Package ‘quantmod’

March 31, 2020

Type Package
Title Quantitative Financial Modelling Framework
Version 0.4.17
Depends R (>= 3.2.0), xts(>= 0.9-0), zoo, TTR(>= 0.2), methods
Imports curl
Suggests DBI, RMySQL, RSQLite, timeSeries, XML, downloader, jsonlite(>= 1.1)
Description Specify, build, trade, and analyse quantitative financial trading strategies.
LazyLoad yes
License GPL-3
BugReports https://github.com/joshuaulrich/quantmod/issues
NeedsCompilation no
Author Jeffrey A. Ryan [aut, cph],

The `quantmod` package for R is designed to assist the quantitative trader in the development, testing, and deployment of statistically based trading models.

**What quantmod IS**

A rapid prototyping environment, with comprehensive tools for data management and visualization, where quant traders can quickly and cleanly explore and build trading models.

**What quantmod is NOT**
A replacement for anything statistical. It has no 'new' modelling routines or analysis tool to speak of. It does now offer charting not currently available elsewhere in R, but most everything else is more of a wrapper to what you already know and love about the language and packages you currently use.

quantmod makes modelling easier by removing the repetitive workflow issues surrounding data management, modelling interfaces, and performance analysis.

---

**addADX**

Add Directional Movement Index

### Usage

```r
addADX(n = 14, maType="EMA", wilder=TRUE)
```

### Arguments

- `n`: periods to use for DX calculation
- `maType`: moving average type
- `wilder`: should Welles Wilder EMA be used?

### Details

See 'ADX' in **TTR** for specific details and references.

### Value

An ADX indicator will be draw in a new window on the current chart. A chobTA object will be returned silently.

### Author(s)

Jeffrey A. Ryan

### References

see ADX in **TTR** written by Josh Ulrich
addBBands

See Also
addTA

Examples

```r
## Not run:
addADX()

## End(Not run)
```

---

**addBBands**  
*Add Bollinger Bands to Chart*

**Description**

Add Bollinger Bands to current chart.

**Usage**

```r
addBBands(n = 20, sd = 2, maType = "SMA", draw = 'bands', on = -1)
```

**Arguments**

- `n` number of moving average periods
- `maType` type of moving average to be used
- `sd` number of standard deviations
- `draw` indicator to draw: bands, percent, or width
- `on` which figure area of chart to apply to

**Details**

The primary addition to this function call over the TTR version is in the `draw` argument. ‘bands’ will draw standard Bollinger Bands, ‘percent’ will draw Bollinger %b and ‘width’ will draw Bolinger Bands Width. The last two will be drawn in new figure regions.

See bollingerBands in TTR for specific details as to implementation and references.

**Value**

Bollinger Bands will be drawn, or scheduled to be drawn, on the current chart. If `draw` is either percent or width a new figure will be added to the current TA figures charted.

A chobTA object will be returned silently.

**Author(s)**

Jeffrey A. Ryan
**Description**
Add Commodity Channel Index

**Usage**
```
addCCI(n = 20, maType="SMA", c=0.015)
```

**Arguments**
- `n`: periods to use for DX calculation
- `maType`: moving average type
- `c`: Constant to apply to the mean deviation.

**Details**
See 'CCI' in **TTR** for specific details and references.

**Value**
An CCI indicator will be draw in a new window on the current chart. A chobTA object will be returned silently.

**Author(s)**
Jeffrey A. Ryan

**References**
see CCI in **TTR** written by Josh Ulrich
addExpiry

See Also
addTA

Examples
## Not run:
addCCI()

## End(Not run)

addExpiry Add Contract Expiration Bars to Chart

Description
Apply options or futures expiration vertical bars to current chart.

Usage
addExpiry(type = "options", lty = "dotted")

Arguments
type options or futures expiration
lty type of lines to draw

Details
See options.expiry and futures.expiry in quantmod for details and limitations.

Value
Expiration lines will be drawn at appropriate dates. A chibTA object will be returned silently.

Author(s)
Jeffrey A. Ryan

See Also
addTA

Examples
## Not run:
addExpiry()

## End(Not run)
addMA

Add Moving Average to Chart

Description
Add one or more moving averages to a chart.

Usage
addSMA(n = 10, on = 1, with.col = Cl, overlay = TRUE, col = "brown")
addEMA(n = 10, wilder = FALSE, ratio=NULL, on = 1, with.col = Cl, overlay = TRUE, col = "blue")
addWMA(n = 10, wts=1:n, on = 1, with.col = Cl, overlay = TRUE, col = "green")
addDEMA(n = 10, on = 1, with.col = Cl, overlay = TRUE, col = "pink")
addEVWMA(n = 10, on = 1, with.col = Cl, overlay = TRUE, col = "yellow")
addZLEMA(n = 10, ratio=NULL, on = 1, with.col = Cl, overlay = TRUE, col = "red")

Arguments
n periods to average over
wilder logical; use wilder?
wts a vector of weights
ratio a smoothing/decay ratio
on apply to which figure (see below)
with.col using which column of data (see below)
overlay draw as overlay
col color of MA

Details
see the appropriate base MA functions in TTR for more details and references.

Value
A moving average indicator will be draw on the current chart. A chobTA object will be returned silently.

Author(s)
Jeffrey A. Ryan
addMACD

References

see MovingAverages in TTR written by Josh Ulrich

See Also

addTA

Examples

## Not run:
addSMA()
addEMA()
addWMA()
addDEMA()
addEVWMA()
addZLEMA()

## End(Not run)

addMACD  Add Moving Average Convergence Divergence to Chart

Description

Add Moving Average Convergence Divergence indicator to chart.

Usage

addMACD(fast = 12, slow = 26, signal = 9, type = "EMA", histogram = TRUE, col)

Arguments

fast   fast period
slow   slow period
signal signal period
type   type of MA to use. Single values will be replicated
histogram include histogram
col    colors to use for lines (optional)

Details

See and 'MACD' in TTR for specific details and implementation references.

Value

A MACD indicator will be draw in a new window on the current chart. A chobTA object will be returned silently.
addROC

Author(s)
Jeffrey A. Ryan

References
see MACD in TTR written by Josh Ulrich

See Also
addTA

Examples
### Not run:
addMACD()

### End(Not run)

---

**addROC**

*Add Rate Of Change to Chart*

Description
Add Rate Of Change indicator to chart.

Usage
addROC(n = 1, type = c("discrete", "continuous"), col = "red")

Arguments
- **n**: periods
- **type**: compounding type
- **col**: line color (optional)

Details
See 'ROC' in TTR for specific details and references.

Value
A ROC indicator will be draw in a new window on the current chart. A chobTA object will be returned silently.

Author(s)
Jeffrey A. Ryan
addRSI

References

see ROC in TTR written by Josh Ulrich

See Also

addTA

Examples

```r
## Not run:
addROC()
```

```r
## End(Not run)
```

---

### addRSI

**Add Relative Strength Index to Chart**

**Description**

Add a Relative Strength Index indicator to chart.

**Usage**

```r
addRSI(n = 14, maType = "EMA", wilder = TRUE)
```

**Arguments**

- `n`: periods
- `maType`: type of MA to use
- `wilder`: use wilder (see EMA)

**Details**

see 'RSI' in TTR for specific details and references.

**Value**

An RSI indicator will be draw in a new window on the current chart. A chobTA object will be returned silently.

**Author(s)**

Jeffrey A. Ryan

**References**

see RSI in TTR written by Josh Ulrich
addSAR

See Also

addTA

Examples

## Not run:
addRSI()

## End(Not run)

---

addSAR  
Add Parabolic Stop and Reversal to Chart

Description

Add Parabolic Stop and Reversal indicator overlay to chart.

Usage

addSAR(accel = c(0.02, 0.2), col = "blue")

Arguments

accel Accelleration factors - see SAR
col color of points (optional)

Details

see 'SAR' in TTR for specific details and references.

Value

A SAR overlay will be drawn on the current chart. A chobTA object will be returned silently.

Author(s)

Jeffrey A. Ryan

References

see SAR in TTR written by Josh Ulrich

See Also

addTA
addSMI

Examples

```r
## Not run:
addSAR()

## End(Not run)
```
### Description

Add Volume of a series, if available, to the current chart. This is the default TA argument for all charting functions.

### Usage

```r
addVo(log.scale=FALSE)
```

### Arguments

- `log.scale`: use log-scale for volume

### Details

Add volume bars to current chart if data object contains appropriate volume column. `log.scale` will transform the series via standard R graphics mechanisms.

### Value

Volume will be draw in a new window on the current chart. A `chartTA` object will be returned silently.

### Author(s)

Jeffrey A. Ryan

### See Also

- `addTA`

### Examples

```r
## Not run:
addSMI()

## End(Not run)
```
addWPR

Add William’s Percent R to Chart

Description

Add William’s percent R indicator to the current chart.

Usage

addWPR(n = 14)

Arguments

n periods

Details

see ‘WPR’ in TTR for details and references.

Value

A William’s percent R indicator will be drawn in a new window on the current chart. A chobTA object will be returned silently.

Author(s)

Jeffrey A. Ryan

References

see ‘WPR’ in TTR written by Josh Ulrich

See Also

addTA

Examples

## Not run:
addWPR()

## End(Not run)
**Description**

Adjust all columns of an OHLC object for split and dividend.

**Usage**

```r
adjustOHLC(x,
    adjust = c("split","dividend"),
    use.Adjusted = FALSE,
    ratio = NULL,
    symbol.name=deparse(substitute(x)))
```

**Arguments**

- `x` An OHLC object
- `adjust` adjust by split, dividend, or both (default)
- `use.Adjusted` use the ‘Adjusted’ column in Yahoo! data to adjust
- `ratio` ratio to adjust with, bypassing internal calculations
- `symbol.name` used if `x` is not named the same as the symbol adjusting

**Details**

This function calculates the adjusted Open, High, Low, and Close prices according to split and dividend information.

There are three methods available to calculate the new OHLC object prices.

By default, `getSplits` and `getDividends` are called to retrieve the respective information. These may dispatch to custom methods following the “:\” methodology used by quantmod dispatch. See `getSymbols` for information related to extending quantmod. This information is passed to `adjRatios` from the **TTR** package, and the resulting ratio calculations are used to adjust to observed historical prices. This is the most precise way to adjust a series.

The second method works only on standard Yahoo! data containing an explicit Adjusted column.

A final method allows for one to pass a `ratio` into the function directly.

All methods proceed as follows:

New columns are derived by taking the ratio of adjusted value to original Close, and multiplying by the difference of the respective column and the original Close. This is then added to the modified Close column to arrive at the remaining ‘adjusted’ Open, High, Low column values.

If no adjustment is needed, the function returns the original data unaltered.

**Value**

An object of the original class, with prices adjusted for splits and dividends.
Warning

Using `use.Adjusted = TRUE` will be less precise than the method that employs actual split and dividend information. This is due to loss of precision from Yahoo! using Adjusted columns of only two decimal places. The advantage is that this can be run offline, and for short series or those with few adjustments the loss of precision will be small.

The resulting precision loss will be from row observation to row observation, as the calculation will be exact for intraday values.

Author(s)

Jeffrey A. Ryan

`getSymbols.yahoo` `getSplits` `getDividends`

Examples

```r
## Not run:
getSymbols("AAPL", from="1990-01-01", src="yahoo")
head(AAPL)
head(AAPL.a <- adjustOHLC(AAPL))
head(AAPL.uA <- adjustOHLC(AAPL, use.Adjusted=TRUE))

# intraday adjustments are precise across all methods
# an example with Open to Close (OpCl)
head(cbind(OpCl(AAPL),OpCl(AAPL.a),OpCl(AAPL.uA)))

# Close to Close changes may lose precision
head(cbind(ClCl(AAPL),ClCl(AAPL.a),ClCl(AAPL.uA)))

## End(Not run)
```

attachSymbols

Attach a demand database (lazy load) as a new environment.
Usage

attachSymbols(DB = DDB_Yahoo(),
              pos = 2,
              prefix = NULL,
              postfix = NULL,
              mem.cache = TRUE,
              file.cache = !mem.cache,
              cache.dir = tempdir())

flushSymbols(DB = DDB_Yahoo())

Arguments

DB A DDB data base object
pos position in search path to attach DB
prefix character to prefix all symbols with
postfix character to postfix all symbols with
mem.cache should objects be cached in memory
file.cache should objects be cached in on disk
cache.dir directory to use for file.cache=TRUE

details

An experimental function to allow access to remote objects without requiring explicit calls to a
loading function.

attachSymbols requires a DDB object to define where the data is to come from, as well as what
symbols are loaded on-demand.

attachSymbols calls the method referred to by the DDB object. In the default case this is DDB_Yahoo.
See this function for specific details about the Yahoo implementation.

The individual methods make use of getSymbols to load the data. This requires a corresponding
getSymbols method.

Internally, attachSymbols makes use of quantmod’s unexported create.bindings to dynamically cre-
ate active bindings to each symbol listed in the DDB object.

In turn, create.bindings uses one of two R methods to create the binding to the names required. This
depends on the cache method requested.

Immediately after a call to attachSymbols, a new environment is attached that contains the names
of objects yet to be loaded. This is similar to the lazy-load mechanism in R, though extended to be
both more general and easier to use.

It is important to note that no data is loaded at this stage. What occurs instead is that these sym-
mbols now have active bindings using either delayedAssign (mem.cache) or makeActiveBinding
(file.cache).

During all future requests for the object(s) in question, the binding will be used to determine how
this data is loaded into R. mem.cache will simply load the data from its corresponding source (as
defined by the DDB object) and leave it in the environment specified in the original call. The effect
of this is to allow lazy-loading of data from a variety of external sources (Yahoo in the default case). Once loaded, these are cached in \texttt{R}'s memory. Nothing further differentiates these from standard variables. This also means that the environment will grow as more symbols are loaded.

If the \texttt{file.cache} option is set, the data is loaded from its source the first time the symbol is referenced. The difference is that the data is then written to a temporary file and maintained there. Data is loaded and subsequently removed upon each request for the object. See \texttt{makeActiveBinding} for details of how this occurs at the \texttt{R} level.

A primary advantage of using the \texttt{file.cache} option is the ability to maintain hundreds or thousands of objects in your current session without using memory, or explicitly loading and removing. The main downside of this approach is that data must be loaded from disk each time, with the corresponding (if generally negligible) overhead of file access.

\textbf{Note}

This function is new, and all aspects may change in the near future.

---

\textbf{buildData} \hspace{1cm} \textit{Create Data Object for Modelling}

\textbf{Description}

Create one data object from multiple sources, applying transformations via standard \texttt{R} formula mechanism.

\textbf{Usage}

\texttt{buildData(formula, na.rm = TRUE, return.class = "zoo")}
Arguments

- **formula**: An object of class formula (or one that can be coerced to that class): a symbolic description of the desired output data object, with the dependent side corresponding to first column, and the independent parameters of the formula assigned to the remaining columns.
- **na.rm**: Drop rows with missing values?
- **return.class**: One of "zoo", "data.frame", "ts", "timeSeries"

Details

Makes available for use outside the quantmod workflow a dataset of appropriately transformed variables, using the same mechanism underlying specifyModel. Offers the ability to apply transformations to raw data using a common formula mechanism, without having to explicitly merge different data objects.

Internally calls specifyModel followed by modelData, with the returned object being coerced to the desired 'return.class' if possible, otherwise returns a zoo object.

See getSymbols and specifyModel for more information regarding proper usage.

Value

An object of class return.class.

Author(s)

Jeffrey A. Ryan

See Also

getSymbols, specifyModel, modelData

Examples

```r
## Not run:
buildData(Next(OpCl(DIA)) ~ Lag(TBILL) + I(Lag(OpHi(DIA))^2))
buildData(Next(OpCl(DIA)) ~ Lag(TBILL), na.rm=FALSE)
buildData(Next(OpCl(DIA)) ~ Lag(TBILL), na.rm=FALSE, return.class="ts")

## End(Not run)
```
**buildModel**

*Build quantmod model given specified fitting method*

**Description**

Construct and attach a fitted model of type method to quantmod object.

**Usage**

`buildModel(x, method, training.per, ...)`

**Arguments**

- `x`: An object of class `quantmod` created with `specifyModel` or an R formula.
- `training.per`: character vector representing dates in ISO 8601 format “CCYY-MM-DD” or “CCYY-MM-DD HH:MM:SS” of length 2.
- `method`: A character string naming the fitting method. See details section for available methods, and how to create new methods.
- `...`: Additional arguments to method call.

**Details**

Currently available methods include:

- `lm`, `glm`, `loess`, `step`, `ppr`, `rpart`, `tree`, `randomForest`, `mars`, `polymars`, `lars`, `rq`, `lqs`, `rlm`, `svm`, `nnet`.

The `training.per` should match the underlying date format of the time-series data used in modelling. Any other style may not return what you expect.

Additional methods wrappers can be created to allow for modelling using custom functions. The only requirements are for a wrapper function to be constructed taking parameters `quantmod`, `training.data`, and `...`. The function must return the fitted model object and have a predict method available. It is possible to add predict methods if non exist by adding an S3 method for `predictModel`. The `buildModel.skeleton` function can be used for new methods.

**Value**

An object of class `quantmod` with fitted model attached

**Note**

See `buildModel.skeleton` for information on adding additional methods.

**Author(s)**

Jeffrey Ryan

`specifyModel`, `tradeModel`

Examples

```r
## Not run:
getSymbols("QQQQ", src="yahoo")
q.model = specifyModel(Next(OpCl(QQQQ)) ~ Lag(OpHi(QQQQ),0:3))
builtModel(q.model, method="lm", training.per=c('2006-08-01', '2006-09-30'))

## End(Not run)
```

`chartSeries`  
Create Financial Charts

Description

Charting tool to create standard financial charts given a time series like object. Serves as the base function for future technical analysis additions. Possible chart styles include candles, matches (1 pixel candles), bars, and lines. Chart may have white or black background.

`reChart` allows for dynamic changes to the chart without having to respecify the full chart parameters.

Usage

```r
chartSeries(x,
  type = c("auto", "candlesticks", "matchsticks", "bars", "line"),
  subset = NULL,
  show.grid = TRUE,
  name = NULL,
  time.scale = NULL,
  log.scale = FALSE,
  TA = 'addVo()',
  TAsep=':',
  line.type = "l",
  bar.type = "ohlc",
  theme = chartTheme("black"),
  layout = NA,
  major.ticks='auto', minor.ticks=TRUE,
  yrange=NULL,
  plot=TRUE,
  up.col,dn.col,color.vol = TRUE, multi.col = FALSE,
  ...)
reChart(type = c("auto", "candlesticks", "matchsticks", "bars", "line"),
  subset = NULL,
  show.grid = TRUE,
  ...)
```
Arguments

- **x**: an OHLC object - see details
- **type**: style of chart to draw
- **subset**: xts style date subsetting argument
- **show.grid**: display price grid lines?
- **name**: name of chart
- **time.scale**: what is the timescale? automatically deduced (broken)
- **log.scale**: should the y-axis be log-scaled?
- **TA**: a vector of technical indicators and params, or character strings
- **TAsep**: TA delimiter for TA strings
- **line.type**: type of line in line chart
- **bar.type**: type of barchart - ohlc or hlc
- **theme**: a chart.theme object
- **layout**: if NULL bypass internal layout
- **major.ticks**: where should major ticks be drawn
- **minor.ticks**: should minor ticks be draw?
- **yrange**: override y-scale
- **plot**: should plot be drawn
- **up.col**: up bar/candle color
- **dn.col**: down bar/candle color
- **color.vol**: color code volume?
- **multi.col**: 4 color candle pattern
- **...**: additional parameters

Details

Currently displays standard style OHLC charts familiar in financial applications, or line charts when not passes OHLC data. Works with objects having explicit time-series properties.

Line charts are created with close data, or from single column time series.

The subset argument can be used to specify a particular area of the series to view. The underlying series is left intact to allow for TA functions to use the full data set. Additionally, it is possible to use syntax borrowed from the `first` and `last` functions, e.g. 'last 4 months'.
TA allows for the inclusion of a variety of chart overlays and technical indicators. A full list is available from addTA. The default TA argument is addVo() - which adds volume, if available, to the chart being drawn.

theme requires an object of class chart.theme, created by a call to chartTheme. This function can be used to modify the look of the resulting chart. See chart.theme for details.

line.type and bar.type allow further fine-tuning of chart styles to user tastes.

multi.col implements a color coding scheme used in some charting applications, and follows the following rules:

- grey => Op[t] < Cl[t] and Op[t] < Cl[t-1]
- white => Op[t] < Cl[t] and Op[t] > Cl[t-1]
- red => Op[t] > Cl[t] and Op[t] < Cl[t-1]
- black => Op[t] > Cl[t] and Op[t] > Cl[t-1]

reChart takes any number of arguments from the original chart call — and redraws the chart with the updated parameters. One item of note: if multiple color bars/candles are desired, it is necessary to respecify the theme argument. Additionally it is not possible to change TA parameters at present. This must be done with addTA/dropTA/swapTA/moveTA commands.

Value

Returns a standard chart plus volume, if available, suitably scaled.

If plot=FALSE a chob object will be returned.

Note

Most details can be fine-tuned within the function, though the code does a reasonable job of scaling and labelling axes for the user.

The current implementation maintains a record of actions carried out for any particular chart. This is used to recreate the original when adding new indicator. A list of applied TA actions is available with a call to listTA. This list can be assigned to a variable and used in new chart calls to recreate a set of technical indicators. It is also possible to force all future charts to use the same indicators by calling setTA.

Additional motivation to add outlined candles to allow for scaling and advanced color coding is owed to Josh Ulrich, as are the base functions (from TTR) for the yet to be released technical analysis charting code.

Many improvements in the current version were the result of conversations with Gabor Grothendieck. Many thanks to him.

setTA()
chartSeries(YHOO)  #draws chart again, this time will all indicators present

## End(Not run)

chartTheme  

Create A Chart Theme

Description

Create a chart.theme object for use within chartSeries to manage desired chart colors.

Usage

chartTheme(theme = "black", ...)

Arguments

theme  name of base theme
...
name=value pairs to modify

Details

Used as an argument to the chartSeries family of functions, chartTheme allows for on-the-fly modification of pre-specified chart ‘themes’. Users can modify a pre-built theme in-place, or copy the theme to a new variable for use in subsequent charting calls.

Internally a chart.theme object is nothing more than a list of values organized by chart components. The primary purpose of this is to facilitate minor modification on the fly, as well as provide a template for larger changes.

Setting style arguments for TA calls via chartTheme requires the user to pass the styles as name=value pairs with a name containing the TA call in question. See examples for assistance.

Current components that may be modified with appropriate values:
- fg.colforeground color
- bg.colbackground color
- grid.colgrid color
- border.border color
- minor.tickminor tickmark color
- major.tickmajor tickmark color
- up.colup bar/candle color
- dn.coldown bar/candle color
- up.up.colup after up bar/candle color
- up.dn.colup after down bar/candle color
- dn.dn.coldown after down bar/candle color
- dn.up.coldown after up bar/candle color
- up.borderup bar/candle border color
- dn.borderdown bar/candle border color
- up.up.borderup after up bar/candle border color
- up.dn.borderup after down bar/candle border color
- dn.dn.borderdown after down bar/candle border color
- dn.up.borderdown after up bar/candle border color

**Value**

A chart.theme object

**Author(s)**

Jeffrey A. Ryan

**See Also**

chartSeries

**Examples**

```r
chartTheme()
chartTheme('white')
chartTheme('white', up.col='blue', dn.col='red')

# A TA example
chartTheme(addRSI.col='red')

str(chartTheme())
```
**chart_Series**

**Experimental Charting Version 2**

**Description**

These are experimental functions for a new version of chartSeries in quantmod. Interface, behavior, and functionality will change.

**Usage**

```r
chart_Series(x,
    name = deparse(substitute(x)),
    type = "candlesticks",
    subset = "",
    TA = "",
    pars = chart_pars(),
    theme = chart_theme(),
    clev = 0,
    ...)
```

**Arguments**

- **x**: time series object
- **name**: name for chart
- **type**: one of:
- **subset**: an ISO8601 style character string indicating date range
- **TA**: a character string of semi-colon separated TA calls.
- **pars**: chart parameters
- **theme**: chart theme
- **clev**: color level (experimental). Indicates the degree of brightness 0 is darkest color.
- **...**: additional parameters

**Details**

These functions, when complete, will revert back to the original chartSeries naming convention.

**Value**

Called for graphical side effects.

**Note**

Highly experimental (read: alpha) use with caution.

**Author(s)**

Jeffrey A. Ryan
A Chart Object Class

Description

Internal Objects for Tracking and Plotting Chart Changes

Objects from the Class

Objects are created internally through the charting functions chartSeries, barChart, lineChart, and candleChart.

Slots

device: Object of class "ANY"
call: Object of class "call"
xdata: Object of class "ANY"
xsubset: Object of class "ANY"
name: Object of class "character"
type: Object of class "character"
passed.args: Object of class "ANY"
windows: Object of class "numeric"
xrange: Object of class "numeric"
yrange: Object of class "numeric"
log.scale: Object of class "logical"
length: Object of class "numeric"
color.vol: Object of class "logical"
multi.col: Object of class "logical"
show.vol: Object of class "logical"
show.grid: Object of class "logical"
line.type: Object of class "character"
bar.type: Object of class "character"
xlab: Object of class "character"
ylab: Object of class "character"
spacing: Object of class "numeric"
width: Object of class "numeric"
bp: Object of class "numeric"
x.labels: Object of class "character"
colors: Object of class "ANY"
layout: Object of class "ANY"
time.scale: Object of class "ANY"
major.ticks: Object of class "ANY"
minor.ticks: Object of class "logical"
chobTA-class

Methods

No methods defined with class "chob" in the signature.

Author(s)

Jeffrey A. Ryan

See Also

chartSeries, or chobTA for links to other classes

Examples

showClass("chob")

---

chobTA-class  A Technical Analysis Chart Object

Description

Internal storage class for handling arbitrary TA objects

Objects from the Class

Objects of class chobTA are created and returned invisibly through calls to addTA-style functions.

Slots

call: Object of class "call" ~~
on: Object of class "ANY" ~~
new: Object of class "logical" ~~
TA.values: Object of class "ANY" ~~
name: Object of class "character" ~~
params: Object of class "ANY" ~~

Methods

show signature(object = "chobTA"): ...

Note

It is of no external value to handle chobTA objects directly

Author(s)

Jeffrey A. Ryan
create.binding

Description

Internal function used in attachSymbols to create active bindings for symbols defined in a DDB object.

Usage

create.binding(s, lsym, rsym, gsrc, mem.cache = TRUE, file.cache = !mem.cache, cache.dir = tempdir(), envir,...)

Arguments

- `s` symbol name
- `lsym` function to convert to local name (legal R name)
- `rsym` function to convert to remote name (source name)
- `gsrc` corresponds to `src` arg in getSymbols call
- `mem.cache` cache to memory
- `file.cache` cache to disk
- `cache.dir` directory to cache to/from
- `envir` environment name (character)
- `...` arguments to pass to getSymbols call

Details

Low level function to create bindings during initial demand-database construction.

Value

Called for its side effect of creating active bindings to symbols.
Note

This is code used internally by attachSymbols. User’s may modify this to accomodate different systems. The upstream functions needn’t maintain consistency with this interface.
Use as a guide or template.

Author(s)

Jeffrey A. Ryan

References

Mark, Roger, ?

---

Description

Use globally specified defaults, if set, in place of formally specified default argument values. Allows user to specify function defaults different than formally supplied values, e.g. to change poorly performing defaults, or satisfy a different preference.

Usage

```r
setDefaults(name, ...)  
unsetDefaults(name, confirm = TRUE)  
getDefaults(name = NULL, arg = NULL)  
importDefaults(calling.fun)
```

Arguments

- `name` name of function, quoted or unquoted
- `...` name=value default pairs
- `confirm` prompt before unsetting defaults
- `arg` values to retrieve
- `calling.fun` name of function to act upon

Details

- `setDefaults` Provides a wrapper to R options that allows the user to specify any name=value pair for a function’s formal arguments. Only formal name=value pairs specified will be updated. Values do not have to be respecified in subsequent calls to `setDefaults`, so it is possible to add new defaults for each function one at a time, without having to retype all previous values. Assigning `NULL` to any argument will remove the argument from the defaults list.
- `unsetDefaults` Removes name=value pairs from the defaults list.
**getDefaults**  Provides access to the stored user defaults. Single arguments need not be quoted, multiple arguments must be in a character vector.

**importDefaults**  A call to importDefaults should be placed on the first line in the body of the function. It checks the user’s environment for globally specified default values for the called function. These defaults can be specified by the user with a call to setDefaults, and will override any default formal parameters, in effect replacing the original defaults with user supplied values instead. Any user-specified values in the parent function (that is, the function containing importDefaults) will override the values set in the global default environment.

**Value**

setDefaults  None. Used for it’s side effect of setting a list of default arguments by function.

unsetDefaults  None. Used for it’s side effect of unsetting default arguments by function.

getDefaults  A named list of defaults and associated values, similar to formals, but only returning values set by setDefaults for the name function. Calling getDefaults() (without arguments) returns in a character vector of all functions currently having defaults set (by setDefaults).

This does not imply that the returned function names are able to accept defaults (via importDefaults), rather that they have been set to store user defaults. All values can also be viewed with a call to getOption(name_of_function.Default).

importDefaults  None. Used for its side-effect of loading all non-NULL user-specified default values into the current function’s environment, effectively changing the default values passed in the parent function call. Like formally defined defaults in the function definition, default values set by importDefaults take lower precedence than arguments specified by the user in the function call.

**Note**

setDefaults  At present it is not possible to specify NULL as a replacement for a non-NULL default, as the process interprets NULL values as being not set, and will simply use the value specified formally in the function. If NULL is what is desired, it is necessary to include this in the function call itself.

Any arguments included in the actual function call will take precedence over setDefaults values, as well as the standard formal function values. This conforms to the current user experience in R.

Like options, default settings are not kept across sessions. Currently, it is not possible to pass values for arguments in setDefaults.

unsetDefaults  unsetDefaults removes the all entries from the options lists for the specified function. To remove single function default values simply set the name of the argument to NULL in setDefaults.

importDefaults  When a function implements importDefaults, non-named arguments may be ignored if a global default has been set (i.e. not NULL). If this is the case, simply name the arguments in the calling function.

This should also work for functions retrieving formal parameter values from options, as it assigns a value to the parameter in a way that looks like it was passed in the function call. So any check on options would presumably disregard importDefaults values if an argument was passed to the function.
Delt

options

Examples

my.fun <- function(x=3)
{
    importDefaults('my.fun')
    x^2
}

my.fun() # returns 9

setDefaults(my.fun, x=10)
my.fun() # returns 100
my.fun(x=4) # returns 16

getDefaults(my.fun)
formals(my.fun)
unsetDefaults(my.fun, confirm=FALSE)
getDefaults(my.fun)

my.fun() # returns 9

Delt Calculate Percent Change

Description
Calculate the k-period percent difference within one series, or between two series. Primarily used to calculate the percent change from one period to another of a given series, or to calculate the percent difference between two series over the full series.

Usage
Delt(x1, x2 = NULL, k = 0, type = c("arithmetic", "log"))

Arguments
x1 m x l vector
x2 m x l vector
k change over k-periods. default k=1 when x2 is NULL.
type type of difference. log or arithmetic (default).
findPeaks

Details

When called with only \( x_1 \), the one period percent change of the series is returned by default. Internally this happens by copying \( x_1 \) to \( x_2 \). A two period difference would be specified with \( k=2 \).

If called with both \( x_1 \) and \( x_2 \), the difference between the two is returned. That is, \( k=0 \). A one period difference would be specified by \( k=1 \). \( k \) may also be a vector to calculate more than one period at a time. The results will then be an \( m \times \text{length}(k) \) matrix.

Arithmetic differences are used by default: \( \text{Lag} = (x_2(t) - x_1(t-k))/x_1(t-k) \)

Log differences are calculated: \( \text{Lag} = \log(x_2(t)/x_1(t-k)) \)

Value

An matrix of \( \text{length}(x_1) \) rows and \( \text{length}(k) \) columns.

Jeffrey A. Ryan

See Also

OpOp OpCl

Examples

Stock.Open <- c(102.25, 102.87, 102.25, 100.87, 103.44, 103.87, 103.00)
Stock.Close <- c(102.12, 102.62, 100.12, 103.00, 103.87, 103.12, 105.12)

Delt(Stock.Open)      # one period pct. price change
Delt(Stock.Open,k=1)  # same
Delt(Stock.Open,type='arithmetic') # using arithmetic differences (default)
Delt(Stock.Open,type='log') # using log differences

Delt(Stock.Open,Stock.Close) # Open to Close pct. change
Delt(Stock.Open,Stock.Close,k=0:2) #...for 0,1, and 2 periods
Arguments

x a time series or vector
thresh minimum peak/valley threshold

Value

A vector of integers corresponding to peaks/valleys.
As a peak[valley] is defined as the highest[lowest] value in a series, the function can only define it after a change in direction has occurred. This means that the function will always return the first period after the peak/valley of the data, so as not to accidentally induce a look-ahead bias.

Author(s)

Jeffrey A. Ryan

Examples

findPeaks(sin(1:10))
p <- findPeaks(sin(seq(1,10,.1)))
sin(seq(1,10,.1))[p]
plot(sin(seq(1,10,.1))[p])
plot(sin(seq(1,10,.1)),type='l')
points(p,sin(seq(1,10,.1))[p])

---

fittedModel quantmod Fitted Objects

Description

Extract and replace fitted models from quantmod objects built with buildModel. All objects fitted through methods specified in buildModel calls can be extracted for further analysis.

Usage

fittedModel(object)

## S3 method for class 'quantmod'
formula(x, ...)

## S3 method for class 'quantmod'
plot(x, ...)

## S3 method for class 'quantmod'
coefficients(object, ...)
## S3 method for class 'quantmod'
coef(object, ...)

## S3 method for class 'quantmod'
residuals(object, ...)

## S3 method for class 'quantmod'
resid(object, ...)

## S3 method for class 'quantmod'
fitted.values(object, ...)

## S3 method for class 'quantmod'
fitted(object, ...)

## S3 method for class 'quantmod'
anova(object, ...)

## S3 method for class 'quantmod'
logLik(object, ...)

## S3 method for class 'quantmod'
vcov(object, ...)

### Arguments

- **object**: a quantmod object
- **x**: a suitable object
- **...**: additional arguments

### Details

Most often used to extract the final fitted object of the modelling process, usually for further analysis with tools outside the quantmod package.

Most common methods to apply to fitted objects are available to the parent quantmod object. At present, one can call directly the following S3 methods on a built model as if calling directly on the fitted object. See *Usage* section.

It is also possible to add a fitted model to an object. This may be of value when applying heuristic rule sets for trading approaches, or when fine tuning already fit models by hand.

### Value

Returns an object matching that returned by a call to the method specified in buildModel.

### Note

The replacement function fittedModel<- is highly experimental, and may or may not continue into further releases.
The fitted model added must use the same names as appear in the quantmod object’s dataset.

Examples

```r
## Not run:
x <- specifyModel(Next(OpCl(DIA)) ~ OpCl(VIX))
x.lm <- buildModel(x, method = 'lm', training.per = c('2001-01-01', '2001-04-01'))

fittedModel(x.lm)
coef(fittedModel(x.lm))
coef(x.lm)    # same
vcov(fittedModel(x.lm))
vcov(x.lm)   # same

## End(Not run)
```

getDividends

Load Financial Dividend Data

Description

Download, or download and append stock dividend data from Yahoo! Finance.

Usage

```r
getDividends(Symbol,
              from = "1970-01-01",
              to = Sys.Date(),
              env = parent.frame(),
              src = "yahoo",
              auto.assign = FALSE,
              auto.update = FALSE,
              verbose = FALSE,
              split.adjust = TRUE, ...)
```
Arguments

Symbol      The Yahoo! stock symbol
from        date from in CCYY-MM-DD format
to          date to in CCYY-MM-DD format
env         where to create object
dst         data source (only yahoo is valid at present)
auto.assign should results be loaded to env
auto.update automatically add dividend to data object
verbose     display status of retrieval
split.adjust adjust dividends for splits (TRUE by default because that’s what Yahoo returns)
...         currently unused

Details

Eventually destined to be a wrapper function along the lines of getSymbols to different sources - this currently only support Yahoo data.

Value

If auto.assign is TRUE, the symbol will be written to the environment specified in env with a .div appended to the name.

If auto.update is TRUE and the object is of class xts, the dividends will be included as an attribute of the original object and be reassigned to the environment specified by env.

All other cases will return the dividend data as an xts object.

Note

This function is very preliminary - and will most likely change significantly in the future.

Author(s)

Jeffrey A. Ryan

getSymbols
getFinancials

Examples

```r
## Not run:
getSymbols("MSFT")
getDividends("MSFT")

getDividends(MSFT)
## End(Not run)
```

diff

diff

diff

diff

Description

Usage

```r
getFinancials(Symbol, env = parent.frame(), src = "google",
  auto.assign = TRUE,
  ...
)

viewFinancials(x, type=c("BS","IS","CF"), period=c("A","Q"),
  subset = NULL)
```

Arguments

- **Symbol**: one or more valid google symbol, as a character vector or semi-colon delimited string
- **env**: where to create the object
- **src**: currently no sources are implemented
- **auto.assign**: should results be loaded to the environment
- **...**: currently unused
- **x**: an object of class financials
- **type**: type of statement to view
- **period**: period of statement to view
- **subset**: ‘xts’ style subset string

Details

A utility to download financial statements for publicly traded companies. Individual statements can be accessed using standard R list extraction tools, or by using viewFinancials. viewFinancials allows for the use of date subsetting as available in the xts package, as well as the specification of the type of statement to view. BS for balance sheet, IS for income statement, and CF for cash flow statement. The period argument is used to identify which statements to view - (A) for annual and (Q) for quarterly.
getFX

Value

Six individual matrices organized in a list of class ‘financials’:

- **IS** a list containing (Q)uarterly and (A)nnual Income Statements
- **BS** a list containing (Q)uarterly and (A)nnual Balance Sheets
- **CF** a list containing (Q)uarterly and (A)nnual Cash Flow Statements

Note

As with all free data, you may be getting exactly what you pay for. Sometimes that may be absolutely nothing.

Author(s)

Jeffrey A. Ryan

Examples

```r
## Not run:
getFinancials(quote("JAVA")) # returns JAVA.f to "env"
getFin(quote("AAPL")) # returns AAPL.f to "env"

viewFin(JAVA.f, "IS", "Q") # Quarterly Income Statement
viewFin(AAPL.f, "CF", "A") # Annual Cash Flows

str(AAPL.f)

## End(Not run)
```

getFX

Download Exchange Rates

Description

Download exchange rates or metals prices from oanda.

Usage

```r
getFX(Currencies, 
     from = Sys.Date() - 179, 
     to = Sys.Date(), 
     env = parent.frame(), 
     verbose = FALSE, 
     warning = TRUE, 
     auto.assign = TRUE, ...)
```
Arguments

Currencies   Currency pairs expressed as ‘CUR/CUR’
from      start date expressed in ISO CCYY-MM-DD format
to         end date expressed in ISO CCYY-MM-DD format
e               which environment should they be loaded into
verbose   be verbose
warning  show warnings
auto.assign  use auto.assign
                additional parameters to be passed to getSymbols.oanda method

Details

A convenience wrapper to getSymbols(x,src='oanda'). See getSymbols and getSymbols.oanda for more detail.

Value

The results of the call will be the data will be assigned automatically to the environment specified (parent by default). Additionally a vector of downloaded symbol names will be returned. See getSymbols and getSymbols.oanda for more detail.

Author(s)

Jeffrey A. Ryan

Examples

## Not run:

getFX("USD/JPY")
getFX("EUR/USD",from="2005-01-01")

## End(Not run)
getMetals

Download Daily Metals Prices

Description
Download daily metals prices from oanda.

Usage
getMetals(Metals,
  from = Sys.Date() - 179,
  to = Sys.Date(),
  base.currency="USD",
  env = parent.frame(),
  verbose = FALSE,
  warning = TRUE,
  auto.assign = TRUE, ...)

Arguments
Metals         metals expressed in common name or symbol form
from           start date expressed in ISO CCYY-MM-DD format
to             end date expressed in ISO CCYY-MM-DD format
base.currency  which currency should the price be in
env            which environment should they be loaded into
verbose        be verbose
warning        show warnings
auto.assign    use auto.assign
...            additional parameters to be passed to getSymbols.oanda method

Details
A convenience wrapper to getSymbols(x,src='oanda').
The most useful aspect of getMetals is the ability to specify the Metals in terms of underlying 3 character symbol or by name (e.g. XAU (gold), XAG (silver), XPD (palladium), or XPT (platinum)).
There are unique aspects of any continuously traded commodity, and it is recommended that the user visit https://www.oanda.com for details on specific pricing issues.
See getSymbols and getSymbols.oanda for more detail.

Value
Data will be assigned automatically to the environment specified (parent by default). If auto.assign is set to FALSE, the data from a single metal request will simply be returned from the function call.
If auto.assign is used (the default) a vector of downloaded symbol names will be returned.
See getSymbols and getSymbols.oanda for more detail.

class = "OHLC"

getModelData Update model’s dataset

Description
Update currently specified or built model with most recent data.

Usage
getCodeModelData(x, na.rm = TRUE)

Arguments
x
An object of class quantmod

na.rm
Boolean. Remove NA values. Defaults to TRUE

Details
Primarily used within specify model calls, getModelData is used to retrieve the appropriate underlying variables, and apply model specified transformations automatically. It can be used to also update a current model in memory with the most recent data.

Value
Returns object of class quantmod.OHLC
**getOptionChain**

**Author(s)**

Jeffrey Ryan

**See Also**

`getSymbols` load data `specifyModel` create model structure `buildModel` construct model `modelData` extract model dataset

**Examples**

```r
## Not run:
my.model <- specifyModel(Next(OpCl(QQQQ)) ~ Lag(Cl(NDX),0:5))
getModelData(my.model)

## End(Not run)
```

---

**getOptionChain**

**Download Option Chains**

**Description**

Function to download option chain data from data providers.

**Usage**

```r
ggetOptionChain(Symbols, Exp = NULL, src="yahoo", ...)
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Symbols</td>
<td>The name of the underlying symbol.</td>
</tr>
<tr>
<td>Exp</td>
<td>One or more expiration dates, NULL, or an ISO-8601 style string. If Exp is missing, only the front month contract will be returned.</td>
</tr>
<tr>
<td>src</td>
<td>Source of data. Currently only 'yahoo' is provided.</td>
</tr>
<tr>
<td>...</td>
<td>Additional parameters.</td>
</tr>
</tbody>
</table>

**Details**

This function is a wrapper to data-provider specific APIs. By default the data is sourced from yahoo.

**Value**

A named list containing two data.frames, one for calls and one for puts. If more than one expiration was requested, this two-element list will be contained within list of length length(Exp). Each element of this list will be named with the expiration month, day, and year (for Yahoo sourced data).

If Exp is set to NULL, all expirations will be returned. Not explicitly setting will only return the front month.
**getQuote**

**Author(s)**

Jeffrey A. Ryan, Joshua M. Ulrich

**References**

http://finance.yahoo.com

**Examples**

```r
# Not run:
# Only the front-month expiry
AAPL.OPT <- getOptionChain("AAPL")
# All expiries
AAPL.OPTS <- getOptionChain("AAPL", NULL)
# All 2015 and 2016 expiries
AAPL.2015 <- getOptionChain("AAPL", "2015/2016")
```

**Description**

Fetch current stock quote(s) from specified source. At present this only handles sourcing quotes from Yahoo Finance and Alpha Vantage, but it can be extended to additional sources.

**Usage**

getQuote(Symbols, src = "yahoo", what, ...)

standardQuote(src="yahoo")

yahooQF(names)

yahooQuote.EOD

**Arguments**

- **Symbols**: character string of symbols, separated by semi-colons
- **src**: source of data ("yahoo" and "av" are currently implemented)
- **what**: what should be retrieved
- **names**: which data should be retrieved
- **...**: currently unused
Value

The number of symbols per request is limited to 200 for Yahoo! and 100 for Alpha Vantage. `getQuote` will make multiple requests if more than the maximum number of symbols are requested. It will then combine the results of all the requests and return one data frame. The data frame will contain a column for each requested data field, and the requested symbols will be stored in the row names.

In order to import quotes from Alpha Vantage, you must obtain an API key by completing a free, one-time registration at their website: [https://www.alphavantage.co/](https://www.alphavantage.co/). Then you can call `getQuote` with `src = "av"` and `api.key = "[your key]"`.

The `what` argument allows for specific data to be requested. For `getQuote.yahoo`, the value of `what` should be a `quoteFormat` object like that returned by `standardQuote`. The `yahooQF` function will create an interactive selection tool if the `what` argument is missing. The `what` argument is currently ignored for Alpha Vantage data because only a few fields are available.

`standardQuote` currently only applies to the Yahoo! data source. It returns a `quoteFormat` object to use with the `getQuote` function.

`yahooQuote.EOD` is a constant `quoteFormat` object for OHLCV data.

Author(s)

Jeffrey A. Ryan (Yahoo) Ethan B. Smith (Alpha Vantage)

Load Financial Split Data

Description

Download, or download and append stock split data from Yahoo! Finance.

Usage

getSplits(Symbol, 
from = "1970-01-01", 
to = Sys.Date(), 
env = parent.frame(), 
src = "yahoo", 
auto.assign = FALSE, 
auto.update = FALSE, 
verbose = FALSE, ...)

Arguments

Symbol The Yahoo! stock symbol
from date from in CCYY-MM-DD format
to date to in CCYY-MM-DD format
env where to create object
src data source (only yahoo is valid at present)
auto.assign should results be loaded to env
auto.update automatically add split to data object
verbose display status of retrieval
... currently unused

Details

Eventually destined to be a wrapper function along the lines of getSymbols to different sources - this currently only support Yahoo data.

Value

If auto.assign is TRUE, the symbol will be written to the environment specified in env with a .div appended to the name.

If auto.update is TRUE and the object is of class xts, the dividends will be included as an attribute of the original object and be reassigned to the environment specified by env.

All other cases will return the split data as an xts object. NA is returned if there is no split data.
Note

This function is very preliminary - and will most likely change significantly in the future.

 Examples

```r
## Not run:
getSymbols("MSFT")
getSplits("MSFT")

getSplits(MSFT)
## End(Not run)
```

getSymbols

Load and Manage Data from Multiple Sources

Description

Functions to load and manage Symbols in specified environment. Used by specifyModel to retrieve symbols specified in first step of modelling procedure. Not a true S3 method, but methods for different data sources follow an S3-like naming convention. Additional methods can be added by simply adhering to the convention.

Current src methods available are: yahoo, google, MySQL, FRED, csv, RData, oanda, and av.

Data is loaded silently without user assignment by default.

Usage

```r
getSymbols(Symbols = NULL,
env = parent.frame(),
reload.Symbols = FALSE,
verbose = FALSE,
warnings = TRUE,
src = "yahoo",
symbol.lookup = TRUE,
auto.assign = getOption('getSymbols.auto.assign',TRUE),
```

getSymbols

...)

loadSymbols(Symbols = NULL,
  env = parent.frame(),
  reload.Symbols = FALSE,
  verbose = FALSE,
  warnings = TRUE,
  src = "yahoo",
  symbol.lookup = TRUE,
  auto.assign = getOption("loadSymbols.auto.assign", TRUE),
...

showSymbols(env = parent.frame())
removeSymbols(Symbols = NULL, env = parent.frame())
saveSymbols(Symbols = NULL,
  file.path = stop("must specify 'file.path'"),
  env = parent.frame())

Arguments

Symbols           a character vector specifying the names of each symbol to be loaded
env               where to create objects. Setting env=NULL is equal to auto.assign=FALSE
reload.Symbols    boolean to reload current symbols in specified environment. (FALSE)
verbose           boolean to turn on status of retrieval. (FALSE)
warnings          boolean to turn on warnings. (TRUE)
src               character string specifying sourcing method. (yahoo)
symbol.lookup     retrieve symbol's sourcing method from external lookup (TRUE)
auto.assign       should results be loaded to env If FALSE, return results instead. As of 0.4-0, this
                  is the same as setting env=NULL. Defaults to TRUE
file.path         character string of file location
...                additional parameters

Details

getSymbols is a wrapper to load data from various sources, local or remote. Data is fetched via one
of the available getSymbols methods and either saved in the env specified - the parent.frame() by
default – or returned to the caller. The functionality derives from base::load behavior and
semantics, i.e. is assigned automatically to a variable in the specified environment without the
user explicitly assigning the returned data to a variable. The assigned variable name is that of the
respective Symbols value.

The previous sentence’s point warrants repeating - getSymbols is called for its side effects, and by
defaultdoes not return the data object loaded. The data is ‘loaded’ silently by the function into the
environment specified.

If automatic assignment is not desired, env may be set to NULL, or auto.assign set to FALSE.
The early versions of getSymbols assigned each object into the user’s .GlobalEnv by name (pre 2009
up to versions less than 0.4-0). This behavior is now supported by manually setting env=.GlobalEnv.
As of version 0.4-0, the environment is set to parent.frame(), which preserved the user workspace when called within another scope.

This behavior is expected to change for `getSymbols` as of 0.5-0, and all results will instead be explicitly returned to the caller unless a `auto.assign` is set to `TRUE`. Many thanks to Kurt Hornik and Achim Zeileis for suggesting this change, and further thanks to Dirk Eddelbuettel for encouraging the move to a more functional default by 0.5-0.

Using `auto.assign=TRUE`, the variable chosen is an R-legal name derived from the symbol being loaded. It is possible, using `setSymbolLookup` to specify an alternate name if the default is not desired. See that function for details.

If `auto.assign=FALSE` or `env=NULL` (as of 0.4-0) the data will be returned from the call, and will require the user to assign the results himself. Note that only one symbol at a time may be requested when auto assignment is disabled.

Most, if not all, documentation and functionality related to model construction and testing in `quantmod` assumes that `auto.assign` remains set to `TRUE` and `env` is a valid environment object for the calls related to those functions.

Upon completion a list of loaded symbols is stored in the specified environment under the name `.getSymbols`.

Objects loaded by `getSymbols` with `auto.assign=TRUE` can be viewed with `showSymbols` and removed by a call to `removeSymbols`. Additional data loading “methods” can be created simply by following the S3-like naming convention where `getSymbols.NAME` is used for your function NAME. See `getSymbols` source code.

`setDefaults(getSymbols)` can be used to specify defaults for `getSymbols` arguments. `setDefaults(getSymbols.MySQL)` may be used for arguments specific to `getSymbols.MySQL`, etc.

The “sourcing” of data is managed internally through a complex lookup procedure. If `symbol.lookup` is `TRUE` (the default), a check is made if any symbol has had its source specified by `setSymbolLookup`.

If not set, the process continues by checking to see if `src` has been specified by the user in the function call. If not, any `src` defined with `setDefaults(getSymbols,src=)` is used.

Finally, if none of the other source rules apply the default `getSymbols src` method is used (‘yahoo’).

**Value**

Called for its side-effect with `env` set to a valid environment and `auto.assign=TRUE`, `getSymbols` will load into the specified `env` one object for each `Symbol` specified, with class defined by `return.class`. Presently this may be `ts`, `zoo`, `xts`, or `timeSeries`.

If `env=NULL` or `auto.assign=FALSE` an object of type `return.class` will be returned.

**Note**

As of version 0.4-0, the default `env` value is now `parent.frame()`. In interactive use this should provide the same functionality as the previous version.

While it is possible to load symbols as classes other than `zoo`, `quantmod` requires most, if not all, data to be of class `zoo` or inherited from `zoo` - e.g. `xts`. The additional methods are meant mainly to be of use for those using the functionality outside of the `quantmod` workflow.

Examples

## Not run:

```r
setSymbolLookup(QQQ='yahoo', SPY='google')
```

# loads QQQ from yahoo (set with setSymbolLookup)
# loads SPY from MySQL (set with setSymbolLookup)
getSymbols(c('QQQ','SPY'))

# loads Ford market data from yahoo (the formal default)
getSymbols('F')

# loads symbol from MySQL database (set with setDefaults)
getSymbols('DIA', verbose=TRUE, src='MySQL')

# loads Ford as time series class ts
getSymbols('F', src='yahoo', return.class='ts')

# load into a new environment

data.env <- new.env()
getSymbols("YHOO", env=data.env)
ls.str(data.env)

# constrain to local scope

try(local(
    getSymbols("AAPL") # or getSymbols("AAPL", env=environment())
    str(AAPL)
))

exists("AAPL") # FALSE

# assign into an attached environment

attach(NULL, name="DATA.ENV")
getSymbols("AAPL", env=as.environment("DATA.ENV"))
ls("DATA.ENV")
detach("DATA.ENV")

# directly return to caller
str( getSymbols("AAPL", env=NULL) )
str( getSymbols("AAPL", auto.assign=FALSE) ) # same

## End(Not run)
getSymbols.av  

**Description**

Downloads historical or realtime equity price data from [https://www.alphavantage.co/](https://www.alphavantage.co/). Free registration is required.

**Usage**

```r
getSymbols.av(Symbols, env, api.key, 
  return.class = "xts", 
  periodicity = "daily", 
  adjusted = FALSE, 
  interval = "1min", 
  output.size = "compact", 
  data.type = "json", 
  ...
)
```

**Arguments**

- **Symbols**: a character vector specifying the names of the symbols to be loaded
- **env**: where to create objects (environment)
- **api.key**: the API key issued by Alpha Vantage when you registered (character)
- **return.class**: class of returned object, see Value (character)
- **periodicity**: one of "daily", "weekly", "monthly", or "intraday"
- **adjusted**: if TRUE, include a column of closing prices adjusted for dividends and splits
- **interval**: one of "1min", "5min", "15min", "30min", or "60min" (intraday data only)
- **output.size**: either "compact" or "full"
- **data.type**: either "json" or "csv"
- **...**: additional parameters as per `getSymbols`

**Details**

Meant to be called internally by `getSymbols` only. This method is not meant to be called directly, instead a call to `getSymbols("x", src="av")` will in turn call this method. It is documented for the sole purpose of highlighting the arguments accepted.

You must register with Alpha Vantage in order to download their data, but the one-time registration is fast and free. Register at their web site, [https://www.alphavantage.co/](https://www.alphavantage.co/), and you will receive an **API key**: a short string of alphanumeric characters (e.g., "FU4U"). Provide the API key every time you call `getSymbols`; or set it globally using `setDefaults(getSymbols.av, api.key="yourKey")`.

The Alpha Vantage site provides daily, weekly, monthly, and intraday data. Use **periodicity** to select one. Note that intraday data will includes today’s data (delayed) if downloaded while the market is open, which is pretty cool.
getSymbols.av

Set `adjusted=TRUE` to include a column of closing prices adjusted for dividends and stock splits (available only for daily, weekly, and monthly data).

The intraday data is provided as a sequence of OHLC bars. Use the `interval` argument to determine the "width" of the bars: 1 minute bars, 5 minutes bars, 15 minutes bars, etc.

By default Alpha Vantage returns the 100 most-recent data points (`output.size="compact"`). Set `output.size="full"` to obtain the entire available history. For daily, weekly, and monthly data, Alpha Vantage says the available data is up to 20 years; for intraday data, the available history is the most recent 10 or 15 days. Be forewarned that downloading full data requires more time than compact data, of course.

Alpha Vantage provides access to data via two APIs. You can choose the API via the `data.type` argument. `data.type="json"`, the default, will import data using the JSON API. This API includes additional metadata (e.g. last updated time, timezone, etc) that is not provided via the CSV API.

Value

A call to `getSymbols(Symbols, src="av")` will create objects in the specified environment, one object for each `Symbol` specified. The object class of the object(s) is determined by `return.class`. Presently this may be "ts", "zoo", "xts", or "timeSeries".

getSymbols, getSymbols.yahoo, getSymbols.google

Examples

```r
## Not run:
# You'll need the API key given when you registered
getSymbols("IBM", src="av", api.key="yourKey")

# The default output.size="compact" returns only the most recent 100 rows.
# Set output.size="full" for all available data.
getSymbols("IBM", src="av", api.key="yourKey", output.size="full")

# Intraday data is available for the most recent 10 or 15 days
# and includes quasi-realtime data (i.e., 20-minute delayed)
getSymbols("IBM", src="av", api.key="yourKey", output.size="full", periodicity="intraday")

# Repeating your API key every time is tedious.
# Fortunately, you can set a global default.
setDefaults(getSymbols.av, api.key="yourKey")
getSymbols("IBM", src="av")
```
Description

Downloads Symbols to specified env from local comma separated file. This method is not to be called directly, instead a call to `getSymbols(Symbols, src='csv')` will in turn call this method. It is documented for the sole purpose of highlighting the arguments accepted, and to serve as a guide to creating additional getSymbols ‘methods’.

Usage

```
getSymbols.csv(Symbols,
               env,
               dir="",
               return.class = "xts",
               extension="csv",
               col.names=c("Open","High","Low","Close","Volume","Adjusted"),
               ...
)
```

Arguments

- **Symbols**: a character vector specifying the names of each symbol to be loaded
- **env**: where to create objects. (.GlobalEnv)
- **dir**: directory of csv file
- **return.class**: class of returned object
- **extension**: extension of csv file
- **col.names**: data column names
- **...**: additional parameters

Details

Meant to be called internally by `getSymbols` (see also).

One of a few currently defined methods for loading data for use with `quantmod`. Essentially a simple wrapper to the underlying R `read.csv`.

Value

A call to `getSymbols.csv` will load into the specified environment one object for each Symbol specified, with class defined by `return.class`. Presently this may be `ts`, `zoo`, `xts`, or `timeSeries`. 
Note

This has yet to be tested on a windows platform. It should work though file separators may be an issue.

getSymbols('MSFT', src='csv')

## Method #2
setDefaults(getSymbols, src='csv')
  # OR
setSymbolLookup(MSFT='csv')

getSymbols('MSFT')

####################################################
## NOT RECOMMENDED!!!
####################################################
## Method #3
getSymbols.csv('MSFT', verbose=TRUE, env=globalenv())

## End(Not run)
```

Description

R access to over 11,000 data series accessible via the St. Louis Federal Reserve Bank’s FRED system.

Downloads Symbols to specified env from ‘research.stlouisfed.org’. This method is not to be called directly, instead a call to `getSymbols(Symbols, src='FRED')` will in turn call this method. It is documented for the sole purpose of highlighting the arguments accepted, and to serve as a guide to creating additional getSymbols ‘methods’.
Usage

getSymbols.FRED(Symbols,
   env,
   return.class = "xts",
   ...
)

Arguments

Symbols a character vector specifying the names of each symbol to be loaded
env where to create objects (.GlobalEnv)
return.class class of returned object
... additional parameters

Details

Meant to be called internally by getSymbols (see also).

One of many methods for loading data for use with quantmod. Essentially a simple wrapper to the underlying FRED data download site.

Naming conventions must follow those as seen on the Federal Reserve Bank of St Louis’s website for FRED. A lookup facility will hopefully be incorporated into quantmod in the near future.

Value

A call to getSymbols.FRED will load into the specified environment one object for each Symbol specified, with class defined by return.class. Presently this may be ts, zoo, xts, or timeSeries.

Note

FRED changed its URL scheme for the downloads from http:// to https://. If getSymbols.FRED fails for this reason, try one of the following solutions:

1. Explicitly pass method via the getSymbols call (or via setDefaults).
2. Install downloader, which may be able to automagically determine a suitable method.
3. Set the download.file.method global option.

getSymbols.MySQL Retrieve Data from MySQL Database

Description

Fetch data from MySQL database. As with other methods extending the getSymbols function, this should NOT be called directly. Its documentation is meant to highlight the formal arguments, as well as provide a reference for further user contributed data tools.

Usage

getSymbols.MySQL(Symbols,
                  env,
                  return.class = 'xts',
                  db.fields = c("date", "o", "h", "l", "c", "v", "a"),
                  field.names = NULL,
                  user = NULL,
                  password = NULL,
                  dbname = NULL,
                  host = "localhost",
                  port = 3306,
                  ...)
Arguments

Symbols a character vector specifying the names of each symbol to be loaded
env where to create objects. (.GlobalEnv)
return.class desired class of returned object. Can be xts, zoo, data.frame, or ts. (zoo)
db.fields character vector indicating names of fields to retrieve
field.names names to assign to returned columns
user username to access database
password password to access database
dbname database name
host database host
port database port
... currently not used

Details

Meant to be called internally by getSymbols (see also)

One of a few currently defined methods for loading data for use with quantmod. Its use requires the packages DBI and MySQL, along with a running MySQL database with tables corresponding to the Symbol name.

The purpose of this abstraction is to make transparent the ‘source’ of the data, allowing instead the user to concentrate on the data itself.

Value

A call to getSymbols.MySQL will load into the specified environment one object for each Symbol specified, with class defined by return.class.

Note

The default configuration needs a table named for the Symbol specified (e.g. MSFT), with column names date,o,h,l,c,v,a. For table layout changes it is best to use setDefaults(getSymbols.MySQL,...) with the new db.fields values specified.

getSymbols.oanda Download Currency and Metals Data from Oanda.com

Description

Access to 191 currency and metal prices, downloadable as more that 36000 currency pairs from Oanda.com.

Downloads Symbols to specified env from https://www.oanda.com historical currency database.
This method is not meant to be called directly, instead a call to getSymbols("x", src="oanda")
will in turn call this method. It is documented for the sole purpose of highlighting the arguments
accepted, and to serve as a guide to creating additional getSymbols 'methods'.

Usage

getSymbols.oanda(Symbol, env,
getSymbols.oanda

```r
return.class = "xts",
from = Sys.Date() - 179,
to = Sys.Date(),
...)```

Arguments

- **Symbols**: a character vector specifying the names of each symbol to be loaded - expressed as a currency pair. (e.g. U.S. Dollar to Euro rate would be expressed as a string “USD/EUR”. The naming convention follows from Oanda.com, and a table of possible values is available by calling `oanda.currencies`.
- **env**: where to create objects.
- **return.class**: class of returned object.
- **from**: Start of series expressed as “CCYY-MM-DD”.
- **to**: Start of series expressed as “CCYY-MM-DD”.
- **...**: additional parameters.

Details

Meant to be called internally by `getSymbols` only.

Oanda data is 7 day daily average price data, that is Monday through Sunday. Oanda only provides historical data for the past 180 days. `getSymbols` will return as much data as possible, and warn when the from date is more than 180 days ago.

Value

A call to `getSymbols(Symbols,src="oanda")` will load into the specified environment one object for each ‘Symbol’ specified, with class defined by ‘return.class’. Presently this may be ‘ts’, ‘zoo’, ‘xts’, or ‘timeSeries’.

Note

Oanda rates are quoted as one unit of base currency to the equivalent amount of foreign currency.

Load Data from R Binary File

Description

Downloads Symbols to specified env from local R data file. This method is not to be called directly, instead a call to getSymbols(Symbols,src='rda') will in turn call this method. It is documented for the sole purpose of highlighting the arguments accepted, and to serve as a guide to creating additional getSymbols 'methods'.

Usage

getSymbols.rda(Symbols, 
   env, 
   dir='', 
   return.class = "xts", 
   extension="rda", 
   col.names=c("Open","High","Low","Close","Volume","Adjusted"), 
   ...)

Arguments

Symbols a character vector specifying the names of each symbol to be loaded 
env where to create objects. (.GlobalEnv)
dir directory of rda/RData file 
return.class class of returned object 
extension extension of R data file 
col.names data column names 
... additional parameters

Details

Meant to be called internally by getSymbols (see also).
One of a few currently defined methods for loading data for use with quantmod. Essentially a simple wrapper to the underlying R load.
getSymbols.SQLite

Value

A call to getSymbols.csv will load into the specified environment one object for each Symbol specified, with class defined by return.class. Presently this may be ts, zoo, xts, data.frame, or timeSeries.

getSymbols.SQLite Retrieve Data from SQLite Database

Description

Fetch data from SQLite database. As with other methods extending getSymbols this function should NOT be called directly.
getSymbols.SQLite

Usage

getSymbols.SQLite(Symbols,
    env,
    return.class = 'xts',
    db.fields = c("row_names",
        "Open",
        "High",
        "Low",
        "Close",
        "Volume",
        "Adjusted"),
    field.names = NULL,
    dbname = NULL,
    POSIX = TRUE,
    ...)

Arguments

Symbols a character vector specifying the names of each symbol to be loaded
env where to create the objects
return.class desired class of returned object
db.fields character vector naming fields to retrieve
field.names names to assign to returned columns
dbname database name
POSIX are rownames numeric
... additional arguments

Details

Meant to be called internally by getSymbols (see also)

One of a few currently defined methods for loading data for use with 'quantmod'. Its use requires
the packages 'DBI' and 'RSQLite', along with a SQLite database.

The purpose of this abstraction is to make transparent the 'source' of the data, allowing instead the
user to concentrate on the data itself.

Value

A call to getSymbols.SQLite will load into the specified environment one object for each 'Symbol'
specified, with class defined by 'return.class'.

Note

This function is experimental at best, and has not been thoroughly tested. Use with caution, and
please report any bugs to the maintainer of quantmod.
getSymbols.tiingo

Description

Downloads historical or realtime equity price data from https://api.tiingo.com/. Registration is required.

Usage

getSymbols.tiingo(Symbols, env, api.key, return.class="xts", periodicity="daily", adjust=FALSE, from='2007-01-01', to=Sys.Date(), data.type="json", ...)

Arguments

Symbols a character vector specifying the names of the symbols to be loaded
env where to create objects (environment)
api.key the API key issued by Tiingo when you registered (character)
return.class class of returned object, see Value (character)
periodicity one of "daily", "weekly", "monthly", or "Annually"
adjust         adjust for dividends and splits? (FALSE)
from          Retrieve data no earlier than this date. (2007-01-01)
to            Retrieve data through this date (Sys.Date())
data.type      either "json" or "csv"
...           additional parameters as per getSymbols

Details

Meant to be called internally by getSymbols only. This method is not meant to be called directly, instead a call to getSymbols("x", src="tiingo") will in turn call this method. It is documented for the sole purpose of highlighting the arguments accepted.

You must register with Tiingo in order to download their data. Register at their web site, https://api.tiingo.com, and you will receive an API key: a short string of alphanumeric characters (e.g., "FU4U"). Provide the API key every time you call getSymbols; or set it globally using setDefaults(getSymbols.tiingo, api.key="yourKey").

Tiingo provides daily, weekly, monthly, and annual data. Use periodicity to select one. This API accessor will return adjusted or unadjusted OHLC as well as split and dividend information.

For daily, weekly, and monthly data, Tiingo says the available data is up to 30 years;

Tiingo provides access to data via two APIs. You can choose the API via the data.type argument.

data.type="json", the default, will import data using the JSON API. This API includes additional metadata (e.g. last updated time, timezone, etc) that is not provided via the CSV API.

Value

A call to getSymbols(Symbols, src="tiingo") will create objects in the specified environment, one object for each Symbol specified. The object class of the object(s) is determined by return.class. Presently this may be "ts", "zoo", "xts", or "timeSeries".

# You'll need the API key given when you registered
gtSymbols("IBM", src="tiingo", api.key="yourKey")

# Repeating your API key every time is tedious.
# Fortunately, you can set a global default.
getSymbols.yahoo

**GetSymbols.yahoo**

**Description**

Downloads Symbols to specified env from 'finance.yahoo.com'. This method is not to be called
directly, instead a call to getSymbols(Symbols, src='yahoo') will in turn call this method. It is
documented for the sole purpose of highlighting the arguments accepted, and to serve as a guide to
creating additional getSymbols 'methods'.

**Usage**

```r
getSymbols.yahoo(Symbols, 
  env, 
  return.class = 'xts',
  index.class = 'Date',
  from = "2007-01-01",
  to = Sys.Date(),
  ...,
  periodicity = "daily",
  curl.options = list())
```

**Arguments**

- **Symbols**: a character vector specifying the names of each symbol to be loaded
- **env**: where to create objects. (.GlobalEnv)
- **return.class**: class of returned object
- **index.class**: class of returned object index (xts only)
- **from**: Retrieve data no earlier than this date. (2007-01-01)
- **to**: Retrieve data through this date (Sys.Date())
- ... additional parameters
- **periodicity**: periodicity of data to query and return. Must be one of "daily", "weekly",
  "monthly". ("daily")
- **curl.options**: options passed to curl::handle_setopt

**Details**

Meant to be called internally by getSymbols (see also).

One of a few currently defined methods for loading data for use with quantmod. Essentially a
simple wrapper to the underlying Yahoo! finance site’s historical data download.
Value

A call to `getSymbols.yahoo` will load into the specified environment one object for each `Symbol` specified, with class defined by `return.class`. Presently this may be `ts`, `zoo`, `xts`, or `timeSeries`. In the case of `xts` objects, the indexing will be by Date. This can be altered with the `index.class` argument. See `indexClass` for more information on changing index classes.

Warning

As of `quantmod` 0.4-9, `getSymbols.yahoo` has been patched to work with changes to Yahoo Finance, which also included the following changes to the raw data:

- The adjusted close column appears to no longer include dividend adjustments
- The close column appears to be adjusted for splits twice
- The open, high, and low columns are adjusted for splits, and
- The raw data may contain missing values.

```

```
# NOT RECOMMENDED!!!
```

## Method #3
getSymbols.yahoo('MSFT', env=globalenv())

## End(Not run)

getSymbols.yahooj

Download OHLC Data From Yahoo! Japan Finance

Description

Downloads Symbols to specified env from 'finance.yahoo.co.jp'. This method is not to be called directly, instead a call to getSymbols(Symbols, src='yahooj') will in turn call this method. It is documented for the sole purpose of highlighting the arguments accepted, and to serve as a guide to creating additional getSymbols 'methods'.

Usage

getSymbols.yahooj(Symbols, env, return.class = 'xts', index.class = 'Date', from = "2007-01-01", to = Sys.Date(), ...)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

Details

Meant to be called internally by getSymbols (see also).

One of the few currently defined methods for loading data for use with quantmod. Essentially a simple wrapper to the underlying Yahoo! Japan finance site’s historical data download.

The string ‘YJ’ will be prepended to the Symbols because Japanese ticker symbols usually start with a number and it is cumbersome to use variable names that start with a number in the R environment.

It is recommended to prepend the ticker symbols with ‘YJ’ yourself if you use setSymbolLookup. That will make it possible for the main getSymbols function to find the symbols in the lookup table.
Value

A call to getSymbols.yahooj will load into the specified environment one object for each Symbol specified, with class defined by return.class. Presently this may be ts, zoo, xts, or timeSeries. In the case of xts objects, the indexing will be by Date. This can be altered with the index.class argument. See indexClass for more information on changing index classes.

###############################################################
## NOT RECOMMENDED!!!
###############################################################

## Method #4
getSymbols.yahooj('6758.T', env=globalenv())

## End(Not run)
Description

A set of functions to check for appropriate OHLC and HLC column names within a data object, as well as the availability and position of those columns.

Usage

```r
is.OHLC(x)
has.OHLC(x, which = FALSE)

is.OHLCV(x)
has.OHLCV(x, which = FALSE)

is.HLC(x)
has.HLC(x, which = FALSE)

has.Op(x, which = FALSE)
has.Hi(x, which = FALSE)
has.Lo(x, which = FALSE)
has.Cl(x, which = FALSE)
has.Vo(x, which = FALSE)
has.Ad(x, which = FALSE)

is.BBO(x)
is.TBBO(x)

has.Ask(x, which = FALSE)
has.Bid(x, which = FALSE)
has.Price(x, which = FALSE)
has.Qty(x, which = FALSE)
has.Trade(x, which = FALSE)
```

Arguments

- `x` data object
- `which` display position of match

Details

 Mostly used internally by `quantmod`, they can be useful for checking whether an object can be used in OHLC requiring functions like Op, OpCl, etc.

Columns names must contain the full description of data, that is, Open, High, Low, Close, Volume or Adjusted. Abbreviations will return FALSE (or NA when which=TRUE). See `quantmod.OHLC` for details of `quantmod` naming conventions.
is.OHLC (and is.HLC, similarly) will only return TRUE if there are columns for Open, High, Low and Close. Additional columns will not affect the value.

Value

A logical value indicating success or failure by default.

If which=TRUE, a numeric value representing the column position will be returned.

is.OHLC and is.HLC return a single value of TRUE or FALSE.

specifyModel, tradeModel

Lag  

Lag a Time Series

Description
Create a lagged series from data, with NA used to fill.

Usage
Lag(x, k = 1)

## S3 method for class 'quantmod.OHLC'
Lag(x, k = 1)

## S3 method for class 'zoo'
Lag(x, k = 1)

## S3 method for class 'data.frame'
Lag

Lag(x, k = 1)

## S3 method for class 'numeric'
Lag(x, k = 1)

Arguments

x vector or series to be lagged
k periods to lag.

Details

Shift series k-periods down, prepending NAs to front of series.
Specifically designed to handle quantmod.OHLC and zoo series within the quantmod workflow.
If no S3 method is found, a call to lag in base is made.

Value

The original x prepended with k NAs and missing the trailing k values.
The returned series maintains the number of obs. of the original.

Note

This function differs from lag by returning the original series modified, as opposed to simply changing the time series properties. It differs from the like named Lag in the Hmisc as it deals primarily with time-series like objects.
It is important to realize that if there is no applicable method for Lag, the value returned will be from lag in base. That is, coerced to 'ts' if necessary, and subsequently shifted.

lag

Examples

Stock.Close <- c(102.12,102.62,100.12,103.00,103.87,103.12,105.12)
Close.Dates <- as.Date(c(10660,10661,10662,10665,10666,10667,10668),origin="1970-01-01")

Lag(Stock.Close) #lag by 1 period
Lag(Stock.Close,k=1) #same
Lag(Stock.Close,k=1:3) #lag 1,2 and 3 periods
modelData

Extract Dataset Created by specifyModel

Description

Extract from a quantmod object the dataset created for use in modelling.
specifyModel creates a zoo object for use in subsequent workflow stages (buildModel, tradeModel) that combines all model inputs, from a variety of sources, into one model frame.
modelData returns this object.

Usage

modelData(x, data.window = NULL, exclude.training = FALSE)

Arguments

x a quantmod object
data.window a character vector of subset start and end dates to return
exclude.training remove training period

Details

When a model is created by specifyModel, it is attached to the returned object. One of the slots of this S4 class is model.data.

Value

an object of class zoo containing all transformations to data specified in specifyModel.

Author(s)

Jeffrey A. Ryan

See Also

specifyModel, getModelData

Examples

## Not run:
m <- specifyModel(Next(OpCl(SPY)) ~ Cl(SPY) + OpHi(SPY) + Lag(Cl(SPY)))
modelData(m)

## End(Not run)
modelSignal

Extract Model Signal Object

Description

Extract model signal object from quantmodResults object as an object of class zoo.

Usage

modelSignal(x)

Arguments

x object of class quantmodResults

Details

For use after a call to tradeModel to extract the generated signal of a given quantmod model. Normally this would not need to be called by the end user unless he was manually post processing the trade results.

Value

A zoo object indexed by signal dates.

tradeModel

newTA

Create A New TA Indicator For chartSeries

Description

Functions to assist in the creation of indicators or content to be drawn on plots produced by chartSeries.
Usage

addTA(ta,
    order = NULL,
    on = NA,
    legend = "auto",
    yrange = NULL,
    ...)

newTA(FUN,
    preFUN,
    postFUN,
    on = NA,
    yrange = NULL,
    legend.name,
    fdots = TRUE,
    cdots = TRUE,
    data.at = 1,
    ...)

Arguments

ta       data to be plotted
order    which should the columns (if > 1) be plotted
legend   what custom legend text should be added to the chart.
FUN      Main filter function name - as a symbol
preFUN   Pre-filter transformation or extraction function
postFUN  Post-filter transformation or extraction function
on       where to draw
yrange   length 2 vector of y-axis range
legend.name optional legend heading, automatically derived otherwise
fdots    should any ... be included in the main filter call
cdots   should any ... be included in the resultant function object. fdots=TRUE will override this to TRUE.
data.at   which argument to the main filter function is for data.
...      any additional graphical parameters/default to be included.

Details

Both addTA and newTA can be used to dynamically add custom content to a displayed chart.
addTA takes a series of values, either in a form coercible to xts or of the same length as the charted series has rows, and displays the results in either a new TA sub-window, or over/underlaid on the main price chart. If the object can be coerced to xts, the time values present must only be within the original series time-range. Internally a merge of dates occurs and will allow for the plotting of discontinuous series.
The order argument allows for multiple column data to be plotted in an order that makes the most visual sense.

Specifying a legend will override the standard parsing of the addTA call to attempt a guess at a suitable title for the sub-chart. Specifying this will cause the standard last value to not be printed.

The . . . arg to addTA is used to set graphical parameters interpretable by lines.

newTA acts as more of a skeleton function, taking functions as arguments, as well as charting parameters, and returns a function that can be called in the same manner as the built-in TA tools, such as addRSI and addMACD. Essentially a dynamic code generator that allows for highly customizable chart tools with minimal (possibly zero) coding. It is also possible to modify the resultant code to further change behavior.

To create a new TA function with newTA certain arguments must be specified.

The FUN argument is a function symbol (or coercible to such) that is the primary filter to be used on the core-data of a chartSeries chart. This can be like most of the functions within the TTR package — e.g. RSI or EMA. The resultant object of the function call will be equal to calling the function on the original data passed into the chartSeries function that created the chart. It should be coercible to a matrix object, of one or more columns of output. By default all columns of output will be added to the chart, unless suppressed by passing the appropriately positioned type=’n’ as the . . . arg. Note that this will not suppress the labels added to the chart.

The preFUN argument will be called on the main chart’s data prior to passing it to FUN. This must be a function symbol or a character string of the name function to be called.

The postFUN argument will be called on the resultant data returned from the FUN filter. This is useful for extracting the relevant data from the returned filter data. Like preFUN it must be a function symbol or a character string of the name of the function to be called.

The yrange argument is used to provide a custom scale to the y-axis. If NULL the min and max of the data to be plotted will be used for the y-axis range.

The on is used to identify which subchart to add the graphic to. By default, on=NA will draw the series in a new subchart below the last indicator. Setting this to either a positive or negative value will allow for the series to be super-imposed on, or under, the (sub)chart specified, respectively. A value of 1 refers to the main chart, and at present is the only location supported.

legend.name will change the main label for a new plot.

fdots and cdots enable inclusion or suppression of the . . . within the resulting TA code’s call to FUN, or the argument list of the new TA function, respectively. In order to facilitate user-specified graphical parameters it is usually desirable to not impose artificial limits on the end-user with constraints on types of parameters available. By default the new TA function will include the dots argument, and the internal FUN call will keep all arguments, including the dots. This may pose issues if the internal function then passes those . . . arguments to a function that can’t handle them.

The final argument is data.at which is the position in the FUN argument list which expects the data to be passed in at. This default to the sensible first position, though can be changed at the time of creation by setting this argument to the required value.

While the above functions are usually sufficient to construct very pleasing graphical additions to a chart, it may be necessary to modify by-hand the code produced. This can be accomplished by dumping the function to a file, or using fix on it during an interactive session.

Another item of note, with respect to newTA is the naming of the main legend label. Following addTA convention, the first ‘add’ is stripped from the function name, and the rest of the call’s name
is used as the label. This can be overridden by specifying `legend.name` in the construction of the new TA call, or by passing `legend` into the new TA function. Subtle differences exist, with the former being the preferred solution.

While both functions can be used to build new indicators without any understanding of the internal chartSeries process, it may be beneficial in more complex cases to have a knowledge of the multi-step process involved in creating a chart via chartSeries.

to be added...

**Value**

`addTA` will invisibly return an S4 object of class `chobTA`. If this function is called interactively, the `chobTA` object will be evaluated and added to the current chart.

`newTA` will return a function object that can either be assigned or evaluated. Evaluating this function will follow the logic of any standard addTA-style call, returning invisibly a `chobTA` object, or adding to the chart.

**Note**

Both interfaces are meant to facilitate custom chart additions. `addTA` is for adding any arbitrary series to a chart, where-as `newTA` works with the underlying series with the main chart object. The latter also acts as a dynamic TA skeleton generation tool to help develop reusable TA generation code for use on any chart.

**Author(s)**

Jeffrey A. Ryan

**See Also**

`chartSeries`, `TA`, `chob`, `chobTA`

**Examples**

```r
## Not run:
getSymbols("SBUX")
barChart(SBUX)
addTA(EMA(Cl(SBUX)), on=1, col=6)
addTA(OpCl(SBUX), col=4, type="b", lwd=2)
# create new EMA TA function
newEMA <- newTA(EMA, Cl, on=1, col=7)
newEMA()
newEMA(on=NA, col=5)
```

## End(Not run)
Description

Create a new series with all values advanced forward one period. The value of period 1, becomes the value at period 2, value at 2 becomes the original value at 3, etc. The opposite of Lag. NA is used to fill.

Usage

Next(x, k = 1)

## S3 method for class 'quantmod.OHLC'
Next(x,k=1)

## S3 method for class 'zoo'
Next(x,k=1)

## S3 method for class 'data.frame'
Next(x,k=1)

## S3 method for class 'numeric'
Next(x,k=1)

Arguments

x vector or series to be advanced
k periods to advance

Details

Shift series k-periods up, appending NAs to end of series.
Specifically designed to handle quantmod.OHLC and zoo series within the quantmod workflow.
If no S3 method is found, a call to lag in base is made, with the indexing reversed to shift the time series forward.

Value

The original x appended with k NAs and missing the leading k values.
The returned series maintains the number of obs. of the original.
Unlike Lag, only one value for k is allowed.
**OHL.C.Transformations**

**Extract and Transform OHL.C Time-Series Columns**

**Description**

Extract (transformed) data from a suitable OHL.C object. Column names must contain the complete description - either “Open”, “High”, “Low”, “Close”, “Volume”, or “Adjusted” - though may also contain additional characters. This is the default for objects returned from most getSymbols calls.

In the case of functions consisting of combined Op, Hi, Lo, Cl (e.g. ClCl(x)) the one period transformation will be applied.

For example, to return the Open to Close of a object it is possible to call OpCl(x). If multiple periods are desired a call to the function Delta is necessary.
seriesLo and seriesHi will return the low and high, respectively, of a given series.

seriesAccel, seriesDecel, seriesIncr, and seriesDecr, return a vector of logicals indicating if the series is accelerating, decelerating, increasing, or decreasing. This is managed by diff, which provides NA fill and suitable re-indexing. These are here to make trade rules easier to read.

HLC extracts the High, Low, and Close columns. OHLC extracts the Open, High, Low, and Close columns.

These functions are merely to speed the model specification process. All columns may also be extracted through standard R methods.

Assignment will not work at present.

getPrice will attempt to extract price column(s) from a time series, using sensible defaults. Additionally, the user may provide by symbol and price preference.

Usage

\begin{verbatim}
Op(x)
Hi(x)
Lo(x)
Cl(x)
Vo(x)
Ad(x)

seriesHi(x)
seriesLo(x)
seriesIncr(x, thresh=0, diff.=1L)
seriesDecr(x, thresh=0, diff.=1L)

OpCl(x)
ClCl(x)
HiCl(x)
LoCl(x)
LoHi(x)
OpHi(x)
OpLo(x)
OpOp(x)

HLC(x)
OHLC(x)
OHLCV(x)

getPrice(x, symbol=NULL, prefer=NULL, ...)
\end{verbatim}

Arguments

\begin{itemize}
  \item \texttt{x} \hspace{1cm} A data object with columns containing data to be extracted.
  \item \texttt{thresh} \hspace{1cm} noise threshold (seriesIncr/seriesDecr)
  \item \texttt{diff.} \hspace{1cm} differencing (seriesIncr/seriesDecr)
  \item \texttt{symbol} \hspace{1cm} text string containing the symbol to extract
\end{itemize}
prefer  price type preference (see Details)
...  not currently used

Details

Internally, the code uses grep to locate the appropriate columns. Therefore it is necessary to use inputs with column names matching the requirements in the description section, though the exact naming convention is not as important.

prefer can be used with getPrice to extract many commonly used financial time series prices descriptions (e.g. open, high, low, close, bid, ask/offer, midpoint, trade, price). If the value of prefer does not match one of the currently supported types, it will be matched against the object column names using grep.

Value

Returns an object of the same class as the original series, with the appropriately column names if applicable and/or possible. The only exceptions are for quantmod.OHLC objects which will be returned as zoo objects, and calls to seriesLo and seriesHi which may return a numeric value instead of the original object type.

seriesHi(Lo(IBM))
removeSymbols('IBM')
## End(Not run)
```
options.expiry  

**Calculate Contract Expirations**

**Description**

Return the index of the contract expiration date. The third Friday of the month for options, the last third Friday of the quarter for futures.

**Usage**

```r
options.expiry(x)  
futures.expiry(x)
```

**Arguments**

- `x` a time-indexed zoo object

**Details**

Designed to be used within a charting context via `addExpiry`, the values returned are based on the description above. Exceptions, though rare, are not accounted for.

**Value**

A numeric vector of values to index on.

**Note**

There is currently no accounting for holidays that may interfere with the general rule. Additionally all efforts have been focused on US equity and futures markets.

options.expiry(AAPL)
futures.expiry(AAPL)

AAPL[options.expiry(AAPL)]

## End(Not run)
```

### Calculate Periodic Returns

**Description**

Given a set of prices, return periodic returns.

**Usage**

```r
periodReturn(x,  
  period='monthly',  
  subset=NULL,  
  type='arithmetic',  
  leading=TRUE,  
  ...)

dailyReturn(x, subset=NULL, type='arithmetic',  
  leading=TRUE, ...)  
weeklyReturn(x, subset=NULL, type='arithmetic',  
  leading=TRUE, ...)  
monthlyReturn(x, subset=NULL, type='arithmetic',  
  leading=TRUE, ...)  
quarterlyReturn(x, subset=NULL, type='arithmetic',  
  leading=TRUE, ...)  
annualReturn(x, subset=NULL, type='arithmetic',  
  leading=TRUE, ...)  
yearlyReturn(x, subset=NULL, type='arithmetic',  
  leading=TRUE, ...)  
allReturns(x, subset=NULL, type='arithmetic',  
  leading=TRUE)
```

**Arguments**

- **x**: object of state prices, or an OHLC type object
- **period**: character string indicating time period. Valid entries are ‘daily’, ‘weekly’, ‘monthly’, ‘quarterly’, ‘yearly’. All are accessible from wrapper functions described below. Defaults to monthly returns (same as monthlyReturn)
periodReturn

subset an xts/ISO8601 style subset string
type type of returns: arithmetic (discrete) or log (continuous)
leading should incomplete leading period returns be returned
... passed along to to.period

Details

periodReturn is the underlying function for wrappers:

- allReturns: calculate all available return periods
- dailyReturn: calculate daily returns
- weeklyReturn: calculate weekly returns
- monthlyReturn: calculate monthly returns
- quarterlyReturn: calculate quarterly returns
- annualReturn: calculate annual returns

Value

Returns object of the class that was originally passed in, with the possible exception of monthly and quarterly return indices being changed to class yearmon and yearqtr where available. This can be overridden with the indexAt argument passed in the ...to the to.period function.

By default, if subset is NULL, the full dataset will be used.

Note

Attempts are made to re-convert the resultant series to its original class, if supported by the xts package. At present, objects inheriting from the ‘ts’ class are returned as xts objects. This is to make the results more visually appealing and informative. All xts objects can be converted to class ts with as.ts if that is desirable.

The first and final row of returned object will have the period return to last date, i.e. this week/month/quarter/year return to date even if the start/end is not the start/end of the period. Leading period calculations can be suppressed by setting leading=FALSE.

Examples

```r
## Not run:
getSymbols('QQQQ', src='yahoo')
allReturns(QQQQ) # returns all periods
periodReturn(QQQQ, period='yearly', subset='2003::') # returns years 2003 to present
periodReturn(QQQQ, period='yearly', subset='2003') # returns year 2003
rm(QQQQ)
## End(Not run)
```

quantmod-class

Class "quantmod"

Description

Objects of class quantmod help to manage the process of model building within the quantmod package. Created automatically by a call to specifyModel they carry information to be used by a variety of accessor functions and methods.

Objects from the Class

Objects can be created by calls of the form new("quantmod",...).

Normally objects are created as a result of a call to specifyModel.

Slots

- `model.id`: Object of class "character"
- `model.spec`: Object of class "formula"
- `model.formula`: Object of class "formula"
- `model.target`: Object of class "character"
- `model.inputs`: Object of class "character"
- `build.inputs`: Object of class "character"
- `symbols`: Object of class "character"
- `product`: Object of class "character"
- `price.levels`: Object of class "zoo"
- `training.data`: Object of class "Date"
- `build.date`: Object of class "Date"
- `fitted.model`: Object of class "ANY"
- `model.data`: Object of class "zoo"
- `quantmod.version`: Object of class "numeric"
Methods

No methods defined with class "quantmod" in the signature.

Author(s)

Jeffrey A. Ryan

Examples

showClass("quantmod")

quantmod.OHLC Create Open High Low Close Object

Description

Coerce an object with the appropriate columns to class quantmod.OHLC, which extends zoo.

Usage

as.quantmod.OHLC(x, 
    col.names = c("Open", "High", 
                  "Low", "Close", 
                  "Volume", "Adjusted"), 
    name = NULL, ...)

Arguments

x object of class zoo

col.names suffix for columns

name name to attach unique column suffixes to, defaults to the object name

... additional arguments (unused)

Details

quantmod.OHLC is actually just a renaming of an object of class zoo, with the convention of NAME.Open, NAME.High, ... for the column names.

Additionally methods may be written to handle or check for the above conditions within other functions - as is the case within the quantmod package.

Value

An object of class c('quantmod.OHLC','zoo')

OHLC.Transformations, getSymbols

Description

Save selected chart to an external file.

Usage

saveChart(.type = "pdf", ..., dev = dev.cur())

Arguments

.type type of export. See Details.
... arguments to pass to device
dev which device should be exported

Details

This function wraps the base R function pdf, postscript, png, jpeg, and bitmap. The .type argument must specify which device driver is desired.

The currently active device is used if dev is missing. The result is an exact copy (within the device limits) of the chart specified.

The name of the resultant file is derived from the name of the chart, with the appropriate extension appended. (from .type). Specifying the appropriate device file/filename will override this name.

The caller may specify any parameters that are valid for the device called. Internally, effort is made to match the dimensions of the device being used to create the output file. User supplied dimensions will override this internal calculation.

Value

A file in the current directory (default) matching the type of the output requested.

Note

As this uses do.call internally to create the new output device, any device that makes use of R conventions should be acceptable as a value for .type

Examples

## Not run:
getSymbols("AAPL")

chartSeries(AAPL)

require(TTR)
addBBands()

saveChart('pdf')
saveChart('pdf', width=13)

## End(Not run)

setSymbolLookup

Manage Symbol Lookup Table

Description

Create and manage Symbol defaults lookup table within R session for use in getSymbols calls.

Usage

setSymbolLookup(...)
getSymbolLookup(Symbols=NULL)

saveSymbolLookup(file,dir="")
loadSymbolLookup(file,dir="")

Arguments

... name=value pairs for symbol defaults
Symbols name of symbol(s)
file filename
dir directory of filename

Details

Use of these functions allows the user to specify a set of default parameters for each Symbol to be loaded.

Different sources (e.g. yahoo, MySQL, csv), can be specified for each Symbol of interest. The sources must be valid getSymbols methods - see getSymbols for details on which methods are available, as well as how to add additional methods.
The argument list to `setSymbolLookup` is simply the unquoted name of the Symbol matched to the desired default source, or list of Symbol specific parameters.

For example, to signify that the stock data for Sun Microsystems (JAVA) should be downloaded from Yahoo! Finance, one would call `setSymbolLookup(JAVA='yahoo')` or `setSymbolLookup(JAVA=list(src='yahoo'))`.

It is also possible to specify additional, possibly source specific, lookup details on a per symbol basis. These include an alternate naming convention (useful for sites like Yahoo! where certain non-traded symbols are prepended with a caret, or more correctly a circumflex accent. In that case one would specify `setSymbolLookup(DJI=list(name="^DJI",src="yahoo"))`) as well as passed parameters like `dbname` and `password` for database sources. See the specific `getSymbols` function related to the source in question for more details of each implementation.

If a single named list is passed into the function without naming the list as a parameter, the names of this list will be presumed to be symbol names to be added to the current list of symbols.

All changes are made to the current list, and will persist only until the end of the session. To always use the same defaults it is necessary to call `setSymbolLookup` with the appropriate parameters from a startup file (e.g. `.Rprofile`) or to use `saveSymbolLookup` and `loadSymbolLookup` to save and restore lookup tables.

To unset a specific Symbol’s defaults, simply assign `NULL` to the Symbol.

Value

Called for its side effects, the function changes the options value for the specified Symbol through a call to `options(getSymbols.sources=...)`

Note

Changes are NOT persistent across sessions, as the table is stored in the session options by default. This may change to allow for an easier to manage process, as for now it is designed to minimize the clutter created during a typical session.

Examples

```r
setSymbolLookup(QQQQ='yahoo',DIA='MySQL')
getSymbolLookup('QQQQ')
getSymbolLookup(c('QQQQ','DIA'))

## Not run:
## Will download QQQ from yahoo
## and load DIA from MySQL
getSymbols(c('QQQQ','DIA'))
```
## End(Not run)

## Use something like this to always retrieve
## from the same source

.First <- function() {
  require(quantmod, quietly=TRUE)
  quantmod::setSymbolLookup(JAVA="MySQL")
}

## OR

## Not run:
saveSymbolLookup()
loadSymbolLookup()

## End(Not run)

--

### Manage TA Argument Lists

**Description**

Used to manage the TA arguments used inside chartSeries calls.

**Usage**

```r
setTA(type = c("chartSeries", "barChart", "candleChart"))
```

```r
listTA(dev)
```

**Arguments**

- **type**: the function to apply defaults TAs to
- **dev**: the device to display TA arguments for

**Details**

`setTA` and `unsetTA` provide a simple way to reuse the same TA arguments for multiple charts. By default all charting functions will be set to use the current chart’s defaults.

It is important to note that the current device will be used to extract the list of TA arguments to apply. This is done with a call to `listTA` internally, and followed by calls to `setDefault` of the appropriate functions.

An additional way to set default TA arguments for subsequent charts is via `setDefaults`. See the examples.

**Value**

Called for its side-effect of setting the default TA arguments to quantmod’s charting functions.
**Note**

Using `setDefaults` directly will require the vector of default TA calls to be wrapped in a call to `substitute` to prevent unintended evaluations; OR a call to `listTA` to get the present TA arguments. This last approach is what `setTA` wraps.

**Author(s)**

Jeffrey A. Ryan

**See Also**

`chartSeries`, `addTA`

**Examples**

```r
## Not run:
listTA()
setTA()

# a longer way to accomplish the same
setDefaults(chartSeries,TA=listTA())
setDefaults(barCart,TA=listTA())
setDefaults(candleChart,TA=listTA())

setDefaults(chartSeries,TA=substitute(c(addVo(),addBBands())))

## End(Not run)
```

---

**specifyModel**

**Specify Model Formula For quantmod Process**

**Description**

Create a single reusable model specification for subsequent `buildModel` calls. An object of class `quantmod` is created that can be then be reused with different modelling methods and parameters. No data frame is specified, as data is retrieved from potentially multiple environments, and internal calls to `getSymbols`.

**Usage**

`specifyModel(formula, na.rm=TRUE)`

**Arguments**

- `formula`: an object of class `formula` (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under Details.
- `na.rm`: remove all incomplete rows.
Models are specified through the standard formula mechanism.

As financial models may include a variety of financial and economic indicators, each differing in source, frequency, and/or class, a single mechanism to specify sources is included within a call to specifyModel. See getModelData for details of how this process works.

Currently, objects of class quantmod.OHLC, zoo and ts are supported within the model formula. All symbols are first retrieved from the global environment, without inheritance. If an object is not found in the global environment, it is added to a list of objects to load through the getSymbols function. getSymbols retrieves each object specified by using information as to its location specified apriori via setDefaults or setSymbolLookup.

Internally all data is coerced to zoo, data.frame, or numeric classes.

Returns an object of class quantmod. Use modelData to extract full data set as zoo object.

It is possible to include any supported series in the formula by simply specifying the object's symbol. See *Details* for a list of currently supported classes.

Use getSymbols.skeleton to create additional methods of data sourcing, e.g. from a proprietary data format or currently unimplemented source (Bloomberg, Oracle).

See getSymbols.MySQL and getSymbols.yahoo for examples of adding additional functionality

Jeffrey Ryan

quantmod.com http://www.quantmod.com

getModelData, getSymbols, buildModel, tradeModel, formula setSymbolLookup

## Not run:
# if QQQQ is not in the Global environment, an attempt will be made # to retrieve it from the source specified with getSymbols.Default
specifyModel(Next(OpCl(QQQQ)) ~ Lag(OpHi(QQQQ),0:3) + Hi(DIA))

## End(Not run)
**Add Technical Indicator to Chart**

**Description**

Functions to add technical indicators to a chart.

**Details**

The general mechanism to add technical analysis studies or overlays to a financial chart created with `chartSeries`.

Functionality marked with a ‘*’ is via the TTR package.

General TA charting tool functions:

- addTA add data as custom indicator
- dropTA remove technical indicator
- moveTA move a technical indicator
- swapTA swap two technical indicators

Current technical indicators include:

- addADX add Welles Wilder’s Directional Movement Indicator*
- addATR add Average True Range *
- addAroon add Aroon Indicator *
- addAroonOsc add Aroon Oscillator *
- addBBands add Bollinger Bands *
- addCCI add Commodity Channel Index *
- addCMF add Chaiken Money Flow *
- addChAD add Chaiken Accumulation Distribution Line *
- addChVol add Chaiken Volatility *
- addCMO add Chande Momentum Oscillator *
- addDEMA add Double Exponential Moving Average *
- addDPO add Detrended Price Oscillator *
- addEMA add Exponential Moving Average *
- addEMV add Arm’s Ease of Movement *
- addEnvelope add Moving Average Envelope
- addEWMMA add Exponential Volume Weighted Moving Average *
- addExpiry add options or futures expiration lines
- addKST add Know Sure Thing *
- addLines add line(s)
• addMACD: add Moving Average Convergence Divergence *
• addMFI: add Money Flow Index *
• addMomentum: add Momentum *
• addOBV: add On-Balance Volume *
• addPoints: add point(s)
• addROC: add Rate of Change *
• addRSI: add Relative Strength Indicator *
• addSAR: add Parabolic SAR *
• addSMA: add Simple Moving Average *
• addSMI: add Stochastic Momentum Index *
• addTDI: add Trend Direction Index *
• addTRIX: add Triple Smoothed Exponential Oscillator *
• addVo: add Volume if available
• addVolatility: add volatility *
• addWMA: add Weighted Moving Average *
• addWPR: add Williams Percent R *
• addZigZag: add Zig Zag *
• addZLEMA: add ZLEMA *

See the individual functions for specific implementation and argument details. Details of the underlying TTR implementations can be found in TTR.

The primary changes between the add*** version of an indicator and the TTR base function is the absence of the data argument in the former.

Notable additions include on, with.col.

Value

Called for its side effects, an object to class chobTA will be returned invisibly. If called from the R command line the method will draw the appropriate indicator on the current chart.

Note

Calling any of the above methods from within a function or script will generally require them to be wrapped in a plot call as they rely on the context of the call to initiate the actual charting addition.

tradeModel

Simulate Trading of Fitted quantmod Object

Description

Simulated trading of fitted quantmod object. Given a fitted model, tradeModel calculates the signal generated over a given historical period, then applies specified trade.rule to calculate and return a tradeLog object. Additional methods can then be called to evaluate the performance of the model’s strategy.

Usage

tradeModel(x,  
  signal.threshold = c(0, 0),  
  leverage = 1,  
  return.model = TRUE,  
  plot.model = FALSE,  
  trade.dates = NULL,  
  exclude.training = TRUE,  
  ret.type = c("weeks", "months", "quarters", "years"),  
  ...)

Arguments

x a quantmod object from buildModel
signal.threshold a numeric vector describing simple lower and upper thresholds before trade occurs
leverage amount of leverage to apply - currently a constant
return.model should the full model be returned?
plot.model plot the model?
trade.dates specific trade interval - defaults to full dataset
exclude.training exclude the period trained on?
ret.type a table of period returns
... additional parameters needed by the underlying modelling function, if any

Details

Still highly experimental and changing. The purpose is to apply a newly contructed model from buildModel to a new dataset to investigate the model’s trading potential.

At present all parameters are very basic. The near term changes include allowing for a trade.rule argument to allow for a dynamic trade rule given a set of signals. Additional the application of variable leverage and costs will become part of the final structure.

Any suggestions as to inclusions or alterations are appreciated and should be directed to the maintainer of the package.
Value

A quantmodResults object

## Not run:
m <- specifyModel(Next(OpCl(QQQQ)) ~ Lag(OpHi(QQQQ)))
m.built <- buildModel(m,method='rpart',training.per=c('2007-01-01','2007-04-01'))

tradeModel(m.built)
tradeModel(m.built,leverage=2)

## End(Not run)
```

### Description

Using `xts` style date subsetting, zoom into or out of the current chart.

### Usage

```r
zoomChart(subset, yrange=NULL)
```

### Arguments

- `n`: the number of interactive view changes per call
- `eps`: the distance between clicks to be considered a valid subset request
- `subset`: a valid subset string
- `yrange`: override y-scale
Details

These function allow for viewing of specific areas of a chart produced by chartSeries by simply specifying the dates of interest.

zoomChart is an interactive chart version of zoomChart which utilizes the standard R device interaction tool locator to estimate the subset desired. This estimate is then passed to zoomChart for actual redrawing. At present it is quite experimental in its interface and arguments. Its usage entails a call to zoomChart() followed by the selection of the leftmost and rightmost points desired in the newly zoomed chart. This selection is accomplished by the user left-clicking each extreme point. Two click are required to determine the level of zooming. Double clicking will reset the chart to the full data range. The arguments and internal working of this function are likely to change dramatically in future releases, though its use will likely remain.

Standard format for the subset argument is the same as the subsetting for xts objects, which is how the data is stored internally for rendering.

Calling zoomChart with no arguments (NULL) resets the chart to the original data.

Examples include '2007' for all of the year 2007, '2007::2008' for years 2007 through 2008, '::2007' for all data from the beginning of the set to the end of 2007, '2007::' all data from the beginning of 2007 through the end of the data. For specifics regarding the level of detail and internal interpretation please see [.xts

Value

This function is called for its side effect - notably changing the perspective of the current chart, and changing its formal subset level. The underlying data attached to the chart is left unchanged.
