

Package ‘prevalence’

April 20, 2015

Type Package

Title Tools for Prevalence Assessment Studies

Version 0.4.0

Date 2015-04-20

Author Brecht Devleesschauwer [aut, cre], Paul Torgerson [aut],
Johannes Charlier [aut], Bruno Levecke [aut], Nicolas Praet [aut],
Sophie Roelandt [aut], Suzanne Smit [aut], Pierre Dorny [aut],
Dirk Berkvens [aut], Niko Speybroeck [aut]

Maintainer Brecht Devleesschauwer <brechtdv@gmail.com>

BugReports <https://github.com/brechtdv/prevalence/issues>

Description The prevalence package provides Frequentist and Bayesian methods for prevalence assessment studies. **IMPORTANT:** the truePrev functions in the prevalence package call on JAGS (Just Another Gibbs Sampler), which therefore has to be available on the user's system. JAGS can be downloaded from <http://mcmc-jags.sourceforge.net/>.

Depends R (>= 3.0.0), rjags, coda, methods

SystemRequirements JAGS (>= 3.2.0) (see
<http://mcmc-jags.sourceforge.net>)

License GPL (>= 2)

prevalence-package	<i>Tools for prevalence assessment studies</i>
--------------------	--

Description

The **prevalence** package provides Frequentist and Bayesian methods useful in prevalence assessment studies. Visit <http://prevalence.cbira.be/> for more information and tutorials.

Details

Package:	prevalence
Type:	Package
Version:	0.4.0
Date:	2015-04-20
BugReports:	https://github.com/brechtvd/prevalence/issues
Depends:	R (>= 3.0.0), rjags, coda, methods
SystemRequirements:	JAGS (>= 3.2.0) (see http://mcmc-jags.sourceforge.net)
License:	GNU >= 2

Available functions in the **prevalence** package:

propCI	Derive confidence intervals for an apparent prevalence estimate
truePrev	Estimate TP from AP obtained by testing individual samples with a single test
truePrevMulti	Estimate TP from AP obtained by testing individual samples with multiple tests, using a conditional probability
truePrevMulti2	Estimate TP from AP obtained by testing individual samples with multiple tests, using a covariance scheme
truePrevPools	Estimate TP from AP obtained by testing pooled samples
betaPERT	Calculate the parameters of a Beta-PERT distribution
betaExpert	Calculate the parameters of a Beta distribution based on expert opinion

IMPORTANT: the `truePrev` functions in the **prevalence** package call on **JAGS (Just Another Gibbs Sampler)**, through the [rjags](#) package. Therefore, JAGS has to be installed on the user's

system.

JAGS can be downloaded from <http://sourceforge.net/projects/mcmc-jags/>

betaExpert	<i>Calculate the parameters of a Beta distribution based on expert information</i>
------------	--

Description

The `betaExpert` function fits a (standard) Beta distribution to expert opinion. The expert provides information on a best-guess estimate (mode or mean), and an uncertainty range:

- The parameter value is with $100 \cdot p\%$ certainty greater than lower
- The parameter value is with $100 \cdot p\%$ certainty smaller than upper
- The parameter value lies with $100 \cdot p\%$ in between lower and upper

Usage

```
betaExpert(best, lower, upper, p = 0.95, method = "mode")
```

```
## S3 method for class 'betaExpert'
print(x, conf.level = .95, ...)
## S3 method for class 'betaExpert'
plot(x, y, ...)
```

Arguments

best	Best-guess estimate; see argument method
lower	Lower uncertainty limit
upper	Upper uncertainty limit
p	Expert's certainty level
method	Does best-guess estimate correspond to the mode or to the mean? Defaults to mode
x	Object of class betaExpert
y	Currently not implemented
conf.level	Confidence level used in printing quantiles of resulting Beta distribution
...	Other arguments to pass to function print and plot

Details

The methodology behind the `betaExpert` function is presented by Branscum et al. (2005) and implemented in the *BetaBuster* software, written by Chun-Lung Su.

The parameters of a standard Beta distribution are calculated based on a best-guess estimate and a $100(p)\%$ uncertainty range, defined by a lower and/or upper limit. The `betaExpert` function uses minimization (`optimize`) to derive α and β from this best guess and lower and/or upper limit. The resulting distribution is a standard 2-parameter Beta distribution: $\text{Beta}(\alpha, \beta)$.

Value

A list of class "betaExpert":

alpha	Parameter α (shape1) of the Beta distribution
beta	Parameter β (shape2) of the Beta distribution

The `print` method for "betaExpert" additionally calculates the mean, median, mode, variance and range of the corresponding Beta distribution.

[betaPERT](#), for modelling a generalized Beta distribution based on expert opinion

Examples

```
## Most likely value (mode) is 90%
## Expert states with 95% certainty that true value is larger than 70%
betaExpert(best = 0.90, lower = 0.70, p = 0.95)

## Most likely value (mode) is 0%
## Expert states with 95% certainty that true value is smaller than 40%
betaExpert(best = 0, upper = 0.40, p = 0.95)

## Most likely value (mode) is 80%
## Expert states with 90% certainty that true value lies in between 40% and 90%
betaExpert(best = 0.80, lower = 0.40, upper = 0.90, p = 0.90)
```

```
## Mean value is assumed to be 80%
## Expert states with 90% certainty that true value lies in between 40% and 90%
betaExpert(best = 0.80, lower = 0.40, upper = 0.90, p = 0.90, method = "mean")
```

betaPERT

Calculate the parameters of a Beta-PERT distribution

Description

The Beta-PERT methodology allows to parametrize a generalized Beta distribution based on expert opinion regarding a pessimistic estimate (minimum value), a most likely estimate (mode), and an optimistic estimate (maximum value). The betaPERT function incorporates two methods of calculating the parameters of a Beta-PERT distribution, designated "classic" and "vose".

Usage

```
betaPERT(a, m, b, k = 4, method = c("classic", "vose"))

## S3 method for class 'betaPERT'
print(x, conf.level = .95, ...)
## S3 method for class 'betaPERT'
plot(x, y, ...)
```

Arguments

a	Pessimistic estimate (Minimum value)
m	Most likely estimate (Mode)
b	Optimistic estimate (Maximum value)
k	Scale parameter
method	"classic" or "vose"; see details below
x	Object of class betaExpert
y	Currently ignored
conf.level	Confidence level used in printing quantiles of resulting Beta-PERT distribution
...	Other arguments to pass to function print and plot

Details

The Beta-PERT methodology was developed in the context of Program Evaluation and Review Technique (PERT). Based on a pessimistic estimate (minimum value), a most likely estimate (mode), and an optimistic estimate (maximum value), typically derived through expert elicitation, the parameters of a Beta distribution can be calculated. The Beta-PERT distribution is used in stochastic modeling and risk assessment studies to reflect uncertainty regarding specific parameters.

Different methods exist in literature for defining the parameters of a Beta distribution based on PERT. The two most common methods are included in the betaPERT function:

Classic: The standard formulas for mean, standard deviation, α and β , are as follows:

$$\begin{aligned} \text{mean} &= \frac{a + k * m + b}{k + 2} \\ \text{sd} &= \frac{b - a}{k + 2} \\ \alpha &= \frac{\text{mean} - a}{b - a} * \left\{ (\text{mean} - a) * \frac{b - \text{mean}}{\text{sd}^2} - 1 \right\} \\ \beta &= \alpha * \frac{b - \text{mean}}{\text{mean} - a} \end{aligned}$$

The resulting distribution is a 4-parameter Beta distribution: Beta(α , β , a, b).

Vose: Vose (2000) describes a different formula for α :

$$(\text{mean} - a) * \frac{2 * m - a - b}{(m - \text{mean}) * (b - a)}$$

Mean and β are calculated using the standard formulas; as for the classical PERT, the resulting distribution is a 4-parameter Beta distribution: Beta(α , β , a, b).

Note: If $m = \text{mean}$, α is calculated as $1 + k/2$, in accordance with the **mc2d** package (see 'Note').

Value

A list of class "betaPERT":

alpha	Parameter α (shape1) of the Beta distribution
beta	Parameter β (shape2) of the Beta distribution
a	Pessimistic estimate (Minimum value)
m	Most likely estimate (Mode)
b	Optimistic estimate (Maximum value)
method	Applied method

Available generic functions for class "betaPERT" are print and plot.

Note

The **mc2d** package provides the probability density function, cumulative distribution function, quantile function and random number generation function for the PERT distribution, parametrized by the "vose" method.

Examples

```
## The value of a parameter of interest is believed to lie between 0 and 50
## The most likely value is believed to be 10

# Classical PERT
betaPERT(a = 0, m = 10, b = 50, method = "classic")

# Vose parametrization
betaPERT(a = 0, m = 10, b = 50, method = "vose")
```

convert-methods

Methods for Function as.matrix in Package **prevalence**

Description

Convert objects of class prev to matrix

Usage

```
## S4 method for signature 'prev'
as.matrix(x, iters = FALSE, chains = FALSE)
```

Arguments

x	An object of class prev
iters	Logical flag, indicating whether a column should be added for iteration number; defaults to FALSE
chains	Logical flag, indicating whether a column should be added for chain number; defaults to FALSE

Methods

signature(x = "prev") Convert objects of class prev to [matrix](#)

See Also

[prev-class](#)

Examples

```

## Not run:

## Taenia solium cysticercosis 1-test model
cysti <-
truePrev(x = 142, n = 742,
         SE = ~dunif(0.60, 1.00), SP = ~dunif(0.75, 1.00))

head(as.matrix(cysti))

## Campylobacter 2-test model
campy <-
truePrevMulti(
  x = c(113, 46, 156, 341),
  n = 656,
  prior = {
    theta[1] ~ dunif(0.45, 0.80)
    theta[2] ~ dunif(0.24, 0.50)
    theta[3] <- 1
    theta[4] ~ dbeta(30, 12)
    theta[5] ~ dbeta(1, 1)
    theta[6] <- 1
    theta[7] <- 1
  }
)

head(as.matrix(campy, iters = TRUE, chains = TRUE))

## End(Not run)

```

define *Definition of truePrevMulti and truePrevMulti2 model*

Description

These utility functions generate definitions for the test results and priors used by `truePrevMulti` and `truePrevMulti2`.

Usage

```

define_x(h)
define_prior(h)
define_prior2(h)

```

Arguments

h Number of tests

Details

The vector of apparent tests results, x , must contain the number of samples corresponding to each combination of test results. The models assume that the first value corresponds to the number of samples that tested positive on all tests and that the last value corresponds to the number of samples that tested negative on all tests.

Function `truePrevMulti` estimates true prevalence from individual samples tested with h tests, using the approach of Berkvens et al. (2006). The prior in the multinomial model consists of a vector `theta`, which holds values for the true prevalence (TP), the sensitivity and specificity of the first test (SE1, SP1), and the conditional dependencies between the results of the subsequent tests and the preceding one(s). `define_prior` generates the definition of prior for h tests.

Function `truePrevMulti2` implements and extends the approach described by Dendukuri and Joseph (2001), which uses a multinomial distribution to model observed test results, and in which conditional dependence between tests is modelled through covariances. Argument `prior` consists of prior distributions for:

- True Prevalence: TP
- SEnsitivity of each individual test: vector SE
- SPecificity of each individual test: vector SP
- Conditional covariance of all possible test combinations given a truly positive disease status: vector a
- Conditional covariance of all possible test combinations given a truly negative disease status: vector b

`define_prior2` generates the definition of prior for h tests.

```

plot-methods

*Methods for Function plot in Package **prevalence***

Description

Plot objects of class prev

Usage

```

## S4 method for signature 'prev,ANY'
plot(x, y = NULL, ...)

```

Arguments

x	An object of class prev
y	Which parameter to plot? Defaults to NULL, in which case TP will be used
...	Other arguments to pass to the plot function

Methods

signature(x = "prev", y = "ANY") Show [density](#), [trace](#), [Brooks-Gelman-Rubin](#) and [autocorrelation](#) plots.

See Also

[prev-class](#)
[densplot-methods](#), [traceplot-methods](#), [gelman.plot-methods](#), [autocorr.plot-methods](#)

plot-methods-coda *Plotting functions from package **coda***

Description

Different plotting functions from package **coda** have been made available as method to class `prev`

Usage

```
## S4 method for signature 'prev'
densplot(x, exclude_fixed = TRUE, ...)

## S4 method for signature 'prev'
traceplot(x, exclude_fixed = TRUE, ...)

## S4 method for signature 'prev'
autocorr.plot(x, exclude_fixed = TRUE, chain = 1, ...)
```

Arguments

<code>x</code>	An object of class <code>prev</code>
<code>exclude_fixed</code>	Should fixed parameters be excluded from plotting? defaults to TRUE
<code>chain</code>	Which chain to plot in <code>autocorr.plot</code> ; defaults to 1
<code>...</code>	Other arguments to pass to the specific plot function.

Methods

`signature(x = "prev")` Show [density](#), [trace](#), [Brooks-Gelman-Rubin](#) and [autocorrelation](#) plots.

[plot-methods](#)
[densplot](#), [traceplot](#), [gelman.plot](#), [autocorr.plot](#)

```
prev-class          Class "prev"
```

Description

The "prev" class represents output from Bayesian true prevalence estimation models.

Objects from the Class

Objects of class "prev" are created by [truePrev](#), [truePrevMulti](#), [truePrevMulti2](#) and [truePrevPools](#).

Slots

Objects of class "prev" contain the following four slots:

par: A list of input parameters

model: The fitted Bayesian model, in BUGS language (S3 class "prevModel")

mcmc: A list, with one element per chain, of the simulated true prevalences, sensitivities and specificities

diagnostics: A list with elements for the Deviance Information Criterion (\$DIC), the Brooks-Gelman-Rubin statistic (\$BGR), and in the case of [truePrevMulti](#) and [truePrevMulti2](#), the Bayes-P statistic (\$bayesP)

SE <- list(dist = "uniform", min = 0.60, max = 1.00)
SP <- list(dist = "uniform", min = 0.75, max = 1.00)
TP <- truePrev(x = 142, n = 742, SE = SE, SP = SP)

## Summarize estimates per chain
summary(TP)

## Diagnostic plots
par(mfrow = c(2, 2))
plot(TP)

## Generic plots from package coda
par(mfrow = c(1, 1))
```

```

densplot(TP)
traceplot(TP)
gelman.plot(TP)
autocorr.plot(TP)

## Use 'str()' to see the structure of object TP
str(TP)

## Every slot can be accessed using the '@' operator
TP@par      # input parameters
TP@model    # fitted model
TP@mcmc     # simulated TP, SE, SP
TP@diagnostics # DIC and BGR (and bayesP)

## Each element of TP@mcmc inherits from coda class 'mcmc.list'
## List all available methods for this class
methods(class = "mcmc.list")
## List all available functions in the coda package
library(help = "coda")

## Highest Posterior Density interval, from coda package
HPDinterval(TP@mcmc$TP)

```

print-methods

Methods for Function print in Package prevalence

Description

Print objects of class `prev`

Usage

```
## S4 method for signature 'prev'
print(x, conf.level = 0.95, dig = 3, ...)
```

Arguments

<code>x</code>	An object of class <code>prev</code>
<code>conf.level</code>	Confidence level to be used in credibility interval
<code>dig</code>	Number of decimal digits to print
<code>...</code>	Other arguments to pass to the <code>print</code> function

Methods

`signature(x = "prev")` Print mean, median, mode, standard deviation and credibility interval of estimated true prevalence, sensitivities and specificities. In addition, print multivariate [Brooks-Gelman-Rubin statistic](#) (or univariate BGR statistic with corresponding upper confidence limit in case of a single stochastic node). BGR values substantially above 1 indicate lack of convergence. For `prev` objects created by `truePrevMulti`, the Bayes-P statistic is also printed. Bayes-P should be as close to 0.5 as possible.

propCI *Calculate confidence intervals for prevalences and other proportions*

Description

The propCI function calculates five types of confidence intervals for proportions:

- Wald interval (= Normal approximation interval, asymptotic interval)
- Agresti-Coull interval (= adjusted Wald interval)
- Exact interval (= Clopper-Pearson interval)
- Jeffreys interval (= Bayesian interval)
- Wilson score interval

Usage

```
propCI(x, n, method = "all", level = 0.95, sortby = "level")
```

Arguments

x	Number of successes (positive samples)
n	Number of trials (sample size)
method	Confidence interval calculation method; see details
level	Confidence level for confidence intervals
sortby	Sort results by "level" or "method"

Details

Five methods are available for calculating confidence intervals. For convenience, synonyms are allowed. Please refer to the PDF version of the manual for proper formatting of the below formulas.

"agresti.coull", "agresti-coull", "ac"

$$\tilde{n} = n + z_{1-\frac{\alpha}{2}}^2$$

$$\tilde{p} = \frac{1}{\tilde{n}} \left(x + \frac{1}{2} z_{1-\frac{\alpha}{2}}^2 \right)$$

$$\tilde{p} \pm z_{1-\frac{\alpha}{2}} \sqrt{\frac{\tilde{p}(1-\tilde{p})}{\tilde{n}}}$$

"exact", "clopper-pearson", "cp"

$$\left(\text{Beta}\left(\frac{\alpha}{2}; x, n - x + 1\right), \text{Beta}\left(1 - \frac{\alpha}{2}; x + 1, n - x\right) \right)$$

"jeffreys", "bayes"

$$\left(\text{Beta}\left(\frac{\alpha}{2}; x + 0.5, n - x + 0.5\right), \text{Beta}\left(1 - \frac{\alpha}{2}; x + 0.5, n - x + 0.5\right) \right)$$

"wald", "asymptotic", "normal"

$$p \pm z_{1-\frac{\alpha}{2}} \sqrt{\frac{p(1-p)}{n}}$$

"wilson"

$$\frac{p + \frac{z_{1-\frac{\alpha}{2}}^2}{2n} \pm z_{1-\frac{\alpha}{2}} \sqrt{\frac{p(1-p)}{n} + \frac{z_{1-\frac{\alpha}{2}}^2}{4n^2}}}{1 + \frac{z_{1-\frac{\alpha}{2}}^2}{n}}$$

Value

Data frame with seven columns:

x	Number of successes (positive samples)
n	Number of trials (sample size)
p	Proportion of successes (prevalence)
method	Confidence interval calculation method
level	Confidence level
lower	Lower confidence limit
upper	Upper confidence limit

Note

In case the observed prevalence equals 0% (ie, $x == 0$), an upper one-sided confidence interval is returned. In case the observed prevalence equals 100% (ie, $x == n$), a lower one-sided confidence interval is returned. In all other cases, two-sided confidence intervals are returned.

Author(s)

Brecht Devleeschauwer <<brechtdv@gmail.com>>

Examples

```
## All methods, 95% confidence intervals
propCI(x = 142, n = 742)
```

```
## Wald-type 90%, 95% and 99% confidence intervals
propCI(x = 142, n = 742, method = "wald", level = c(0.90, 0.95, 0.99))
```

show-methods

Methods for Function show in Package prevalence

Description

Show objects of class prev

Usage

```
## S4 method for signature 'prev'  
show(object)
```

Arguments

object An object of class prev

Methods

signature(object = "prev") Corresponds to print(object)

See Also

[prev-class](#)

summary-methods

Methods for Function summary in Package prevalence

Description

Summarize objects of class prev

Usage

```
## S4 method for signature 'prev'  
summary(object, conf.level)
```

Arguments

object An object of class prev
conf.level Confidence level to be used in credibility intervals

Methods

signature(object = "prev") Obtain mean, median, mode, standard deviation, variance, credibility interval and number of samples for each chain separately and for all chains combined.

See Also[prev-class](#)

`truePrev`*Estimate true prevalence from individuals samples*

Description

Bayesian estimation of true prevalence from apparent prevalence obtained by testing *individual* samples.

Usage

```
truePrev(x, n, SE = 1, SP = 1, prior = c(1, 1),
         nchains = 2, burnin = 10000, update = 10000,
         verbose = FALSE)
```

Arguments

<code>x</code>	The apparent number of positive samples
<code>n</code>	The sample size
<code>SE, SP</code>	The prior distribution for sensitivity (SE) and specificity (SP); see 'Details' below for specification of these distributions
<code>prior</code>	The parameters of the prior Beta distribution for true prevalence; defaults to <code>c(1, 1)</code>
<code>nchains</code>	The number of chains used in the estimation process; 'n' must be ≥ 2
<code>burnin</code>	The number of discarded model iterations; defaults to 10,000
<code>update</code>	The number of withheld model iterations; defaults to 10,000
<code>verbose</code>	Logical flag, indicating if JAGS process output should be printed to the R console; defaults to FALSE

Details

`truePrev` calls on [JAGS/rjags](#) to estimate the true prevalence from the apparent prevalence in a Bayesian framework. The default model, in BUGS language, is given below. To see the actual fitted model, see the model slot of the [prev-object](#).

```
model {
  x ~ dbin(AP, n)
  AP <- SE * TP + (1 - SP) * (1 - TP)
  # SE ~ user-defined (see below)
  # SP ~ user-defined (see below)
  TP ~ dbeta(prior[1], prior[2])
}
```

The test sensitivity (SE) and specificity (SP) can be specified, independently, as one of "fixed", "uniform", "beta", "pert", or "beta-expert", with "fixed" as the default.

Distribution parameters can be specified in a *named* list() as follows:

- **Fixed:** list(dist = "fixed", par)
- **Uniform:** list(dist = "uniform", min, max)
- **Beta:** list(dist = "beta", alpha, beta)
- **Beta-PERT:** list(dist = "pert", method, a, m, b, k)
'method' must be "classic" or "vose";
'a' denotes the pessimistic (minimum) estimate, 'm' the most likely estimate, and 'b' the optimistic (maximum) estimate;
'k' denotes the scale parameter.
See [betaPERT](#) for more information on Beta-PERT parametrization.
- **Beta-Expert:** list(dist = "beta-expert", mode, mean, lower, upper, p)
'mode' denotes the most likely estimate, 'mean' the mean estimate;
'lower' denotes the lower bound, 'upper' the upper bound;
'p' denotes the confidence level of the expert.
Only mode or mean should be specified; lower and upper can be specified together or alone.
See [betaExpert](#) for more information on Beta-Expert parametrization.

For Uniform, Beta and Beta-PERT distributions, BUGS-style short-hand notation is also allowed:

- **Uniform:** ~dunif(min, max)
- **Beta:** ~dbeta(alpha, beta)
- **Beta-PERT:** ~dpert(min, mode, max)

Value

An object of class `prev`.

Note

Markov chain Monte Carlo sampling in truePrev is performed by **JAGS (Just Another Gibbs Sampler)** through the `rjags` package. JAGS can be downloaded from <http://sourceforge.net/projects/mcmc-jags/>.

```

truePrevMulti

*Estimate true prevalence from individuals samples using multiple tests
– conditional probability scheme*

Description

Bayesian estimation of true prevalence from apparent prevalence obtained by applying *multiple* tests to *individual* samples. **truePrevMulti** implements the approach described by Berkvens et al. (2006), which uses a multinomial distribution to model observed test results, and in which conditional dependence between tests is modelled through conditional probabilities.

Usage

```
truePrevMulti(x, n, prior, nchains = 2, burnin = 10000, update = 10000,
              verbose = FALSE)
```

Arguments

x	Vector of apparent test results; see 'Details' below
n	The total sample size
prior	The prior distribution for theta; see 'Details' below
nchains	The number of chains used in the estimation process; must be ≥ 2
burnin	The number of discarded model iterations; defaults to 10,000
update	The number of withheld model iterations; defaults to 10,000
verbose	Logical flag, indicating if JAGS process output should be printed to the R console; defaults to FALSE

Details

`truePrevMulti` calls on **JAGS** via the **rjags** package to estimate true prevalence from apparent prevalence in a Bayesian framework. `truePrevMulti` fits a multinomial model to the apparent test results obtained by testing individual samples with a given number of tests. To see the actual fitted model, see the model slot of the `prev`-object.

The vector of apparent tests results, `x`, must contain the number of samples corresponding to each combination of test results. To see how this vector is defined for the number of tests `h` at hand, use `define_x`.

The prior in the multinomial model consists of a vector `theta`, which holds values for the true prevalence (TP), the sensitivity and specificity of the first test (SE1, SP1), and the conditional dependencies between the results of the subsequent tests and the preceding one(s). To see how this vector is defined for the number of tests `n` at hand, use `define_prior`.

The values of `prior` can be specified in two ways, referred to as BUGS-style and list-style, respectively. See also below for some examples.

For BUGS-style specification, the values of `theta` should be given between curly brackets (i.e., `{}`), separated by line breaks. `theta` values can be specified to be deterministic (i.e., fixed), using the `<-` operator, or stochastic, using the `~` operator. In the latter case, the following distributions can be used:

- **Uniform:** `dunif(min, max)`
- **Beta:** `dbeta(alpha, beta)`
- **Beta-PERT:** `dpert(min, mode, max)`

Alternatively, `theta` values can be specified in a `named list()` as follows:

- **Fixed:** `list(dist = "fixed", par)`

- **Uniform:** `list(dist = "uniform", min, max)`
- **Beta:** `list(dist = "beta", alpha, beta)`
- **Beta-PERT:** `list(dist = "pert", method, a, m, b, k)`
 'method' must be "classic" or "vose";
 'a' denotes the pessimistic (minimum) estimate, 'm' the most likely estimate, and 'b' the optimistic (maximum) estimate;
 'k' denotes the scale parameter.
 See [betaPERT](#) for more information on Beta-PERT parameterization.
- **Beta-Expert:** `list(dist = "beta-expert", mode, mean, lower, upper, p)`
 'mode' denotes the most likely estimate, 'mean' the mean estimate;
 'lower' denotes the lower bound, 'upper' the upper bound;
 'p' denotes the confidence level of the expert.
 Only mode or mean should be specified; lower and upper can be specified together or alone.
 See [betaExpert](#) for more information on Beta-Expert parameterization.

Value

An object of class [prev](#).

Note

Markov chain Monte Carlo sampling in `truePrevMulti` is performed by **JAGS (Just Another Gibbs Sampler)** through the [rjags](#) package. JAGS can be downloaded from <http://sourceforge.net/projects/mcmc-jags/>.

Description

Bayesian estimation of true prevalence from apparent prevalence obtained by applying *multiple* tests to *individual* samples. `truePrevMulti2` implements and extends the approach described by Dendukuri and Joseph (2001), which uses a multinomial distribution to model observed test results, and in which conditional dependence between tests is modelled through covariances.

Usage

```
truePrevMulti2(x, n, prior, nchains = 2, burnin = 10000, update = 10000,
               verbose = FALSE)
```

Arguments

<code>x</code>	Vector of apparent test results; see 'Details' below
<code>n</code>	The total sample size
<code>prior</code>	The prior distributions; see 'Details' below
<code>nchains</code>	The number of chains used in the estimation process; must be ≥ 2
<code>burnin</code>	The number of discarded model iterations; defaults to 10,000
<code>update</code>	The number of withheld model iterations; defaults to 10,000
<code>verbose</code>	Logical flag, indicating if JAGS process output should be printed to the R console; defaults to FALSE

Details

`truePrevMulti2` calls on **JAGS** via the `rjags` package to estimate true prevalence from apparent prevalence in a Bayesian framework. `truePrevMulti2` fits a multinomial model to the apparent test results obtained by testing individual samples with a given number of tests. To see the actual fitted model, see the model slot of the `prev`-object.

The vector of apparent tests results, `x`, must contain the number of samples corresponding to each combination of test results. To see how this vector is defined for the number of tests `h` at hand, use `define_x`.

Argument `prior` consists of prior distributions for:

- True Prevalence: TP
- SEnsitivity of each individual test: vector SE
- SPecificity of each individual test: vector SP
- Conditional covariance of all possible test combinations given a truly positive disease status: vector a
- Conditional covariance of all possible test combinations given a truly negative disease status: vector b

To see how `prior` is defined for the number of tests `h` at hand, use `define_prior2`.

The values of prior can be specified in two ways, referred to as BUGS-style and list-style, respectively. See also below for some examples.

For BUGS-style specification, the values of prior should be given between curly brackets (i.e., {}), separated by line breaks. Priors can be specified to be deterministic (i.e., fixed), using the <- operator, or stochastic, using the ~ operator. In the latter case, the following distributions can be used:

- **Uniform:** `dunif(min, max)`
- **Beta:** `dbeta(alpha, beta)`
- **Beta-PERT:** `dpert(min, mode, max)`

Alternatively, priors can be specified in a *named* `list()` as follows:

- **Fixed:** `list(dist = "fixed", par)`
- **Uniform:** `list(dist = "uniform", min, max)`
- **Beta:** `list(dist = "beta", alpha, beta)`
- **Beta-PERT:** `list(dist = "pert", method, a, m, b, k)`
'method' must be "classic" or "vose";
'a' denotes the pessimistic (minimum) estimate, 'm' the most likely estimate, and 'b' the optimistic (maximum) estimate;
'k' denotes the scale parameter.
See [betaPERT](#) for more information on Beta-PERT parameterization.
- **Beta-Expert:** `list(dist = "beta-expert", mode, mean, lower, upper, p)`
'mode' denotes the most likely estimate, 'mean' the mean estimate;
'lower' denotes the lower bound, 'upper' the upper bound;
'p' denotes the confidence level of the expert.
Only mode or mean should be specified; lower and upper can be specified together or alone.
See [betaExpert](#) for more information on Beta-Expert parameterization.

Value

An object of class `prev`.

Note

Markov chain Monte Carlo sampling in `truePrevMulti2` is performed by **JAGS (Just Another Gibbs Sampler)** through the `rjags` package. JAGS can be downloaded from <http://sourceforge.net/projects/mcmc-jags/>.

```

truePrevPools

Estimate true prevalence from pooled samples

Description

Bayesian estimation of true prevalence from apparent prevalence obtained by testing *pooled* samples.

Usage

```

truePrevPools(x, n, SE = 1, SP = 1, prior = c(1, 1),
              nchains = 2, burnin = 10000, update = 10000,
              verbose = FALSE)

```

Arguments

x	The vector of indicator variables, indicating whether a pool was positive ("1") or negative ("0")
n	The vector of pool sizes
SE, SP	The prior distribution for sensitivity (SE) and specificity (SP); see 'Details' below for specification of these distributions
prior	The parameters of the prior Beta distribution for true prevalence; defaults to c(1, 1)
nchains	The number of chains used in the estimation process; nchains must be ≥ 2
burnin	The number of discarded model iterations; defaults to 10,000
update	The number of withheld model iterations; defaults to 10,000
verbose	Logical flag, indicating if JAGS process output should be printed to the R console; defaults to FALSE

Details

truePrevPools calls on **JAGS/rjags** to estimate the true prevalence from the apparent prevalence in a Bayesian framework. The default model, in BUGS language, is given below. To see the actual fitted model, see the model slot of the [prev](#)-object.

```
model {
  for (i in 1:N) {
    x[i] ~ dbern(AP[i])
    AP[i] <- SEpool[i] * (1 - pow(1 - TP, n[i])) + (1 - SPpool[i]) * pow(1 - TP, n[i])
    SEpool[i] <- 1 - (pow(1 - SE, n[i] * TP) * pow(SP, n[i] * (1 - TP)))
    SPpool[i] <- pow(SP, n[i])
  }
  # SE ~ user-defined (see below)
  # SP ~ user-defined (see below)
  TP ~ dbeta(prior[1], prior[2])
}
```

The test sensitivity (SE) and specificity (SP) can be specified by the user, independently, as one of "fixed", "uniform", "beta", "pert", or "beta-expert", with "fixed" as the default. Note that SE and SP must correspond to the test characteristics for testing individual samples; truePrevPools will calculate SEpool and SPpool, the sensitivity and specificity for testing pooled samples, based on Boelaert et al. (2000).

Distribution parameters can be specified in a *named* list() as follows:

- **Fixed:** list(dist = "fixed", par)
- **Uniform:** list(dist = "uniform", min, max)
- **Beta:** list(dist = "beta", alpha, beta)
- **PERT:** list(dist = "pert", method, a, m, b, k)
'method' must be "classic" or "vose";
'a' denotes the pessimistic (minimum) estimate, 'm' the most likely estimate, and 'b' the optimistic (maximum) estimate;
'k' denotes the scale parameter.
See [betaPERT](#) for more information on Beta-PERT parametrization.
- **Beta-Expert:** list(dist = "beta-expert", mode, mean, lower, upper, p)
'mode' denotes the most likely estimate, 'mean' the mean estimate;
'lower' denotes the lower bound, 'upper' the upper bound;
'p' denotes the confidence level of the expert.
Only mode or mean should be specified; lower and upper can be specified together or alone.
See [betaExpert](#) for more information on Beta-Expert parameterization.

For Uniform, Beta and Beta-PERT distributions, BUGS-style short-hand notation is also allowed:

- **Uniform:** ~dunif(min, max)
- **Beta:** ~dbeta(alpha, beta)
- **Beta-PERT:** ~dpert(min, mode, max)

Value

An object of class `prev`.

Note

Markov chain Monte Carlo sampling in `truePrevPools` is performed by **JAGS (Just Another Gibbs Sampler)** through the `rjags` package. JAGS can be downloaded from <http://sourceforge.net/projects/mcmc-jags/>.

See Also

`coda` for various functions that can be applied to the `prev@mcmc` object

`truePrev`: estimate true prevalence from apparent prevalence obtained by testing *individual* samples with a single test

`truePrevMulti`: estimate true prevalence from apparent prevalence obtained by testing *individual* samples with multiple tests, using a conditional probability scheme

`truePrevMulti2`: estimate true prevalence from apparent prevalence obtained by testing *individual* samples with multiple tests, using a covariance scheme

`betaPERT`: calculate the parameters of a Beta-PERT distribution

`betaExpert`: calculate the parameters of a Beta distribution based on expert opinion

Examples

```
## Sandflies in Aurabani, Nepal, 2007
pool_results <- c(0, 0, 0, 0, 0, 0, 0, 0, 1, 0)
pool_sizes <- c(2, 1, 6, 10, 1, 7, 1, 4, 1, 3)

## Sensitivity ranges uniformly between 60% and 95%
## Specificity is considered to be 100%

#> BUGS-style:
truePrevPools(x = pool_results, n = pool_sizes,
              SE = ~dunif(0.60, 0.95), SP = 1)

#> list-style:
SE <- list(dist = "uniform", min = 0.60, max = 0.95)
truePrevPools(x = pool_results, n = pool_sizes,
```

SE = SE, SP = 1)
