method clone(): The objects of this class are cloneable with this method.

Usage:
PlumberStep$clone(deep = FALSE)

Arguments:
deep  Whether to make a deep clone.

Description

So that packages can ship multiple plumber routers, users should store their Plumber APIs in the inst subfolder plumber ./inst/plumber/API_1/plumber.R).

Usage

plumb_api(package = NULL, name = NULL, edit = FALSE)

available_apis(package = NULL)

Arguments

package  Package to inspect
name  Name of the package folder to plum().
edit  Whether or not to open the API source code for viewing / editing

Details

To view all available Plumber APIs across all packages, please call available_apis(). A package value may be provided to only display a particular package’s Plumber APIs.

Value

A Plumber object. If either package or name is null, the appropriate available_apis() will be returned.

Functions

• plumb_api(): plumb()s a package’s Plumber API. Returns a Plumber router object
• available_apis(): Displays all available package Plumber APIs. Returns a data.frame of package, name, and source_directory information.
**pr**

*Create a new Plumber router*

**Description**

Create a new Plumber router

**Usage**

```r
pr(
  file = NULL,
  filters = defaultPlumberFilters,
  envir = new.env(parent = .GlobalEnv)
)
```

**Arguments**

- `file` Path to file to plumb
- `filters` A list of Plumber filters
- `envir` An environment to be used as the enclosure for the routers execution

**Value**

A new *Plumber* router

**Examples**

```r
## Not run:
pr() %>%
  pr_run()
## End(Not run)
```

---

**pr_cookie**

*Store session data in encrypted cookies.*

**Description**

Plumber uses the crypto R package sodium, to encrypt/decrypt `req$session` information for each server request.
Usage

```r
pr_cookie(
  pr,
  key,
  name = "plumber",
  expiration = FALSE,
  http = TRUE,
  secure = FALSE,
  same_site = FALSE,
  path = NULL
)
```

Arguments

- **pr**: A Plumber API. Note: The supplied Plumber API object will also be updated in place as well as returned by the function.
- **key**: The secret key to use. This must be consistent across all R sessions where you want to save/restore encrypted cookies. It should be produced using `random_cookie_key`. Please see the "Storing secure keys" section for more details complex character string to bolster security.
- **name**: The name of the cookie in the user's browser.
- **expiration**: A number representing the number of seconds into the future before the cookie expires or a POSIXt date object of when the cookie expires. Defaults to the end of the user's browser session.
- **http**: Boolean that adds the `HttpOnly` cookie flag that tells the browser to save the cookie and to NOT send it to client-side scripts. This mitigates cross-site scripting. Defaults to `TRUE`.
- **secure**: Boolean that adds the `Secure` cookie flag. This should be set when the route is eventually delivered over HTTPS.
- **same_site**: A character specifying the SameSite policy to attach to the cookie. If specified, one of the following values should be given: "Strict", "Lax", or "None". If "None" is specified, then the secure flag MUST also be set for the modern browsers to accept the cookie. An error will be returned if `same_site = "None"` and `secure = FALSE`. If not specified or a non-character is given, no SameSite policy is attached to the cookie.
- **path**: The URI path that the cookie will be available in future requests. Defaults to the request URI. Set to "/" to make cookie available to all requests at the host.

Details

The cookie’s secret encryption key value must be consistent to maintain `req$session` information between server restarts.

Storing secure keys

While it is very quick to get started with user session cookies using `plumber`, please exercise precaution when storing secure key information. If a malicious person were to gain access to the secret key, they would be able to eavesdrop on all `req$session` information and/or tamper with `req$session` information being processed.

Please:
• Do NOT store keys in source control.
• Do NOT store keys on disk with permissions that allow it to be accessed by everyone.
• Do NOT store keys in databases which can be queried by everyone.

Instead, please:

• Use a key management system, such as 'keyring' (preferred)
• Store the secret in a file on disk with appropriately secure permissions, such as "user read only" (Sys.chmod("myfile.txt", mode = "0600")), to prevent others from reading it.

Examples of both of these solutions are done in the Examples section.

See Also

• 'sodium': R bindings to 'libsodium'
• 'libsodium': A Modern and Easy-to-Use Crypto Library
• 'keyring': Access the system credential store from R
• Set-Cookie flags: Descriptions of different flags for Set-Cookie
• Cross-site scripting: A security exploit which allows an attacker to inject into a website malicious client-side code

Examples

## Not run:
```r
## Set secret key using 'keyring' (preferred method)
keyring::key_set_with_value("plumber_api", password = plumber::random_cookie_key())
```

```r
pr() %>%
  pr_cookie(
    keyring::key_get("plumber_api"),
    name = "counter"
  ) %>%
  pr_get("/sessionCounter", function(req) {
    count <- 0
    if (!is.null(req$session$counter)){
      count <- as.numeric(req$session$counter)
    }
    req$session$counter <- count + 1
    return(paste0("This is visit ", count))
  }) %>%
  pr_run()
```

#### -------------------------------- ###

## Save key to a local file
```r
pswd_file <- "normal_file.txt"
cat(plumber::random_cookie_key(), file = pswd_file)
# Make file read-only
Sys.chmod(pswd_file, mode = "0600")
```
Add a filter to Plumber router

Description

Filters can be used to modify an incoming request, return an error, or return a response prior to the request reaching an endpoint.

Usage

pr_filter(pr, name, expr, serializer)

Arguments

- **pr**: A Plumber API. Note: The supplied Plumber API object will also be updated in place as well as returned by the function.
- **name**: A character string. Name of filter
- **expr**: An expr that resolve to a filter function or a filter function
- **serializer**: A serializer function

Value

The Plumber router with the defined filter added

Examples

```r
## Not run:
pr() %>%
  pr_cookie(
    readLines(pswd_file, warn = FALSE),
    name = "counter"
  ) %>%
  pr_get("/sessionCounter", function(req) {
    count <- 0
    if (!is.null(req$session$counter)){
      count <- as.numeric(req$session$counter)
    }
    req$session$counter <- count + 1
    return(paste0("This is visit ", count))
  }) %>%
  pr_run()
## End(Not run)
```
**pr_handle**

---

**Add handler to Plumber router**

**Description**

This collection of functions creates handlers for a Plumber router.

**Usage**

- `pr_handle(pr, methods, path, handler, preempt, serializer, endpoint, ...)`
- `pr_get(pr, path, handler, preempt, serializer, endpoint, ...)`
- `pr_post(pr, path, handler, preempt, serializer, endpoint, ...)`
- `pr_put(pr, path, handler, preempt, serializer, endpoint, ...)`
- `pr_delete(pr, path, handler, preempt, serializer, endpoint, ...)`
- `pr_head(pr, path, handler, preempt, serializer, endpoint, ...)`

**Arguments**

- `pr` A Plumber API. Note: The supplied Plumber API object will also be updated in place as well as returned by the function.
- `methods` Character vector of HTTP methods
- `path` The endpoint path
- `handler` A handler function
- `preempt` A preempt function
- `serializer` A Plumber serializer
- `endpoint` A PlumberEndpoint object
- `...` Additional arguments for PlumberEndpoint

**Details**

The generic `pr_handle()` creates a handle for the given method(s). Specific functions are implemented for the following HTTP methods:

- GET
- POST
- PUT
- DELETE
- HEAD Each function mutates the Plumber router in place and returns the updated router.

**Value**

A Plumber router with the handler added
Examples

```r
## Not run:
pr() %>%
  pr_handle("GET", "/hi", function() "Hello World") %>%
  pr_run()

pr() %>%
  pr_handle(c("GET", "POST"), "/hi", function() "Hello World") %>%
  pr_run()

pr() %>%
  pr_get("/hi", function() "Hello World") %>%
  pr_post("/echo", function(req, res) {
    if (is.null(req$body)) return("No input")
    list(
      input = req$body
    )
  }) %>%
  pr_run()

## End(Not run)
```

---

**pr_hook**

Register a hook

Description

Plumber routers support the notion of "hooks" that can be registered to execute some code at a particular point in the lifecycle of a request. Plumber routers currently support four hooks:

1. preroute(data, req, res)
2. postroute(data, req, res, value)
3. preserialize(data, req, res, value)
4. postserialize(data, req, res, value)

In all of the above you have access to a disposable environment in the `data` parameter that is created as a temporary data store for each request. Hooks can store temporary data in these hooks that can be reused by other hooks processing this same request.

Usage

```r
pr_hook(pr, stage, handler)
pr_hooks(pr, handlers)
```

Arguments

- `pr` A Plumber API. Note: The supplied Plumber API object will also be updated in place as well as returned by the function.
- `stage` A character string. Point in the lifecycle of a request.
- `handler` A hook function.
- `handlers` A named list of hook handlers
Details

One feature when defining hooks in Plumber routers is the ability to modify the returned value. The convention for such hooks is: any function that accepts a parameter named `value` is expected to return the new value. This could be an unmodified version of the value that was passed in, or it could be a mutated value. But in either case, if your hook accepts a parameter named `value`, whatever your hook returns will be used as the new value for the response.

You can add hooks using the `pr_hook`, or you can add multiple hooks at once using `pr_hooks`, which takes a named list in which the names are the names of the hooks, and the values are the handlers themselves.

Value

A Plumber router with the defined hook(s) added

Examples

```r
## Not run:
pr() %>%
  pr_hook("preroute", function(req){
    cat("Routing a request for", req$PATH_INFO, "...
"
  }) %>%
  pr_hooks(list(
    preserialize = function(req, value){
      print("About to serialize this value:"
      print(value)

      # Must return the value since we took one in. Here we're not choosing
      # to mutate it, but we could.
      value
    },
    postserialize = function(res){
      print("We serialized the value as:"
      print(res$body)
    }
  )) %>%
  pr_handle("GET", "/", function(){ 123 }) %>%
  pr_run()
## End(Not run)
```

---

**pr_mount**  
Mount a Plumber router

Description

Plumber routers can be “nested” by mounting one into another using the `mount()` method. This allows you to compartmentalize your API by paths which is a great technique for decomposing large APIs into smaller files. This function mutates the Plumber router (`pr()`) in place and returns the updated router.
Usage

```r
pr_mount(pr, path, router)
```

Arguments

- **pr**: The host Plumber router.
- **path**: A character string. Where to mount router.
- **router**: A Plumber router. Router to be mounted.

Value

A Plumber router with the supplied router mounted

Examples

```r
## Not run:
pr1 <- pr() %>%
  pr_get("/hello", function() "Hello")

pr() %>%
  pr_get("/goodbye", function() "Goodbye") %>%
  pr_mount("/hi", pr1) %>%
  pr_run()
## End(Not run)
```
Arguments

pr  A Plumber API. Note: The supplied Plumber API object will also be updated in place as well as returned by the function.

host  A string that is a valid IPv4 or IPv6 address that is owned by this server, which the application will listen on. "0.0.0.0" represents all IPv4 addresses and "::/0" represents all IPv6 addresses.

port  A number or integer that indicates the server port that should be listened on. Note that on most Unix-like systems including Linux and Mac OS X, port numbers smaller than 1025 require root privileges.

... Should be empty.

debug  If TRUE, it will provide more insight into your API errors. Using this value will only last for the duration of the run. If pr_set_debug() has not been called, debug will default to interactive() at pr_run() time.

docs  Visual documentation value to use while running the API. This value will only be used while running the router. If missing, defaults to information previously set with pr_set_docs(). For more customization, see pr_set_docs() for examples.

swaggerCallback  An optional single-argument function that is called back with the URL to an OpenAPI user interface when one becomes ready. If missing, defaults to information set with pr_set_docs_callback(). This value will only be used while running the router.

quiet  If TRUE, don’t print routine startup messages.

Examples

## Not run:
pr() %>%
  pr_run()

pr() %>%
  pr_run(
    # manually set port
    port = 5762,
    # turn off visual documentation
    docs = FALSE,
    # do not display startup messages
    quiet = TRUE
  )

## End(Not run)

---

pr_set_404  
Set the handler that is called when the incoming request can’t be served

Description

This function allows a custom error message to be returned when a request cannot be served by an existing endpoint or filter.
pr_set_api_spec

Usage

pr_set_404(pr, fun)

Arguments

pr A Plumber API. Note: The supplied Plumber API object will also be updated in place as well as returned by the function.

fun A handler function

Value

The Plumber router with a modified 404 handler

Examples

## Not run:
handler_404 <- function(req, res) {
  res$status <- 404
  res$body <- "Oops"
}

pr() %>%
  pr_get("/hi", function() "Hello") %>%
  pr_set_404(handler_404) %>%
  pr_run()

## End(Not run)

pr_set_api_spec

Set the OpenAPI Specification

Description

Allows to modify OpenAPI Specification autogenerated by plumber.

Usage

pr_set_api_spec(pr, api)

Arguments

pr A Plumber API. Note: The supplied Plumber API object will also be updated in place as well as returned by the function.

api This can be

• an OpenAPI Specification formatted list object
• a function that accepts the OpenAPI Specification autogenerated by plumber and returns a OpenAPI Specification formatted list object.
• a path to an OpenAPI Specification

The value returned will not be validated for OAS compatibility.
Details

Note, the returned value will be sent through `serializer_unboxed_json()` which will turn all length 1 vectors into atomic values. To force a vector to serialize to an array of size 1, be sure to call `as.list()` on your value. `list()` objects are always serialized to an array value.

Value

The Plumber router with the new OpenAPI Specification object or function.

Examples

```r
## Not run:
# Set the API Spec to a function to use the auto-generated OAS object
pr() %>%
  pr_set_api_spec(function(spec) {
    spec$INFO$title <- Sys.time()
    spec
  }) %>%
  pr_get("/plus/<a:int>/<b:int>", function(a, b) { a + b }) %>%
  pr_run()

# Set the API Spec using an object
pr() %>%
  pr_set_api_spec(my_custom_object) %>%
  pr_get("/plus/<a:int>/<b:int>", function(a, b) { a + b }) %>%
  pr_run()

## End(Not run)
```

pr_set_debug

Set debug value to include error messages of routes cause an error

Description

To hide any error messages in production, set the debug value to `FALSE`. The debug value is enabled by default for `interactive()` sessions.

Usage

`pr_set_debug(pr, debug = interactive())`

Arguments

- `pr` A Plumber API. Note: The supplied Plumber API object will also be updated in place as well as returned by the function.
- `debug` `TRUE` provides more insight into your API errors.

Value

The Plumber router with the new debug setting.
Examples

```r
## Not run:
# Will contain the original error message
pr() %>%
  pr_set_debug(TRUE) %>%
  pr_get("/boom", function() stop("boom")) %>%
  pr_run()

# Will NOT contain an error message
pr() %>%
  pr_set_debug(FALSE) %>%
  pr_get("/boom", function() stop("boom")) %>%
  pr_run()

## End(Not run)
```

---

**pr_set_docs**

*Set the API visual documentation*

**Description**

docs should be either a logical or a character value matching a registered visual documentation. Multiple handles will be added to Plumber object. OpenAPI json file will be served on paths /openapi.json. Documentation will be served on paths/__/docs__/index.html and /__/docs__/.

**Usage**

```r
pr_set_docs(pr, docs = get_option_or_env("plumber.docs", TRUE), ...)
```

**Arguments**

- **pr** A Plumber API. Note: The supplied Plumber API object will also be updated in place as well as returned by the function.
- **docs** a character value or a logical value. If using `options_plumber()`, the value must be set before initializing your Plumber router.
- **...** Arguments for the visual documentation. See each visual documentation package for further details.

**Value**

The Plumber router with the new docs settings.

**Examples**

```r
## Not run:
## View API using Swagger UI
# Official Website: https://swagger.io/tools/swagger-ui/
# install.packages("swagger")
if (require(swagger)) {
  pr() %>%
    pr_set_docs("swagger") %>%
    pr_get("/plus/<a:int>/<b:int>", function(a, b) { a + b }) %>%
```
## View API using Redoc

Official Website: https://github.com/Redocly/redoc

```r
if (require(redoc)) {
  pr() %>%
  pr_set_docs("redoc") %>%
  pr_get("/plus/<a:int>/<b:int>", function(a, b) { a + b }) %>%
  pr_run()
}
```

## View API using RapiDoc

Official Website: https://github.com/mrin9/RapiDoc

```r
if (require(rapidoc)) {
  pr() %>%
  pr_set_docs("rapidoc") %>%
  pr_get("/plus/<a:int>/<b:int>", function(a, b) { a + b }) %>%
  pr_run()
}
```

## Disable the OpenAPI Spec UI

```r
pr() %>%
pr_set_docs(FALSE) %>%
pr_get("/plus/<a:int>/<b:int>", function(a, b) { a + b }) %>%
pr_run()
```

## End(Not run)

---

### pr_set_docs_callback

Set the callback to tell where the API visual documentation is located

---

**Description**

When set, it will be called with a character string corresponding to the API visual documentation url. This allows RStudio to locate visual documentation.

**Usage**

```r
pr_set_docs_callback(
  pr,
  callback = get_option_or_env("plumber.docs.callback", NULL)
)
```

**Arguments**

- **pr** A Plumber API. Note: The supplied Plumber API object will also be updated in place as well as returned by the function.
- **callback** a callback function for taking action on the docs url.

**Details**

If using `options_plumber()`, the value must be set before initializing your Plumber router.
Value

The Plumber router with the new docs callback setting.

Examples

```r
## Not run:
pr() %>%
  pr_set_docs_callback(function(url) { message("API location: ", url) }) %>%
  pr_get("/plus/<a:int>/<b:int>", function(a, b) { a + b }) %>%
  pr_run()
## End(Not run)
```

---

**pr_set_error**  
Set the error handler that is invoked if any filter or endpoint generates an error

Description

Set the error handler that is invoked if any filter or endpoint generates an error

Usage

```
pr_set_error(pr, fun)
```

Arguments

- **pr**  
  A Plumber API. Note: The supplied Plumber API object will also be updated in place as well as returned by the function.

- **fun**  
  An error handler function. This should accept `req`, `res`, and the error value

Value

The Plumber router with a modified error handler

Examples

```r
## Not run:
handler_error <- function(req, res, err){
  res$status <- 500
  list(error = "Custom Error Message")
}

pr() %>%
  pr_get("/error", function() log("a")) %>%
  pr_set_error(handler_error) %>%
  pr_run()
## End(Not run)
```
pr_set_parsers

Set the default endpoint parsers for the router

Description

By default, Plumber will parse JSON, text, query strings, octet streams, and multipart bodies. This function updates the default parsers for any endpoint that does not define their own parsers.

Usage

pr_set_parsers(pr, parsers)

Arguments

pr A Plumber API. Note: The supplied Plumber API object will also be updated in place as well as returned by the function.
parsers Can be one of:

• A NULL value
• A character vector of parser names
• A named list() whose keys are parser names names and values are arguments to be applied with do.call()
• A TRUE value, which will default to combining all parsers. This is great for seeing what is possible, but not great for security purposes

If the parser name "all" is found in any character value or list name, all remaining parsers will be added. When using a list, parser information already defined will maintain their existing argument values. All remaining parsers will use their default arguments.

Example:

# provide a character string
parsers = "json"

# provide a named list with no arguments
parsers = list(json = list())

# provide a named list with arguments; include `rds`
parsers = list(json = list(simplifyVector = FALSE), rds = list())

# default plumber parsers
parsers = c("json", "form", "text", "octet", "multi")

Details

Note: The default set of parsers will be completely replaced if any value is supplied. Be sure to include all of your parsers that you would like to include. Use registered_parsers() to get a list of available parser names.

Value

The Plumber router with the new default PlumberEndpoint parsers
pr_set_serializer  Set the default serializer of the router

Description

By default, Plumber serializes responses to JSON. This function updates the default serializer to the function supplied via serializer

Usage

pr_set_serializer(pr, serializer)

Arguments

pr
A Plumber API. Note: The supplied Plumber API object will also be updated in place as well as returned by the function.

serializer
A serializer function

Value

The Plumber router with the new default serializer

pr_static  Add a static route to the plumber object

Description

Add a static route to the plumber object

Usage

pr_static(pr, path, direc)

Arguments

pr
A Plumber API. Note: The supplied Plumber API object will also be updated in place as well as returned by the function.

path
The mounted path location of the static folder

direc
The local folder to be served statically

Examples

## Not run:
pr() %>%
  pr_static("/path", ".\my_folder/location") %>%
  pr_run()

## End(Not run)
random_cookie_key

Description

Uses a cryptographically secure pseudorandom number generator from `sodium::helpers()` to generate a 64 digit hexadecimal string. `sodium` wraps around `libsodium`.

Usage

random_cookie_key()

Details

Please see `session_cookie` for more information on how to save the generated key.

Value

A 64 digit hexadecimal string to be used as a key for cookie encryption.

See Also

`session_cookie`

register_docs

Add visual documentation for plumber to use

Description

`register_docs()` is used by other packages like swagger, rapidoc, and redoc. When you load these packages, it calls `register_docs()` to provide a user interface that can interpret your plumber OpenAPI Specifications.

Usage

register_docs(name, index, static = NULL)

registered_docs()

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Name of the visual documentation</td>
</tr>
<tr>
<td>index</td>
<td>A function that returns the HTML content of the landing page of the documentation. Parameters (besides <code>req</code> and <code>res</code>) will be supplied as if it is a regular GET route. Default parameter values may be used when setting the documentation index function. See the example below.</td>
</tr>
<tr>
<td>static</td>
<td>A function that returns the path to the static assets (images, javascript, css, fonts) the Docs will use.</td>
</tr>
</tbody>
</table>
Examples

```r
## Not run:
# Example from the `swagger` R package
register_docs(
  name = "swagger",
  index = function(version = "3", ...) {
    swagger::swagger_spec(
      api_path = paste0(
        "window.location.origin + ",
        "window.location.pathname.replace(" ,
        "/(\__docs__/|\__docs__/index.html)/", ", ",
        "\"openapi\""
      ),
      version = version
    ),
    static = function(version = "3", ...) {
      swagger::swagger_path(version)
    }
  },
  # When setting the docs, `index` and `static` function arguments can be supplied
  # * via `pr_set_docs`
  # * or through URL query string variables
  pr() %>%
  # Set default argument `version = "3"` for the swagger `index` and `static` functions
  pr_set_docs("swagger", version = "3") %>%
  pr_get("/plus/<a:int>/<b:int>", function(a, b) { a + b })) %>%
  pr_run()
)

## End(Not run)
```

register_parser

Manage parsers

Description

A parser is responsible for decoding the raw body content of a request into a list of arguments that

Usage

```r
register_parser(alias, parser, fixed = NULL, regex = NULL, verbose = TRUE)

registered_parsers()
```

Arguments

- **alias**
  
  An alias to map parser from the @parser plumber tag to the global parsers list.

- **parser**
  
  The parser function to be added. This build the parser function. See Details for
  more information.
**register_parser**

fixed A character vector of fixed string to be matched against a request content-type to use parser.

regex A character vector of regex string to be matched against a request content-type to use parser.

verbose Logical value which determines if a warning should be displayed when alias in map are overwritten.

**Details**

When parser is evaluated, it should return a parser function. Parser matching is done first by content-type header matching with fixed then by using regular expressions with regex. Note that plumber strips ; charset* from content-type header before matching.

Plumber will try to use parser_json() (if available) when no content-type header is found and the request body starts with { or [.

Functions signature should include value, ... and possibly content_type, filename. Other parameters may be provided if you want to use the headers from webutils::parse_multipart().

Parser function structure is something like below.

```r
function(parser_arguments_here) {
  # return a function to parse a raw value
  function(value, ...) {
    # do something with raw value
  }
}
```

**Functions**

- `registered_parsers()`: Return all registered parsers

**Examples**

```r
# 'content-type' header is mostly used to look up charset and adjust encoding
parser_dcf <- function(...) {
  function(value, content_type = "text/x-dcf", ...) {
    charset <- get_character_set(content_type)
    value <- rawToChar(value)
    Encoding(value) <- charset
    read.dcf(value, ...)
  }
}

# Could also leverage existing parsers
parser_dcf <- function(...) {
  parser_read_file(function(tmpfile) {
    read.dcf(tmpfile, ...)
  })
}

# Register the newly created parser
## Not run: register_parser("dcf", parser_dcf, fixed = "text/x-dcf")
```
register Serializer

Description

A serializer is responsible for translating a generated R value into output that a remote user can understand. For instance, the serializer_json serializes R objects into JSON before returning them to the user. The list of available serializers in plumber is global.

Usage

register_serializer(name, serializer, verbose = TRUE)
registered_serializers()

Arguments

name
The name of the serializer (character string)

serializer
The serializer function to be added. This function should accept arguments that can be supplied when plumb()ing a file. This function should return a function that accepts four arguments: value, req, res, and errorHandler. See print(serializer_json) for an example.

verbose
Logical value which determines if a message should be printed when overwriting serializers

Details

There are three main building-block serializers:

• serializer_headers: the base building-block serializer that is required to have as_attachment() work

• serializer_content_type(): for setting the content type. (Calls serializer_headers())

• serializer_device(): add endpoint hooks to turn a graphics device on and off in addition to setting the content type. (Uses serializer_content_type())

Functions

• register_serializer(): Register a serializer with a name

• registered_serializers(): Return a list of all registered serializers

Examples

# `serializer_json()` calls `serializer_content_type()` and supplies a serialization function
print(serializer_json)

# `serializer_content_type()` calls `serializer_headers()` and supplies a serialization function
print(serializer_content_type)
Serializer Headers

Description

Serializers are used in Plumber to transform the R object produced by a filter/endpoint into an HTTP response that can be returned to the client. See here for more details on Plumber serializers and how to customize their behavior.

Usage

serializer_headers(headers = list(), serialize_fn = identity)

serializer_content_type(type, serialize_fn = identity)

serializer_octet(..., type = "application/octet-stream")

serializer_csv(..., type = "text/csv; charset=UTF-8")

serializer_tsv(..., type = "text/tab-separated-values; charset=UTF-8")

serializer_html(type = "text/html; charset=UTF-8")

serializer_json(..., type = "application/json")

serializer_unboxed_json(auto_unbox = TRUE, ..., type = "application/json")

serializer_geojson(..., type = "application/geo+json")

serializer_rds(version = "2", ascii = FALSE, ..., type = "application/rds")

serializer_feather(type = "application/vnd.apache.arrow.file")

serializer_parquet(type = "application/vnd.apache.parquet")

serializer_yaml(..., type = "text/x-yaml; charset=UTF-8")

serializer_text(
    ..., 
    serialize_fn = as.character, 
    type = "text/plain; charset=UTF-8"
)

serializer_format(..., type = "text/plain; charset=UTF-8")

serializer_print(..., type = "text/plain; charset=UTF-8")

serializer_cat(..., type = "text/plain; charset=UTF-8")

serializer_write_file(type, write_fn, fileext = NULL)
serializer_htmlwidget(..., type = "text/html; charset=UTF-8")
serializer_device(type, dev_on, dev_off = grDevices::dev.off)
serializer_jpeg(..., type = "image/jpeg")
serializer_png(..., type = "image/png")
serializer_svg(..., type = "image/svg+xml")
serializer_bmp(..., type = "image/bmp")
serializer_tiff(..., type = "image/tiff")
serializer_pdf(..., type = "application/pdf")

Arguments
headers list() of headers to add to the response object
serialize_fn Function to serialize the data. The result object will be converted to a character
string. Ex: jsonlite::toJSON().
type The value to provide for the Content-Type HTTP header.
... extra arguments supplied to respective internal serialization function.
auto_unbox automatically unbox() all atomic vectors of length 1. It is usually safer to avoid
this and instead use the unbox() function to unbox individual elements. An
exception is that objects of class AsIs (i.e. wrapped in I()) are not automatically
unboxed. This is a way to mark single values as length-1 arrays.
version the workspace format version to use. NULL specifies the current default version
(3). The only other supported value is 2, the default from R 1.4.0 to R 3.5.0.
ascii a logical. If TRUE or NA, an ASCII representation is written; otherwise (default)
a binary one. See also the comments in the help for save.
write_fn Function that should write serialized content to the temp file provided. write_fn
should have the function signature of function(value, tmp_file){}
fileext A non-empty character vector giving the file extension. This value will try to be
inferred from the content type provided.
dev_on Function to turn on a graphics device. The graphics device dev_on function
will receive any arguments supplied to the serializer in addition to filename.
filename points to the temporary file name that should be used when saving
content.
dev_off Function to turn off the graphics device. Defaults to grDevices::dev.off()

Functions
- serializer_headers(): Add a static list of headers to each return value. Will add Content-Disposition
  header if a value is the result of as_attachment().
- serializer_content_type(): Adds a Content-Type header to the response object
- serializer_octet(): Octet serializer. If content is received that does not have a "raw" type,
  then an error will be thrown.
- serializer_csv(): CSV serializer. See also: readr::format_csv()
- `serializer_tsv()`: TSV serializer. See also: `readr::format_tsv()`
- `serializer_html()`: HTML serializer
- `serializer_json()`: JSON serializer. See also: `jsonlite::toJSON()`
- `serializer_unboxed_json()`: JSON serializer with auto_unbox defaulting to TRUE. See also: `jsonlite::toJSON()`
- `serializer_geojson()`: GeoJSON serializer. See also `geojsonsf::sf_geojson()` and `geojsonsf::sfc_geojson()`.
- `serializer_rds()`: RDS serializer. See also: `base::serialize()`
- `serializer_feather()`: feather serializer. See also: `arrow::write_feather()`
- `serializer_parquet()`: parquet serializer. See also: `arrow::write_parquet()`
- `serializer_yaml()`: YAML serializer. See also: `yaml::as.yaml()`
- `serializer_text()`: Text serializer. See also: `as.character()`
- `serializer_format()`: Text serializer. See also: `format()`
- `serializer_print()`: Text serializer. Captures the output of `print()`
- `serializer_cat()`: Text serializer. Captures the output of `cat()`
- `serializer_write_file()`: Write output to a temp file whose contents are read back as a serialized response. `serializer_write_file()` creates (and cleans up) a temp file, calls the serializer (which should write to the temp file), and then reads the contents back as the serialized value. If the content type starts with "text", the return result will be read into a character string, otherwise the result will be returned as a raw vector.
- `serializer_htmlwidget()`: htmlwidget serializer. See also: `htmlwidgets::saveWidget()`
- `serializer_device()`: Helper method to create graphics device serializers, such as `serializer_png()`. See also: `endpoint_serializer()`
- `serializer_jpeg()`: JPEG image serializer. See also: `grDevices::jpeg()`
- `serializer_png()`: PNG image serializer. See also: `grDevices::png()`
- `serializer_svg()`: SVG image serializer. See also: `grDevices::svg()`
- `serializer_bmp()`: BMP image serializer. See also: `grDevices::bmp()`
- `serializer_tiff()`: TIFF image serializer. See also: `grDevices::tiff()`
- `serializer_pdf()`: PDF image serializer. See also: `grDevices::pdf()`

---

**session_cookie**

Store session data in encrypted cookies.

---

**Description**

`plumber` uses the crypto R package `sodium`, to encrypt/decrypt `req$session` information for each server request.

**Usage**

```r
session_cookie(
  key,
  name = "plumber",
  expiration = FALSE,
  http = TRUE,
  secure = FALSE,
  same_site = FALSE,
  path = NULL
)
```
Arguments

key  The secret key to use. This must be consistent across all R sessions where you want to save/restore encrypted cookies. It should be produced using `random_cookie_key`. Please see the "Storing secure keys" section for more details complex character string to bolster security.

name  The name of the cookie in the user’s browser.

expiration  A number representing the number of seconds into the future before the cookie expires or a POSIXt date object of when the cookie expires. Defaults to the end of the user’s browser session.

http  Boolean that adds the `HttpOnly` cookie flag that tells the browser to save the cookie and to NOT send it to client-side scripts. This mitigates cross-site scripting. Defaults to `TRUE`.

secure  Boolean that adds the `Secure` cookie flag. This should be set when the route is eventually delivered over HTTPS.

same_site  A character specifying the SameSite policy to attach to the cookie. If specified, one of the following values should be given: "Strict", "Lax", or "None". If "None" is specified, then the `secure` flag MUST also be set for the modern browsers to accept the cookie. An error will be returned if `same_site = "None"` and `secure = FALSE`. If not specified or a non-character is given, no SameSite policy is attached to the cookie.

path  The URI path that the cookie will be available in future requests. Defaults to the request URI. Set to "/" to make cookie available to all requests at the host.

Details

The cookie’s secret encryption key value must be consistent to maintain `req$session` information between server restarts.

Storing secure keys

While it is very quick to get started with user session cookies using `plumber`, please exercise precaution when storing secure key information. If a malicious person were to gain access to the secret key, they would be able to eavesdrop on all `req$session` information and/or tamper with `req$session` information being processed.

Please:

- Do NOT store keys in source control.
- Do NOT store keys on disk with permissions that allow it to be accessed by everyone.
- Do NOT store keys in databases which can be queried by everyone.

Instead, please:

- Use a key management system, such as `keyring` (preferred)
- Store the secret in a file on disk with appropriately secure permissions, such as "user read only" (`Sys.chmod("myfile.txt", mode = "0600")) to prevent others from reading it.

Examples of both of these solutions are done in the Examples section.
See Also

- 'sodium': R bindings to 'libsodium'
- 'libsodium': A Modern and Easy-to-Use Crypto Library
- 'keyring': Access the system credential store from R
- Set-Cookie flags: Descriptions of different flags for Set-Cookie
- Cross-site scripting: A security exploit which allows an attacker to inject into a website malicious client-side code

Examples

```r
## Not run:
## Set secret key using 'keyring' (preferred method)
keyring::key_set_with_value("plumber_api", plumber::random_cookie_key())

# Load a plumber API
plumb_api("plumber", "01-append") %>%
  # Add cookie support via 'keyring'
  pr_cookie(
    keyring::key_get("plumber_api")
  ) %>
  pr_run()

### -------------------------------- ###
## Save key to a local file
pswd_file <- "normal_file.txt"
cat(plumber::random_cookie_key(), file = pswd_file)
# Make file read-only
Sys.chmod(pswd_file, mode = "0600")

# Load a plumber API
plumb_api("plumber", "01-append") %>%
  # Add cookie support and retrieve secret key from file
  pr_cookie(
    readLines(pswd_file, warn = FALSE)
  ) %>
  pr_run()

## End(Not run)
```

validate_api_spec

Validate OpenAPI Spec

Description

Validate an OpenAPI Spec using Swagger CLI which calls Swagger Parser.
validate_api_spec

Usage

validate_api_spec(pr, verbose = TRUE)

Arguments

pr A Plumber API
verbose Logical that determines if a "is valid" statement is displayed. Defaults to TRUE

Details

If the api is deemed invalid, an error will be thrown.

This function is VERY [Experimental] and may be altered, changed, or removed in the future.

Examples

## Not run:
pr <- plumb_api("plumber", "01-append")
validate_api_spec(pr)

## End(Not run)
