Package ‘quadmesh’

October 13, 2022

Type Package
Title Quadrangle Mesh
Version 0.5.5
Description Create surface forms from matrix or 'raster' data for flexible plotting and conversion to other mesh types. The functions 'quadmesh' or 'triangmesh' produce a continuous surface as a 'mesh3d' object as used by the 'rgl' package. This is used for plotting raster data in 3D (optionally with texture), and allows the application of a map projection without data loss and many processing applications that are restricted by inflexible regular grid rasters. There are discrete forms of these continuous surfaces available with 'dquadmesh' and 'dtriangmesh' functions.
License GPL-3
LazyData TRUE
RoxygenNote 7.2.1
Depends R (>= 2.10)
Encoding UTF-8
Imports raster, gridBase, png, sp, geometry, reproj (>= 0.4.0), scales, palr

<table>
<thead>
<tr>
<th>bary_index</th>
<th>Barycentric triangle index for interpolation</th>
</tr>
</thead>
</table>

**Description**

This function returns the barycentric weight for a grid of coordinates from a geographic raster.

**Usage**

bary_index(x, coords = NULL, grid = NULL, ...)

**Arguments**

- **x**
  - a 'RasterLayer' source
- **coords**
  - optional input coordinates
- **grid**
  - target 'RasterLayer', a target regular grid
- **...**
  - ignored

**Details**

It’s not as fast as `raster::projectRaster()` (e.g. `projectRaster(x, grid)`) but it also accepts a `coords` argument and so can be used for non-regular raster reprojection.

'coords' may be 'NULL' or longitude, latitude in a 2-layer raster brick or stack as with `mesh_plot`.

**Value**

RasterLayer
Examples

```r
library(raster)
p_srs <- "+proj=stere +lat_0=-90 +lat_ts=-71 +datum=WGS84"
polar <- raster(extent(-5e6, 5e6, -5e6, 5e6), crs = p_srs, res = 25000)
etopo <- aggregate(etopo, fact = 4)
index <- bary_index(etopo, grid = polar)
ok <- !is.na(index$idx)
r <- setValues(polar, NA_integer_)
r[ok] <- colSums(matrix(values(etopo)[index$tri[, index$idx[ok]]], nrow = 3) * t(index$p)[, ok])
plot(r)
```

cmip6

**CMIP6 sample**

**Description**

A small extract of model output and native grid ('gn') coordinates from CMIP6. Derived from 'CMIP6/ssp245/intpp/intpp_Omon_MPI-ESM1-2-LR_ssp245_r1i1p1f1_gn_201501-203412.nc'.

**Usage**

cmip6

**Format**

An object of class RasterBrick of dimension 220 x 256 x 3.

**Details**

The cmip6 object is a 'RasterBrick', defined by the raster package with three layers: 'intpp', 'longitude', 'latitude'. The model data is primary organic carbon production 'intpp'.

**Source**

- A small extract of data and grid coordinates from CMIP 6 produced by the MPI-M.
  - Description: Primary Organic Carbon Production by All Types of Phytoplankton.
  - Source: Max Planck Institute for Meteorology, Hamburg 20146, Germany (MPI-M)
  - URL: https://data.camlr.org/dataset/small-scale-management-units
  - Reference: doi:10.1029/2017MS001217
  - License: CC BY-SA 4.0

**Examples**

```r
mesh_plot(cmip6[[1]])
```
etopo                        World topography map

Description
A simplified version of 'Etopo2'. The Etopo2 data set was reduced 20X to create this raster layer of global relief. See code in 'data-raw/topo.R'.

Usage
etopo

Format
An object of class RasterLayer of dimension 135 x 540 x 1.

llh2xyz                        Angular coordinates to X, Y, Z.

Description
Angular coordinates to X, Y, Z.

Usage
llh2xyz(lonlatheight, rad = 6378137, exag = 1)

Arguments
lonlatheight matrix or data.frame of lon, lat, height values
rad radius of sphere
exag exaggeration to apply to height values (added to radius)

Value
matrix
### Description

Convert to a quadmesh and plot in efficient vectorized form using 'grid'.

Plot mesh

### Usage

```r
mesh_plot(
  x,
  crs = NULL,
  col = NULL,
  add = FALSE,
  zlim = NULL,
  ...
)
```

```r
## S3 method for class 'BasicRaster'
mesh_plot(
  x,
  crs = NULL,
  col = NULL,
  add = FALSE,
  zlim = NULL,
  ...
)
```

```r
## S3 method for class 'RasterLayer'
mesh_plot(
  x,
  crs = NULL,
  col = NULL,
  add = FALSE,
  zlim = NULL,
  ...
)
```

```r
## S3 method for class 'stars'
mesh_plot(
  x,
  crs = NULL,
  ...)
Arguments

- **x**: object to convert to mesh and plot
- **crs**: target map projection
- **col**: colours to use, defaults to that used by `graphics::image()`
- **add**: add to existing plot or start a new one
The mesh may be reprojected prior to plotting using the ‘crs’ argument to define the target map projection in ‘PROJ string’ format. (There is no "reproject" function for quadmesh, this is performed directly on the x-y coordinates of the ‘quadmesh’ output). The ‘col’ argument are mapped to the input applied object data as in ‘image’, and applied relative to ‘zlim’ if su. If 'coords' is supplied, it is currently assumed to be a 2-layer RasterBrick with longitude and latitude as the cell values. These are used to geographically locate the resulting mesh, and will be transformed to the crs if that is supplied. This is modelled on the approach to curvilinear grid data used in the angstroms package. There the function angstroms::romsmap() and ‘angstroms::romscoords()’ are used to separate the complicated grid geometry from the grid data itself. A small fudge is applied to extend the coordinates by 1 cell to avoid losing any data due to the half cell outer margin (get in touch if this causes problems!).

If 'color' is present on the object it is used. This can be overridden by using the 'col' argument, and controlled with 'zlim' and 'breaks' in the usual graphics::image() way.

### Examples

```r
##mesh_plot(worldll)
## crop otherwise out of bounds from PROJ
rr <- raster::crop(worldll, raster::extent(-179, 179, -89, 89))
mesh_plot(rr, crs = "+proj=laea +datum=WGS84")
mesh_plot(worldll, crs = "+proj=moll +datum=WGS84")
prj <- "+proj=lcc +datum=WGS84 +lon_0=147 +lat_0=-40 +lat_1=-55 +lat_2=-20"
mesh_plot(etopo, crs = prj, add = FALSE, col = grey(seq(0, 1, length = 20)))
mesh_plot(rr, crs = prj, add = TRUE)
```

### qm_as_raster

Approximate re-creation of a raster from a quadmesh.
Usage
qm_as_raster(x, index = NULL)

Arguments
x 'mesh3d' object
index optional index to specify which z coordinate to use as raster values

Details
The raster is populated with the mean of the values at each corner, which is closest to the interpretation use to create mesh3d from rasters. This can be over ridden by setting 'index' to 1, 2, 3, or 4.

Value
RasterLayer

Examples
qm_as_raster(quadmesh(etopo))

qsc

Quadrilateralized Spherical Cube (QSC)

Description
The QSC is a set of six equal area projections for each side of the cube. Here a raw rendition of the cube is returned as six quad primitives in a mesh3d object.

Usage
qsc()

Details
It’s not clear if this is useful.

Value
mesh3d

Examples
str(qsc())
quadmesh

Create a quad-type mesh for use in rgl.

Description

Convert an object to a mesh3d quadrangle mesh, with methods for `raster::raster()` and `matrix`.

Usage

```r
dquadmesh(
  x,
  z = x,
  na.rm = FALSE,
  ..., 
  texture = NULL,
  texture_filename = NULL
)
## Default S3 method:
dquadmesh(
  x,
  z = x,
  na.rm = FALSE,
  ..., 
  texture = NULL,
  texture_filename = NULL
)
quadmesh(x, z = x, na.rm = FALSE, ..., texture = NULL, texture_filename = NULL)
## S3 method for class 'BasicRaster'
quadmesh(x, z = x, na.rm = FALSE, ..., texture = NULL, texture_filename = NULL)
## S3 method for class 'matrix'
quadmesh(x, z = x, na.rm = FALSE, ..., texture = NULL, texture_filename = NULL)
```

Arguments

- `x` : raster object for mesh structure
- `z` : raster object for height values
- `na.rm` : remove quads where missing values?
- `...` : ignored
- `texture` : optional input RGB raster, 3-layers
- `texture_filename` : optional input file path for PNG texture
Details
quadmesh() generates the cell-based interpretation of a raster (AREA) but applies a continuous interpretation of the values of the cells to each quad corner. quadmesh splits the mesh and applies a discrete interpretation directly. Loosely, the quadmesh is a continuous surface and the quadmesh is free-floating cells, but it’s a little more complicated and depends on the options applied. (The interpolation) applied in the quadmesh case is not entirely consistent.

The output is described as a mesh because it is a dense representation of a continuous shape, in this case plane-filling quadrilaterals defined by index of four of the available vertices.

The z argument defaults to the input x argument, though may be set to NULL, a constant numeric value, or another raster. If the coordinate system of z and x don’t match the z values are queried by reprojection.

Any raster RGB object (3-layers, ranging in 0-255) may be used as a texture on the resulting mesh3d object. If texture is a palette raster it will be auto-expanded to RGB.

It is not possible to provide rgl with an object of data for texture, it must be a PNG file and so the in-memory texture argument is written out to PNG file (with a message). The location of the file may be set explicitly with texture_filename. Currently it’s not possible to not use the texture object in-memory.

Value
mesh3d

Examples
library(raster)
data(volcano)
r <- setExtent(raster(volcano), extent(0, 100, 0, 200))
qm <- quadmesh(r)

triangmesh

Create a triangle-type mesh for use in rgl.

Description
Convert an object to a mesh3d (of rgl package) triangle mesh, with methods for raster::raster() and matrix.

Usage
triangmesh(
  x,
  z = x,
  na.rm = FALSE,
  ...,  
texture = NULL,
texture_filename = NULL)
triangmesh

)  

## S3 method for class 'matrix'
triangmesh(
  x,
  z = x,
  na.rm = FALSE,
  ...
  texture = NULL,
  texture_filename = NULL
)

## S3 method for class 'BasicRaster'
triangmesh(
  x,
  z = x,
  na.rm = FALSE,
  ...
  texture = NULL,
  texture_filename = NULL
)

dtriangmesh(
  x,
  z = x,
  na.rm = FALSE,
  ...
  texture = NULL,
  texture_filename = NULL
)

## Default S3 method:
dtriangmesh(
  x,
  z = x,
  na.rm = FALSE,
  ...
  texture = NULL,
  texture_filename = NULL
)

Arguments

x  raster object for mesh structure
z  raster object for height values
na.rm  remove quads where missing values?
...  ignored
texture  optional input RGB raster, 3-layers
triangulate_quads

Texture filename
optional input file path for PNG texture

Details

triangmesh() generates the point-based interpretation of a raster (POINT) with the obvious continuous interpretation. dtriangmesh splits the mesh so that each primitive is independent. This is more coherent than the analogous distinction for quadmesh, though both will appear the same on creation.

The output is described as a mesh because it is a dense representation of a continuous shape, in this case plane-filling triangles defined by index of three of the available vertices.

The z argument defaults to the input x argument, though may be set to NULL, a constant numeric value, or another raster. If the coordinate system of z and x don’t match the z values are queried by reprojection.

Any raster RGB object (3-layers, ranging in 0-255) may be used as a texture on the resulting mesh3d object. It is not possible to provide rgl with an object of data for texture, it must be a PNG file and so the in-memory texture argument is written out to PNG file (with a message). The location of the file may be set explicitly with texture_filename. Currently it’s not possible to not use the texture object in-memory.

Value

mesh3d (primitivetype triangle)

Examples

library(raster)
r <- setExtent(raster(volcano), extent(0, nrow(volcano), 0, ncol(volcano)))
tm <- triangmesh(r)

## jitter the mesh just enough to show that they are distinct in the discrete case
a <- dtriangmesh(r)
a$vb[3L, ] <- jitter(a$vb[3L, ], factor = 10)

triangulate_quads Triangles from quads

Description

Convert quad index to triangles, this converts the 'rgl mesh3d (ib)' quad index to the complementary triangle index '(it)'.

Usage

triangulate_quads(quad_index, clockwise = FALSE)
## use_crs

### In-use coordinate system

#### Description

Set or return the coordinate system currently in use.

#### Usage

```r
use_crs(crs = NULL)
```

#### Arguments

- **crs**
  
  Provide PROJ string to set the value

#### Details

If argument `crs` is NULL, the function returns the current value (which may be “NULL“).

## Arguments

### quad_index

the 'ib' index of quads from 'quadmesh'

### clockwise

if true triangles are wound clockwise, if false anticlockwise. This affects which faces rendering engines consider to be the 'front' and 'back' of the triangle. If your mesh appears 'inside out', try the alternative setting.

#### Details

Triangle pairs from each quad are interleaved in the result, so that neighbour triangles from a single quad are together.

#### Value

matrix of triangle indices

#### Examples

```r
triangulate_quads(cbind(c(1, 2, 4, 3), c(3, 4, 6, 5)))
qm <- quadmesh(raster::crop(etopo, raster::extent(140, 160, -50, -30)))
tri <- triangulate_quads(qm$ib)
plot(t(qm$vb))
tri_avg <- colMeans(matrix(qm$vb[3, tri], nrow = 3), na.rm = TRUE)
scl <- function(x) (x - min(x))/diff(range(x))
tri_col <- grey(seq(0, 1, length = 100))[scl(tri_avg) * 99 + 1]
## tri is qm$ib converted to triangles for the same vertex set
polygon(t(qm$vb)[rbind(tri, NA), ])
polygon(t(qm$vb)[rbind(tri, NA), ], col = tri_col)
```
Examples

```r
## Not run:
use_crs()
use_crs("+proj=laea +datum=WGS84")
use_crs()
## End(Not run)
```

### worldll

#### World raster map

**Description**

A rasterized version of `wrld_simpl`, created by burning the country polygon ID number into a one-degree world raster. (This is a very out of date polygon data set used for example only). See code in `data-raw/worldll.R`.

**Usage**

```r
worldll
```

**Format**

An object of class `RasterLayer` of dimension 180 x 360 x 1.

### xymap

#### World map

**Description**

The world coastline coordinates. A simple matrix of lon, lat, separated by NA.

**Usage**

```r
xymap
```

**Format**

An object of class `matrix` (inherits from `array`) with 82403 rows and 2 columns.

**Details**

From the maps package, see `data-raw/xymap.R`.
