Package ‘quanteda’

August 16, 2017

Version  0.99
Title   Quantitative Analysis of Textual Data
Description  A fast, flexible, and comprehensive framework for
quantitative text analysis in R. Provides functionality for corpus management,
creating and manipulating tokens and n-grams, exploring keywords in context,
forming and manipulating sparse matrices
of documents by features and feature co-
occurrents, analyzing keywords, computing feature similarities and
distances, applying content dictionaries, applying supervised and unsupervised machine learning,
visually representing text and text analyses, and more.
License   GPL-3
Depends  R (>= 3.2.2), methods
Imports  utils, stats, Matrix (>= 1.2), data.table (>= 1.9.6),
         SnowballC, wordcloud, Rcpp (>= 0.12.12), RcppParallel,
         RSpectra, stringi, fastmatch, ggplot2 (>= 2.2.0), XML, yaml,
         lubridate
LinkingTo  Rcpp, RcppParallel, RcppArmadillo (>= 0.7.600.1.0)
Suggests  knitr, rmarkdown, lda, proxy, topicmodels, tm (>= 0.6), slam,
           testthat, RColorBrewer, xtable, DT, ca
URL  http://quanteda.io
Encoding  UTF-8

quanteda-package

An R package for the quantitative analysis of textual data

Description

A set of functions for creating and managing text corpora, extracting features from text corpora, and analyzing those features using quantitative methods.

quanteda makes it easy to manage texts in the form of a corpus, defined as a collection of texts that includes document-level variables specific to each text, as well as meta-data for documents and for the collection as a whole. quanteda includes tools to make it easy and fast to manipulate the texts in a corpus, by performing the most common natural language processing tasks simply and quickly, such as tokenizing, stemming, or forming ngrams. quanteda’s functions for tokenizing texts and forming multiple tokenized documents into a document-feature matrix are both extremely fast and extremely simple to use. quanteda can segment texts easily by words, paragraphs, sentences, or even user-supplied delimiters and tags.

Built on the text processing functions in the stringi package, which is in turn built on C++ implementation of the ICU libraries for Unicode text handling, quanteda pays special attention to fast and correct implementation of Unicode and the handling of text in any character set.
quanteda is built for efficiency and speed, through its design around three infrastructures: the stringi package for text processing, the data.table package for indexing large documents efficiently, and the Matrix package for sparse matrix objects. If you can fit it into memory, quanteda will handle it quickly. (And eventually, we will make it possible to process objects even larger than available memory.)

quanteda is principally designed to allow users a fast and convenient method to go from a corpus of texts to a selected matrix of documents by features, after defining what the documents and features. The package makes it easy to redefine documents, for instance by splitting them into sentences or paragraphs, or by tags, as well as to group them into larger documents by document variables, or to subset them based on logical conditions or combinations of document variables. The package also implements common NLP feature selection functions, such as removing stopwords and stemming in numerous languages, selecting words found in dictionaries, treating words as equivalent based on a user-defined "thesaurus", and trimming and weighting features based on document frequency, feature frequency, and related measures such as tf-idf.

Once constructed, a quanteda document-feature matrix ("dfm") can be easily analyzed using either quanteda's built-in tools for scaling document positions, or used with a number of other text analytic tools, such as: topic models (including converters for direct use with the topicmodels, LDA, and stm packages) document scaling (using quanteda's own functions for the "wordfish" and "Wordscores" models, direct use with the ca package for correspondence analysis, or scaling with the austin package) machine learning through a variety of other packages that take matrix or matrix-like inputs.

Additional features of quanteda include:

- powerful, flexible tools for working with dictionaries;
- the ability to identify keywords associated with documents or groups of documents;
- the ability to explore texts using key-words-in-context;
- fast computation of a variety of readability indexes;
- fast computation of a variety of lexical diversity measures;
- quick computation of word or document similarities, for clustering or to compute distances for other purposes;
- a comprehensive suite of descriptive statistics on text such as the number of sentences, words, characters, or syllables per document; and
- flexible, easy to use graphical tools to portray many of the analyses available in the package.

---

## as.corpus.corpuszip

*coerce a compressed corpus to a standard corpus*

**Description**

Recast a compressed corpus object into a standard (uncompressed) corpus object.

**Usage**

```r
## S3 method for class 'corpuszip'
as.corpus(x)
```

**Arguments**

- `x` a compressed `corpus` object

---

## as.dictionary

*coercion and checking functions for dictionary objects*

**Description**

Convert a dictionary from a different format into a `quanteda` dictionary, or check to see if an object is a dictionary.

**Usage**

```r
as.dictionary(x)

is.dictionary(x)
```

**Arguments**

- `x` object to be coerced or checked; current legal values are a data.frame with the fields `word` and `sentiment` (as per the `tidytext` package)
Value

`as.dictionary` returns a `dictionary` object. This conversion function differs from the `dictionary` constructor function in that it converts an existing object rather than creates one from components or from a file.

`is.dictionary` returns TRUE if an object is a `quanteda` dictionary.

Examples

```r
## Not run:
data(sentiments, package = "tidytext")
as.dictionary(subset(sentiments, lexicon == "nrc"))
as.dictionary(subset(sentiments, lexicon == "bing"))
# to convert AFINN into polarities - adjust thresholds if desired
afinn <- subset(sentiments, lexicon == "AFINN")
afinn[["sentiment"]]
  with(afinn,
    sentiment <- ifelse(score < 0, "negative",
                        ifelse(score > 0, "positive", "neutral"))
  )
with(afinn, table(score, sentiment))
as.dictionary(afinn)

## End(Not run)

is.dictionary(dictionary(list(key1 = c("val1", "val2"), key2 = "val3")))
## [1] TRUE
is.dictionary(list(key1 = c("val1", "val2"), key2 = "val3"))
## [1] FALSE
```

---

**as.list.dist**

**coerce a dist object into a list**

**Description**

Coerce a dist matrix into a list of selected target terms and similar terms, in descending order of similarity. Can be used after calling `textstat_simil` or `textstat_dist`.

**Usage**

```r
## S3 method for class 'dist'
as.list(x, sorted = TRUE, n = NULL, ...)
```

**Arguments**

- `x` dist class object
- `sorted` sort results in descending order if TRUE
- `n` the top n highest-ranking items will be returned. If n is NULL, return all items.
- `...` unused
## Examples

```r
## Not run:
## compare to tm

# tm version
require(tm)
data("crude")
crude <- tm_map(crude, content_transformer(tolower))
crude <- tm_map(crude, remove_punctuation)
crude <- tm_map(crude, remove_numbers)
crude <- tm_map(crude, stemDocument)
tdm <- TermDocumentMatrix(crude)
findAssocs(tdm, c("oil", "opec", "xyz"), c(0.75, 0.82, 0.1))

# in quanteda
quantedaDfm <- as.dfm(t(as.matrix(tdm)))
as.list(textstat_simil(quantedaDfm, c("oil", "opec", "xyz"), margin = "features"), n = 14)

# in base R
corMat <- as.matrix(proxy::simil(as.matrix(quantedaDfm), by_rows = FALSE))
round(head(sort(corMat[, "oil"], decreasing = TRUE), 14), 2)
round(head(sort(corMat[, "opec"], decreasing = TRUE), 9), 2)

## End(Not run)
```

### Description

Methods for coercing a dfm object to a matrix or data.frame object.

### Usage

```r
## S3 method for class 'dfm'
as.matrix(x, ...)

## S3 method for class 'dfm'
as.data.frame(x, row.names = NULL, ...)
```

### Arguments

- **x**: dfm to be coerced
- **...**: unused
- **row.names**: if FALSE, do not set the row names of the data.frame to the docnames of the dfm (default); or a vector of values to which the row names will be set.
Examples

# coercion to matrix
mydfm <- dfm(data_corpus_inaugural)
str(as.matrix(mydfm))

# coercion to a data.frame
inaugDFm <- dfm(data_corpus_inaugural[1:5])
as.data.frame(inaugDFm[, 1:10])
as.data.frame(inaugDFm[, 1:10], row.names = FALSE)

as.tokens coercion, checking, and combining functions for tokens objects

Description

Coercion functions to and from tokens objects, checks for whether an object is a tokens object, and functions to combine tokens objects.

Usage

as.tokens(x, concatenator = "_")

## S3 method for class 'list'
as.tokens(x, concatenator = "_")

## S3 method for class 'tokens'
as.list(x, ...)

## S3 method for class 'tokens'
unlist(x, recursive = FALSE, use.names = TRUE)

## S3 method for class 'tokens'
as.character(x, use.names = FALSE, ...)

is.tokens(x)

## S3 method for class 'tokens'
t1 + t2

## S3 method for class 'tokens'
c(...)

Arguments

x object to be coerced or checked
concatenator character between multi-word expressions, default is the underscore character. See Details.
... for \texttt{c.tokens} only, \texttt{tokens} objects to be concatenated

\texttt{recursive} \hspace{1cm} \texttt{a required argument for unlist but inapplicable to tokens objects}

\texttt{use.names} \hspace{1cm} \texttt{logical; preserve names if TRUE. For as.character and unlist only.}

\texttt{t1} \hspace{1cm} \texttt{tokens one to be added}

\texttt{t2} \hspace{1cm} \texttt{tokens two to be added}

\textbf{Details}

The \texttt{concatenator} is used to automatically generate dictionary values for multi-word expressions in \texttt{tokens\_lookup} and \texttt{dfm\_lookup}. The underscore character is commonly used to join elements of multi-word expressions (e.g. "piece\_of\_cake", "New\_York"), but other characters (e.g. whitespace " ", or a hyphen ".") can also be used. In those cases, users have to tell the system what is the concatenator in your tokens so that the conversion knows to treat this character as the inter-word delimiter, when reading in the elements that will become the tokens.

\textbf{Value}

\texttt{as.tokens} returns a quanteda \texttt{tokens} object.

\texttt{as.list} returns a simple list of characters from a \texttt{tokens} object.

\texttt{unlist} returns a simple vector of characters from a \texttt{tokens} object.

\texttt{as.character} returns a character vector from a \texttt{tokens} object.

\texttt{is.tokens} returns \texttt{TRUE} if the object is of class \texttt{tokens}, \texttt{FALSE} otherwise.

\texttt{C(...) and +} return a tokens object whose documents have been added as a single sequence of documents.

\textbf{Examples}

```r
# create tokens object from list of characters with custom concatenator
dict <- dictionary(list(country = 'United States',
                     sea = c('Atlantic Ocean', 'Pacific Ocean')))
lis <- list(c('The', 'United-States', 'has', 'the', 'Atlantic-Ocean',
             'and', 'the', 'Pacific-Ocean', '.'))
toks <- as.tokens(lis, concatenator = ' - ')
tokens\_lookup(toks, dict)

# combining tokens
toks1 <- tokens(c(doc1 = "a b c d e", doc2 = "f g h"))
toks2 <- tokens(c(doc3 = "1 2 3"))
toks1 + toks2
c(toks1, toks2)
```
**as.yaml**

convert quanteda dictionary objects to the YAML format

**Description**

Converts a quanteda dictionary object constructed by the dictionary function into the YAML format. The YAML files can be edited in text editors and imported into quanteda again.

**Usage**

as.yaml(x)

**Arguments**

x a dictionary object

**Value**

as.yaml a dictionary in the YAML format, as a character object

**Examples**

```r
## Not run:
dict <- dictionary(list(one = c("a", "b", "c"), two = c("x", "y", "z??")))
cat(yaml <- as.yaml(dict))
cat(yaml, file = (yamlfile <- paste0(tempfile(), ".yaml")))
dictionary(file = yamlfile)

## End(Not run)
```

---

**bootstrap_dfm**

bootstrap a dfm

**Description**

Create an array of resampled dfms.

**Usage**

bootstrap_dfm(x, n = 10, ..., verbose = quanteda_options("verbose"))

**Arguments**

x a character or corpus object

n number of resamples

... additional arguments passed to dfm

verbose if TRUE print status messages
Details

Function produces multiple, resampled dfm objects, based on resampling sentences (with replacement) from each document, recombining these into new "documents" and computing a dfm for each. Resampling of sentences is done strictly within document, so that every resampled document will contain at least some of its original tokens.

Value

A named list of dfm objects, where the first, dfm_0, is the dfm from the original texts, and subsequent elements are the sentence-resampled dfms.

Author(s)

Kenneth Benoit

Examples

# bootstrapping from the original text
txt <- c(textone = "This is a sentence. Another sentence. Yet another.",
        texttwo = "Premiere phrase. Deuxieme phrase.")
bootstrap_dfm(txt, n = 3)

Description

char_tolower and char_toupper are replacements for tolower and toupper based on the stringi package. The stringi functions for case conversion are superior to the base functions because they correctly handle case conversion for Unicode. In addition, the *_tolower functions provide an option for preserving acronyms.

Usage

char_tolower(x, keep_acronyms = FALSE, ...)

char_toupper(x, ...)

Arguments

x the input object whose character/tokens/feature elements will be case-converted
keep_acronyms logical; if TRUE, do not lowercase any all-uppercase words (applies only to *_tolower functions)
... additional arguments passed to stringi functions, (e.g. stri_trans_tolower), such as locale
Examples

txt <- c(txt1 = "b A A", txt2 = "C C a b B")
char_tolower(txt)
char_toupper(txt)

# with acronym preservation
txt2 <- c(txt1 = "England and France are members of NATO and UNESCO",
    txt2 = "NASA sent a rocket into space."
char_tolower(txt2)
char_tolower(txt2, keep_acronyms = TRUE)
char_toupper(txt2)

doctest

doctest

doctest

doctest

doctest

doctest

Description

Extract text model coefficients for documents and features, in a manner similar to coef and coefficients. (coefficients is an alias for coef.)

Usage

doctest

Arguments

object a fitted or predicted text model object whose coefficients will be extracted
...

Value

Returns a list of named numeric vectors with the following elements:

doctest

doctest

doctest

doctest

doctest

doctest

An element that is not applicable for a particular object class will be NULL, for instance coef_documents has no meaning for a fitted wordscores object.
**convert**

**convert a dfm to a non-quanteda format**

**Description**

Convert a quanteda dfm object to a format useable by other text analysis packages. The general function `convert` provides easy conversion from a dfm to the document-term representations used in all other text analysis packages for which conversions are defined. See also `convert-wrappers` for convenience functions for specific package converters.

**Usage**

```r
convert(x, to = c("lda", "tm", "stm", "austin", "topicmodels", "lsa", "matrix", "data.frame"), docvars = NULL, ...)
```

**Arguments**

- **x**
  - dfm to be converted
- **to**
  - target conversion format, consisting of the name of the package into whose document-term matrix representation the dfm will be converted:
    - "lda" a list with components "documents" and "vocab" as needed by the function `lda.collapsed.gibbs.sampler` from the `lda` package
    - "tm" a `DocumentTermMatrix` from the `tm` package
    - "stm" the format for the `stm` package
    - "austin" the `wfm` format from the `austin` package
    - "topicmodels" the "dtm" format as used by the `topicmodels` package
    - "lsa" the "textmatrix" format as used by the `lsa` package
- **docvars**
  - optional data.frame of document variables used as the meta information in conversion to the STM package format. This aids in selecting the document variables only corresponding to the documents with non-zero counts.
- **...**
  - unused

**Value**

A converted object determined by the value of `to` (see above). See conversion target package documentation for more detailed descriptions of the return formats.

**Note**

There also exist a variety of converter shortcut commands, designed to mimic the idioms of the packages into whose format they convert. See `convert-wrappers` for details.
Examples

mycorpus <- corpus_subset(data_corpus_inaugural, Year > 1970)
quantdfm <- dfm(mycorpus, verbose = FALSE)

# austin's wfm format
identical(dim(quantdfm), dim(convert(quantdfm, to = "austin")))

# stem package format
stmdfm <- convert(quantdfm, to = "stm")
str(stmdfm)
# illustrate what happens with zero-length documents
quantdfm2 <- dfm(c(punctOnly = "!!!", mycorpus[-1]), verbose = FALSE)
rowSums(quantdfm2)
stmdfm2 <- convert(quantdfm2, to = "stm", docvars = docvars(mycorpus))
str(stmdfm2)

## Not run:
##' # tm's DocumentTermMatrix format
tmdfm <- convert(quantdfm, to = "tm")
str(tmdfm)

## topicmodels package format
str(convert(quantdfm, to = "topicmodels"))

## lda package format
ldadfm <- convert(quantdfm, to = "lda")
str(ldadfm)

## End(Not run)

corpus  construct a corpus object

Description

Creates a corpus object from available sources. The currently available sources are:

- a character vector, consisting of one document per element; if the elements are named, these names will be used as document names.
- a data.frame, whose default document id is a variable identified by docid_field; the text of the document is a variable identified by textid_field; and other variables are imported as document-level meta-data. This matches the format of data.frames constructed by the readtext package.
- a kwic object constructed by kwic.
- a tm VCorpus or SimpleCorpus class object, with the fixed metadata fields imported as docvars and corpus-level metadata imported as metacorpus information.
- a corpus object.
Usage

```r
corpus(x, ...)
```

### S3 method for class 'corpus'
```r
corpus(x, docnames = quanteda::docnames(x),
       docvars = quanteda::docvars(x), metacorpus = quanteda::metacorpus(x),
       compress = FALSE, ...)
```

### S3 method for class 'character'
```r
corpus(x, docnames = NULL, docvars = NULL,
       metacorpus = NULL, compress = FALSE, ...)
```

### S3 method for class 'data.frame'
```r
corpus(x, docid_field = "doc_id", text_field = "text",
       metacorpus = NULL, compress = FALSE, ...)
```

### S3 method for class 'kwic'
```r
corpus(x, ...)
```

### S3 method for class 'Corpus'
```r
corpus(x, metacorpus = NULL, compress = FALSE, ...)
```

Arguments

- **x**: a valid corpus source object
- **...**: not used directly
- **docnames**: Names to be assigned to the texts. Defaults to the names of the character vector (if any); `doc_id` for a `data.frame`; the document names in a `tm` corpus; or a vector of user-supplied labels equal in length to the number of documents. If none of these are round, then "text1", "text2", etc. are assigned automatically.
- **docvars**: a data.frame of document-level variables associated with each text
- **metacorpus**: a named list containing additional (character) information to be added to the corpus as corpus-level metadata. Special fields recognized in the `summary.corpus` are:
  - `source`: a description of the source of the texts, used for referencing;
  - `citation`: information on how to cite the corpus; and
  - `notes`: any additional information about who created the text, warnings, to do lists, etc.
- **compress**: logical; if TRUE, compress the texts in memory using gzip compression. This significantly reduces the size of the corpus in memory, but will slow down operations that require the texts to be extracted.
- **docid_field**: column index of a document identifier; defaults to `doc_id` but if this is not found, will use the row.names of the `data.frame` if these are assigned
- **text_field**: the character name or numeric index of the source `data.frame` indicating the variable to be read in as text, which must be a character vector. All other variables in the `data.frame` will be imported as `docvars`. This argument is only used for `data.frame` objects (including those created by `readtext`).
Details

The texts and document variables of corpus objects can also be accessed using index notation. Indexing a corpus object as a vector will return its text, equivalent to `texts(x)`. Note that this is not the same as subsetting the entire corpus – this should be done using the `subset` method for a corpus.

Indexing a corpus using two indexes (integers or column names) will return the document variables, equivalent to `docvars(x)`. It is also possible to access, create, or replace docvars using list notation, e.g.

```r
myCorpus["newSerialDocvar"] <- paste0("tag", 1:ndoc(myCorpus)).
```

For details, see `corpus-class`.

Value

A `corpus-class` class object containing the original texts, document-level variables, document-level metadata, corpus-level metadata, and default settings for subsequent processing of the corpus.

A warning on accessing corpus elements

A corpus currently consists of an S3 specially classed list of elements, but **you should not access these elements directly**. Use the extractor and replacement functions instead, or else your code is not only going to be uglier, but also likely to break should the internal structure of a corpus object change (as it inevitably will as we continue to develop the package, including moving corpus objects to the S4 class system).

Author(s)

Kenneth Benoit and Paul Nulty

See Also

`corpus-class, docvars, metadoc, metacorpus, settings, texts, ndoc, docnames`

Examples

```r
# create a corpus from texts
corpus(data_char_ukimmig2010)

# create a corpus from texts and assign meta-data and document variables
summary(corpus(data_char_ukimmig2010,  
    docvars = data.frame(party = names(data_char_ukimmig2010)), 5))

# import a tm VCorpus
if (requireNamespace("tm", quietly = TRUE)) {
    data(crude, package = "tm")  # load in a tm example VCorpus
    mytmCorpus <- corpus(crude)
    summary(mytmCorpus, showmeta=TRUE)
}
```
corpus_reshape

recast the document units of a corpus

description

For a corpus, reshape (or recast) the documents to a different level of aggregation. Units of aggregation can be defined as documents, paragraphs, or sentences. Because the corpus object records its current "units" status, it is possible to move from recast units back to original units, for example from documents, to sentences, and then back to documents (possibly after modifying the sentences).

Usage

corpus_reshape(x, to = c("sentences", "paragraphs", "documents"), ...)

Arguments

x corpus whose document units will be reshaped
to new document units in which the corpus will be recast
... additonal arguments passed to corpus_segment

Value

A corpus object with the documents defined as the new units, including document-level meta-data identifying the original documents.
Examples

# simple example
mycorpus <- corpus(c(textone = "This is a sentence. Another sentence. Yet another. ",
texttwo = "Premiere phrase. Deuxieme phrase."),

## Note that Bush 2005 is recorded as a single paragraph because that text used a single 
## \n to mark the end of a paragraph.

---

**corpus_sample**

* randomly sample documents from a corpus

---

**Description**

Take a random sample or documents of the specified size from a corpus or document-feature matrix, with or without replacement. Works just as **sample** works for the documents and their associated document-level variables.

**Usage**

corpus_sample(x, size = ndoc(x), replace = FALSE, prob = NULL,
by = NULL, ...)

**Arguments**

- **x**
  - a corpus object whose documents will be sampled
- **size**
  - a positive number, the number of documents to select
- **replace**
  - Should sampling be with replacement?
- **prob**
  - A vector of probability weights for obtaining the elements of the vector being sampled.
- **by**
  - a grouping variable for sampling. Useful for resampling sub-document units such as sentences, for instance by specifying by = "document"
- **...**
  - unused

**Value**

A corpus object with number of documents equal to size, drawn from the corpus x. The returned corpus object will contain all of the meta-data of the original corpus, and the same document variables for the documents selected.
Examples

# sampling from a corpus
summary(corpus_sample(data_corpus_inaugural, 5))
summary(corpus_sample(data_corpus_inaugural, 10, replace = TRUE))

# sampling sentences within document
doccorpus <- corpus(c(one = "Sentence one. Sentence two. Third sentence.",
two = "First sentence, doc2. Second sentence, doc2."))
sentcorpus <- corpus_reshape(doccorpus, to = "sentences")
texts(sentcorpus)
texts(corpus_sample(sentcorpus, replace = TRUE, by = "document"))

corpus_segment  segment texts into component elements

Description

Segment corpus text(s) or a character vector into tokens, sentences, paragraphs, or other sections. segment works on a character vector or corpus object, and allows the delimiters to be user-defined. This is useful for breaking the texts of a corpus into smaller documents based on sentences, or based on a user defined "tag" pattern. See Details.

Usage

corpus_segment(x, what = c("sentences", "paragraphs", "tokens", "tags", "other"), delimiter = NULL, valuetype = c("regex", "fixed", "glob"), omit_empty = TRUE, use_docvars = TRUE, ...)
char_segment(x, what = c("sentences", "paragraphs", "tokens", "tags", "other"), delimiter = NULL, valuetype = c("regex", "fixed", "glob"), omit_empty = TRUE, use_docvars = TRUE, ...)

Arguments

x character or corpus object whose texts will be segmented
what unit of segmentation. Current options are "sentences" (default), "paragraphs", "tokens", "tags", and "other".
Segmenting on "other" allows segmentation of a text on any user-defined value, and must be accompanied by the delimiter argument. Segmenting on "tags" performs the same function but preserves the tags as a document variable in the segmented corpus.
delimiter delimiter defined as a regex for segmentation; only relevant for what = "paragraphs" (where the default is two newlines), "tags" (where the default is a tag preceded by two pound or "hash" signs #), and "other".
valuetype how to interpret keyword expressions: "glob" for "glob"-style wildcard expressions; "regex" for regular expressions; or "fixed" for exact matching. See valuetype for details.
**corpus_segment**

| ommit_empty | if TRUE, empty texts are removed |
| use_docvars  | (for corpus objects only) if TRUE, repeat the docvar values for each segmented text; if FALSE, drop the docvars in the segmented corpus. Dropping the docvars might be useful in order to conserve space or if these are not desired for the segmented corpus. |

... provides additional arguments passed to **tokens**, if what = "tokens" is used

**Details**

Tokens are delimited by separators. For tokens and sentences, these are determined by the tokenizer behaviour in **tokens**.

For paragraphs, the default is two carriage returns, although this could be changed to a single carriage return by changing the value of **delimiter** to "\n{1}" which is the R version of the **regex** for one newline character. (You might need this if the document was created in a word processor, for instance, and the lines were wrapped in the window rather than being hard-wrapped with a newline character.)

**Value**

- corpus_segment returns a corpus of segmented texts, with a tag docvar if what = "tags".
- char_segment returns a character vector of segmented texts

**Using delimiters**

One of the most common uses for **corpus_segment** is to partition a corpus into sub-documents using tags. By default, the tag value is any word that begins with a double "hash" sign and is followed by a whitespace. This can be modified but be careful to use the syntax for the trailing word boundary (\b)

The default values for **delimiter** are, according to valuetype:

- **paragraphs** "\n{2}", regular expression meaning two newlines. If you wish to define a paragraph as a single newline, change the 2 to a 1.
- **tags** "#\w+\b", a regular expression meaning two "hash" characters followed by any number of word characters followed by a word boundary (a whitespace or the end of the text).
- **other** No default; user must supply one.

**tokens, sentences** Delimiters do not apply to these, and a warning will be issued if you attempt to supply one.

Delimiters may be defined for different **valuetypes** but these may produce unexpected results, for example the lack of the ability in a "glob" expression to define the word boundaries.

**Note**

Does not currently record document segments if segmenting a multi-text corpus into smaller units. For this, use **corpus_reshape** instead.
Description

Returns subsets of a corpus that meet certain conditions, including direct logical operations on docvars (document-level variables). corpus_subset functions identically to subset.data.frame, using non-standard evaluation to evaluate conditions based on the docvars in the corpus.

Usage

corpus_subset(x, subset, select, ...)
corpus_trim

Arguments

x  corpus object to be subsetted
subset  logical expression indicating the documents to keep: missing values are taken as false
select  expression, indicating the docvars to select from the corpus
...  not used

Value

corpus object, with a subset of documents (and docvars) selected according to arguments

See Also

subset.data.frame

Examples

summary(corpus_subset(data_corpus_inaugural, Year > 1980))
summary(corpus_subset(data_corpus_inaugural, Year > 1930 & President == "Roosevelt", select = Year))

corpus_trim  remove sentences based on their token lengths or a pattern match

Description

Removes sentences from a corpus or a character vector shorter than a specified length.

Usage

corpus_trim(x, what = c("sentences", "paragraphs", "documents"),
               min_ntoken = 1, max_ntoken = NULL, exclude_pattern = NULL)
char_trim(x, what = c("sentences", "paragraphs", "documents"),
               min_ntoken = 1, max_ntoken = NULL, exclude_pattern = NULL)

Arguments

x  corpus or character object whose sentences will be selected.
what  units of trimming, "sentences" or "paragraphs", or "documents"
min_ntoken, max_ntoken  minimum and maximum lengths in word tokens (excluding punctuation)
exclude_pattern  a stringi regular expression whose match (at the sentence level) will be used to exclude sentences
Value

a corpus or character vector equal in length to the input. If the input was a corpus, then the all
docvars and metadata are preserved. For documents whose sentences have been removed entirely,
a null string (""") will be returned.

Examples

txt <- c("PAGE 1. This is a single sentence. Short sentence. Three word sentence.",
"PAGE 2. Very short! Shorter.",
"Very long sentence, with multiple parts, separated by commas. PAGE 3.")

mycorp <- corpus(txt, docvars = data.frame(serial = 1:3))
texts(mycorp)

# exclude sentences shorter than 3 tokens
texts(corpus_trim(mycorp, min_ntoken = 3))
# exclude sentences that start with "PAGE <digit(s)>"
texts(corpus_trim(mycorp, exclude_pattern = "PAGE \d+"))

# trimming character objects
char_trim(txt, "sentences", min_ntoken = 3)
char_trim(txt, "sentences", exclude_pattern = "sentence\.")

data_char_sampletext  a paragraph of text for testing various text-based functions

Description

This is a long paragraph (2,914 characters) of text taken from a debate on the Irish budget in Dáil
Éireann by Socialist Teachta Dála (TD) Joe Higgins, delivered December 8, 2011.

Usage

data_char_sampletext

Format

corpus or character vector with one element

Source

749, no. 1.

Examples

tokens(data_char_sampletext, remove_punct = TRUE)
**data_char_ukimmig2010**  
*immigration-related sections of 2010 UK party manifestos*

**Description**

Extracts from the election manifestos of 9 UK political parties from 2010, related to immigration or asylum-seekers.

**Usage**

`data_char_ukimmig2010`

**Format**

A named character vector of plain ASCII texts

**Examples**

```r
data_corpus_ukimmig2010 <-
corpus(data_char_ukimmig2010,
docvars = data.frame(party = names(data_char_ukimmig2010)))
metadoc(data_corpus_ukimmig2010, "language") <- "english"
summary(data_corpus_ukimmig2010, showmeta = TRUE)
```

---

**data_corpus_inaugural**  
*US presidential inaugural address texts*

**Description**

US presidential inaugural address texts, and metadata (for the corpus), from 1789 to present.

**Usage**

`data_corpus_inaugural`

**Format**

A corpus object with the following docvars:

- **Year** a four-digit integer year
- **President** character; President’s last name
- **FirstName** character; President’s first name (and possibly middle initial)
Details

data_corpus_inaugural is the quanteda-package corpus object of US presidents' inaugural addresses since 1789. Document variables contain the year of the address and the last name of the president.

Source

Examples

# some operations on the inaugural corpus
summary(data_corpus_inaugural)
head(docvars(data_corpus_inaugural), 10)

data_corpus_irishbudget2010

Irish budget speeches from 2010

Description

Speeches and document-level variables from the debate over the Irish budget of 2010.

Usage

data_corpus_irishbudget2010

Format

The corpus object for the 2010 budget speeches, with document-level variables for year, debate, serial number, first and last name of the speaker, and the speaker’s party.

Source

References

Examples

summary(data_corpus_irishbudget2010)
Description

Constructed example data to demonstrate the Wordscores algorithm, from Laver Benoit and Garry (2003), Table 1.

Usage

data_dfm_lbgexample

Format

A dfm object with 6 documents and 37 features.

Details

This is the example word count data from Laver, Benoit and Garry’s (2003) Table 1. Documents R1 to R5 are assumed to have known positions: -1.5, -0.75, 0, 0.75, 1.5. Document V1 is assumed unknown, and will have a raw text score of approximately -0.45 when computed as per LBG (2003).

References

Description

Construct a sparse document-feature matrix, from a character, corpus, tokens, or even other dfm object.

Usage

dfm(x, tolower = TRUE, stem = FALSE, select = NULL, remove = NULL, dictionary = NULL, thesaurus = NULL, valuetype = c("glob", "regex", "fixed"), groups = NULL, verbose = quanteda_options("verbose"), ...)

Arguments

- **x** character, corpus, tokens, or dfm object
- **tolower** convert all features to lowercase
- **stem** if TRUE, stem words
- **select** a pattern of user-supplied features to keep, while excluding all others. This can be used in lieu of a dictionary if there are only specific features that a user wishes to keep. To extract only Twitter usernames, for example, set `select = "@*"` and make sure that `remove_twitter = FALSE` as an additional argument passed to `tokenize`. Note: `select = "^@[\w+\b"` would be the regular expression version of this matching pattern. The pattern matching type will be set by `valuetype`. See also `tokens_remove`.
- **remove** a pattern of user-supplied features to ignore, such as "stop words". To access one possible list (from any list you wish), use `stopwords()`. The pattern matching type will be set by `valuetype`. See also `tokens_select`. For behaviour of `remove` with `ngrams > 1`, see Details.
- **dictionary** a dictionary object to apply to the tokens when creating the dfm
- **thesaurus** a dictionary object that will be applied as if `exclusive = FALSE`. See also `tokens_lookup`. For more fine-grained control over this and other aspects of converting features into dictionary/thesaurus keys from pattern matches to values, consider creating the dfm first, and then applying `dfm_lookup` separately, or using `tokens_lookup` on the tokenized text before calling `dfm`.
- **valuetype** how to interpret keyword expressions: "glob" for "glob"-style wildcard expressions; "regex" for regular expressions; or "fixed" for exact matching. See `valuetype` for details.
- **groups** either: a character vector containing the names of document variables to be used for grouping; or a factor or object that can be coerced into a factor equal in length or rows to the number of documents. See `groups` for details.
- **verbose** display messages if TRUE
- **...** additional arguments passed to `tokens`; not used when `x` is a dfm

Details

The default behavior for `remove/select` when constructing ngrams using `dfm(x, ngrams > 1)` is to remove/select any ngram constructed from a matching feature. If you wish to remove these before constructing ngrams, you will need to first tokenize the texts with ngrams, then remove the features to be ignored, and then construct the dfm using this modified tokenization object. See the code examples for an illustration.

Value

- a dfm-class object

Note

When `x` is a dfm, `groups` provides a convenient and fast method of combining and refactoring the documents of the dfm according to the groups.
See Also
dfm_select, dfm-class

Examples

```r
## for a corpus
corpus_post0inaug <- corpus_subset(data_corpus_inaugural, Year > 1980)

                "Zall the ha$ers including my bro #justinbieber #emabiggestfansjustinbieber",
                "#justinbieber, #beliebers a..."
"Justin Bieber #justinbieber #belieber #fetusjustin #EMABiggestFansJustinBieber")
dfm(testTweets, select = "#*", remove_twitter = FALSE) # keep only hashtags
dfm(testTweets, select = "^#\.*$", valuetype = "regex", remove_twitter = FALSE)

# for a dfm
dfm1 <- dfm(data_corpus_irishbudget2010)
dfm2 <- dfm(dfm1,
  groups = ifelse(docvars(data_corpus_irishbudget2010, "party") %in% c("FF", "Green", "Govt", "Opposition"),
  tolower = FALSE, verbose = TRUE)

---

**dfm_compress**

*recombine a dfm or fcm by combining identical dimension elements*

**Description**

"Compresses" or groups a dfm or fcm whose dimension names are the same, for either documents or features. This may happen, for instance, if features are made equivalent through application of a thesaurus. It could also be needed after a `cbind.dfm` or `rbind.dfm` operation. In most cases, you will not need to call `dfm_compress`, since it is called automatically by functions that change the dimensions of the dfm, e.g. `dfm_tolower`.

**Usage**

```r
dfm_compress(x, margin = c("both", "documents", "features"))
```

**Arguments**

- `x`: input object, a dfm or fcm
- `margin`: character indicating on which margin to compress a dfm, either "documents", "features", or "both" (default). For fcm objects, "documents" has no effect.
- `...`: additional arguments passed from generic to specific methods

**Value**

dfm_compress returns a dfm whose dimensions have been recombined by summing the cells across identical dimension names (docnames or featnames). The docvars will be preserved for combining by features but not when documents are combined.

cfm_compress returns an fcm whose features have been recombined by combining counts of identical features, summing their counts.

**Note**

fcm_compress works only when the fcm was created with a document context.
**Examples**

```r
defm_compress examples
mat <- rbind(dfm(c("b A A", "C C a b B"), tolower = FALSE),
dfm("A C C C C C", tolower = FALSE))
colnames(mat) <- char_tolower(featnames(mat))
mat
defm_compress(mat, margin = "documents")
defm_compress(mat, margin = "features")
defm_compress(mat)

# no effect if no compression needed
compactdfm <- dfm(data_corpus_inaugural[1:5])
dim(compactdfm)
dim(dfm_compress(compactdfm))

# compress an fcm
myfcm <- fcm(tokens("A D a C E a d F e B A C E D"),
context = "window", window = 3)
## this will produce an error:
# fcm_compress(myfcm)

txt <- c("The fox JUMPED over the dog.",
"The dog jumped over the fox.")
toks <- tokens(txt, remove_punct = TRUE)
myfcm <- fcm(toks, context = "document")
colnames(myfcm) <- rownames(myfcm) <- tolower(colnames(myfcm))
colnames(myfcm)[5] <- rownames(myfcm)[5] <- "fox"
myfcm
fcm_compress(myfcm)
```

---

**dfm_group**

*combine documents in a dfm by a grouping variable*

**Description**

Combine documents in a dfm by a grouping variable, which can also be one of the docvars attached to the dfm. This is identical in functionality to using the "groups" argument in dfm.

**Usage**

```r
dfm_group(x, groups = NULL, fill = FALSE)
```

**Arguments**

- **x** a dfm
- **groups** either: a character vector containing the names of document variables to be used for grouping; or a factor or object that can be coerced into a factor equal in length or rows to the number of documents. See groups for details.
dfm_lookup

Apply a dictionary to a dfm

Description

Apply a dictionary to a dfm by looking up all dfm features for matches in a set of dictionary values, and replace those features with a count of the dictionary's keys. If exclusive = FALSE then the behaviour is to apply a "thesaurus", where each value match is replaced by the dictionary key, converted to capitals if capkeys = TRUE (so that the replacements are easily distinguished from features that were terms found originally in the document).

Usage

dfm_lookup(x, dictionary, levels = 1:5, exclusive = TRUE,valuetype = c("glob", "regex", "fixed"), case_insensitive = TRUE, capkeys = !exclusive, nomatch = NULL,verbose = quanteda_options("verbose"))

Value

dfm_group returns a dfm whose documents are equal to the unique group combinations, and whose cell values are the sums of the previous values summed by group. This currently erases any docvars in the dfm.

Setting the fill = TRUE offers a way to "pad" a dfm with document groups that may not have been observed, but for which an empty document is needed, for various reasons. If groups is a factor of dates, for instance, then using fill = TRUE ensures that the new documents will consist of one row of the dfm per date, regardless of whether any documents previously existed with that date.

Examples

```r
mycorpus <- corpus(c("a a b", "a b c c", "a c d d", "a c c d"),
docvars = data.frame(grp = c("grp1", "grp1", "grp2", "grp2")))
mydfm <- dfm(mycorpus)
dfm_group(mydfm, groups = "grp")
dfm_group(mydfm, groups = c(1, 1, 2, 2))

# equivalent
dfm(mydfm, groups = "grp")
dfm(mydfm, groups = c(1, 1, 2, 2))
```
**Arguments**

- **x**  
  the dfm to which the dictionary will be applied

- **dictionary**  
  a dictionary class object

- **levels**  
  levels of entries in a hierarchical dictionary that will be applied

- **exclusive**  
  if TRUE, remove all features not in dictionary, otherwise, replace values in dictionary with keys while leaving other features unaffected

- **valuetype**  
  how to interpret keyword expressions: "glob" for "glob"-style wildcard expressions; "regex" for regular expressions; or "fixed" for exact matching. See valuetype for details.

- **case_insensitive**  
  ignore the case of dictionary values if TRUE

- **capkeys**  
  if TRUE, convert dictionary keys to uppercase to distinguish them from other features

- **nomatch**  
  an optional character naming a new feature that will contain the counts of features of x not matched to a dictionary key. If NULL (default), do not tabulate unmatched features.

- **verbose**  
  print status messages if TRUE

**Note**

If using dfm_lookup with dictionaries containing multi-word values, matches will only occur if the features themselves are multi-word or formed from ngrams. A better way to match dictionary values that include multi-word patterns is to apply tokens_lookup to the tokens, and then construct the dfm.

**Examples**

```r
myDict <- dictionary(list(christmas = c("Christmas", "Santa", "holiday"),
                         opposition = c("Opposition", "reject", "notincorpus"),
                         taxglob = "tax*",
                         taxregex = "tax.*$",
                         country = c("United_States", "Sweden")))

myDf <- dfm(c("My Christmas was ruined by your opposition tax plan. ",
               "Does the United_States or Sweden have more progressive taxation?"),
           remove = stopwords("english"), verbose = FALSE)

myDf

# glob format
dfm_lookup(myDf, myDict, valuetype = "glob")

# regex v. glob format: note that "united_states" is a regex match for "tax*
dfm_lookup(myDf, myDict, valuetype = "glob")

# fixed format: no pattern matching
dfm_lookup(myDf, myDict, valuetype = "fixed")
```

```r
# show unmatched tokens
dfm_lookup(myDfm, myDict, nomatch = "_UNMATCHED")
```

---

**dfm_sample**

**randomly sample documents or features from a dfm**

---

**Description**

Sample randomly from a dfm object, from documents or features.

**Usage**

```r
dfm_sample(x, size = ndoc(x), replace = FALSE, prob = NULL,
           margin = c("documents", "features"))
```

**Arguments**

- `x` the dfm object whose documents or features will be sampled
- `size` a positive number, the number of documents or features to select
- `replace` logical; should sampling be with replacement?
- `prob` a vector of probability weights for obtaining the elements of the vector being sampled.
- `margin` dimension (of a dfm) to sample: can be documents or features

**Value**

A dfm object with number of documents or features equal to `size`, drawn from the dfm `x`.

**See Also**

`sample`

**Examples**

```r
set.seed(10)
myDfm <- dfm(data_corpus_inaugural[1:10])
head(myDfm)
head(dfm_sample(myDfm))
head(dfm_sample(myDfm, replace = TRUE))
head(dfm_sample(myDfm, margin = "features"))
```
dfm_select

select features from a dfm or fcm

Description

This function selects or discards features from a dfm or fcm, based on feature name matches with pattern. The most common usages are to eliminate features from a dfm already constructed, such as stopwords, or to select only terms of interest from a dictionary.

Usage

```r
dfm_select(x, pattern, selection = c("keep", "remove"),
    valuetype = c("glob", "regex", "fixed"), case_insensitive = TRUE,
    min_nchar = 1L, max_nchar = 63L, verbose = quanteda_options("verbose"),
    ...
)
dfm_remove(x, pattern, ...)

fcm_select(x, pattern = NULL, selection = c("keep", "remove"),
    valuetype = c("glob", "regex", "fixed"), case_insensitive = TRUE,
    verbose = TRUE, ...)
fcm_remove(x, pattern, ...)
```

Arguments

- **x**: the dfm or fcm object whose features will be selected
- **pattern**: a character vector, list of character vectors, dictionary, collocations, or dfm. See pattern for details.
- **selection**: whether to keep or remove the features
- **valuetype**: how to interpret keyword expressions: "glob" for "glob"-style wildcard expressions; "regex" for regular expressions; or "fixed" for exact matching. See valuetype for details.
- **case_insensitive**: ignore the case of dictionary values if TRUE
- **min_nchar, max_nchar**: numerics specifying the minimum and maximum length in characters for features to be removed or kept; defaults are 1 and 79. (Set max_nchar to NULL for no upper limit.) These are applied after (and hence, in addition to) any selection based on pattern matches.
- **verbose**: if TRUE print message about how many pattern were removed
- **...**: used only for passing arguments from *_remove to *_select functions
dfm_select

Details

dfm_remove and fcm_remove are simply a convenience wrappers to calling dfm_select and fcm_select with `selection = "remove"`.

Value

A dfm or fcm object, after the feature selection has been applied.

When `pattern` is a dfm object, then the returned object will be identical in its feature set to the dfm supplied as the pattern argument. This means that any features in `x` not in the dfm provided as `pattern` will be discarded, and that any features in found in the dfm supplied as `pattern` but not found in `x` will be added with all zero counts. Because selecting on a dfm is designed to produce a selected dfm with an exact feature match, when `pattern` is a dfm object, then the following settings are always used: `case_insensitive = FALSE`, and `valuetype = "fixed"`.

Selecting on a dfm is useful when you have trained a model on one dfm, and need to project this onto a test set whose features must be identical. It is also used in bootstrap_dfm. See examples.

Note

This function selects features based on their labels. To select features based on the values of the document-feature matrix, use dfm_trim.

Examples

```r
myDfm <- dfm(c("My Christmas was ruined by your opposition tax plan.",
    "Does the United_States or Sweden have more progressive taxation?"),
    tolower = FALSE, verbose = FALSE)
mydict <- dictionary(list(countries = c("United_States", "Sweden", "France"),
    wordsEndingInY = c("by", "my"),
    notin_text = "blahblah"))
dfm_select(myDfm, mydict)
dfm_select(myDfm, mydict, case_insensitive = FALSE)
dfm_select(myDfm, c("$", ".y"), selection = "keep", valuetype = "regex")
dfm_select(myDfm, c("$", ".y"), selection = "remove", valuetype = "regex")
dfm_select(myDfm, stopwords("english"), selection = "keep", valuetype = "fixed")
dfm_select(myDfm, stopwords("english"), selection = "remove", valuetype = "fixed")

# select based on character length
dfm_select(myDfm, min_nchar = 5)

# selecting on a dfm
txts <- c("This is text one", "The second text", "This is text three")
(dfm1 <- dfm(txts[1:2]))
(dfm2 <- dfm(txts[2:3]))
(dfm3 <- dfm_select(dfm1, dfm2, valuetype = "fixed", verbose = TRUE))
setequal(featnames(dfm2), featnames(dfm3))

tmpdfm <- dfm(c("This is a document with lots of stopwords. ",
    "No if, and, or but about it: lots of stopwords."),
    verbose = FALSE)
tmpdfm
```

dfm_sort

dfm_remove(tmpdfm, stopwords("english"))
toks <- tokens(c("this contains lots of stopwords", "no if, and, or but about it: lots"), remove_punct = TRUE)
tmpfcm <- fcm(toks)
tmpfcm
fcm_remove(tmpfcm, stopwords("english"))

---

**dfm_sort**  
*sort a dfm by frequency of one or more margins*

**Description**

Sorts a dfm by descending frequency of total features, total features in documents, or both.

**Usage**

```r
dfm_sort(x, decreasing = TRUE, margin = c("features", "documents", "both"))
```

**Arguments**

- **x**  
  Document-feature matrix created by **dfm**

- **decreasing**  
  logical; if TRUE, the sort will be in descending order, otherwise sort in increasing order

- **margin**  
  which margin to sort on features to sort by frequency of features, documents to sort by total feature counts in documents, and both to sort by both

**Value**

A sorted dfm matrix object

**Author(s)**

Ken Benoit

**Examples**

```r
dtm <- dfm(data_corpus_inaugural)
head(dtm)
head(dfm_sort(dtm))
head(dfm_sort(dtm, decreasing = FALSE, "both"))
```
dfm_subset

**Description**

Returns document subsets of a dfm that meet certain conditions, including direct logical operations on docvars (document-level variables). `dfm_subset` functions identically to `subset.data.frame`, using non-standard evaluation to evaluate conditions based on the docvars in the dfm.

**Usage**

```r
dfm_subset(x, subset, select, ...)  
```

**Arguments**

- `x` dfm object to be subbedted
- `subset` logical expression indicating the documents to keep: missing values are taken as FALSE
- `select` expression, indicating the docvars to select from the dfm; or a dfm, in which case the returned dfm will contain the same documents as the original dfm, even if these are empty. See Details.
- `...` not used

**Details**

To select or subset features, see `dfm_select` instead.

When `select` is a dfm, then the returned dfm will be equal in row dimensions and order to the dfm used for selection. This is the document-level version of using `dfm_select` where `pattern` is a dfm: that function matches features, while `dfm_subset` will match documents.

**Value**

dfm object, with a subset of documents (and docvars) selected according to arguments

**See Also**

`subset.data.frame`

**Examples**

```r
testcorp <- corpus(c(d1 = "a b c d", d2 = "a a b e", d3 = "b b c e", d4 = "e e f a b"),
  docvars = data.frame(grp = c(1, 1, 2, 3)))
testdfm <- dfm(testcorp)
# selecting on a docvars condition
dfm_subset(testdfm, grp > 1)
# selecting on a supplied vector
```
dfm_tolower

dfm_subset(testdfm, c(TRUE, FALSE, TRUE, FALSE))

# selecting on a dfm
dfm1 <- dfm(c(d1 = "a b b c", d2 = "b b c d"))
dfm2 <- dfm(c(d1 = "x y z", d2 = "a b c d", d3 = "x x x"))
dfm_subset(dfm1, subset = dfm2)
dfm_subset(dfm1, subset = dfm2[c(3,1,2), ])

dfm_tolower

Description

dfm_tolower and dfm_toupper convert the features of the dfm or fcm to lower and upper case, respectively, and then recombine the counts.

Usage

dfm_tolower(x, keep_acronyms = FALSE, ...)
dfm_toupper(x, ...)
fcm_tolower(x, keep_acronyms = FALSE, ...)
fcm_toupper(x, ...)

Arguments

x

the input object whose character/tokens/feature elements will be case-converted

keep_acronyms

logical; if TRUE, do not lowercase any all-uppercase words (applies only to *_tolower functions)

... additional arguments passed to stringi functions, (e.g. stri_trans_tolower), such as locale

Details

fcm_tolower and fcm_toupper convert both dimensions of the fcm to lower and upper case, respectively, and then recombine the counts. This works only on fcm objects created with context = “document”.

Examples

# for a document-feature matrix
mydfm <- dfm(c("b A A", "C C a b B"),
            tolower = FALSE, verbose = FALSE)
mydfm
dfm_tolower(mydfm)
dfm_toupper(mydfm)
# for a feature co-occurrence matrix
myfcm <- fcm(tokens(c("b A A d", "C C a b e")),
              context = "document")
myfcm
fcm_tolower(myfcm)
fcm_toupper(myfcm)

dfm_trim

trim a dfm using frequency threshold-based feature selection

Description
Returns a document by feature matrix reduced in size based on document and term frequency, usually in terms of a minimum frequencies, but may also be in terms of maximum frequencies. Setting a combination of minimum and maximum frequencies will select features based on a range.

Usage

dfm_trim(x, min_count = 1, min_docfreq = 1, max_count = NULL,
          max_docfreq = NULL, sparsity = NULL,
          verbose = quanteda_options("verbose"))

Arguments

x a dfm object
min_count, max_count
  minimum/maximum count or fraction of features across all documents, below/above which features will be removed
min_docfreq, max_docfreq
  minimum/maximum number or fraction of documents in which a feature appears, below/above which features will be removed
sparsity equivalent to 1 - min_docfreq, included for comparison with tm
verbose print messages

Value

A dfm reduced in features (with the same number of documents)

Note

Trimming a dfm object is an operation based on the values in the document-feature matrix. To select subsets of a dfm based on the features themselves (meaning the feature labels from featnames) – such as those matching a regular expression, or removing features matching a stopword list, use dfm_select.
dfm_weight

Author(s)

Ken Benoit and Paul Nulty, with some inspiration from Will Lowe (see trim from the austin package)

dfm_select, dfm_sample

Examples

    (myDfm <- dfm(data_corpus_inaugural[1:5]))

    # keep only words occuring >=10 times and in >=2 docs
    dfm_trim(myDfm, min_count = 10, min_docfreq = 2)

    # keep only words occuring >=10 times and in at least 0.4 of the documents
    dfm_trim(myDfm, min_count = 10, min_docfreq = 0.4)

    # keep only words occuring <=10 times and in <=2 docs
    dfm_trim(myDfm, max_count = 10, max_docfreq = 2)

    # keep only words occuring <=10 times and in at most 3/4 of the documents
    dfm_trim(myDfm, max_count = 10, max_docfreq = 0.75)

    # keep only words occuring at least 0.01 times and in >=2 documents
    dfm_trim(myDfm, min_count = .01, min_docfreq = 2)

    # keep only words occuring 5 times in 1000, and in 2 of 5 of documents
    dfm_trim(myDfm, min_docfreq = 0.4, min_count = 0.005)

    ## Not run:
    # compare to removeSparseTerms from the tm package
    if (require(tm)) {
        (tmdtm <- convert(myDfm, "tm"))
        removeSparseTerms(tmdtm, 0.7)
        dfm_trim(td, min_docfreq = 0.3)
        dfm_trim(td, sparsity = 0.7)
    }

    ## End(Not run)

dfm_weight

weight the feature frequencies in a dfm

Description

Returns a document by feature matrix with the feature frequencies weighted according to one of several common methods. Some shortcut functions that offer finer-grained control are:

- **tf** compute term frequency weights
dfm_weight

- tfidf compute term frequency-inverse document frequency weights
- docfreq compute document frequencies of features

Usage

```r
dfm_weight(x, type = c("frequency", "relfreq", "relmaxfreq", "logfreq", "tfidf"), weights = NULL)
dfm_smooth(x, smoothing = 1)
```

Arguments

- `x` document-feature matrix created by dfm
- `type` a label of the weight type:
  - "frequency" integer feature count (default when a dfm is created)
  - "relfreq" the proportion of the feature counts of total feature counts (aka relative frequency)
  - "relmaxfreq" the proportion of the feature counts of the highest feature count in a document
  - "logfreq" take the logarithm of 1 + the feature count, for base 10
  - "tfidf" Term-frequency * inverse document frequency. For a full explanation, see, for example, http://nlp.stanford.edu/IR-book/html/htmledition/term-frequency-and-weighting-1.html. This implementation will not return negative values. For finer-grained control, call tfidf directly.
- `weights` if type is unused, then weights can be a named numeric vector of weights to be applied to the dfm, where the names of the vector correspond to feature labels of the dfm, and the weights will be applied as multipliers to the existing feature counts for the corresponding named features. Any features not named will be assigned a weight of 1.0 (meaning they will be unchanged).
- `smoothing` constant added to the dfm cells for smoothing, default is 1

Value

- `dfm_weight` returns the dfm with weighted values.
- `dfm_smooth` returns a dfm whose values have been smoothed by adding the smoothing amount. Note that this effectively converts a matrix from sparse to dense format, so may exceed memory requirements depending on the size of your input matrix.

Note

For finer grained control, consider calling the convenience functions directly.

str <- c("apple is better than banana", "banana banana apple much better")
(mydfm <- dfm(str, remove = stopwords("english")))
dfm_weight(mydfm, weights = c(apple = 5, banana = 3, much = 0.5))

# smooth the dfm
dfm_smooth(mydfm, 0.5)

dictionary

create a dictionary

Description

Create a *quanteda* dictionary class object, either from a list or by importing from a foreign format. Currently supported input file formats are the Wordstat, LIWC, Lexicoder v2 and v3, and Yoshikoder formats. The import using the LIWC format works with all currently available dictionary files supplied as part of the LIWC 2001, 2007, and 2015 software (see References).

Usage
dictionary(x, file = NULL, format = NULL, separator = " ",
tolower = TRUE, encoding = "auto")
Arguments

- **x**: a named list of character vector dictionary entries, including `valuetype` pattern matches, and including multi-word expressions separated by `concatenator`. See examples. This argument may be omitted if the dictionary is read from file.

- **file**: file identifier for a foreign dictionary

- **format**: character identifier for the format of the foreign dictionary. If not supplied, the format is guessed from the dictionary file’s extension. Available options are:
  - "wordstat" format used by Provalis Research’s Wordstat software
  - "LIWC" format used by the Linguistic Inquiry and Word Count software
  - "yoshikoder" format used by Yoshikoder software
  - "lexicoder" format used by Lexicoder
  - "YAML" the standard YAML format

- **separator**: the character in between multi-word dictionary values. This defaults to " ".

- **tolower**: if TRUE, convert all dictionary values to lowercase

- **encoding**: additional optional encoding value for reading in imported dictionaries. This uses the `iconv` labels for encoding. See the “Encoding” section of the help for file.

Value

A dictionary class object, essentially a specially classed named list of characters.

References

- Lexicoder format, [http://www.lexicoder.com](http://www.lexicoder.com)

dfm

Examples

```r
mycorpus <- corpus_subset(data_corpus_inaugural, Year>1900)
mydict <- dictionary(list(christmas = c("Christmas", "Santa", "holiday"),
                        opposition = c("Opposition", "reject", "notincorpus"),
                        taxing = "taxing",
                        taxation = "taxation",
                        taxregex = "tax*",
                        country = "america"))
head(dfm(mycorpus, dictionary = mydict))
```
## Not run:

```r
# import the Laver-Garry dictionary from Provalis Research
dictfile <- tempfile()
download.file("https://provalisresearch.com/Download/LaverGarry.zip", dictfile, mode = "wb")
unzip(dictfile, exdir = (td <- tempdir()))
lgdict <- dictionary(file = paste(td, "LaverGarry.cat", sep = "/"))
head(dfm(data_corpus_inaugural, dictionary = lgdict))

# import a LIWC formatted dictionary from http://www.moralfoundations.org
download.file("https://goo.gl/5gmxWq", tf <- tempfile())
mfdict <- dictionary(file = tf, format = "LIWC")
head(dfm(data_corpus_inaugural, dictionary = mfdict))
```

## docnames

### get or set document names

**Description**

Get or set the document names of a corpus, tokens, or dfm object.

**Usage**

```r
docnames(x)
docnames(x) <- value
```

**Arguments**

- `x`: the object with docnames
- `value`: a character vector of the same length as `x`

**Value**

- `docnames` returns a character vector of the document names
- `docnames <-` assigns new values to the document names of an object.

**See Also**

`featnames`
Examples

```r
# query the document names of a corpus
docnames(data_corpus_irishbudget2010)

# query the document names of a tokens object
docnames(tokens(data_char_ukimmig2010))

# query the document names of a dfm
docnames(dfm(data_corpus_inaugural[1:5]))

# reassign the document names of the inaugural speech corpus
docnames(data_corpus_inaugural) <- paste("Speech", 1:ndoc(data_corpus_inaugural), sep="")
```

### docvars

Get or set for document-level variables

**Description**

Get or set variables associated with a document in a corpus, tokens or dfm object.

**Usage**

```r
docvars(x, field = NULL)
docvars(x, field = NULL) <- value
```

**Arguments**

- **x**: corpus, tokens, or dfm object whose document-level variables will be read or set
- **field**: string containing the document-level variable name
- **value**: the new values of the document-level variable

**Value**

docvars returns a data.frame of the document-level variables, dropping the second dimension to form a vector if a single docvar is returned.
docvars<- assigns value to the named field

**Index access to docvars in a corpus**

Another way to access and set docvars is through indexing of the corpus j element, such as `data_corpus_irishbudget2010[j, c("foren","name")]; or, for a single docvar, data_corpus_irishbudget2010[["name"]]. The latter also permits assignment, including the easy creation of new document variables, e.g. `data_corpus_irishbudget2010[["newvar"]]<-1:ndoc(data_corpus_irishbudget2010). See [.corpus for details.
Note

Reassigning document variables for a tokens or dfm object is allowed, but discouraged. A better, more reproducible workflow is to create your docvars as desired in the corpus, and let these continue to be attached "downstream" after tokenization and forming a document-feature matrix. Recognizing that in some cases, you may need to modify or add document variables to downstream objects, the assignment operator is defined for tokens or dfm objects as well. Use with caution.

Examples

# retrieving docvars from a corpus
head(docvars(data_corpus_inaugural))
tail(docvars(data_corpus_inaugural, "President"), 10)

# assigning document variables to a corpus
corp <- data_corpus_inaugural
docvars(corp, "President") <- paste("prez", 1:ndoc(corp), sep = "")
head(docvars(corp))

# alternative using indexing
head(corp[,"Year"])
corp["President2"] <- paste("prezTwo", 1:ndoc(corp), sep = "")
head(docvars(corp))

$fcm$

create a feature co-occurrence matrix

Description

Create a sparse feature co-occurrence matrix, measuring co-occurrences of features within a user-defined context. The context can be defined as a document or a window within a collection of documents, with an optional vector of weights applied to the co-occurrence counts.

Usage

fcm(x, context = c("document", "window"), count = c("frequency", "boolean", "weighted"), window = 5L, weights = 1L, ordered = FALSE, span_sentence = TRUE, tri = TRUE, ...)

Arguments

x character, corpus, tokens, or dfm object from which to generate the feature co-occurrence matrix
context the context in which to consider term co-occurrence: "document" for co-occurrence counts within document; "window" for co-occurrence within a defined window of words, which requires a positive integer value for window. Note: if x is a dfm object, then context can only be "document".
count how to count co-occurrences:
"frequency" count the number of co-occurrences within the context
"boolean" count only the co-occurrence or not within the context, irrespective of how many times it occurs.
"weighted" count a weighted function of counts, typically as a function of distance from the target feature. Only makes sense for context = "window".

window positive integer value for the size of a window on either side of the target feature, default is 5, meaning 5 words before and after the target feature

weights a vector of weights applied to each distance from 1:window, strictly decreasing by default; can be a custom-defined vector of the same length as length(weights)

ordered if TRUE the number of times that a term appears before or after the target feature are counted seperately. Only makes sense for context = "window".

span_sentence if FALSE, then word windows will not span sentences

tri if TRUE return only upper triangle (including diagonal)

... not used here

Details

The function \texttt{fcm} provides a very general implementation of a "context-feature" matrix, consisting of a count of feature co-occurrence within a defined context. This context, following Momtazi et al. (2010), can be defined as the \textit{document}, \textit{sentences} within documents, \textit{syntactic relationships} between features (nouns within a sentence, for instance), or according to a \textit{window}. When the context is a window, a weighting function is typically applied that is a function of distance from the target word (see Jurafsky and Martin 2015, Ch. 16) and ordered co-occurrence of the two features is considered (see Church & Hanks 1990).

\texttt{fcm} provides all of this functionality, returning a $V \times V$ matrix (where $V$ is the vocabulary size, returned by \texttt{nfeature}). The \texttt{tri = TRUE} option will only return the upper part of the matrix.

Unlike some implementations of co-occurrences, \texttt{fcm} counts feature co-occurrences with themselves, meaning that the diagonal will not be zero.

\texttt{fcm} also provides "boolean" counting within the context of "window", which differs from the counting within "document".

\texttt{is.fcm(x) returns TRUE if and only if its x is an object of type fcm.}

Kenneth Benoit (R), Haiyan Wang (R, C++), Kohei Watanabe (C++)

References

Church, K. W. & P. Hanks (1990) "Word association norms, mutual information, and lexicography" 

**Examples**

```r
# see http://bit.ly/29b2zOa

txt <- c("A D A C E A D F E B A C E D")
fcm(txt, context = "window", window = 2)
fcm(txt, context = "window", count = "weighted", window = 3)
fcm(txt, context = "window", count = "weighted", window = 3,
   weights = c(3, 2, 1), ordered = TRUE, tri = FALSE)

# with multiple documents

txts <- c("a a b b c", "a a c e", "a c e f g")
fcm(txts, context = "document", count = "frequency")
fcm(txts, context = "document", count = "boolean")
fcm(txts, context = "window", window = 2)

# from tokens

txt <- c("The quick brown fox jumped over the lazy dog.",
   "The dog jumped and ate the fox.")
toks <- tokens(char_tolower(txt), remove_punct = TRUE)
fcm(toks, context = "document")
fcm(toks, context = "window", window = 3)
```

---

**fcm_sort**

*sort an fcm in alphabetical order of the features*

**Description**

Sorts an `fcm` in alphabetical order of the features.

**Usage**

```
fcm_sort(x)
```

**Arguments**

- `x`  
  `fcm` object

**Value**

A `fcm` object whose features have been alphabetically sorted. Differs from `fcm_sort` in that this function sorts the fcm by the feature labels, not the counts of the features.

**Author(s)**

Ken Benoit

**Examples**

```r
# with tri = FALSE
myfcm <- fcm(tokens(c("A X Y C B A", "X Y C A B B")), tri = FALSE)
rownames(myfcm)[3] <- colnames(myfcm)[3] <- "Z"
myfcm
fcm_sort(myfcm)

# with tri = TRUE
myfcm <- fcm(tokens(c("A X Y C B A", "X Y C A B B")), tri = TRUE)
rownames(myfcm)[3] <- colnames(myfcm)[3] <- "Z"
myfcm
fcm_sort(myfcm)
```

**Description**

Get the features from a document-feature matrix, which are stored as the column names of the dfm object.

**Usage**

```
featnames(x)
```

**Arguments**

- `x` the dfm whose features will be extracted

**Value**

character vector of the feature labels

**Examples**

```
inaugDfm <- dfm(data_corpus_inaugural, verbose = FALSE)

# first 50 features (in original text order)
head(featnames(inaugDfm), 50)

# first 50 features alphabetically
head(sort(featnames(inaugDfm)), 50)

# contrast with descending total frequency order from topfeatures()
names(topfeatures(inaugDfm, 50))
```
Description

For a dfm object, returns the first or last n documents and first nfeature features for inspection.

Usage

```r
## S3 method for class 'dfm'
head(x, n = 6L, nfeature = 6L, ...)

## S3 method for class 'dfm'
tail(x, n = 6L, nfeature = 6L, ...)
```

Arguments

- `x`: a dfm object
- `n`: a single integer. If positive, size for the resulting object: number of first/last documents for the dfm. If negative, all but the n last/first number of documents of x.
- `nfeature`: the number of features to return, where the resulting object will contain the first ncol features
- `...`: additional arguments passed to other functions

Value

A dfm class object corresponding to the subset defined by n and nfeature.

Examples

```r
myDfm <- dfm(data_corpus_inaugural, ngrams = 2, verbose = FALSE)
head(myDfm)
tail(myDfm)
tail(myDfm, nfeature = 4)
```

Description

Check for a dfm, or convert a matrix into a dfm.
kwic
locate keywords-in-context

Description
For a text or a collection of texts (in a quanteda corpus object), return a list of a keyword supplied by the user in its immediate context, identifying the source text and the word index number within the source text. (Not the line number, since the text may or may not be segmented using end-of-line delimiters.)

Usage

kwic(x, pattern, window = 5, valuetype = c("glob", "regex", "fixed"),
     case_insensitive = TRUE, join = FALSE, ...)

is.kwic(x)

## S3 method for class 'kwic'
as.tokens(x, ...)

Arguments

x a character, corpus, or tokens object
pattern a character vector, list of character vectors, dictionary, collocations, or dfm. See pattern for details.
window the number of context words to be displayed around the keyword.
how to interpret keyword expressions: "glob" for "glob"-style wildcard expressions; "regex" for regular expressions; or "fixed" for exact matching. See valuetype for details.

match without respect to case if TRUE

join adjacent keywords in the concordance view if TRUE

additional arguments passed to tokens, for applicable object types

A kwic classed data.frame, with the document name (docname), the token index positions (from and to, which will be the same for single-word patterns, or a sequence equal in length to the number of elements for multi-word phrases), the context before (pre), the keyword in its original format (keyword, preserving case and attached punctuation), and the context after (post). The return object has its own print method, plus some special attributes that are hidden in the print view. If you want to turn this into a simple data.frame, simply wrap the result in data.frame.

as.tokens.kwic converts the kwic object into a tokens object, with each new "document" consisting of one keyword match, and the contents of the pre, keyword, and post fields forming the tokens. This is one way to save the output for subsequent usage; another way is to form a corpus from the return object.

pattern will be a keyword pattern or phrase, possibly multiple patterns, that may include punctuation. If a pattern contains whitespace, it is best to wrap it in phrase to make this explicit. However if pattern is a collocations or dictionary object, then the collocations or multi-word dictionary keys will automatically be considered phrases where each whitespace-separated element matches a token in sequence.

Kenneth Benoit and Kohei Watanabe

Examples

head(kwic(data_corpus_inaugural, "secure*", window = 3, valuetype = "glob"))
head(kwic(data_corpus_inaugural, "secur", window = 3, valuetype = "regex"))
head(kwic(data_corpus_inaugural, "security", window = 3, valuetype = "fixed"))

toks <- tokens(data_corpus_inaugural)
kwic(data_corpus_inaugural, phrase("war against"))
kwic(data_corpus_inaugural, phrase("war against"), valuetype = "regex")

mykwic <- kwic(data_corpus_inaugural, "provident*")
is.kwic(mykwic)
is.kwic("Not a kwic")
get or set corpus metadata

Description

Get or set the corpus-level metadata in a corpus object.

Usage

metacorpus(x, field = NULL)

metacorpus(x, field) <- value

Arguments

x a corpus object
field metadata field name(s); if NULL (default), return all metadata names
value new value of the corpus metadata field

Value

For metacorpus, a named list of the metadata fields in the corpus.
For metacorpus <-, the corpus with the updated metadata.

Examples

metacorpus(data_corpus_inaugural)
metacorpus(data_corpus_inaugural, "source")
metacorpus(data_corpus_inaugural, "citation") <- "Presidential Speeches Online Project (2014)."
metacorpus(data_corpus_inaugural, "citation")

get or set document-level meta-data

Description

Get or set document-level meta-data. Document-level meta-data are a special type of docvars, meant to contain information about documents that would not be used as a "variable" for analysis. An example could be the source of the document, or notes pertaining to its transformation, copyright information, etc.

Document-level meta-data differs from corpus-level meta-data in that the latter pertains to the collection of texts as a whole, whereas the document-level version can differ with each document.
**ndoc**

**Usage**

```r
metadoc(x, field = NULL)
metadoc(x, field = NULL) <- value
```

**Arguments**

- `x`: a corpus object
- `field`: character, the name of the metadata field(s) to be queried or set
- `value`: the new value of the new meta-data field

**Value**

For texts, a character vector of the texts in the corpus.
For texts `<`, the corpus with the updated texts.

**Note**

Document-level meta-data names are preceded by an underscore character, such as `_language`, but when named in in the `field` argument, do *not* need the underscore character.

**See Also**

- `metacorpus`

**Examples**

```r
mycorp <- corpus_subset(data_corpus_inaugural, Year > 1990)
summary(mycorp, showmeta = TRUE)
metadoc(mycorp, "encoding") <- "UTF-8"
metadoc(mycorp)
metadoc(mycorp, "language") <- "english"
summary(mycorp, showmeta = TRUE)
```

---

**ndoc**  
*count the number of documents or features*

**Description**

Get the number of documents or features in an object.

**Usage**

```r
don(x)
nfeature(x)
```
Arguments

- `x` : a `quanteda` object: a `corpus`, `dfm`, or `tokens` object, or a `readtext` object from the `readtext` package.

Details

- `ndoc` returns the number of documents in a `corpus`, `dfm`, or `tokens` object, or a `readtext` object from the `readtext` package.
- `nfeature` returns the number of features in a `dfm` object.
- `nfeature` returns the number of features from a `dfm`; it is an alias for `ntype` when applied to `dfm` objects. This function is only defined for `dfm` objects because only these have "features". (To count tokens, see `ntoken`.)

Value

- an integer (count) of the number of documents or features

See Also

- `ntoken`

Examples

```r
# number of documents
ndoc(data_corpus_inaugural)
ndoc(corpus_subset(data_corpus_inaugural, Year > 1980))
ndoc(tokens(data_corpus_inaugural))
ndoc(dfm(corpus_subset(data_corpus_inaugural, Year > 1980)))

# number of features
nfeature(dfm(corpus_subset(data_corpus_inaugural, Year > 1980), remove_punct = FALSE))
nfeature(dfm(corpus_subset(data_corpus_inaugural, Year > 1980), remove_punct = TRUE))
```

---

**nscrabble**

`count the Scrabble letter values of text`

---

Description

Tally the Scrabble letter values of text given a user-supplied function, such as the sum (default) or mean of the character values.

Usage

```r
nscrabble(x, FUN = sum)
```
Arguments
- **x**: a character vector
- **FUN**: function to be applied to the character values in the text; default is `sum`, but could also be `mean` or a user-supplied function.

Value
- a (named) integer vector of Scabble letter values, computed using `FUN`, corresponding to the input text(s).

Note
- Character values are only defined for non-accented Latin a-z, A-Z letters. Lower-casing is unnecessary.
- We would be happy to add more languages to this *extremely useful function* if you send us the values for your language!

Author(s)
- Kenneth Benoit

Examples
- `nscoreabble(c("muzjks", "excellency"))`
- `nscoreabble(data_corpus_inaugural[1:5], mean)`

---

### nsentence

<table>
<thead>
<tr>
<th>nsentence</th>
<th>count the number of sentences</th>
</tr>
</thead>
</table>

**Description**
- Return the count of sentences in a corpus or character object.

**Usage**
- `nsentence(x, ...)`

**Arguments**
- **x**: a character or `corpus` whose sentences will be counted
- **...**: additional arguments passed to `tokens`

**Value**
- count(s) of the total sentences per text
Note

nsentence() relies on the boundaries definitions in the stringi package (see stri_opts_brkiter). It does not count sentences correctly if the text has been transformed to lower case, and for this reason nsentence() will issue a warning if it detects all lower-cased text.

Examples

```r
# simple example
txt <- c(text1 = "This is a sentence: second part of first sentence.",
         text2 = "A word. Repeated repeated.",
         text3 = "Mr. Jones has a PhD from the LSE. Second sentence.")
nsentence(txt)
```

nsyllable

**count syllables in a text**

Description

Returns a count of the number of syllables in texts. For English words, the syllable count is exact and looked up from the CMU pronunciation dictionary, from the default syllable dictionary data_int_syllables. For any word not in the dictionary, the syllable count is estimated by counting vowel clusters.

data_int_syllables is a quanteda-supplied data object consisting of a named numeric vector of syllable counts for the words used as names. This is the default object used to count English syllables. This object that can be accessed directly, but we strongly encourage you to access it only through the nsyllable() wrapper function.

Usage

```r
nsyllable(x, syllable_dictionary = quanteda::data_int_syllables,
          use.names = FALSE)
```

Arguments

- `x` character vector or tokens object whose syllables will be counted
- `syllable_dictionary` optional named integer vector of syllable counts where the names are lower case tokens. When set to NULL (default), then the function will use the quanteda data object data_int_syllables, an English pronunciation dictionary from CMU.
- `use.names` logical; if TRUE, assign the tokens as the names of the syllable count vector

Value

If `x` is a character vector, a named numeric vector of the counts of the syllables in each element. If `x` is a tokens object, return a list of syllable counts where each list element corresponds to the tokens in a document.
**ntoken**

**Note**

All tokens are automatically converted to lowercase to perform the matching with the syllable dictionary, so there is no need to perform this step prior to calling `nsyllable()`.

**Examples**

```r
# character
syllable(c("cat", "syllable", "supercalifragilisticexpialidocious", "Brexit", "Administration"), use.names = TRUE)

# tokens
txt <- c(doc1 = "This is an example sentence.",
          doc2 = "Another of two sample sentences.")
syllable(tokens(txt, remove_punct = TRUE))
# punctuation is not counted
syllable(tokens(txt), use.names = TRUE)
```

---

**Description**

Get the count of tokens (total features) or types (unique tokens).

**Usage**

```r
ntoken(x, ...)
nype(x, ...)
```

**Arguments**

- `x` a quantified object: a character, corpus, tokens, or dfm object
- `...` additional arguments passed to `tokens`

**Details**

The precise definition of "tokens" for objects not yet tokenized (e.g. character or corpus objects) can be controlled through optional arguments passed to `tokens` through `...`

For `dfm` objects, `ntype` will only return the count of features that occur more than zero times in the dfm.

**Value**

- count of the total tokens or types
Note

Due to differences between raw text tokens and features that have been defined for a dfm, the counts may be different for dfm objects and the texts from which the dfm was generated. Because the method tokenizes the text in order to count the tokens, your results will depend on the options passed through to tokens.

Examples

# simple example
txt <- c(text1 = "This is a sentence, this.", text2 = "A word. Repeated repeated.")
ntoken(txt)
ntype(txt)
ntoken(char_tolower(txt)) # same
ntype(char_tolower(txt))  # fewer types
ntoken(char_tolower(txt), remove_punct = TRUE)
ntype(char_tolower(txt), remove_punct = TRUE)

# with some real texts
ntoken(corpus_subset(data_corpus_inaugural, Year<1800), remove_punct = TRUE)
ntype(corpus_subset(data_corpus_inaugural, Year<1800), remove_punct = TRUE)
ntoken(dfm(corpus_subset(data_corpus_inaugural, Year<1800)))
ntype(dfm(corpus_subset(data_corpus_inaugural, Year<1800)))

<table>
<thead>
<tr>
<th>phrase</th>
</tr>
</thead>
<tbody>
<tr>
<td>declare a compound character to be a sequence of separate pattern matches</td>
</tr>
</tbody>
</table>

Description

Declares that a whitespace-separated expression consists of multiple patterns, separated by whitespace. This is typically used as a wrapper around pattern to make it explicit that the pattern elements are to be used for matches to multi-word sequences, rather than individual, unordered matches to single words.

Usage

phrase(x)

is.phrase(x)

Arguments

x the sequence, as a character object containing whitespace separating the patterns
**Value**

phrase returns a specially classed list whose white-spaced elements have been parsed into separate character elements.

is.phrase returns TRUE if the object was created by phrase; FALSE otherwise.

**Examples**

```r
# make phrases from characters
phrase(c("a b", "c d e", "f"))

# from a dictionary
phrase(dictionary(list(catone = c("a b"), cattwo = "c d e", catthree = "f")))

# from a collocations object
(coll <- textstat_collocations(tokens("a b c a b d e b d a b")))
phrase(coll)
```

---

**Description**

Get or set global options affecting functions across `quanteda`.

**Usage**

```r
quanteda_options(..., reset = FALSE, initialize = FALSE)
```

**Arguments**

- `...` options to be set, as key-value pair, same as `options`. This may be a list of valid key-value pairs, useful for setting a group of options at once (see examples).
- `reset` logical; if TRUE, reset all `quanteda` options to their default values
- `initialize` logical; if TRUE, reset only the `quanteda` options that are not already defined. Used for setting initial values when some have been defined previously, such as in `.Rprofile`.

**Details**

Currently available options are:

- `verbose` logical; if TRUE then use this as the default for all functions with a `verbose` argument
- `threads` integer; specifies the number of threads to use in use this as the setting in all functions that use parallelization
- `print_dfm_max_ndoc` integer; specifies the number of documents to display when using the defaults for printing a dfm
print_dfm_max_nfeature integer; specifies the number of features to display when using the defaults for printing a dfm

base_docname character; stem name for documents that are unnamed when a corpus, tokens, or dfm are created or when a dfm is converted from another object

base_featname character; stem name for features that are unnamed when they are added, for whatever reason, to a dfm through an operation that adds features

base_featname character; stem name for features that are unnamed when they are added, for whatever reason, to a dfm through an operation that adds features

base_featname character; stem name for features that are unnamed when they are added, for whatever reason, to a dfm through an operation that adds features

Value

When called using a key = value pair (where key can be a label or quoted character name), the option is set and TRUE is returned invisibly.

When called with no arguments, a named list of the package options is returned.

When called with reset = TRUE as an argument, all arguments are options are reset to their default values, and TRUE is returned invisibly.

Examples

(qopts <- quanteda_options())

quanteda_options(verbose = TRUE)
quanteda_options("verbose" = FALSE)
quanteda_options("threads")
quanteda_options(print_dfm_max_ndoc = 50L)
# reset to defaults
quanteda_options(reset = TRUE)
# reset to saved values
quanteda_options(qopts)

spacyr-methods extensions of methods defined in the quanteda package

Description

Extensions to quanteda functions. You must have attached quanteda for these to work.

Arguments

x an object returned by spacy_parse

... unused
Usage

docnames(x) returns the document names
ndoc(x) returns the number of documents
ntoken(x, ...) returns the number of tokens by document
ntype(x, ...) returns the number of types (unique tokens) by document

Examples

```r
## Not run:
require(spacyr)
spacy_initialize()

txt <- c(doc1 = "And now, now, now for something completely different.",
doc2 = "Jack and Jill are children.")
parsed <- spacy_parse(txt)
ntype(parsed)
ntoken(parsed)
ndoc(parsed)
docnames(parsed)

## End(Not run)
```

sparsity  
compute the sparsity of a document-feature matrix

Description

Return the proportion of sparseness of a document-feature matrix, equal to the proportion of cells that have zero counts.

Usage

sparsity(x)

Arguments

x  the document-feature matrix

Examples

```r
inaug_dfm <- dfm(data_corpus_inaugural, verbose = FALSE)
sparsity(inaug_dfm)
sparsity(dfm_trim(inaug_dfm, min_count = 5))
```
Description

This function retrieves stopwords from the type specified in the kind argument and returns the
stopword list as a character vector. The default is English.

Usage

stopwords(kind = quanteda_options("language_stopwords"))

Arguments

kind The pre-set kind of stopwords (as a character string). Allowed values are english,
SMART, danish, french, greek, hungarian, norwegian, russian, swedish,
catalan, dutch, finnish, german, italian, portuguese, spanish, arabic.

Details

The stopword list is an internal data object named data_char_stopwords, which consists of En-
glish stopwords from the SMART information retrieval system (obtained from Lewis et. al. (2004)
and a set of stopword lists from the Snowball stemmer project in different languages (see http:
//snowballstem.org/projects.html). See data_char_stopwords for details.

Value

a character vector of stopwords

A note of caution

Stop words are an arbitrary choice imposed by the user, and accessing a pre-defined list of words to
ignore does not mean that it will perfectly fit your needs. You are strongly encourged to inspect the
list and to make sure it fits your particular requirements.

Source

The English stopwords are taken from the SMART information retrieval system (obtained from

Additional stopword lists are taken from the Snowball stemmer project in different languages (see http:
//snowballstem.org/projects.html).

The Greek stopwords were supplied by Carsten Schwemmer (see GitHub issue #282).
Examples

```r
head(stopwords("english"))
head(stopwords("italian"))
head(stopwords("arabic"))
head(stopwords("SMART"))

# adding to the built-in stopword list

toks <- tokens("The judge will sentence Mr. Adams to nine years in prison", remove_punct = TRUE)
tokens_remove(toks, c(stopwords("english"), "will", "mr", "nine"))
```

Description

textmodel_ca implements correspondence analysis scaling on a dfm. The method is a fast/sparse version of function `ca`, and returns a special class of `ca` object.

Usage

```r
textmodel_ca(x, smooth = 0, nd = NA, sparse = FALSE, threads = 1, residual_floor = 0.1)
```

Arguments

- `x` the dfm on which the model will be fit
- `smooth` a smoothing parameter for word counts; defaults to zero.
- `nd` Number of dimensions to be included in output; if NA (the default) then the maximum possible dimensions are included.
- `sparse` retains the sparsity if set to TRUE; set it to TRUE if x (the dfm) is too big to be allocated after converting to dense
- `threads` the number of threads to be used; set to 1 to use a serial version of the function; only applicable when sparse = TRUE
- `residual_floor` specifies the threshold for the residual matrix for calculating the truncated svd. Larger value will reduce memory and time cost but might sacrifice the accuracy; only applicable when sparse = TRUE

Details

`svds` in the RSpectra package is applied to enable the fast computation of the SVD.
**Note**

Setting threads larger than 1 (when sparse = TRUE) will trigger parallel computation, which retains sparsity of all involved matrices. You may need to increase the value of residual_floor to ignore less important information and hence to reduce the memory cost when you have a very big dfm.

If your attempt to fit the model fails due to the matrix being too large, this is probably because of the memory demands of computing the $V \times V$ residual matrix. To avoid this, consider increasing the value of residual_floor by 0.1, until the model can be fit.

**Author(s)**

Kenneth Benoit and Haiyan Wang

**References**

**Examples**

```r
ieDfm <- dfm(data_corpus_irishbudget2010)
wca <- textmodel_ca(ieDfm)
summary(wca)
```

---

**textmodel_NB**

*Naive Bayes classifier for texts*

**Description**

Fit a multinomial or Bernoulli Naive Bayes model, given a dfm and some training labels.

**Usage**

```r
textmodel_NB(x, y, smooth = 1, prior = c("uniform", "docfreq", "termfreq"),
             distribution = c("multinomial", "Bernoulli"), ...)
```

**Arguments**

- `x`: the dfm on which the model will be fit. Does not need to contain only the training documents.
- `y`: vector of training labels associated with each document identified in `train`. (These will be converted to factors if not already factors.)
- `smooth`: smoothing parameter for feature counts by class
- `prior`: prior distribution on texts; see Details
- `distribution`: count model for text features, can be multinomial or Bernoulli. To fit a "binary multinomial" model, first convert the dfm to a binary matrix using `tf(x, "boolean")`
- `...`: more arguments passed through
Value

A list of return values, consisting of:

call       original function call
PwGc       probability of the word given the class (empirical likelihood)
Pc          class prior probability
PcGw       posterior class probability given the word
Pw          baseline probability of the word
data        list consisting of x training class, and y test class
distribution the distribution argument
prior       argument passed as a prior
smooth      smoothing parameter

Predict Methods

A predict method is also available for a fitted Naive Bayes object, see predict.textmodel_NB_fitted.

Author(s)

Kenneth Benoit

Examples

```r
## Example from 13.1 of _An Introduction to Information Retrieval_
txt <- c(d1 = "Chinese Beijing Chinese",
        d2 = "Chinese Chinese Shanghai",
        d3 = "Chinese Macao",
        d4 = "Tokyo Japan Chinese",
        d5 = "Chinese Chinese Chinese Tokyo Japan")
trainingset <- dfm(txt, tolower = FALSE)
trainingclass <- factor(c("Y", "Y", "Y", "N", NA), ordered = TRUE)

## replicate IIR p261 prediction for test set (document 5)
(nb.p261 <- textmodel_NB(trainingset, trainingclass, prior = "docfreq"))
predict(nb.p261, newdata = trainingset[5, ])

# contrast with other priors
predict(textmodel_NB(trainingset, trainingclass, prior = "uniform"))
predict(textmodel_NB(trainingset, trainingclass, prior = "termfreq"))

## replicate IIR p264 Bernoulli Naive Bayes
```
(nb.p261.bern <- textmodel_NB(trainingset, trainingclass, distribution = "Bernoulli",
    prior = "docfreq"))
predict(nb.p261.bern, newdata = trainingset[5, 3])

Description

Usage

textmodel_wordfish(x, dir = c(1, 2), priors = c(Inf, Inf, 3, 1),
    tol = c(1e-06, 1e-08), dispersion = c("poisson", "quasipoisson"),
    dispersion_level = c("feature", "overall"), dispersion_floor = 0,
    sparse = TRUE, threads = quanteda_options("threads"), abs_err = FALSE,
    svd_sparse = TRUE, residual_floor = 0.5)

Arguments

x the dfm on which the model will be fit

dir set global identification by specifying the indexes for a pair of documents such that \( \hat{\theta}_{dir[1]} < \hat{\theta}_{dir[2]} \).

priors prior precisions for the estimated parameters \( \alpha_i, \psi_j, \beta_j, \) and \( \theta_i \), where \( i \) indexes documents and \( j \) indexes features

tol tolerances for convergence. The first value is a convergence threshold for the log-posterior of the model, the second value is the tolerance in the difference in parameter values from the iterative conditional maximum likelihood (from conditionally estimating document-level, then feature-level parameters).

dispersion sets whether a quasi-poisson quasi-likelihood should be used based on a single dispersion parameter ("poisson"), or quasi-Poisson ("quasipoisson")

dispersion_level sets the unit level for the dispersion parameter, options are "feature" for term-level variances, or "overall" for a single dispersion parameter

dispersion_floor constraint for the minimal underdispersion multiplier in the quasi-Poisson model. Used to minimize the distorting effect of terms with rare term or document frequencies that appear to be severely underdispersed. Default is 0, but this only applies if dispersion = "quasipoisson".

sparse specifies whether the "dfm" is coerced to dense

threads specifies the number of threads to use; set to 1 to override the package settings and use a serial version of the function

abs_err specifies how the convergence is considered
svd_sparse uses svd to initialize the starting values of theta, only applies when sparse = TRUE
residual_floor specifies the threshold for residual matrix when calculating the svds, only applies when sparse = TRUE

Details

The returns match those of Will Lowe’s R implementation of wordfish (see the austin package), except that here we have renamed words to be features. (This return list may change.) We have also followed the practice begun with Slapin and Proksch’s early implementation of the model that used a regularization parameter of se(σ) = 3, through the third element in priors.

Value

An object of class textmodel_fitted_wordfish. This is a list containing:

- dir: global identification of the dimension
- theta: estimated document positions
- alpha: estimated document fixed effects
- beta: estimated feature marginal effects
- psi: estimated word fixed effects
- docs: document labels
- features: feature labels
- sigma: regularization parameter for betas in Poisson form
- ll: log likelihood at convergence
- se.theta: standard errors for theta-hats
- x: dfm to which the model was fit

Note

In the rare situation where a warning message of "The algorithm did not converge." shows up, removing some documents may work.

## End(Not run)

textmodel_wordscores  Wordscores text model

Description

Usage

textmodel_wordscores(x, y, scale = c("linear", "logit"), smooth = 0)

Arguments

x  the dfm on which the model will be trained
y  vector of training scores associated with each document in x
scale  scale on which to score the words; "linear" for classic LBG linear posterior weighted word class differences, or "logit" for log posterior differences
smooth  a smoothing parameter for word counts; defaults to zero for the to match the LBG (2003) method.
Details

Fitting a `textmodel_wordscores` results in an object of class `textmodel_wordscores_fitted` containing the following slots:

Slots

- `scale`: linear or logit, according to the value of `scale`
- `Sw`: the scores computed for each word in the training set
- `x`: the dfm on which the wordscores model was called
- `y`: the reference scores
- `call`: the function call that fitted the model
- `method`: takes a value of `wordscores` for this model

Predict Methods

A predict method is also available for a fitted wordscores object, see `predict.textmodel_wordscores_fitted`.

Examples

```r
(ws <- textmodel_wordscores(data_dfm_lbgexample, c(seq(-1.5, 1.5, .75), NA)))
predict(ws)
predict(ws, rescaling = "mv")
predict(ws, rescaling = "lbg")
```
textmodel_wordshoal  wordshoal text model

Description

Estimate Lauderdale and Herzog’s (2016) model for one-dimensional document author (e.g. speakers) positions based on multiple groups of texts (e.g. debates). Each group of texts is scaled using Slapin and Proksch’s (2008) "wordfish" Poisson scaling model of one-dimensional document positions, and then the positions from a particular author are scaled across groups using a second-level linear factor model, using conditional maximum likelihood.

Usage

textmodel_wordshoal(x, groups, authors, dir = c(1, 2), tol = 0.001)

Arguments

- `x`: the dfm from which the model will be fit
- `groups`: the name of a variable in the document variables for data giving the document group for each document
- `authors`: the name of a variable in the document variables for data giving the author of each document
- `dir`: set global identification by specifying the indexes for a pair of authors such that \( \hat{\theta}_{dir[1]} < \hat{\theta}_{dir[2]} \)
- `tol`: a convergence threshold for the log-posterior of the model

Details

Returns estimates of relative author positions across the full corpus of texts.

Value

An object of class textmodel_fitted_wordshoal. This is a list containing:

- `tol`: log-posterior tolerance used in fitting
- `dir`: global identification of the dimension
- `theta`: estimated document positions
- `beta`: debate marginal effects
- `alpha`: estimated document fixed effects
- `psi`: estimated document debate-level positions
- `groups`: document groups
- `authors`: document authors
- `ll`: log likelihood at convergence
- `se.theta`: standard errors for theta-hats
- `data`: corpus to which the model was fit

Examples
```r
## Not run:
data(data_corpus_irish30, package = "quantedaData")
iedfm <- dfm(data_corpus_irish30, remove_punct = TRUE)
wordshoalfit <-
textmodel_wordshoal(iedfm, dir = c(7,1),
  groups = docvars(data_corpus_irish30, "debateID"),
  authors = docvars(data_corpus_irish30, "member.name"))
fitdf <- merge(as.data.frame(summary(wordshoalfit)),
  docvars(data_corpus_irish30),
  by.x = "row.names", by.y = "member.name")
fitdf <- subset(fitdf, !duplicated(memberID))
aggregate(theta ~ party.name, data = fitdf, mean)

## End(Not run)
```

Description
Plot the results of a "keyword" of features comparing their differential associations with a target and a reference group, after calculating keyness using `textstat_keyness`.

Usage
```
textplot_keyness(x, show_reference = TRUE, n = 20L, min_count = 2L)
```

Arguments
- `x` a return object from `textstat_keyness`
- `show_reference` logical; if TRUE, show key reference features in addition to key target features
- `n` integer; number of features to plot
- `min_count` numeric; minimum total count of feature across the target and reference categories, for a feature to be included in the plot

Value
- a `ggplot2` object
Author(s)
Haiyan Wang

textstat_keyness

Examples

```r
## Not run:
# compare Trump v. Obama speeches
prescorpus <- corpus_subset(data_corpus_inaugural,
    President %in% c("Obama", "Trump"))
presdfm <- dfm(prescorpus, groups = "President", remove = stopwords("english"),
    remove_punct = TRUE)
result <- textstat_keyness(presdfm, target = "Trump")

# plot estimated word keyness
textplot_keyness(result)
textplot_keyness(result, show_reference = FALSE)

## End(Not run)
```

Description

Plot the results of a fitted scaling model, from (e.g.) a predicted textmodel_wordscores model or a fitted textmodel_wordfish or textmodel_ca model. Either document or feature parameters may be plotted: an ideal point-style plot (estimated document position plus confidence interval on the x-axis, document labels on the y-axis) with optional renaming and sorting, or as a plot of estimated feature-level parameters (estimated feature positions on the x-axis, and a measure of relative frequency or influence on the y-axis, with feature names replacing plotting points with some being chosen by the user to be highlighted).

Usage

```r
textplot_scale1d(x, margin = c("documents", "features"), doclabels = NULL,
    sort = TRUE, groups = NULL, highlighted = NULL, alpha = 0.7,
    highlighted_color = "black")
```

Arguments

- **x**: the fitted or predicted scaling model object to be plotted
- **margin**: "documents" to plot estimated document scores (the default) or "features" to plot estimated feature scores by a measure of relative frequency
textplot_scale1d

doclabels a vector of names for document; if left NULL (the default), docnames will be used

sort if TRUE (the default), order points from low to high score. If a vector, order according to these values from low to high. Only applies when margin = "documents".

groups either: a character vector containing the names of document variables to be used for grouping; or a factor or object that can be coerced into a factor equal in length or rows to the number of documents. See groups for details.

highlighted a vector of feature names to draw attention to in a feature plot; only applies if margin = "features"

alpha A number between 0 and 1 (default 0.5) representing the level of alpha transparency used to overplot feature names in a feature plot; only applies if margin = "features"

highlighted_color color for highlighted terms in highlighted

Value
a ggplot2 object

Note
The groups argument only applies when margin = "documents".

     highlighted = c("minister", "have", "our", "budget"))
# plot estimated document positions
textplot_scale1d(pred, margin = "documents",
dooclables = doclab,
groups = drvars(data_corpus_irishbudget2010, "party"))

## wordfish
textplot_wordcloud

Description

Plot a dfm or tokens object as a wordcloud, where the feature labels are plotted with their sizes proportional to their numerical values in the dfm. When comparison = TRUE, it plots comparison word clouds by document.

Usage

textplot_wordcloud(x, comparison = FALSE, ...)

Arguments

x a dfm object
comparison if TRUE, plot a comparison.cloud instead of a simple wordcloud, one grouping per document
...
additional parameters passed to to wordcloud or to text (and strheight, strwidth)

Details

The default is to plot the word cloud of all features, summed across documents. To produce word cloud plots for specific document or set of documents, you need to slice out the document(s) from the dfm or tokens object.

Comparison wordcloud plots may be plotted by setting comparison = TRUE, which plots a separate grouping for each document in the dfm. This means that you will need to slice out just a few documents from the dfm, or to create a dfm where the "documents" represent a subset or a grouping of documents by some document variable.
textplot_xray

wordcloud, comparison.cloud

Examples

# plot the features (without stopwords) from Obama's two inaugural addresses
mydfm <- dfm(corpus_subset(data_corpus_inaugural, President=="Obama"), verbose = FALSE,
            remove = stopwords("english"))
textplot_wordcloud(mydfm)

# plot in colors with some additional options passed to wordcloud
textplot_wordcloud(mydfm, random.color = TRUE, rot.per = .25,
            colors = sample(colors()[2:128], 5))

## Not run:
# comparison plot of Irish government vs opposition
docvars(data_corpus_irishbudget2010, "govtopp") <-
    factor(ifelse(data_corpus_irishbudget2010[, "party"] %in% c("FF", "Green"), "Govt", "Opp"))
govtoppDfm <- dfm(data_corpus_irishbudget2010, groups = "govtopp", verbose = FALSE)
textplot_wordcloud(tfidf(govtoppDfm), comparison = TRUE)
# compare to non-tf-idf version
textplot_wordcloud(govtoppDfm, comparison = TRUE)

## End(Not run)

---

**textplot_xray**  
_plot the dispersion of keyword(s)_

**Description**

Plots a dispersion or "x-ray" plot of selected word pattern(s) across one or more texts. The format of the plot depends on the number of kwic class objects passed: if there is only one document, keywords are plotted one below the other. If there are multiple documents the documents are plotted one below the other, with keywords shown side-by-side. Given that this returns a ggplot2 object, you can modify the plot by adding ggplot2 layers (see example).

**Usage**

textplot_xray(..., scale = c("absolute", "relative"), sort = FALSE)

**Arguments**

... any number of kwic class objects

scale whether to scale the token index axis by absolute position of the token in the document or by relative position. Defaults are absolute for single document and relative for multiple documents.

sort whether to sort the rows of a multiple document plot by document name
Value

- a *ggplot2* object

Author(s)

Adam Obeng

Examples

```r
## Not run:
data_corpus_inauguralPost70 <- corpus_subset(data_corpus_inaugural, Year > 1970)
# compare multiple documents
textplot_xray(kwic(data_corpus_inauguralPost70, "american"))
textplot_xray(kwic(data_corpus_inauguralPost70, "american"), scale = "absolute")
# compare multiple terms across multiple documents
textplot_xray(kwic(data_corpus_inauguralPost70, "america"),
              kwic(data_corpus_inauguralPost70, "people"))

# how to modify the ggplot with different options
library(ggplot2)
g <- textplot_xray(kwic(data_corpus_inauguralPost70, "american"),
                   kwic(data_corpus_inauguralPost70, "people"))
g + aes(color = keyword) + scale_color_manual(values = c('red', 'blue'))

## End(Not run)
```

Description

Get or replace the texts in a *corpus*, with grouping options. Works for plain character vectors too, if groups is a factor.

Usage

```r
texts(x, groups = NULL, spacer = " ")
texts(x) <- value

## S3 method for class 'corpus'
as.character(x, ...)
```

Arguments

- **x** - a *corpus* or character object
- **groups** - either: a character vector containing the names of document variables to be used for grouping; or a factor or object that can be coerced into a factor equal in length or rows to the number of documents. See *groups* for details.
when concatenating texts by using groups, this will be the spacing added between texts. (Default is two spaces.)

Details

\[ \text{as.character}(x) \]  where \( x \) is a corpus is equivalent to calling \( \text{texts}(x) \)

Value

For \( \text{texts} \), a character vector of the texts in the corpus.

For \( \text{texts} \leftarrow \), the corpus with the updated texts.

For \( \text{texts} \leftarrow \), a corpus with the texts replaced by \( \text{value} \)

\( \text{as.character}(x) \) is equivalent to \( \text{texts}(x) \)

Note

The \( \text{groups} \) will be used for concatenating the texts based on shared values of \( \text{groups} \), without any specified order of aggregation.

You are strongly encouraged as a good practice of text analysis workflow not to modify the substance of the texts in a corpus. Rather, this sort of processing is better performed through downstream operations. For instance, do not lowercase the texts in a corpus, or you will never be able to recover the original case. Rather, apply \( \text{tokens_tolower} \) after applying \( \text{tokens} \) to a corpus, or use the option \( \text{tolower = TRUE} \) in \( \text{dfm} \).

Examples

\[ \text{nchar} \left( \text{texts} \left( \text{corpus_subset(data_corpus_inaugural, Year < 1806)} \right) \right) \]

# grouping on a document variable
\[ \text{nchar} \left( \text{texts} \left( \text{corpus_subset(data_corpus_inaugural, Year < 1806), groups = "President"} \right) \right) \]

# grouping a character vector using a factor
\[ \text{nchar} \left( \text{data_char_ukimmig2010[1:5]} \right) \]
\[ \text{mchar} \left( \text{data_corpus_inaugural[1:5], groups = as.factor(data_corpus_inaugural[1:5, "President"])} \right) \]

\[ \text{BritCorpus} \leftarrow \text{corpus(c("We must prioritise honour in our neighbourhood.", "Aluminium is a valourous metal."))} \]
\[ \text{texts(BritCorpus)} \leftarrow \text{stringi::stri_replace_all_regex(texts(BritCorpus), c("ise", "([\nlbl])our", "nium"), c("ize", "$1or", "num"), vectorize_all = FALSE)} \]
\[ \text{texts(BritCorpus)[2]} \leftarrow \text{"New text number 2."} \]
\[ \text{texts(BritCorpus)} \]
textstat_collocations  identify and score multi-word expressions

Description
Identify and score multi-word expressions, or adjacent fixed-length collocations, from text.

Usage
textstat_collocations(x, method = "lambda", size = 2, min_count = 1,
                    smoothing = 0.5, tolower = TRUE, ...)

is.collocations(x)

Arguments
x  a character, corpus, or tokens object whose collocations will be scored. The tokens object should include punctuation, and if any words have been removed, these should have been removed with padding = TRUE. While identifying collocations for tokens objects is supported, you will get better results with character or corpus objects due to relatively imperfect detection of sentence boundaries from texts already tokenized.
method  association measure for detecting collocations. Currently this is limited to "lambda". See Details.
size  integer; the length of the collocations to be scored
min_count  numeric; minimum frequency of collocations that will be scored
smoothing  numeric; a smoothing parameter added to the observed counts (default is 0.5)
tolower  logical; if TRUE, form collocations as lower-cased combinations
...  additional arguments passed to tokens, if x is not a tokens object already

Details
Documents are grouped for the purposes of scoring, but collocations will not span sentences. If x is a tokens object and some tokens have been removed, this should be done using tokens_remove(x, pattern, padding = TRUE) so that counts will still be accurate, but the pads will prevent those collocations from being scored.

The lambda computed for a size = K-word target multi-word expression the coefficient for the K-way interaction parameter in the saturated log-linear model fitted to the counts of the terms forming the set of eligible multi-word expressions. This is the same as the "lambda" computed in Blaheta and Johnson’s (2001), where all multi-word expressions are considered (rather than just verbs, as in that paper). The z is the Wald z-statistic computed as the quotient of lambda and the Wald statistic for lambda as described below.

In detail:
Consider a K-word target expression x, and let z be any K-word expression. Define a comparison function c(x, z) = (j1, ..., jK) = c such that the kth element of c is 1 if the kth word in z is equal...
to the $k$th word in $x$, and 0 otherwise. Let $c_i = (j_{i1}, \ldots, j_{iK}), i = 1, \ldots, 2^K = M$, be the possible values of $c(x, z)$, with $c_M = (1, 1, \ldots, 1)$. Consider the set of $c(x, z_r)$ across all expressions $z_r$ in a corpus of text, and let $n_i$, for $i = 1, \ldots, M$, denote the number of the $c(x, z_r)$ which equal $c_i$, plus the smoothing constant $\text{smoothing}$. The $n_i$ are the counts in a $2^K$ contingency table whose dimensions are defined by the $c_i$.

$\lambda$: The $K$-way interaction parameter in the saturated loglinear model fitted to the $n_i$. It can be calculated as

$$\lambda = \sum_{i=1}^{M} (-1)^{K-b_i} \log n_i$$

where $b_i$ is the number of the elements of $c_i$ which are equal to 1.

Wald test $z$-statistic $z$ is calculated as:

$$z = \frac{\lambda}{\left(\sum_{i=1}^{M} n_i^{-1}\right)^{1/2}}$$

Value

textstat_collocations returns a data.frame of collocations and their scores and statistics.
is.collocation returns TRUE if the object is of class collocations, FALSE otherwise.

Note

This function is under active development, with more measures to be added in the next release of quanteda.

head(seqs, 10)
textstat_dist

Similarity and distance computation between documents or features

Description

These functions compute matrices of distances and similarities between documents or features from a `dfm` and return a `dist` object (or a matrix if specific targets are selected). They are fast and robust because they operate directly on the sparse `dfm` objects.

Usage

```r
textstat_dist(x, selection = NULL, margin = c("documents", "features"),
              method = "euclidean", upper = FALSE, diag = FALSE, p = 2)

textstat_simil(x, selection = NULL, margin = c("documents", "features"),
               method = "correlation", upper = FALSE, diag = FALSE)
```

Arguments

- `x`: a `dfm` object
- `selection`: character vector of document names or feature labels from `x`. A "dist" object is returned if selection is `NULL`, otherwise, a matrix is returned.
- `margin`: identifies the margin of the `dfm` on which similarity or difference will be computed: documents for documents or features for word/term features.
- `method`: method the similarity or distance measure to be used; see Details
- `upper`: whether the upper triangle of the symmetric $V \times V$ matrix is recorded
- `diag`: whether the diagonal of the distance matrix should be recorded
- `p`: The power of the Minkowski distance.

Details

`textstat_dist` options are: "euclidean" (default), "chisquared", "chisquared2", "hamming", "kullback", "manhattan", "maximum", "canberra", and "minkowski".

`textstat_simil` options are: "correlation" (default), "cosine", "jaccard", "ejaccard", "dice", "edice", "simple matching", "hamann", and "faith".

Value

`textstat_simil` and `textstat_dist` return `dist` class objects.

Note

If you want to compute similarity on a "normalized" `dfm` object (controlling for variable document lengths, for methods such as correlation for which different document lengths matter), then wrap the input `dfm` in `dfm_weight(x, "relfreq")`. 
Author(s)
Kenneth Benoit, Haiyan Wang

References

“hamming” is $\sum x \neq y$.

“kullback” is the Kullback-Leibler distance, which assumes that $P(x_i) = 0$ implies $P(y_i) = 0$, and in case both $P(x_i)$ and $P(y_i)$ equals to zero, then $P(x_i) \ast \log(p(x_i)/p(y_i))$ is assumed to be zero as the limit value. The formula is:

$$\sum P(x) \ast \log(\frac{P(x)}{p(y)})$$

All other measures are described in the *proxy* package.

    remove = stopwords("english"), stem = TRUE, remove_punct = TRUE)

# distances for documents
(d1 <- textstat_dist(presDfm, margin = "documents"))
as.matrix(d1)

# distances for specific documents
textstat_dist(presDfm, "2017-Trump", margin = "documents")
textstat_dist(presDfm, "2005-Bush", margin = "documents", method = "eJaccard")
(d2 <- textstat_dist(presDfm, c("2009-Obama", "2013-Obama"), margin = "documents"))
as.list(d2)

# similarities for documents
(s1 <- textstat_simil(presDfm, method = "cosine", margin = "documents"))
as.matrix(s1)
as.list(s1)

# similarities for specific documents
textstat_simil(presDfm, "2017-Trump", margin = "documents")
textstat_simil(presDfm, "2017-Trump", method = "cosine", margin = "documents")
textstat_simil(presDfm, c("2009-Obama", "2013-Obama"), margin = "documents")
```
# compute some term similarities
s2 <- textstat_simil(presDfm, c("fair", "health", "terror"), method = "cosine",
        margin = "features")
head(as.matrix(s2), 10)
as.list(s2, n = 8)

textstat_frequency  

tabulate feature frequencies

Description

Produces counts and document frequencies summaries of the features in a dfm, optionally grouped by a docvars variable or other supplied grouping variable.

Usage

textstat_frequency(x, n = NULL, groups = NULL)

Arguments

x  
a dfm object

n  
(optional) integer specifying the top n features to be returned, within group if groups is specified

groups  
either: a character vector containing the names of document variables to be used for grouping; or a factor or object that can be coerced into a factor equal in length or rows to the number of documents. See groups for details.

Value

a data.frame containing the following variables:

feature  (character) the feature

frequency  count of the feature

rank  rank of the feature, where 1 indicates the greatest frequency

docf

docf

docf

docf

docf

group  (only if groups is specified) the label of the group. If the features have been grouped, then all counts, ranks, and document frequencies are within group. If groups is not specified, the group column is omitted from the returned data.frame.
Examples

```r
(dfml <- dfm(c("a a b c d", "a d d d", "a a a")))
textstat_frequency(dfml)
textstat_frequency(dfml, groups = c("one", "two", "one"))

obamadfm <- dfm(data_corpus_inaugural[56:57],
remove_punct = TRUE, remove = stopwords("english"))
freq <- textstat_frequency(obamadfm)
head(freq, 10)
```

textstat_keyness  calculate keyness statistics

Description

Calculate "keyness", a score for features that occur differentially across different categories. Here, the categories are defined by reference to a "target" document index in the dfm, with the reference group consisting of all other documents.

Usage

```r
textstat_keyness(x, target = 1L, measure = c("chi2", "exact", "lr", "pmi"),
sort = TRUE, correction = c("default", "yates", "williams", "none"))
```

Arguments

- **x**: a dfm containing the features to be examined for keyness
- **target**: the document index (numeric, character or logical) identifying the document forming the "target" for computing keyness; all other documents’ feature frequencies will be combined for use as a reference
- **measure**: (signed) association measure to be used for computing keyness. Currently available: "chi2"; "exact" (Fisher’s exact test); "lr" for the likelihood ratio; "pmi" for pointwise mutual information.
- **sort**: logical; if TRUE sort features scored in descending order of the measure, otherwise leave in original feature order
- **correction**: if "default", Yates correction is applied to "chi2"; William’s correction is applied to "lr"; and no correction is applied for the "exact" and "pmi" measures. Specifying a value other than the default can be used to override the defaults, for instance to apply the Williams correction to the chi2 measure. Specifying a correction for the "exact" and "pmi" measures has no effect and produces a warning.
Value

A data.frame of computed statistics and associated p-values, where the features scored name each row, and the number of occurrences for both the target and reference groups. For measure = "chi2" this is the chi-squared value, signed positively if the observed value in the target exceeds its expected value; for measure = "exact" this is the estimate of the odds ratio; for measure = "lr" this is the likelihood ratio $G^2$ statistic; for "pmi" this is the pointwise mutual information statistics.

References

Examples

```r
# compare pre- v. post-war terms using grouping
period <- ifelse(docvars(data_corpus_inaugural, "Year") < 1945, "pre-war", "post-war")
mydfm <- dfm(data_corpus_inaugural, groups = period)
head(mydfm) # make sure 'post-war' is in the first row
head(result <- textstat_keyness(mydfm, 10)
tail(result, 10)

# compare pre- v. post-war terms using logical vector
mydfm2 <- dfm(data_corpus_inaugural)
textstat_keyness(mydfm2, docvars(data_corpus_inaugural, "Year") >= 1945)

# compare Trump 2017 to other post-war presidents
podf <- dfm(data_corpus_inaugural, period == "post-war")
head(textstat_keyness(podf, target = "2017-Trump"), 10)
# using the likelihood ratio method
head(textstat_keyness(dfm_smooth(podf), measure = "lr", target = "2017-Trump"), 10)
```

textstat_lexdiv calculate lexical diversity

Description

Calculate the lexical diversity or complexity of text(s).

Usage

```r
textstat_lexdiv(x, measure = c("all", "TTR", "C", "R", "CTTR", "U", "S", "Maas"), log.base = 10, drop = TRUE, ...)
```
Arguments

- **x**: an input object, such as a document-feature matrix object
- **measure**: a character vector defining the measure to calculate.
- **log.base**: a numeric value defining the base of the logarithm (for measures using logs)
- **drop**: if TRUE, the result is returned as a numeric vector if only a single measure is requested; otherwise, a data.frame is returned with each column consisting of a requested measure.

Details

textstat_lexdiv calculates a variety of proposed indices for lexical diversity. In the following formulae, \( N \) refers to the total number of tokens, and \( V \) to the number of types:

- **“TTR”**: The ordinary *Type-Token Ratio*:
  \[
  TTR = \frac{V}{N}
  \]

- **“C”**: Herdan’s \( C \) (Herdan, 1960, as cited in Tweedie & Baayen, 1998; sometimes referred to as LogTTR):
  \[
  C = \frac{\log V}{\log N}
  \]

- **“R”**: Guiraud’s *Root TTR* (Guiraud, 1954, as cited in Tweedie & Baayen, 1998):
  \[
  R = \frac{V}{\sqrt{N}}
  \]

- **“CTTR”**: Carroll’s *Corrected TTR*:
  \[
  CTTR = \frac{V}{\sqrt{2N}}
  \]

- **“U”**: Dugast’s *Uber Index* (Dugast, 1978, as cited in Tweedie & Baayen, 1998):
  \[
  U = \frac{(\log N)^2}{\log N - \log V}
  \]

- **“S”**: Summer’s index:
  \[
  S = \frac{\log \log V}{\log \log N}
  \]

- **“K”**: Yule’s \( K \) (Yule, 1944, as cited in Tweedie & Baayen, 1998) is calculated by:
  \[
  K = 10^4 \times \frac{\left(\sum_{X=1}^{N} f_X X^2\right) - N}{N^2}
  \]

  where \( N \) is the number of tokens, \( X \) is a vector with the frequencies of each type, and \( f_X \) is the frequencies for each \( X \).
"Maas": Maas’ indices ($a$, $\log V_0$ & $\log e V_0$):

$$a^2 = \frac{\log N - \log V}{\log N^2}$$

$$\log V_0 = \frac{\log V}{\sqrt{1 - \frac{\log V^2}{\log N^2}}}$$

The measure was derived from a formula by Mueller (1969, as cited in Maas, 1972). $\log e V_0$ is equivalent to $\log V_0$, only with $e$ as the base for the logarithms. Also calculated are $a$, $\log V_0$ (both not the same as before) and $V'$ as measures of relative vocabulary growth while the text progresses. To calculate these measures, the first half of the text and the full text will be examined (see Maas, 1972, p. 67 ff. for details). Note: for the current method (for a dfm) there is no computation on separate halves of the text.

Value

a data.frame or vector of lexical diversity statistics, each row or vector element corresponding to an input document

Note

This implements only the static measures of lexical diversity, not more complex measures based on windows of text such as the Mean Segmental Type-Token Ratio, the Moving-Average Type-Token Ratio (Covington & McFall, 2010), the MLTD or MLTD-MA (Moving-Average Measure of Textual Lexical Diversity) proposed by McCarthy & Jarvis (2010) or Jarvis (no year), or the HD-D version of vocd-D (see McCarthy & Jarvis, 2007). These are available from the package korRpus.

Author(s)

Kenneth Benoit, adapted from the S4 class implementation written by Meik Michalke in the korRpus package.

References

Examples

```r
mydfm <- dfm(corpus_subset(data_corpus_inaugural, Year > 1980), verbose = FALSE)
(results <- textstat_lexdiv(mydfm, c("CTTR", "TTR", "U")))
cor(textstat_lexdiv(mydfm, "all"))

# with different settings of drop
textstat_lexdiv(mydfm, "TTR", drop = TRUE)
textstat_lexdiv(mydfm, "TTR", drop = FALSE)
```

---

textstat_readability  calculate readability

**Description**

Calculate the readability of text(s) using one of a variety of computed indexes.

**Usage**

```r
```

**Arguments**

- **x**: a character or corpus object containing the texts
- **measure**: character vector defining the readability measure to calculate. Matches are case-insensitive.
- **remove_hyphens**: if TRUE, treat constituent words in hyphenated as separate terms, for purposes of computing word lengths, e.g. “decision-making” as two terms of lengths 8 and 6 characters respectively, rather than as a single word of 15 characters
- **min_sentence_length**, **max_sentence_length**: set the minimum and maximum sentence lengths (in tokens, excluding punctuation) to include in the computation of readability. This makes it easy to exclude "sentences" that may not really be sentences, such as section titles, table elements, and other cruft that might be in the texts following conversion.

For finer-grained control, consider filtering sentences prior first, including through pattern-matching, using `corpus_trim`. 

```r
corpus_trim(corpus_subset(data_corpus_inaugural, Year > 1980))
```
drop if TRUE, the result is returned as a numeric vector if only a single measure is requested; otherwise, a data.frame is returned with each column consisting of a requested measure.

... not used

Value

a data.frame object consisting of the documents as rows, and the readability statistics as columns

Author(s)

Kenneth Benoit, re-engineered from the function of the same name by Meik Michalke in the koRpus package.

Examples

txt <- c("Readability zero one. Ten, Eleven.", "The cat in a dilapidated tophat.")
textstat_readability(txt, "Flesch.Kincaid")
textstat_readability(txt, "Flesch.Kincaid", drop = FALSE)
textstat_readability(txt, c("FOG", "FOG.PSK", "FOG.NRI"))
inaugReadability <- textstat_readability(data_corpus_inaugural, "all")
round(cor(inaugReadability), 2)

_textstat_readability(data_corpus_inaugural, measure = "Flesch.Kincaid")
inaugReadability <- textstat_readability(data_corpus_inaugural, "all")
round(cor(inaugReadability), 2)

tokens

tokenize a set of texts

Description

Tokenize the texts from a character vector or from a corpus.

Usage

tokens(x, what = c("word", "sentence", "character", "fastestword", "fastword"), remove_numbers = FALSE, remove_punct = FALSE, remove_symbols = FALSE, remove_separators = TRUE, remove_twitter = FALSE, remove_hyphens = FALSE, remove_url = FALSE, ngrams = 1L, skip = 0L, concatenator = "_", hash = TRUE, verbose = quanteda_options("verbose"), include_docvars = TRUE, ...)
Arguments

x a character, corpus, or tokens object to be tokenized
what the unit for splitting the text, available alternatives are:
"word" (recommended default) smartest, but slowest, word tokenization method; see stringi-search-boundaries for details.
"fasterword" dumber, but faster, word tokenization method, uses \( \text{stri_split_charclass}(x, \"\p{white_space}\)} \)
"fastestword" dumbest, but fastest, word tokenization method, calls \( \text{stri_split_fixed}(x, \"\)} \)
"character" tokenization into individual characters
"sentence" sentence segmenter, smart enough to handle some exceptions in English such as "Prof. Plum killed Mrs. Peacock." (but far from perfect).
remove_numbers remove tokens that consist only of numbers, but not words that start with digits, e.g. 2day
remove_punct if TRUE, remove all characters in the Unicode "Punctuation" [P] class
remove_symbols if TRUE, remove all characters in the Unicode "Symbol" [S] class
remove_separators remove Separators and separator characters (spaces and variations of spaces, plus tab, newlines, and anything else in the Unicode "separator" category) when remove_punct=FALSE. Only applicable for what = "character" (when you probably want it to be FALSE) and for what = "word" (when you probably want it to be TRUE). Note that if what = "word" and you set remove_punct = TRUE, then remove_separators has no effect. Use carefully.
remove_twitter remove Twitter characters @ and #; set to TRUE if you wish to eliminate these. Note that this will always be set to FALSE if remove_punct = FALSE.
remove_hyphens if TRUE, split words that are connected by hyphenation and hyphenation-like characters in between words, e.g. "self-storage" becomes c("self", "storage"). Default is FALSE to preserve such words as is, with the hyphens. Only applies if what = "word".
remove_url if TRUE, find and eliminate URLs beginning with http(s) – see section "Dealing with URLs".
ngrams integer vector of the \( n \) for \( n \)-grams, defaulting to 1 (unigrams). For bigrams, for instance, use 2; for bigrams and unigrams, use 1:2. You can even include irregular sequences such as 2:3 for bigrams and trigrams only. See tokens_ngrams.
skip integer vector specifying the skips for skip-grams, default is 0 for only immediately neighbouring words. Only applies if ngrams is different from the default of 1. See tokens_skipgrams.
concatenator character to use in concatenating \( n \)-grams, default is "_", which is recommended since this is included in the regular expression and Unicode definitions of "word" characters
hash if TRUE (default), return a hashed tokens object, otherwise, return a classic tokenizedTexts object. (This will be phased out soon in coming versions.)
verbose if TRUE, print timing messages to the console; off by default
include_docvars if TRUE, pass docvars and metadoc fields through to the tokens object. Only applies when tokenizing corpus objects.
... additional arguments not used
Details

The tokenizer is designed to be fast and flexible as well as to handle Unicode correctly. Most of
the time, users will construct `dfm` objects from texts or a corpus, without calling `tokens()` as an
intermediate step. Since `tokens()` is most likely to be used by more technical users, we have set
its options to default to minimal intervention. This means that punctuation is tokenized as well,
and that nothing is removed by default from the text being tokenized except inter-word spacing and
equivalent characters.

Note that a `tokens` constructor also works on `tokens` objects, which allows setting additional op-
tions that will modify the original object. It is not possible, however, to change a setting to "un-remove" something that was removed from the input `tokens` object, however. For instance,
`tokens(tokens("Ha!", remove_punct = TRUE), remove_punct = FALSE)` will not restore
the "!" token. No warning is currently issued about this, so the user should use `tokens().tokens()`
with caution.

Value

`quanteda` tokens class object, by default a hashed list of integers corresponding to a vector of
types.

Dealing with URLs

URLs are tricky to tokenize, because they contain a number of symbols and punctuation characters.
If you wish to remove these, as most people do, and your text contains URLs, then you should set
what = "fasterword" and `remove_url = TRUE`. If you wish to keep the URLs, but do not want
them mangled, then your options are more limited, since removing punctuation and symbols will
also remove them from URLs. We are working on improving this behaviour.

See the examples below.

### tokens(txt, remove_punct = TRUE, ngrams = 2, skip = 1, concatenator = " ")
### tokens(txt, remove_punct = TRUE, ngrams = 1:2)
# removing features from ngram tokens
### removeFeatures(tokens(txt, remove_punct = TRUE, ngrams = 1:2), stopwords("english"))
Description

Replace multi-token sequences with a multi-word, or "compound" token. The resulting compound tokens will represent a phrase or multi-word expression, concatenated with concatenator (by default, the "_" character) to form a single "token". This ensures that the sequences will be processed subsequently as single tokens, for instance in constructing a dfm.

Usage

tokens_compound(x, pattern, concatenator = "_", valuetype = c("glob", "regex", "fixed"), case_insensitive = TRUE, join = TRUE)

Arguments

x an input tokens object
pattern a character vector, list of character vectors, dictionary, collocations, or dfm. See pattern for details.
concatenator the concatenation character that will connect the words making up the multi-word sequences. The default _ is recommended since it will not be removed during normal cleaning and tokenization (while nearly all other punctuation characters, at least those in the Unicode punctuation class [P] will be removed).
valuetype how to interpret keyword expressions: "glob" for "glob"-style wildcard expressions; "regex" for regular expressions; or "fixed" for exact matching. See valuetype for details.
case_insensitive logical; if TRUE, ignore case when matching
join logical; if TRUE, join overlapping compounds

Value

a tokens object in which the token sequences matching pattern have been replaced by compound "tokens" joined by the concatenator

Author(s)

Kenneth Benoit and Kohei Watanabe

Examples

mytexts <- c("The new law included a capital gains tax, and an inheritance tax.",
"New York City has raised taxes: an income tax and inheritance taxes.")
mytoks <- tokens(mytexts, remove_punct = TRUE)
# for lists of sequence elements
myseqs <- list(c("tax"), c("income", "tax"), c("capital", "gains", "tax"), c("inheritance", "tax"))
(cw <- tokens_compound(mytoks, myseqs))
dfm(cw)

# when used as a dictionary for dfm creation
mydict <- dictionary(list(tax=c("tax", "income tax", "capital gains tax", "inheritance tax")))
(cw2 <- tokens_compound(mytoks, mydict))

# to pick up "taxes" in the second text, set valuetype = "regex"
(cw3 <- tokens_compound(mytoks, mydict, valuetype = "regex"))

# dictionaries w/glob matches
myDict <- dictionary(list(negative = c("bad* wordx", "negative", "awful text"),
positive = c("good stuff", "like? th??")))
toks <- tokens(c(txt1 = "I liked this, when we can use bad words, in awful text. ",
txt2 = "Some damn good stuff, like the text, she likes that too.")
tokens_compound(toks, myDict)

# with collocations
cols <-
textstat_collocations(tokens("capital gains taxes are worse than inheritance taxes"),
size = 2, min_count = 1)
toks <- tokens("The new law included capital gains taxes and inheritance taxes.")
tokens_compound(toks, cols)

tokens_lookup apply a dictionary to a tokens object

description
convert tokens into equivalence classes defined by values of a dictionary object.

usage
tokens_lookup(x, dictionary, levels = 1:5, valuetype = c("glob", "regex", "fixed"), case_insensitive = TRUE, capkeys = !exclusive, exclusive = TRUE, nomatch = NULL, verbose = quanteda_options("verbose"))

arguments
x tokens object to which dictionary or thesaurus will be supplied
dictionary the dictionary-class object that will be applied to x
levels integers specifying the levels of entries in a hierarchical dictionary that will be applied. The top level is 1, and subsequent levels describe lower nesting levels. Values may be combined, even if these levels are not contiguous, e.g. `levels = c(1:3)` will collapse the second level into the first, but record the third level (if present) collapsed below the first. (See examples.)
valuetype  
how to interpret keyword expressions: "glob" for "glob"-style wildcard expressions; "regex" for regular expressions; or "fixed" for exact matching. See valuetype for details.

case_insensitive  
ignore the case of dictionary values if TRUE uppercase to distinguish them from other features

capkeys  
if TRUE, convert dictionary keys to uppercase to distinguish them from other features

exclusive  
if TRUE, remove all features not in dictionary, otherwise, replace values in dictionary with keys while leaving other features unaffected

nomatch  
an optional character naming a new key for tokens that do not matched to a dictionary values If NULL (default), do not record unmatched tokens.

verbose  
print status messages if TRUE

Examples

toks <- tokens(data_corpus_inaugural)
dict <- dictionary(list(country = "united states",
  law = c('law', 'constitution'),
  freedom = c('free', 'libert')))
dfm(tokens_lookup(toks, dict, valuetype='glob', verbose = TRUE))
dfm(tokens_lookup(toks, dict, valuetype='glob', verbose = TRUE, nomatch = 'NONE'))

dict_fix <- dictionary(list(country = "united states",
  law = c('law', 'constitution'),
  freedom = c('freedom', 'liberty'))) # dfm(applyDictionary(toks, dict_fix, valuetype='fixed'))
dfm(tokens_lookup(toks, dict_fix, valuetype='fixed'))

# hierarchical dictionary example
txt <- c(d1 = "The United States has the Atlantic Ocean and the Pacific Ocean.",
  d2 = "Britain and Ireland have the Irish Sea and the English Channel.")
toks <- tokens(txt)
dict <- dictionary(list(US = list(Countries = c("States"),
  oceans = c("Atlantic", "Pacific")),
  Europe = list(Countries = c("Britain", "Ireland"),
  oceans = list(west = "Irish Sea",
  east = "English Channel"))))
tokens_lookup(toks, dict, levels = 1)
tokens_lookup(toks, dict, levels = 2)
tokens_lookup(toks, dict, levels = 1:2)
tokens_lookup(toks, dict, levels = 3)
tokens_lookup(toks, dict, levels = c(1,3))
tokens_lookup(toks, dict, levels = c(2,3))

# show unmatched tokens
tokens_lookup(toks, dict, nomatch = "_UNMATCHED")
tokens_ngrams  

create ngrams and skipgrams from tokens

**Description**

Create a set of ngrams (tokens in sequence) from already tokenized text objects, with an optional skip argument to form skipgrams. Both the ngram length and the skip lengths take vectors of arguments to form multiple lengths or skips in one pass. Implemented in C++ for efficiency.

**Usage**

```r
tokens_ngrams(x, n = 2L, skip = 0L, concatenator = "_")
char_ngrams(x, n = 2L, skip = 0L, concatenator = "_")
tokens_skipgrams(x, n, skip, concatenator = "_")
```

**Arguments**

- `x`  
  a tokens object, or a character vector, or a list of characters

- `n`  
  integer vector specifying the number of elements to be concatenated in each ngram. Each element of this vector will define a n in the n-gram(s) that are produced.

- `skip`  
  integer vector specifying the adjacency skip size for tokens forming the ngrams, default is 0 for only immediately neighbouring words. For skipgrams, skip can be a vector of integers, as the "classic" approach to forming skip-grams is to set skip = k where k is the distance for which k or fewer skips are used to construct the n-gram. Thus a "4-skip-n-gram" defined as skip = 0:4 produces results that include 4 skips, 3 skips, 2 skips, 1 skip, and 0 skips (where 0 skips are typical n-grams formed from adjacent words). See Guthrie et al (2006).

- `concatenator`  
  character for combining words, default is _ (underscore) character

**Details**

Normally, these functions will be called through `tokens(x, ngrams = , ...)`, but these functions are provided in case a user wants to perform lower-level ngram construction on tokenized texts.

`tokens_skipgrams` is a wrapper to `ngrams` that requires arguments to be supplied for both n and skip. For k-skip skipgrams, set skip to 0:k, in order to conform to the definition of skip-grams found in Guthrie et al (2006): A k skip-gram is an ngram which is a superset of all ngrams and each \((k - i)\) skipgram until \((k - i) == 0\) (which includes 0 skip-grams).

**Value**

a tokens object consisting a list of character vectors of ngrams, one list element per text, or a character vector if called on a simple character vector
Note

char_ngrams is a convenience wrapper for a (non-list) vector of characters, so named to be consistent with quanteda’s naming scheme.

Author(s)

Kohei Watanabe (C++) and Ken Benoit (R)

References

Examples

# ngrams
tokens_ngrams(tokens(c("a b c d e", "c d e f g")), n = 2:3)
toks <- tokens(c(text1 = "the quick brown fox jumped over the lazy dog"))
tokens_ngrams(toks, n = 1:3)
tokens_ngrams(toks, n = c(2,4), concatenator = " ")
tokens_ngrams(toks, n = c(2,4), skip = 1, concatenator = " ")

# on character
char_ngrams(letters[1:3], n = 1:3)

# skipgrams
toks <- tokens("insurgents killed in ongoing fighting")
tokens_skipgrams(toks, n = 2, skip = 0:1, concatenator = " ")
tokens_skipgrams(toks, n = 2, skip = 0:2, concatenator = " ")
tokens_skipgrams(toks, n = 3, skip = 0:2, concatenator = " ")

tokens_select select or remove tokens from a tokens object

description

This function selects or discards tokens from a tokens objects, with the shortcut tokens_remove(x, pattern) defined as a shortcut for tokens_select(x, pattern, selection = "remove"). The most common usage for tokens_remove will be to eliminate stop words from a text or text-based object, while the most common use of tokens_select will be to select tokens with only positive pattern matches from a list of regular expressions, including a dictionary.

Usage

tokens_select(x, pattern, selection = c("keep", "remove"),
valuetype = c("glob", "regex", "fixed"), case_inensitive = TRUE,
padding = FALSE, verbose = quanteda_options("verbose"))
tokens_remove(x, pattern, valuetype = c("glob", "regex", "fixed"),
            case_insensitive = TRUE, padding = FALSE,
            verbose = quanteda_options("verbose"))

**Arguments**

x  
**tokens** object whose token elements will be selected

pattern  
a character vector, list of character vectors, **dictionary**, **collocations**, or dfm. See **pattern** for details.

selection  
whether to "keep" or "remove" the tokens matching **pattern**

valuetype  
how to interpret keyword expressions: "glob" for "glob"-style wildcard expressions; "regex" for regular expressions; or "fixed" for exact matching. See **valuetype** for details.

case_insensitive  
ignore case when matching, if TRUE

padding  
if TRUE, leave an empty string where the removed tokens previously existed. This is useful if a positional match is needed between the pre- and post-selected tokens, for instance if a window of adjacency needs to be computed.

verbose  
if TRUE print messages about how many tokens were selected or removed

**Value**

a **tokens** object with tokens selected or removed based on their match to **pattern**

**Examples**

```r
## tokens_select with simple examples
toks <- tokens(c("This is a sentence.", "This is a second sentence."),
                remove_punct = TRUE)
tokens_select(toks, c("is", "a", "this"), selection = "keep", padding = FALSE)
tokens_select(toks, c("is", "a", "this"), selection = "keep", padding = TRUE)
tokens_select(toks, c("is", "a", "this"), selection = "remove", padding = FALSE)
tokens_select(toks, c("is", "a", "this"), selection = "remove", padding = TRUE)

# how case_insensitive works
tokens_select(toks, c("is", "a", "this"), selection = "remove", case_insensitive = TRUE)
tokens_select(toks, c("is", "a", "this"), selection = "remove", case_insensitive = FALSE)

## tokens_remove example
txt <- c(wash1 <- "Fellow citizens, I am again called upon by the voice of my country to
execute the functions of its Chief Magistrate.",
         wash2 <- "When the occasion proper for it shall arrive, I shall endeavor to express
the high sense I entertain of this distinguished honor.")
tokens_remove(tokens(txt, remove_punct = TRUE), stopwords("english"))
```
tokens_tolower

convert the case of tokens

Description

tokens_tolower and tokens_toupper convert the features of a tokens object and reindex the types.

Usage

tokens_tolower(x, keep_acronyms = FALSE, ...)
tokens_toupper(x, ...)

Arguments

x the input object whose character/tokens/feature elements will be case-converted
keep_acronyms logical; if TRUE, do not lowercase any all-uppercase words (applies only to *_tolower functions)
... additional arguments passed to stringi functions, (e.g. stri_trans_tolower), such as locale

Examples

# for a document-feature matrix
toks <- tokens(c(txt1 = "b A A", txt2 = "C c a b B"))
tokens_tolower(toks)
tokens_toupper(toks)

tokens_wordstem

stem the terms in an object

Description

Apply a stemmer to words. This is a wrapper to wordStem designed to allow this function to be called without loading the entire SnowballC package. wordStem uses Martin Porter’s stemming algorithm and the C libstemmer library generated by Snowball.

Usage

tokens_wordstem(x, language = quanteda_options("language_stemmer"))
char_wordstem(x, language = quanteda_options("language_stemmer"))
dfm_wordstem(x, language = quanteda_options("language_stemmer"))
Arguments

x a character, tokens, or dfm object whose word stems are to be removed. If
tokenized texts, the tokenization must be word-based.

language the name of a recognized language, as returned by `getStemLanguages`, or a two-
or three-letter ISO-639 code corresponding to one of these languages (see refer-
ences for the list of codes)

Value

tokens_wordstem returns a tokens object whose word types have been stemmed.
char_wordstem returns a character object whose word types have been stemmed.
dfm_wordstem returns a dfm object whose word types (features) have been stemmed, and recom-
bined to consolidate features made equivalent because of stemming.

References

wordStem

Examples

# example applied to tokens
txt <- c(one = "eating eater eaters eats ate",
       two = "taxing taxes taxed my tax return")

th <- tokens(txt)

tokens_wordstem(th)

# simple example

char_wordstem(c("win", "winning", "wins", "won", "winner"))

# example applied to a dfm

(origdfm <- dfm(txt))

dfm_wordstem(origdfm)
Usage

`topfeatures(x, n = 10, decreasing = TRUE, scheme = c("count", "docfreq"), groups = NULL)`

Arguments

- `x`: the object whose features will be returned
- `n`: how many top features should be returned
- `decreasing`: If TRUE, return the `n` most frequent features; otherwise return the `n` least frequent features
- `scheme`: one of `count` for total feature frequency (within group if applicable), or `docfreq` for the document frequencies of features
- `groups`: either: a character vector containing the names of document variables to be used for grouping; or a factor or object that can be coerced into a factor equal in length or rows to the number of documents. See `groups` for details.

Value

A named numeric vector of feature counts, where the names are the feature labels, or a list of these if `groups` is given.

Examples

```r
mydfm <- dfm(corpus_subset(data_corpus_inaugural, Year > 1980), remove_punct = TRUE)
mydfm_nostopw <- dfm_remove(mydfm, stopwords("english"))

# most frequent features
topfeatures(mydfm)
topfeatures(mydfm_nostopw)

# least frequent features
topfeatures(mydfm_nostopw, decreasing = FALSE)

# top features of individual documents
topfeatures(mydfm_nostopw, n = 5, groups = docnames(mydfm_nostopw))

# grouping by president last name
topfeatures(mydfm_nostopw, n = 5, groups = "President")

# features by document frequencies
tail(topfeatures(mydfm, scheme = "docfreq", n = 200))
```
