Package ‘quantreg’

October 25, 2017

Title Quantile Regression

Description Estimation and inference methods for models of conditional quantiles:
Linear and nonlinear parametric and non-parametric (total variation penalized) models
for conditional quantiles of a univariate response and several methods for handling
censored survival data. Portfolio selection methods based on expected shortfall
risk are also included.

Version 5.34

Density Estimation using Adaptive Kernel method

Description

Usage

\texttt{akj(x, z =, p =, h = -1, alpha = 0.5, kappa = 0.9, iker1 = 0)}

Arguments

- \texttt{x}: points used for centers of kernel assumed to be sorted.
- \texttt{z}: points at which density is calculated; defaults to an equispaced sequence covering the range of \texttt{x}.
- \texttt{p}: vector of probabilities associated with \texttt{x}s; defaults to \texttt{1/n} for each \texttt{x}.
- \texttt{h}: initial window size (overall); defaults to Silverman’s normal reference.
- \texttt{alpha}: a sensitivity parameter that determines the sensitivity of the local bandwidth to variations in the pilot density; defaults to 0.5.
- \texttt{kappa}: constant multiplier for initial (default) window width
- \texttt{iker1}: integer kernel indicator: 0 for normal kernel (default) while 1 for Cauchy kernel (\texttt{dcauchy}).
Value

A list structure is with components

- `dens`: the vector of estimated density values $f(z)$
- `psi`: a vector of $\psi = -f'/f$ function values.
- `score`: a vector of score $\psi' = (f'/f)^2 - f''/f$ function values.
- `h`: same as the input argument $h$

Note

If the score function values are of interest, the Cauchy kernel may be preferable.

References

Examples

```r
set.seed(1)
x <- c(rnorm(600), 2 + 2*rnorm(400))
xx <- seq(-5, 8, length=200)
z <- akj(x, xx)
plot(xx, z$dens, ylim=range(0,z$dens), type=", col=2)
abline(h=0, col="gray", lty=2)
plot(xx, z$psi, type="l", col=2, main = expression(hat(psi)(x)))
plot(xx, z$score, type="l", col=2,
     main = expression(score " * hat(psi) * "'" * (x)))

if(require("nor1mix")){
m3 <- norMix(mu= c(-4,0,3), sig2 = c(1/3^2, 1, 2^2),
              w = c(.1,.5,.4))
plot(m3, p.norm = FALSE)
set.seed(11)
x <- rnorMix(1000, m3)
z2 <- akj(x, xx)
lines(xx, z2$dens, col=2)
z3 <- akj(x, xx, kappa = 0.5, alpha = 0.88)
lines(xx, z3$dens, col=3)
}
```
Description

Compute test statistics for two or more quantile regression fits.

Usage

```r
## S3 method for class 'rq'
anova(object, ..., test = "Wald", joint = TRUE, score = "tau", se = "nid", R = 200, trim = NULL)
## S3 method for class 'rqs'
anova(object, ..., se = "nid", joint = TRUE)
## S3 method for class 'rqlist'
anova(object, ..., test = "Wald", joint = TRUE, score = "tau", se = "nid", R = 200, trim = NULL)
```

```r
rq.test.rank(x0, x1, y, v = NULL, score = "wilcoxon", weights = NULL, tau = .5, iid = TRUE, delta0 = rep(0, NCOL(x1)), omega = 1, trim = NULL, pvalue = "F")
rq.test.anowar(x0, x1, y, tau, R)
```

Arguments

- **object, ...** objects of class ‘rq’, originating from a call to ‘rq’. or a single object of class rqs, originating from a call to ‘rq’ with multiple taus specified.
- **test** A character string specifying the test statistic to use. Can be either ‘Wald’ or ‘rank’.
- **joint** A logical flag indicating whether tests of equality of slopes should be done as joint tests on all slope parameters, or whether (when joint = FALSE) separate tests on each of the slope parameters should be reported. This option applies only to the tests of equality of slopes in the case that estimated models correspond to distinct taus.
- **score** A character string specifying the score function to use, only needed or applicable for the ‘rank’ form of the test.
- **trim** optional trimming proportion parameter(s) – only applicable for the Wilcoxon score function – when one value is provided there is symmetric trimming of the score integral to the interval (trim, 1-trim), when there are two values provided, then the trimming restricts the integration to (trim[1], trim[2]).
- **x** objects of class ‘summary.rq’, originating from a call to ‘summary’.
- **x0** design matrix for the null component of the rank and anowar tests.
- **x1** design matrix for the alternative component of the rank and anowar tests.
- **y** response vector for the alternative component of the rank and anowar tests.

optional rq process fit
method for computing standard errors, either "nid" or "ker", note that "boot" cannot be used for testing homogeneity of slopes.
quantile of interest for quantile specific forms of testing.
logical flag for quantile specific forms of testing, if TRUE the test presumes that the conditional densities take identical values, if it is FALSE then local densities are estimated and used, see Koenker(2005) p. 90.
vector of hypothetical parameter values under test, typically zeros but can be specified to be nonzero in cases where simulations are being used to evaluate the validity of the non-central chisquare theory of the test.
value to be used for the score and F dependent constant appearing in the non-centrality parameter, this is only needed/useful when delta0 is specified to be non-zero. In the usual Wilcoxon (untrimmed) case this value is the integral the squared density.
type of p-value to be used, by default a pseudo F-statistic is produced and the corresponding F p-value is computed, otherwise the more conventional chisquared p-values are reported.
optional weight vector to be used for fitting.
The number of resampling replications for the anowar form of the test, used to estimate the reference distribution for the test statistic.

Details
There are two (as yet) distinct forms of the test. In the first the fitted objects all have the same specified quantile (tau) and the intent is to test the hypothesis that smaller models are adequate relative to the largest specified model. In the second form of the test the linear predictor of the fits are all the same, but the specified quantiles (taus) are different.

In the former case there are three options for the argument ‘test’, by default a Wald test is computed as in Bassett and Koenker (1982). If test = ‘anowar’ is specified then the test is based on the procedure suggested in Chen, Ying, Zhang and Zhao (2008); the test is based on the difference in the QR objective functions at the restricted and unrestricted models with a reference distribution computed by simulation. The p-value of this form of the test is produced by fitting a density to the simulation values forming the reference distribution using the logspline function from the logspline package. The acronym anowar stands for analysis of weighted absolute residuals. If test=’rank’ is specified, then a rank test statistic is computed as described in Gutenbrunner, Jureckova, Koenker and Portnoy (1993). In the latter case one can also specify a form for the score function of the rank test, by default the Wilcoxon score is used, the other options are score=’sign’ for median (sign) scores, or score=’normal’ for normal (van der Waerden) scores. A fourth option is score=’tau’ which is a generalization of median scores to an arbitrary quantile, in this case the quantile is assumed to be the one associated with the fitting of the specified objects. The computing of the rank form of the test is carried out in the rqNtestNrank function, see ranks for further details on the score function options. The Wald form of the test is local in sense that the null hypothesis asserts only that a subset of the covariates are “insignificant” at the specified quantile of interest. The rank form of the test can also be used to test the global hypothesis that a subset is “insignificant” over an entire range of quantiles. The use of the score function score = “tau” restricts the rank test to the local hypothesis of the Wald test.
In the latter case the hypothesis of interest is that the slope coefficients of the models are identical. The test statistic is a variant of the Wald test described in Koenker and Bassett (1982).

By default, both forms of the tests return an F-like statistic in the sense that the an asymptotically Chi-squared statistic is divided by its degrees of freedom and the reported p-value is computed for an F statistic based on the numerator degrees of freedom equal to the rank of the null hypothesis and the denominator degrees of freedom is taken to be the sample size minus the number of parameters of the maintained model.

**Value**

An object of class “anova” inheriting from class “data.frame”.

**WARNING**

An attempt to verify that the models are nested in the first form of the test is made, but this relies on checking set inclusion of the list of variable names and is subject to obvious ambiguities when variable names are generic. The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R’s default of ‘na.action = na.omit’ is used. The rank version of the nested model tests involves computing the entire regression quantile process using parametric linear programming and thus can be rather slow and memory intensive on problems with more than several thousand observations.

fit1 <- rq(y.net ~ lgdp2 + fse2 + gedy2 + Iy2 + gcony2, data = barro)
bandwidth.rq

Description

function to compute bandwidth for sparsity estimation

Usage

bandwidth.rq(p, n, hs=TRUE, alpha=0.05)

Arguments

p quantile(s) of interest
n sample size
hs flag for hall-sheather method
alpha alpha level for intended confidence intervals

Details

If hs=TRUE (default) then the Hall-Sheather(1988) rule $O(n^{-1/3})$ is used, if hs=FALSE then the Bofinger $O(n^{-1/5})$ is used.

Value

returns a vector of bandwidths corresponding to the argument p.

Author(s)

**Barro Data**

**Description**

Version of the Barro Growth Data used in Koenker and Machado (1999). This is a regression data set consisting of 161 observations on determinants of cross country GDP growth rates. There are 13 covariates with dimnames corresponding to the original Barro and Lee source. See [http://www.nber.org/pub/barro.lee/](http://www.nber.org/pub/barro.lee/). The first 71 observations are on the period 1965-75, remainder on 1987-85.

**Usage**

data(barro)

**Format**

A data frame containing 161 observations on 14 variables:

- [.1] "Annual Change Per Capita GDP"
- [.2] "Initial Per Capita GDP"
- [.3] "Male Secondary Education"
- [.4] "Female Secondary Education"
- [.5] "Female Higher Education"
- [.6] "Male Higher Education"
- [.7] "Life Expectancy"
- [.8] "Human Capital"
- [.9] "Education/GDP"
- [.10] "Investment/GDP"
- [.11] "Public Consumption/GDP"
- [.12] "Black Market Premium"
- [.13] "Political Instability"
- [.14] "Growth Rate Terms Trade"

**boot.crq**

**Bootstrapping Censored Quantile Regression**

**Description**

Functions used to estimated standard errors, confidence intervals and tests of hypotheses for censored quantile regression models using the Portnoy and Peng-Huang methods.
Usage

boot.crq(x, y, c, taus, method, ctype = "right", R = 100, mboot, bmethod = "jack", ...)

Arguments

x  The regression design matrix
y  The regression response vector
c  The censoring indicator
taus  The quantiles of interest
method  The fitting method: either "P" for Portnoy or "PH" for Peng and Huang.
ctype  Either "right" or "left"
R  The number of bootstrap replications
bmethod  The bootstrap method to be employed. There are (as yet) three options: method = "jack" uses the delete-d jackknife method described by Portnoy (2013), method = "xy-pair" uses the xy-pair method, that is the usual multinomial resampling of xy-pairs, while method = "Bose" uses the Bose and Chatterjee (2003) weighted resampling method with exponential weights. The "jack" method is now the default.
mboot  optional argument for the bootstrap method: for bmethod = "jack" it specifies the number, d, of the delete-d jackknife, for method = "xy-pair" it specifies the size of the bootstrap samples, that permits subsampling (m out of n) bootstrap. By default in the former case it is set to 2 [sqrt(n)], for the latter the default is n. Obviously mboot should be substantially larger than the column dimension of x, and should be less than the sample size in both cases.
...  Optional further arguments to control bootstrapping

Details

There are several refinements that are still unimplemented. Percentile methods should be incorporated, and extensions of the methods to be used in anova.rq should be made. Note that bootstrapping for the Powell method "Powell" is done via boot.rq. For problems with n > 3000 a message is printed indicated progress in the resampling.

Value

A matrix of dimension R by p is returned with the R resampled estimates of the vector of quantile regression parameters. When mofn < n for the "xy" method this matrix has been deflated by the factor sqrt(m/n)

Author(s)

Roger Koenker

**boot.rq**

**Bootstrapping Quantile Regression**

**Description**

These functions can be used to construct standard errors, confidence intervals and tests of hypotheses regarding quantile regression models.

**Usage**

```r
boot.rq(x, y, tau = 0.5, R = 200, bsmethod = "xy", mofn = length(y),
blbn = NULL, cluster = NULL, U = NULL, ...)
```

**Arguments**

- **x**
  
The regression design matrix
- **y**
  
The regression response vector
- **tau**
  
The quantile of interest
- **R**
  
The number of bootstrap replications
- **bsmethod**
  
The method to be employed. There are (as yet) five options: method = "xy" uses the xy-pair method, and method = "pwy" uses the method of Parzen, Wei and Ying (1994) method = "mcmb" uses the Markov chain marginal bootstrap of He and Hu (2002) and Kocherginsky, He and Mu (2003). The fourth method = "wxy" uses the generalized bootstrap of Bose and Chatterjee (2003) with unit exponential weights, see also Chamberlain and Imbens (2003). The fifth method "wild" uses the wild bootstrap method proposed by Feng, He and Hu (2011).
- **mofn**
  
  optional argument for the bootstrap method "xy" that permits subsampling (m out of n) bootstrap. Obviously mofn should be substantially larger than the column dimension of x, and should be less than the sample size.
- **blbn**
  
  orginal sample size for the BLB model
- **cluster**
  
  If non-NULL this argument should specify cluster id numbers for each observation, in which case the clustered version of the bootstrap based on the proposal of Hagemann (2016). If present bsmethod is set to set to "cluster". If this option is used and the fitting method for the original call was "sfn" then the bootstrapping will be carried out with the "sfn" as well. This is usually substantially quicker than the older version which employed the "br" variant of the simplex method. Use of "sfn" also applies to the "pwy" method when the original fitting was done with "sfn". Finally, if na.action = "omit" and length(object$na.action) > 0 then these elements are also removed from the cluster variable. Consequently, the length of the cluster variable should always be the same as the length of the original response variable before any na.action takes place.
If non-NULL this argument should specify an array of indices or gradient evaluations to be used by the corresponding bootstrap method as specified by `bsmethod`. This is NOT intended as a user specified input, instead it is specified in `summary.rqs` to ensure that bootstrap samples for multiple `taus` use the same realizations of the random sampling.

Optional arguments to control bootstrapping

Details

There are several refinements that are still unimplemented. Percentile methods should be incorporated, and extensions of the methods to be used in `anova.rq` should be made. And more flexibility about what algorithm is used would also be good.

Value

A list consisting of two elements: A matrix `B` of dimension `R` by `p` is returned with the `R` resampled estimates of the vector of quantile regression parameters. When `mofn < n` for the "xy" method this matrix has been deflated by the factor `sqrt(m/n)`. A matrix `U` of sampled indices (for `bsmethod in c("xy", "wxy")`) or gradient evaluations (for `bsmethod in c("pwy", "cluster")`) used to generate the bootstrapped realization, and potentially reused for other `taus` when invoked from `summary.rqs`.

Author(s)

summary(fit,se = "boot", bsmethod= "pwy")
#summary(fit,se = "boot", bsmethod= "mcmb")
```

Bosco

Boscovich Data

Description

Boscovich data used to estimate the ellipticity of the earth. There are five measurements of the arc length of one degree of latitude taken at 5 different latitudes. See Koenker (2005) for further details and references.

Usage

data(Bosco)

Format

A data frame containing 5 observations on 2 variables

- `x` sine squared of latitude measured in degrees
- `y` arc length of one degree of latitude measured in toise - 56,700, one toise approximately equals 1.95 meters.

References

Examples

data(Bosco)
plot(0:10/10,0:10*100,xlab="sin^2(latitude)",
    ylab="arc-length of 1 degree of latitude",type="n")
points(Bosco)
text(Bosco, pos = 3, rownames(Bosco))
z <- rq(y ~ x, tau = -1, data = Bosco)
title("Boscovich Ellipticity of the Earth Example")
xb <- c(.85,.9,.6,.6)
yb <- c(400,600,450,600)
for(i in 1:4){
Cobar Ore data

Description
Cobar Ore data from Green and Silverman (1994). The data consists of measurements on the "true width" of an ore-bearing rock layer from a mine in Cobar, Australia.

Usage
data(CobarOre)

Format
A data frame with 38 observations on the following 3 variables.

x x-coordinate of location of mine site
y y-coordinate of location of mine site
z ore thickness

Source

Examples
data(CobarOre)
plot(CobarOre)
Description

All m combinations of the first n integers taken p at a time are computed and return as an p by m matrix. The columns of the matrix are ordered so that adjacent columns differ by only one element. This is just a reordered version of comb in base R, but the ordering is useful for some applications.

Usage

`combos(n, p)`

Arguments

- `n` The n in n choose p
- `p` The p in n choose p

Value

A matrix of dimension p by choose(n, p)

Note

Implementation based on a Pascal algorithm of Limin Xiang and Kazuo Ushijima (2001) translated to ratfor for R. If you have `rgl` installed you might try `demo("combos")` for a visual impression of how this works.

References

Examples

```r
H <- combos(20, 3)
```
Hotelling Critical Values

Description

Critical values for uniform confidence bands for rqss fitting

Usage

critval(kappa, alpha = 0.05, rdf = 0)

Arguments

- kappa: length of the tube
- alpha: desired non-coverage of the band, intended coverage is 1 - alpha
- rdf: "residual" degrees of freedom of the fitted object. If rdf=0 then the Gaussian version of the critical value is computed, otherwise the value is based on standard Student t theory.

Details

The Hotelling tube approach to inference has a long and illustrious history. See Johansen and Johnstone (1989) for an overview. The implementation here is based on Sun and Loader (1994) and Loader's locfit package, although a simpler root finding approach is substituted for the iterative method used there. At this stage, only univariate bands may be constructed.

Value

A scalar critical value that acts as a multiplier for the uniform confidence band construction.

References

plot.rqss
Functions to fit censored quantile regression models

Description

Fits a conditional quantile regression model for censored data. There are three distinct methods: the first is the fixed censoring method of Powell (1986) as implemented by Fitzenberger (1996), the second is the random censoring method of Portnoy (2003). The third method is based on Peng and Huang (2008).

Usage

```r
crq(formula, taus, data, subset, weights = NULL, na.action = NULL, 
   method = c("Powell", "Portnoy", "Portnoy2", "PengHuang"), contrasts = NULL, ...) 
crq.fit.pow(x, y, yc, tau = 0.5, weights = NULL, start = left = TRUE, maxit = 500) 
crq.fit.pen(x, y, cen, weights = NULL, grid, ctype = "right") 
crq.fit.por(x, y, cen, weights = NULL, grid, ctype = "right") 
crq.fit.por2(x, y, cen, weights = NULL, grid, ctype = "right") 
Curv(y, yc, ctype = c("left", "right")) 
```

Arguments

- `formula`: A formula object, with the response on the left of the `~` operator, and the terms on the right. The response must be a `Surv` object as returned by either the `Curv` or `Surv` function. For the Powell method, the `Surv` object should be created by `Curv` and have arguments (event time, censoring time, type), where “type” can take values either "left" or "right". The default (for historical reasons) for type in this case is "left". For the Portnoy and Peng and Huang methods the `Surv` should be created with the usual `Surv` function and have (event time, censoring indicator).

- `y`: The event time.

- `newdata`: An optional data frame in which to look for variables with which to predict. If omitted, the fitted values are used.

- `grid`: A vector of taus on which the quantile process should be evaluated. This should be monotonic, and take values in (0,1). For the "Portnoy" method, grid = "pivot" computes the full solution for all distinct taus. The "Portnoy" method also enforces an equally spaced grid, see the code for details.
x  An object of class crq or crq.

object  An object of class crq or crq.

yc  The censoring times for the "Powell" method.

cptype  Censoring type: for the "Powell" method, used in curv, by default "left". If you don’t like "left", maybe you will like "right". Note that for fixed censoring assumed in the "Powell" method, censoring times yc must be provided for all observations and the event times y must satisfy the (respective) inequality constraints. For the Portnoy and Peng-Huang methods cptype is determined by the specification of the response as specified in Surv.

type  specifies either "left" or "right" as the form of censoring in the Surv function for the "Portnoy" and "PengHuang" methods.

cen  The censoring indicator for the "Portnoy" and "PengHuang" methods.

maxit  Maximum number of iterations allowed for the "Powell" methods.

start  The starting value for the coefs for the "Powell" method. Because the Fitzenberger algorithm stops when it achieves a local minimum of the Powell objective function, the starting value acts as an a priori "preferred point". This is advantageous in some instances since the global Powell solution can be quite extreme. By default the starting value is the "naive rq" solution that treats all the censored observations as uncensored. If start is equal to "global" then an attempt is made to compute to global optimum of the Powell objective. This entails an exhaustive evaluation of all n choose p distinct basic solution so is rather impractical for moderately large problems. Otherwise, the starting value can specify a set of p indices from 1:n defining an initial basic solution, or it may specify a p-vector of initial regression coefficients. In the latter case the initial basic solution is the one closest to the specified parameter vector.

left  A logical indicator for left censoring for the "Powell" method.

taus  The quantile(s) at which the model is to be estimated.

tau  The quantile at which the model is to be estimated.

data  A data.frame in which to interpret the variables named in the 'formula', in the 'subset', and the 'weights' argument.

subset  an optional vector specifying a subset of observations to be used in the fitting process.

weights  vector of observation weights; if supplied, the algorithm fits to minimize the sum of the weights multiplied into the absolute residuals. The length of weights vector must be the same as the number of observations. The weights must be nonnegative and it is strongly recommended that they be strictly positive, since zero weights are ambiguous.

na.action  a function to filter missing data. This is applied to the model.frame after any subset argument has been used. The default (with 'na.fail') is to create an error if any missing values are found. A possible alternative is 'na.omit', which deletes observations that contain one or more missing values.

method  The method used for fitting. There are currently two options: method "Powell" computes the Powell estimator using the algorithm of Fitzenberger (1996), method "Portnoy" computes the Portnoy (2003) estimator. The method is "PengHuang"
uses the method of Peng and Huang (2007), in this case the variable "grid" can be passed to specify the vector of quantiles at which the solution is desired.

**contrasts**
a list giving contrasts for some or all of the factors default = 'NULL' appearing in the model formula. The elements of the list should have the same name as the variable and should be either a contrast matrix (specifically, any full-rank matrix with as many rows as there are levels in the factor), or else a function to compute such a matrix given the number of levels.

... additional arguments for the fitting routine, for method "Powell" it may be useful to pass starting values of the regression parameter via the argument "start", while for methods "Portnoy" or "PengHuang" one may wish to specify an alternative to the default grid for evaluating the fit.

**Details**

The Fitzenberger algorithm uses a variant of the Barrodale and Roberts simplex method. Exploiting the fact that the solution must be characterized by an exact fit to p points when there are p parameters to be estimated, at any trial basic solution it computes the directional derivatives in the 2p distinct directions and choses the direction that (locally) gives steepest descent. It then performs a one-dimensional line search to choose the new basic observation and continues until it reaches a local mimnum. By default it starts at the naive `rq` solution ignoring the censoring; this has the (slight) advantage that the estimator is consequently equivariant to canonical transformations of the data. Since the objective function is no longer convex there can be no guarantee that this produces a global minimum estimate. In small problems exhaustive search over solutions defined by p-element subsets of the n observations can be used, but this quickly becomes impractical for large p and n. This global version of the Powell estimator can be invoked by specifying `start = "global"`. Users interested in this option would be well advised to compute `choose(n, p)` for their problems before trying it. The method operates by pivoting through this many distinct solutions and choosing the one that gives the minimal Powell objective. The algorithm used for the Portnoy method is described in considerable detail in Portnoy (2003). There is a somewhat simplified version of the Portnoy method that is written in R and iterates over a discrete grid. This version should be considered somewhat experimental at this stage, but it is known to avoid some difficulties with the more complicated fortran version of the algorithm that can occur in degenerate problems. Both the Portnoy and Peng-Huang estimators may be unable to compute estimates of the conditional quantile parameters in the upper tail of distribution. Like the Kaplan-Meier estimator, when censoring is heavy in the upper tail the estimated distribution is defective and quantiles are only estimable on a sub-interval of (0,1). The Peng and Huang estimator can be viewed as a generalization of the Nelson Aalen estimator of the cumulative hazard function, and can be formulated as a variant of the conventional quantile regression dual problem. See Koenker (2008) for further details. This paper is available from the package with `vignette("crq")`.

**Value**

An object of class `crq`.

dither

Function to randomly perturb a vector

Description

With malice aforethought, dither adds a specified random perturbation to each element of the input vector, usually employed as a device to mitigate the effect of ties.

Usage

dither(x, type = "symmetric", value = NULL)

Arguments

x a numeric vector

type type is either 'symmetric' or 'right'

value value scale of dequantization

Details

The function dither operates slightly differently than the function jitter in base R, permitting strictly positive perturbations with the option type = "right" and using somewhat different default schemes for the scale of the perturbation. Dithering the response variable is frequently a useful option in quantile regression fitting to avoid deleterious effects of degenerate solutions. See, e.g. Machado and Santos Silva (2005). For a general introduction and some etymology see the Wikipedia article on "dither". For integer data it is usually advisable to use value = 1. When 'x' is a matrix or array dither treats all elements as a vector but returns an object of the original class.

Value

A dithered version of the input vector 'x'.

Note

Some further generality might be nice, for example something other than uniform noise would be desirable in some circumstances. Note that when dithering you are entering into the "state of sin" that John von Neumann famously attributed to anyone considering "arithmetical methods of producing random digits." If you need to preserve reproducibility, then set.seed is your friend.

dynrq  
**Dynamic Linear Quantile Regression**

Description
Interface to `rq.fit` and `rq.wfit` for fitting dynamic linear quantile regression models. The interface is based very closely on Achim Zeileis's `dynlm` package. In effect, this is mainly "syntactic sugar" for formula processing, but one should never underestimate the value of good, natural sweeteners.

Usage
```r
dynrq(formula, tau = 0.5, data, subset, weights, na.action, method = "br", contrasts = NULL, start = NULL, end = NULL, ...)
```

Arguments
- **formula**: a "formula" describing the linear model to be fit. For details see below and `rq`.
- **tau**: the quantile(s) to be estimated, may be vector valued, but all all values must be in (0,1).
- **data**: an optional "data.frame" or time series object (e.g., "ts" or "zoo"), containing the variables in the model. If not found in data, the variables are taken from environment(formula), typically the environment from which `rq` is called.
- **subset**: an optional vector specifying a subset of observations to be used in the fitting process.
- **weights**: an optional vector of weights to be used in the fitting process. If specified, weighted least squares is used with weights weights (that is, minimizing sum(w*e^2)); otherwise ordinary least squares is used.
- **na.action**: a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of `options`, and is `na.fail` if that is unset. The "factory-fresh" default is `na.omit`. Another possible value is `NULL`, no action. Note, that for time series regression special methods like `na.contiguous`, `na.locf` and `na.approx` are available.
method the method to be used; for fitting, by default method = "br" is used; method = "fn"
employment the interior point (Frisch-Newton) algorithm. The latter is advantageous for problems with sample sizes larger than about 5,000.
contrasts an optional list. See the contrasts.arg of model.matrix.default.
start start of the time period which should be used for fitting the model.
end end of the time period which should be used for fitting the model.
... additional arguments to be passed to the low level regression fitting functions.

Details

The interface and internals of dynrq are very similar to rq, but currently dynrq offers two advantages over the direct use of rq for time series applications of quantile regression: extended formula processing, and preservation of time series attributes. Both features have been shamelessly lifted from Achim Zeileis’s package “dynlm”.

For specifying the formula of the model to be fitted, there are several functions available which allow for convenient specification of dynamics (via d() and L()) or linear/cyclical patterns (via trend(), season(), and harmon()). These new formula functions require that their arguments are time series objects (i.e., “ts” or “zoo”).

Dynamic models: An example would be d(y) ~ L(y, 2), where d(x, k) is diff(x, lag = k) and L(x, k) is lag(x, lag = -k), note the difference in sign. The default for k is in both cases 1. For L(), it can also be vector-valued, e.g., y ~ L(y, 1:4).

Trends: y ~ trend(y) specifies a linear time trend where (1:n)/freq is used by default as the covariate, n is the number of observations and freq is the frequency of the series (if any, otherwise freq = 1). Alternatively, trend(y, scale = FALSE) would employ 1:n and time(y) would employ the original time index.

Seasonal/cyclical patterns: Seasonal patterns can be specified via season(x, ref = NULL) and harmonic patterns via harmon(x, order = 1). season(x, ref = NULL) creates a factor with levels for each cycle of the season. Using the ref argument, the reference level can be changed from the default first level to any other. harmon(x, order = 1) creates a matrix of regressors corresponding to cos(2 * o * pi * time(x)) and sin(2 * o * pi * time(x)) where o is chosen from 1:order.

See below for examples.

Another aim of dynrq is to preserve time series properties of the data. Explicit support is currently available for "ts" and "zoo" series. Internally, the data is kept as a "zoo" series and coerced back to "ts" if the original dependent variable was of that class (and no internal NAs were created by the na.action).

Tests of Location and Location Scale Shift Hypotheses for Linear Models

Description

Tests of the hypothesis that a linear model specification is of the location shift or location-scale shift form. The tests are based on the Doob-Meyer Martingale transformation approach proposed by Khmaladze(1981) for general goodness of fit problems, and adapted to quantile regression by Koenker and Xiao (2002).

Usage

KhmaladzeTest(formula, data = NULL, taus = -1, nullH = "location", trim = c(0.05, 0.95), ...)

Arguments

- formula: a formula specifying the model to fit by rqProcess
- data: a data frame within which to interpret the formula
- taus: An equally spaced grid of points on which to evaluate the quantile regression process, if any taus fall outside (0,1) then the full process is computed.
- nullH: a character vector indicating whether the "location" shift hypothesis (default) or the "location-scale" shift hypothesis should be tested.
- trim: a vector indicating the lower and upper bound of the quantiles to included in the computation of the test statistics (only, not estimates).
- ...: other arguments to be passed to summary.rq.

Value

an object of class KhmaladzeTest is returned containing:

- nullH: The form of the null hypothesis.
- Tn: Joint test statistic of the hypothesis that all the slope parameters of the model satisfy the hypothesis.
- THn: Vector of test statistics testing whether individual slope parameters satisfy the null hypothesis.

References

Examples

```r
data(barro)
KhaladzeTest( y.net ~ lgd02 + fse2 + gedy2 + l1y2 + gconi2,
  data = barro, taus = seq(.05,.95,by = .01))
```

---

**kuantile**

*Quicker Sample Quantiles*

Description

The function 'kuantile' computes sample quantiles corresponding to the specified probabilities. The intent is to mimic the generic (base) function 'quantile' but using a variant of the Floyd and Rivest (1975) algorithm which is somewhat quicker, especially for large sample sizes.

Usage

```r
kuantile(x, probs = seq(0, 1, .25), na.rm = FALSE, names = TRUE, type = 7, ...)
```

Arguments

- **x**: numeric vector whose sample quantiles are wanted.
- **probs**: numeric vector of probabilities with values in [0,1].
- **type**: an integer between 1 and 9 selecting one of the nine quantile algorithms detailed below to be used.
- **na.rm**: logical: if true, any ‘NA’ and ‘NaN’’s are removed from ‘x’ before the quantiles are computed.
- **names**: logical: if true, the result has a ‘names’ attribute.
- **...**: further arguments passed to or from other methods.

Details

A vector of length 'length(p)' is returned. See the documentation for 'quantile' for further details on the types. The algorithm was written by K.C. Kiwiel. It is a modified version of the (algol 68) SELECT procedure of Floyd and Rivest (1975), incorporating modifications of Brown(1976). The algorithm has linear growth in the number of comparisons required as sample size grows. For the median, average case behavior requires $1.5n + O((n\log n)^{1/2})$ comparisons. See Kiwiel (2005) and Knuth (1998) for further details. When the number of required elements of p is large, it may be preferable to revert to a full sort.

Value

A vector of quantiles of the same length as the vector p.

latex.table, latex.summary.rqs

latex.summary.rqs  
Make a latex table from a table of rq results

Description

Produces a file with latex commands for a table of rq results.

Usage

## S3 method for class 'summary.rqs'
latex(x, transpose = FALSE, caption = "caption goes here.",
digits = 3, file = as.character(substitute(x)), ...)

Arguments

x        x is an object of class summary.rqs

transpose if TRUE transpose table so that rows are quantiles and columns are covariates.

caption   caption for the table

digits    decimal precision of table entries.

file      name of file

...      optional arguments for latex.table

Details

Calls latex.table.

Value

Returns invisibly after writing the file.

summary.rqs, latex.table
**latex.table**

*W*rites a latex formatted table to a *file*

---

**Description**

Automatically generates a latex formatted table from the matrix `x`. Controls rounding, alignment, etc, etc.

**Usage**

```r
## S3 method for class 'table'
l latex(x, file=as.character(substitute(x)),
rowlabel=file, rowlabel.just="l", cgroup, n.cgroup, rgroup, n.rgroup=NULL,
digits, dec, rdec, cdec, append=FALSE, dcolumn=FALSE, cdot=FALSE,
longtable=FALSE, table.env=TRUE, lines.page=40, caption, caption.lot,
label=file, double.slash=FALSE,...)
```

**Arguments**

- `x` A matrix `x` with dimnames
- `file` Name of output file (.tex will be added)
- `rowlabel` If `x` has row dimnames, `rowlabel` is a character string containing the column heading for the row dimnames. The default is the name of the argument for `x`.
- `rowlabel.just` If `x` has row dimnames, specifies the justification for printing them. Possible values are "l", "r", "c". The heading (`rowlabel`) itself is left justified if `rowlabel.just="l"`, otherwise it is centered.
- `cgroup` a vector of character strings defining major column headings. The default is to have none.
- `n.cgroup` a vector containing the number of columns for which each element in `cgroup` is a heading. For example, specify `cgroup=c("Major 1","Major 2")`, `n.cgroup=c(3,3)` if "Major 1" is to span columns 1-3 and "Major 2" is to span columns 4-6. ‘rowlabel’ does not count in the column numbers. You can omit ‘n.cgroup’ if all groups have the same number of columns.
- `rgroup` a vector of character strings containing headings for row groups. ‘n.rgroup’ must be present when ‘rgroup’ is given. The first ‘n.rgroup[1]’ rows are sectioned off and ‘rgroup[1]’ is used as a bold heading for them. The usual row dimnames (which must be present if ‘rgroup’ is) are indented. The next ‘n.rgroup[2]’ rows are treated likewise, etc.
- `n.rgroup` integer vector giving the number of rows in each grouping. If ‘rgroup’ is not specified, ‘n.rgroup’ is just used to divide off blocks of rows by horizontal lines. If ‘rgroup’ is given but ‘n.rgroup’ is omitted, ‘n.rgroup’ will default so that each row group contains the same number of rows.
- `digits` causes all values in the table to be formatted to ‘digits’ significant digits. ‘dec’ is usually preferred.
If `dec` is a scalar, all elements of the matrix will be rounded to `dec` decimal places to the right of the decimal. `dec` can also be a matrix whose elements correspond to `x`, for customized rounding of each element.

`rdec` a vector specifying the number of decimal places to the right for each row (`cdec` is more commonly used than `rdec`)

`cdec` a vector specifying the number of decimal places for each column

`append` defaults to `F`. Set to `T` to append output to an existing file.

`dcolumn` Set to `T` to use David Carlisles `dcolumn` style for decimal alignment. Default is `F`, which aligns columns of numbers by changing leading blanks to `\~`, the LaTeX space-holder. You will probably want to use `dcolumn` if you use `rdec`, as a column may then contain varying number of places to the right of the decimal. `dcolumn` can line up all such numbers on the decimal point, with integer values right-justified at the decimal point location of numbers that actually contain decimal places.

`cdot` Set to `T` to use centered dots rather than ordinary periods in numbers.

`longtable` Set to `T` to use David Carlisles LaTeX `longtable` style, allowing long tables to be split over multiple pages with headers repeated on each page.

`table.env` Set `table.env=FALSE` to suppress enclosing the table in a LaTeX `table` environment. `table.env` only applies when `longtable=FALSE`. You may not specify a `caption` if `table.env=FALSE`.

`lines.page` Applies if `longtable=TRUE`. No more than `lines.page` lines in the body of a table will be placed on a single page. Page breaks will only occur at `rgroup` boundaries.

`caption` a text string to use as a caption to print at the top of the first page of the table. Default is no caption.

`caption.lot` a text string representing a short caption to be used in the "List of Tables". By default, LaTeX will use `caption`.

`label` a text string representing a symbolic label for the table for referencing with the LaTeX `\ref{label}` command. The default is `file`. `label` is only used if `caption` is given.

`doubleslash` set to `T` to output `\` as `\\` in LaTeX commands. Useful when you are reading the output file back into an S vector for later output.

... other optional arguments

**Value**
returns invisibly

lm.fit.recursive

Recursive Least Squares

Description

This function fits a linear model by recursive least squares. It is a utility routine for the \texttt{khmaladzize} function of the quantile regression package.

Usage

\texttt{lm.fit.recursive(X, y, int=TRUE)}

Arguments

- \(x\): Design Matrix
- \(y\): Response Variable
- \(int\): if TRUE then append intercept to \(X\)

Value

return \(p \times n\) matrix of fitted parameters, where \(p\). The \(i\)th column gives the solution up to "time" \(i\).

\texttt{khmaladzize}

lprq

locally polynomial quantile regression

Description

This is a toy function to illustrate how to do locally polynomial quantile regression univariate smoothing.

Usage

\texttt{lprq(x, y, h, tau = .5, m = 50)}
Arguments

- **x**: The conditioning covariate
- **y**: The response variable
- **h**: The bandwidth parameter
- **tau**: The quantile to be estimated
- **m**: The number of points at which the function is to be estimated

Details

The function obviously only does locally linear fitting but can be easily adapted to locally polynomial fitting of higher order. The author doesn’t really approve of this sort of smoothing, being more of a spline person, so the code is left is its (almost) most trivial form.

Value

The function compute a locally weighted linear quantile regression fit at each of the m design points, and returns:

- **xx**: The design points at which the evaluation occurs
- **fv**: The estimated function values at these design points
- **dev**: The estimated first derivative values at the design points

Note

One can also consider using B-spline expansions see bs.

```
Mammals

Garland (1983) Data on Running Speed of Mammals

Description

Observations on the maximal running speed of mammal species and their body mass.

Usage

data(Mammals)

Format

A data frame with 107 observations on the following 4 variables.

- **weight**: Body mass in Kg for "typical adult sizes"
- **speed**: Maximal running speed (fastest sprint velocity on record)
- **hoppers**: logical variable indicating animals that ambulate by hopping, e.g. kangaroos
- **specials**: logical variable indicating special animals with "lifestyles in which speed does not figure as an important factor": Hippopotamus, raccoon (Procyon), badger (Meles), coati (Nasua), skunk (Mephitis), man (Homo), porcupine (Erithizon), oppossum (didelphis), and sloth (Bradypus)

Details

Used by Chappell (1989) and Koenker, Ng and Portnoy (1994) to illustrate the fitting of piecewise linear curves.

```

**nlrq**  
*Function to compute nonlinear quantile regression estimates*

Description

This function implements an R version of an interior point method for computing the solution to quantile regression problems which are nonlinear in the parameters. The algorithm is based on interior point ideas described in Koenker and Park (1994).

Usage

```
nlrq(formula, data=parent.frame(), start, tau=0.5, 
control, trace=FALSE, method="L-BFGS-B")
```

```
## S3 method for class 'nlrq'
summary(object, ...)
```

```
## S3 method for class 'summary.nlrq'
print(x, digits = max(5, .Options$digits - 2), ...)
```

Arguments

- `formula`: formula for model in nls format; accept self-starting models
- `data`: an optional data frame in which to evaluate the variables in ‘formula’
- `start`: a named list or named numeric vector of starting estimates
- `tau`: a vector of quantiles to be estimated
- `control`: an optional list of control settings. See ‘nlrq.control’ for the names of the settable control values and their effect.
- `trace`: logical value indicating if a trace of the iteration progress should be printed. Default is ‘FALSE’. If ‘TRUE’ intermediary results are printed at the end of each iteration.
- `method`: method passed to optim for line search, default is "L-BFGS-B" but for some problems "BFGS" may be preferable. See `optim` for further details. Note that the algorithm wants to pass upper and lower bounds for the line search to `optim`, which is fine for the L-BFGS-B method. Use of other methods will produce warnings about these arguments – so users should proceed at their own risk.
object an object of class nlrq needing summary.
x an object of class summary.nlrq needing printing.
digits Significant digits reported in the printed table.
... Optional arguments passed to printing function.

Details
An ‘nlrq’ object is a type of fitted model object. It has methods for the generic functions ‘coef’ (parameters estimation at best solution), ‘formula’ (model used), ‘deviance’ (value of the objective function at best solution), ‘print’, ‘summary’, ‘fitted’ (vector of fitted variable according to the model), ‘predict’ (vector of data points predicted by the model, using a different matrix for the independent variables) and also for the function ‘tau’ (quantile used for fitting the model, as the tau argument of the function). Further help is also available for the method ‘residuals’. The summary method for nlrq uses a bootstrap approach based on the final linearization of the model evaluated at the estimated parameters.

Value
A list consisting of:

m an ‘nlrqModel’ object similar to an ‘nlsModel’ in package nls
data the expression that was passed to ‘nlrq’ as the data argument. The actual data values are present in the environment of the ‘m’ component.

Author(s)
Based on S code by Roger Koenker modified for R and to accept models as specified by nls by Philippe Grosjean.

Examples

# build artificial data with multiplicative error
Dat <- NULL; Dat$x <- rep(1:25, 20)
set.seed(1)
Dat$y <- SSlogis(Dat$x, 10, 12, 2)*rnorm(500, 1, 0.1)
plot(Dat)
# fit first a nonlinear least-square regression
Dat.nls <- nls(y ~ SSlogis(x, Asym, mid, scal), data=Dat); Dat.nls
lines(1:25, predict(Dat.nls, newdata=list(x=1:25)), col=1)
# then fit the median using nlrq
Dat.nlrq <- nlrq(y ~ SSlogis(x, Asym, mid, scal), data=Dat, tau=0.5, trace=TRUE)
nlrq.control

Set control parameters for nlrq

Description

Set algorithmic parameters for nlrq (nonlinear quantile regression function)

Usage

nlrq.control(maxiter=100, k=2, InitialStepSize = 1, big=1e+20, eps=1e-07, beta=0.97)

Arguments

- maxiter: maximum number of allowed iterations
- k: the number of iterations of the Meketon algorithm to be calculated in each step, usually 2 is reasonable, occasionally it may be helpful to set k=1
- InitialStepSize: Starting value in optim to determine the step length of iterations. The default value of 1 is sometimes too optimistic. In such cases, the value 0 forces optim to just barely stick its toe in the water.
- big: a large scalar
- eps: tolerance for convergence of the algorithm
- beta: a shrinkage parameter which controls the recentering process in the interior point algorithm.

nlrq
C.S. Peirce’s Auditory Response Data

Description

Data from sequence experiments conducted by C.S. Pierce in 1872 to determine the distribution of response times to an auditory stimulus.

Usage

data(Peirce)

Format

A link{list} of 24 objects each representing one day of the experiment. Each element of the list consists of three components: the date the measurements were made, an x component recording the response time in milliseconds, and an associated y component recording a count of the number of times that the response was recorded to be equal to the corresponding x entry. There are roughly 500 observations (counts) on each of the 24 days.

Details

A detailed description of the experiment can be found in Peirce (1873). A young man of about 18 with no prior experience was employed to respond to a signal “consisting of a sharp sound like a rap, the answer being made upon a telegraph-operator’s key nicely adjusted.” The response times, made with the aid of a Hipp cronoscope were recorded to the nearest millisecond. The data was analyzed by Peirce who concluded that after the first day, when the observer was entirely inexperienced, the curves representing the densities of the response times “differed very little from that derived from the theory of least squares,” i.e. from the Gaussian density.

The data was subsequently analysed by Samama, in a diploma thesis supervised by Maurice Frechet, who reported briefly the findings in Frechet (1924), and by Wilson and Hilferty (1929). In both instances the reanalysis showed that Laplace’s first law of error, the double exponential distribution, was a better representation for the data than was the Gaussian law. Koenker (2009) contains further discussion and an attempt to reproduce the Wilson and Hilferty analysis.

The data is available in two formats: The first in a “raw” form as 24 text files as scanned from the reprinted Peirce source, the second as an R dataset Peirce.rda containing the list. Only the latter is provided here, for the raw data and how to read see the more complete archive at: http://www.econ.uiuc.edu/~roger/research/frechet/frechet.html. See the examples section below for some details on provisional attempt to reproduce part of the Wilson and Hilferty analysis. An open question regarding the dataset is: How did Wilson and Hilferty compute standard deviations for the median as they appear in their table? The standard textbook suggestion of Yule (1917) yields far too small a bandwidth. The methods employed in the example section below, which rely on relatively recent proposals, are somewhat closer, but still deviate somewhat from the results reported by Wilson and Hilferty.

}
```

**plot.rq**  
plot the coordinates of the quantile regression process
plot.rqs

Description

Function to plot quantile regression process.

Usage

## S3 method for class 'rq.process'
plot(x, nrow=3, ncol=2, ...)

Arguments

x an object produced by rq() fitting
nrow rows in mfrow
ncol columns in mfrow
... optional arguments to plot

Author(s)

Roger Koenker rkoenker@uiuc.edu

See Also

rq

plot.rqs  Visualizing sequences of quantile regressions

Description

A sequence of coefficient estimates for quantile regressions with varying tau parameters is visualized.

Usage

## S3 method for class 'rqs'
plot(x, parm = NULL, ols = TRUE,
     mfrow = NULL, mar = NULL, ylim = NULL, main = NULL, col = 1:2, lty = 1:2,
     cex = 0.5, pch = 20, type = "b", xlab = "", ylab = "", ...
)

Arguments

x an object of class "rqs" as produce by rq (with a vector of tau values).
parm a specification of which parameters are to be plotted, either a vector of numbers or a vector of names. By default, all parameters are considered.
ols logical. Should a line for the OLS coefficient (as estimated by lm) be added?
mfrow, mar, ylim, main
    graphical parameters. Suitable defaults are chosen based on the coefficients to be visualized.

col, lty
    graphical parameters. For each parameter, the first element corresponds to the \rq\ coefficients and the second to the \lm\ coefficients.

cex, pch, type, xlab, ylab, ...
    further graphical parameters passed to \texttt{plot}.

## Details

The \texttt{plot} method for \"rqs\" objects visualizes the coefficients only, confidence bands can be added by using the \texttt{plot} method for the associated \"summary.rqs\" object.

## Value

A matrix with all coefficients visualized is returned invisibly.

## See Also

\texttt{rq, plot.summary.rqs}

## Examples

```r
## fit Engel models (in levels) for \texttt{tau} = 0.1, ..., 0.9
data("engel")
fm <- rq(foodexp ~ income, data = engel, tau = 1:9/10)

## visualizations
plot(fm)
plot(fm, parm = 2, mar = c(5.1, 4.1, 2.1, 2.1), main = ", xlab = "tau",
ylab = "income coefficient", cex = 1, pch = 19)
```

---

**plot.rqss**  
*Plot Method for rqss Objects*

## Description

Takes a fitted \texttt{rqss} object produced by \texttt{rqss()} and plots the component smooth functions that make up the ANOVA decomposition. Since the components "omit the intercept" the estimated intercept is added back in – this facilitates the comparison of quantile fits particularly. For models with a partial linear component or several \texttt{qss} components it may be preferable to plot the output of \texttt{predict.rqss}. Note that these functions are intended to plot \texttt{rqss} objects only, attempting to plot \texttt{summary.rqss} objects just generates a warning message.
plot.rqss

Usage

## S3 method for class 'rqss'
plot(x, rug = TRUE, jit = TRUE, bands = NULL, coverage = 0.95,
     add = FALSE, shade = TRUE, select = NULL, pages = 0, titles = NULL,
     bcol = NULL, ...)  
## S3 method for class 'qss1'
plot(x, rug = TRUE, jit = TRUE, add = FALSE, ...)  
## S3 method for class 'qss2'
plot(x, render = "contour", ncol = 100, zcol = NULL, ...)  
## S3 method for class 'summary.rqss'
plot(x, ...)  

Arguments

x  a fitted rqss object produced by rqss().  
...  additional arguments for the plotting algorithm  
rug  if TRUE, a rugplot for the x-coordinate is plotted  
jit  if TRUE, the x-values of the rug plot are jittered  
bands  if TRUE, confidence bands for the smoothed effects are plotted, if "uniform" then uniform bands are plotted, if "both" then both the uniform and the pointwise bands are plotted.  
coverage  desired coverage probability of confidence bands, if requested  
select  vector of indices of qss objects to be plotted, by default all  
pages  number of pages desired for the plots  
render  a character specifying the rendering for bivariate fits; either "contour" (default) or "rgl". The latter requires package rgl.  
add  if TRUE then add qss curve to existing (usually) scatterplot, otherwise initiate a new plot  
shade  if TRUE then shade the confidence band  
titles  title(s) as vector of character strings, by default titles are chosen for each plot as "Effect of CovariateName"  
bcol  vector of two colors for confidence bands  
ncol, zcol  Only for render = "rgl": number of colors and z values for color construction.

Details

If bands == "uniform" then the bands are uniform bands based on the Hotelling (1939) tube approach. See also Naiman (1986), Johansen and Johnstone (1990), Sun and Loader (1994), and Krivobokova, Kneib, and Claeskens (2009), in particular the computation of the "tube length" is based on the last of these references. If bands is non null, and not "uniform" then pointwise bands are returned. Since bands for bivariate components are not (yet) supported, if requested such components will be returned as NULL.
Value

The function produces plots for the ANOVA components as a side effect. For "qss1" the "add = TRUE" can be used to overplot the fit on a scatterplot. When there are multiple pages required "par (ask = TRUE)" is turned on so that the plots may be examined sequentially. If bands != NULL then a list with three components for each qss component is returned (invisibly):

- **x**: The x coordinates of the confidence bands
- **b1o**: The y coordinates of the lower confidence curve, if bands = "both" then this is a matrix with two columns
- **bhi**: The y coordinates of the upper confidence curve, if bands = "both" then this is a matrix with two columns

rqss

Examples

```r
n <- 200
x <- sort(rchisq(n,4))
z <- x + rnorm(n)
y <- log(x)+ .1*(log(x))^2 + log(x)*rnorm(n)/4 + z
plot(x,y-z)
fn <- rqss(y~qss(x,constraint="N")+z)
plot(fn)
fI <- rqss(y~qss(x,constraint="I")+z)
plot(fI, col="blue")
fCI <- rqss(y~qss(x,constraint="CI")+z)
plot(fCI, col="red")
```
## Description

A sequence of coefficient estimates for quantile regressions with varying \( \tau \) parameters is visualized along with associated confidence bands.

## Usage

```r
## S3 method for class 'summary.rqs'

plot(x, parm = NULL, level = 0.9, ols = TRUE, 
    mfrow = NULL, mar = NULL, ylim = NULL, main = NULL, 
    col = gray(c(0, 0.75)), border = NULL, lcol = 2, lty = 1:2, 
    cex = 0.5, pch = 20, type = "b", xlab = "", ylab = "", ...) 
```

## Arguments

- **x**: an object of class "summary.rqs" as produce by applying the `summary` method to a `rq` object (with a vector of \( \tau \) values).
- **parm**: a specification of which parameters are to be plotted, either a vector of numbers or a vector of names. By default, all parameters are considered.
- **level**: Confidence level of bands. When using the rank based confidence intervals in `summary`, which is the default method for sample sizes under 1000, you will need to control the level of the intervals by passing the parameter `alpha` to `summary.rq`, prior to calling `plot.summary.rqs`. Note also that `alpha = 1 - level`.
- **ols**: logical. Should a line for the OLS coefficient and their confidence bands (as estimated by `lm`) be added?
- **mfrow, mar, ylim, main**: graphical parameters. Suitable defaults are chosen based on the coefficients to be visualized.
- **col**: vector of color specification for `rq` coefficients and the associated confidence polygon.
- **border**: color specification for the confidence polygon. By default, the second element of `col` is used.
- **lcol, lty**: color and line type specification for OLS coefficients and their confidence bounds.
- **cex, pch, type, xlab, ylab, ...**: further graphical parameters passed to `points`.

```r
## A bivariate example

data(CobarOre)

fCO <- rqss(z-qss(cbind(x,y),lambda=.08), data = CobarOre)

plot(fCO)
```
Details

The `plot` method for "summary.rq" objects visualizes the coefficients along with their confidence bands. The bands can be omitted by using the `plot` method for "rq" objects directly.

Value

An array with all coefficients visualized (and associated confidence bands) is returned invisibly.

See Also

`rq`, `plot.rqs`

Examples

```r
## fit Engel models (in levels) for tau = 0.1, ..., 0.9
data("engel")
fm <- rq(foodexp ~ income, data = engel, tau = 1:9/10)
sfm <- summary(fm)

## visualizations
plot(sfm)
plot(sfm, parm = 2, mar = c(5.1, 4.1, 2.1, 2.1), main = "", xlab = "tau",
    ylab = "income coefficient", cex = 1, pch = 19)
```

---

**predict.rq**

Quantile Regression Prediction

Description

Prediction based on fitted quantile regression model

Usage

```r
## S3 method for class 'rq'
predict(object, newdata, type = "none", interval = c("none", "confidence"),
    level = .95, na.action = na.pass, ...)
## S3 method for class 'rqs'
predict(object, newdata, type = "Qhat", stepfun = FALSE, na.action = na.pass, ...)
## S3 method for class 'rq.process'
predict(object, newdata, type = "Qhat", stepfun = FALSE, na.action = na.pass, ...)
```

Arguments

- **object**: object of class rq or rqs or rq.process produced by rq
- **newdata**: An optional data frame in which to look for variables with which to predict. If omitted, the fitted values are used.
predict.rq

interval type of interval desired: default is 'none', when set to 'confidence' the function returns a matrix predictions with point predictions for each of the 'newdata' points as well as lower and upper confidence limits.

level

converage probability for the 'confidence' intervals.

type

For predict.rq, the method for 'confidence' intervals, if desired. If 'percentile' then one of the bootstrap methods is used to generate percentile intervals for each prediction, if 'direct' then a version of the Portnoy and Zhou (1998) method is used, and otherwise an estimated covariance matrix for the parameter estimates is used. Further arguments to determine the choice of bootstrap method or covariance matrix estimate can be passed via the ... argument. For predict.rqs and predict.rq.process when stepfun = TRUE, type is "Qhat", "Fhat" or "fhat" depending on whether the user would like to have estimates of the conditional quantile, distribution or density functions respectively. As noted below the two former estimates can be monotonized with the function rearrange. When the "fhat" option is invoked, a list of conditional density functions is returned based on Silverman’s adaptive kernel method as implemented in akj and approxfun.

stepfun

If 'TRUE' return stepfunctions otherwise return matrix of predictions. these functions can be estimates of either the conditional quantile or distribution functions depending upon the type argument. When stepfun = FALSE a matrix of point estimates of the conditional quantile function at the points specified by the newdata argument.

na.action

function determining what should be done with missing values in 'newdata'. The default is to predict 'NA'.

...

Further arguments passed to or from other methods.

Details

Produces predicted values, obtained by evaluating the quantile regression function in the frame 'newdata' (which defaults to 'model.frame(object)'). These predictions purport to estimate the conditional quantile function of the response variable of the fitted model evaluated at the covariate values specified in "newdata" and the quantile(s) specified by the "tau" argument. Several methods are provided to compute confidence intervals for these predictions.

Value

A vector or matrix of predictions, depending upon the setting of 'interval'. In the case that there are multiple taus in object when object is of class 'rqs' setting 'stepfun = TRUE' will produce a stepfun object or a list of stepfun objects. The function rearrange can be used to monotonize these step-functions, if desired.

predict.rqss  
Predict from fitted nonparametric quantile regression smoothing spline models

Description

Additive models for nonparametric quantile regression using total variation penalty methods can be fit with the rqss function. Univarariate and bivariate components can be predicted using these functions.

Usage

## S3 method for class 'rqss'
predict(object, newdata, interval = "none", level = 0.95, ...)
## S3 method for class 'qss1'
predict(object, newdata, ...)
## S3 method for class 'qss2'
predict(object, newdata, ...)

Arguments

object  
is a fitted object produced by rqss
newdata  
a data frame describing the observations at which prediction is to be made. For qss components, newdata should lie in strictly within the convex hull of the fitting data. Newdata corresponding to the partially linear component of the model may require caution concerning the treatment of factor levels, if any.
interval If set to confidence then a level confidence interval for the predictions is returned.
level intended coverage probability for the confidence intervals
... optional arguments

Details

For both univariate and bivariate prediction linear interpolation is done. In the bivariate case, this involves computing barycentric coordinates of the new points relative to their enclosing triangles. It may be of interest to plot individual components of fitted rqss models: this is usually best done by fixing the values of other covariates at reference values typical of the sample data and predicting the response at varying values of one qss term at a time. Direct use of the predict.rqss1 and predict.rqss2 functions is discouraged since it usually corresponds to predicted values at absurd reference values of the other covariates, i.e. zero.

Value

A vector of predictions, or in the case that interval = "confidence") a matrix whose first column is the vector of predictions and whose second and third columns are the lower and upper confidence limits for each prediction.

print.rq

Print an rq object

Description
Print an object generated by rq

Usage
## S3 method for class 'rq'
print(x, ...)
## S3 method for class 'rqs'
print(x, ...)

Arguments
x Object returned from rq representing the fit of the model.

See Also
rq

print.summary.rq

Print Quantile Regression Summary Object

Description
Print summary of quantile regression object
Usage

```r
## S3 method for class 'summary.rq'
print(x, digits=max(5, .Options$digits - 2), ...)
## S3 method for class 'summary.rqs'
print(x, ...)
```

Arguments

- `x` This is an object of class "summary.rq" produced by a call to `summary.rq()`.
- `digits` Significant digits reported in the printed table.
- `...` Optional arguments passed to printing function

See Also

`summary.rq`

qrisk

*Function to compute Choquet portfolio weights*

Description

This function solves a weighted quantile regression problem to find the optimal portfolio weights minimizing a Choquet risk criterion described in Bassett, Koenker, and Kordas (2002).

Usage

```r
qrisk(x, alpha = c(0.1, 0.3), w = c(0.7, 0.3), mu = 0.07,
      R = NULL, r = NULL, lambda = 10000)
```

Arguments

- `x` n by q matrix of historical or simulated asset returns
- `alpha` vector of alphas receiving positive weights in the Choquet criterion
- `w` weights associated with alpha in the Choquet criterion
- `mu` targeted rate of return for the portfolio
- `R` matrix of constraints on the parameters of the quantile regression, see below
- `r` rhs vector of the constraints described by R
- `lambda` Lagrange multiplier associated with the constraints

Details

The function calls `rq.fit.hogg` which in turn calls the constrained Frisch Newton algorithm. The constraints `Rh` are intended to apply only to the slope parameters, not the intercept parameters. The user is completely responsible to specify constraints that are consistent, i.e., that have at least one feasible point. See examples for imposing non-negative portfolio weights.
**Value**

- pihat: the optimal portfolio weights
- muhat: the in-sample mean return of the optimal portfolio
- qrisk: the in-sample Choquet risk of the optimal portfolio

  x3 <- (x3-mean(x3))/sqrt(var(x3))}
```
Additive Nonparametric Terms for rqss Fitting

Description

In the formula specification of rqss nonparametric terms are specified with qss. Both univariate and bivariate specifications are possible, and qualitative constraints may also be specified for the qss terms.

Usage

qss(x, constraint = "N", lambda = 1, ndum = 0, dummies = NULL, w = rep(1, length(x)))

Arguments

- **x**: The covariate determining the nonparametric component, if x is a matrix with two columns then the qss function will construct a penalized triogram term.
- **lambda**: The smoothing parameter governing the tradeoff between fidelity and the penalty component for this term. Larger lambdas produce smoother fits. In future versions there should be an automatic mechanism for default choice of the lambdas. For now, this is the responsibility of the user.
- **constraint**: Optional specification of qualitative constraints on the fitted univariate qss functions, take the values: "N","I","D","V","C","VI","VD","CI","CD" for none, increasing, decreasing, convex, concave, convex and increasing, etc. And for bivariate qss components can take the values "N","V","C" for none, convex, and concave. Note that confidence bands for constrained fits of this sort, while available from plot.rqss as of yet lack a formal justification.
- **ndum**: number of dummy vertices: this is only relevant for qss2 terms. In addition to vertices at the observed (x,y) points ndum dummy vertices are generated – distributed uniformly over the rectangle given by the Cartesian product of the ranges of x and y – observations that fall in the convex hull of the observations are retained. So the actual number of dummy vertices used is smaller than ndum. The values of these vertices are returned in the list dummies, so that they can be reused.
dummies  list of dummy vertices as generated, for example by triogram.fidelity when ndum > 0. Should be a list with x and y components. These points should lie inside the convex hull of the real xy points, but no explicit checking of this assertion is currently done.

w  weights not yet unimplemented

Details

The various pieces returned are stored in sparse matrix.csr form. See rqss for details on how they are assembled. To preserve the sparsity of the design matrix the first column of each qss term is dropped. This differs from the usual convention that would have forced qss terms to have mean zero. This convention has implications for prediction that need to be recognized. The penalty components for qss terms are based on total variation penalization of the first derivative (and gradient, for bivariate x) as described in the references appearing in the help for rqss.

For the bivariate case, package tripack (and for plotting also akima) are required (automatically, by the R code).

Value

F  Fidelity component of the design matrix
dummies List of dummy vertices
A  Penalty component of the design matrix
r  Constraint component of the design matrix
r  Constraint component of the rhs

QTECox  Function to obtain QTE from a Cox model

Description

Computes quantile treatment effects comparable to those of crq model from a coxph object.

Usage

QTECox(x, smooth = TRUE)
Arguments

x An object of class coxph produced by coxph.
smooth Logical indicator if TRUE (default) then Cox survival function is smoothed.

Details

Estimates of the Cox QTE, $\frac{dQ(t|x)}{dx_j}$ at $x = \bar{x}$, can be expressed as a function of $t$ as follows:

$$\frac{dQ(t|x)}{dx_j} = \frac{dt}{dx_j} \frac{dQ(t|x)}{dt}$$

The Cox survival function, $S(y|x) = \exp\{-H_0(y) \exp(b'x)\}$

$$\frac{dS(y|x)}{dx_j} = S(y|x)\log\{S(y|x)\}b_j$$

where $\frac{dQ(t|x)}{dx_j}$ can be estimated by $\frac{\Delta(t)}{\Delta(S)}(1 - t)$ where $SS$ and $S$ denote the surv and time components of the survfit object. Note that since $t = 1 - S(y|x)$, the above is the value corresponding to the argument $(1-t)S$; and furthermore

$$\frac{dt}{dx_j} = -\frac{dS(y|x)}{dx_j} = -(1 - t)\log(1 - t)b_j$$

Thus the QTE at the mean of $x$’s is:

$$(1 - S) = \frac{\Delta(t)}{\Delta(S)} S \log(S)b_j$$

Since $\Delta S$ is negative and $\log(S)$ is also negative this has the same sign as $b_j$ The crq model fits the usual AFT form Surv(log(Time),Status), then

$$\frac{d\log(Q(t|x))}{dx_j} = \frac{dQ(t|x)}{dx_j} / Q(t|x)$$

This is the matrix form returned.

Value

taus points of evaluation of the QTE.
QTE matrix of QTEs, the ith column contains the QTE for the ith covariate effect.
Note that there is no intercept effect. see plot.summary.crq$ for usage.

ranks

Quantile Regression Ranks

Description

Function to compute ranks from the dual (regression rankscore) process.

Usage

ranks(v, score="wilcoxon", tau=0.5, trim = NULL)

Arguments

v

object of class "rq.process" generated by rq()

score

The score function desired. Currently implemented score functions are "wilcoxon", "normal", and "sign" which are asymptotically optimal for the logistic, Gaussian and Laplace location shift models respectively. The "normal" score function is also sometimes called van der Waerden scores. Also implemented are the "tau" which generalizes sign scores to an arbitrary quantile, "interquartile" which is appropriate for tests of scale shift, normalscale for Gaussian scale shift, halfnormalscale for Gaussian scale shift only to the right of the median, and lehmann for Lehmann local alternatives. See Koenker (2010) for further details on the last three of these scores.

tau

the optional value of tau if the "tau" score function is used.

trim

optional trimming proportion parameter(s) – only applicable for the Wilcoxon score function – when one value is provided there is symmetric trimming of the score integral to the interval (trim, 1-trim), when there are two values provided, then the trimming restricts the integration to (trim[1], trim[2]).

Details

See GJKP(1993) for further details.

Value

The function returns two components. One is the ranks, the other is a scale factor which is the $L_2$ norm of the score function. All score functions should be normalized to have mean zero.

rearrange  Rearrangement

Description

Monotonize a step function by rearrangement

Usage

rearrange(f,xmin,xmax)

Arguments

f          object of class stepfun
xmin       minimum of the support of the rearranged f
xmax       maximum of the support of the rearranged f

Details

Given a stepfunction \( Q(u) \), not necessarily monotone, let \( F(y) = \int \{ Q(u) \leq y \} du \) denote the associated cdf obtained by randomly evaluating \( Q \) at \( U \sim U[0,1] \). The rearranged version of \( Q \) is \( \tilde{Q}(u) = \inf \{ u : F(y) \geq u \} \). The rearranged function inherits the right or left continuity of original step function.

Value

Produces transformed stepfunction that is monotonic increasing.

Author(s)

R. Koenker
residuals.nlmq

Return residuals of an nlrq object

Description
Set algorithmic parameters for nlrq (nonlinear quantile regression function)

Usage
## S3 method for class 'nlrq'
residuals(object, type = c("response", "rho"), ...)

Arguments
object an 'nlrq' object as returned by function 'nlrq'
type the type of residuals to return: "response" is the distance between observed and predicted values; "rho" is the weighted distance used to calculate the objective function in the minimisation algorithm as tau * pmax(resid, 0) + (1 - tau) * pmin(resid, 0), where resid are the simple residuals as above (with type="response").
...
... further arguments passed to or from other methods.

plot(zp, do.points = FALSE, xlab = expression(tau), ylab = expression(Q(tau)), main = "Engel Food Expenditure Quantiles")
plot(rearrange(zp), do.points = FALSE, add = TRUE, col.h = "red", col.v = "red")
legend(.6, 3.3, c("Before Rearrangement", "After Rearrangement"), lty = 1, col = c("black", "red"))
Description

Returns an object of class "rq" "rq$s" or "rq.process" that represents a quantile regression fit.

Usage

rq(formula, tau=.5, data, subset, weights, na.action,  
    method="br", model = TRUE, contrasts, ...)

Arguments

formula  
a formula object, with the response on the left of a ~ operator, and the terms,  
separated by + operators, on the right.

tau  
the quantile(s) to be estimated, this is generally a number strictly between 0 and 1, but if specified strictly outside this range, it is presumed that the solutions for all values of tau in (0,1) are desired. In the former case an object of class "rq" is returned, in the latter, an object of class "rq.process" is returned. As of version 3.50, tau can also be a vector of values between 0 and 1; in this case an object of class "rq$s" is returned containing among other things a matrix of coefficient estimates at the specified quantiles.

data  
a data.frame in which to interpret the variables named in the formula, or in the subset and the weights argument. If this is missing, then the variables in the formula should be on the search list. This may also be a single number to handle some special cases – see below for details.

subset  
an optional vector specifying a subset of observations to be used in the fitting process.

weights  
vector of observation weights; if supplied, the algorithm fits to minimize the sum of the weights multiplied into the absolute residuals. The length of weights must be the same as the number of observations. The weights must be nonnegative and it is strongly recommended that they be strictly positive, since zero weights are ambiguous.

na.action  
a function to filter missing data. This is applied to the model.frame after any subset argument has been used. The default (with na.fail) is to create an error if any missing values are found. A possible alternative is na.omit, which deletes observations that contain one or more missing values.

model  
if TRUE then the model frame is returned. This is essential if one wants to call summary subsequently.

method  
the algorithmic method used to compute the fit. There are several options: The default method is the modified version of the Barrodale and Roberts algorithm for $l_1$-regression, used by l1fit in S, and is described in detail in Koenker and d’Orey(1987, 1994), default = "br". This is quite efficient for problems up to several thousand observations, and may be used to compute the full quantile
regression process. It also implements a scheme for computing confidence intervals for the estimated parameters, based on inversion of a rank test described in Koenker (1994). For larger problems it is advantageous to use the Frisch–Newton interior point method "fn". And for very large problems one can use the Frisch–Newton approach after preprocessing "pfn". Both of the latter methods are described in detail in Portnoy and Koenker (1997), this method is primarily well-suited for large n, small p problems where the parametric dimension of the model is modest. For large problems with large parametric dimension it is usually advantageous to use method "sfn" which uses the Frisch-Newton algorithm, but exploits sparse algebra to compute iterates. This is typically helpful when the model includes factor variables that, when expanded, generate design matrices that are very sparse. A sixth option "fnc" that enables the user to specify linear inequality constraints on the fitted coefficients; in this case one needs to specify the matrix R and the vector r representing the constraints in the form \( Rb \geq r \). See the examples. Finally, there are two penalized methods: "lasso" and "scad" that implement the lasso penalty and Fan and Li's smoothly clipped absolute deviation penalty, respectively. These methods should probably be regarded as experimental.

**contrasts**

a list giving contrasts for some or all of the factors default = NULL appearing in the model formula. The elements of the list should have the same name as the variable and should be either a contrast matrix (specifically, any full-rank matrix with as many rows as there are levels in the factor), or else a function to compute such a matrix given the number of levels.

... additional arguments for the fitting routines (see \( \text{rq.fit.br} \) and \( \text{rq.fit.fnb} \) and the functions they call).

**Details**

For further details see the vignette available from R with `vignette("rq", package="quantreg")` and/or the Koenker (2005). For estimation of nonlinear (in parameters) quantile regression models there is the function \( \text{nlrq} \) and for nonparametric additive quantile regression there is the function \( \text{rqss} \). Fitting of quantile regression models with censored data is handled by the \( \text{crq} \) function.

**Value**

See `rq.object` and `rq.process.object` for details. Inferential matters are handled with `summary`. There are extractor methods `logLik` and `AIC` that are potentially relevant for model selection.

**Method**

The function computes an estimate on the tau-th conditional quantile function of the response, given the covariates, as specified by the formula argument. Like \( \text{lm}() \), the function presumes a linear specification for the quantile regression model, i.e. that the formula defines a model that is linear in parameters. For non-linear quantile regression see the package `nlrq()`. The function minimizes a weighted sum of absolute residuals that can be formulated as a linear programming problem. As noted above, there are three different algorithms that can be chosen depending on problem size and other characteristics. For moderate sized problems (\( n \ll 5,000, p \ll 20 \)) it is recommended that the default "br" method be used. There are several choices of methods for computing confidence
intervals and associated test statistics. See the documentation for `summary.rq` for further details and options.

_rq.fit_ 
*Function to choose method for Quantile Regression*

**Description**

Function to choose method for quantile regression

**Usage**

rq.fit(x, y, tau=0.5, method="br", ...)

**Arguments**

- x: the design matrix
- y: the response variable
- tau: the quantile desired, if tau lies outside (0,1) the whole process is estimated.
- method: method of computation: "br" is Barrodale and Roberts exterior point "fn" is the Frisch-Newton interior point method.
- ...: Optional arguments passed to fitting routine.

**See Also**

rq rq.fit.br rq.fit.fnb

---

_rq.fit.br_ 
*Quantile Regression Fitting by Exterior Point Methods*

**Description**

This function controls the details of QR fitting by the simplex approach embodied in the algorithm of Koenker and d'Orey based on the median regression algorithm of Barrodale and Roberts. Typically, options controlling the construction of the confidence intervals would be passed via the ...() argument of rq().
Usage

rq.fit.br(x, y, tau=0.5, alpha=0.1, ci=FALSE, iid=TRUE, interp=TRUE, tcrit=TRUE)

Arguments

x the design matrix
y the response variable
tau the quantile desired, if tau lies outside (0,1) the whole process is estimated.
alpha the nominal noncoverage probability for the confidence intervals, i.e. 1-alpha is the nominal coverage probability of the intervals.

ci logical flag if T then compute confidence intervals for the parameters using the rank inversion method of Koenker (1994). See rq() for more details. If F then return only the estimated coefficients. Note that for large problems the default option ci = TRUE can be rather slow. Note also that rank inversion only works for p>1, an error message is printed in the case that ci=T and p=1.

iid logical flag if T then the rank inversion is based on an assumption of iid error model, if F then it is based on an iid error assumption. See Koenker and Machado (1999) for further details on this distinction.

interp As with typical order statistic type confidence intervals the test statistic is discrete, so it is reasonable to consider intervals that interpolate between values of the parameter just below the specified cutoff and values just above the specified cutoff. If interp = F then the 2 “exact” values above and below on which the interpolation would be based are returned.

tcrit Logical flag if T - Student t critical values are used, if F then normal values are used.

Details

If tau lies in (0,1) then an object of class "rq" is returned with various related inference apparatus. If tau lies outside [0,1] then an object of class rq.process is returned. In this case parametric programming methods are used to find all of the solutions to the QR problem for tau in (0,1), the p-variate resulting process is then returned as the array sol containing the primal solution and dsol containing the dual solution. There are roughly $O(n \log n))$ distinct solutions, so users should be aware that these arrays may be large and somewhat time consuming to compute for large problems.

Value

Returns an object of class "rq" for tau in (0,1), or else of class "rq.process". Note that rq.fit.br when called for a single tau value will return the vector of optimal dual variables. See rq.object and rq.process.object for further details.

References

rq, rq.fit.fnb

Examples

data(stackloss)
rq.fit.br(stack.x, stack.loss, tau=.73, interp=FALSE)

Description
This is a lower level routine called by rq() to compute quantile regression methods using the Frisch-Newton algorithm.

Usage
rq.fit.fnb(x, y, tau=0.5, rhs = (1-tau)*apply(x,2,sum), beta=0.999995, eps=1e-06)

Arguments

x The design matrix
y The response vector
tau The quantile of interest, must lie in (0,1)
rhs The right hand size of the dual equality constraint, modify at your own risk.
beta technical step length parameter – alter at your own risk!
eps tolerance parameter for convergence. In cases of multiple optimal solutions there may be some discrepancy between solutions produced by method "fn" and method "br". This is due to the fact that "fn" tends to converge to a point near the centroid of the solution set, while "br" stops at a vertex of the set.

Details
The details of the algorithm are explained in Koenker and Portnoy (1997). The basic idea can be traced back to the log-barrier methods proposed by Frisch in the 1950’s for constrained optimization. But the current implementation is based on proposals by Mehrotra and others in the recent (explosive) literature on interior point methods for solving linear programming problems. This function replaces an earlier one rq.fit.fn, which required the initial dual values to be feasible. This version allows the user to specify an infeasible starting point for the dual problem, that is one that may not satisfy the dual equality constraints. It still assumes that the starting value satisfies the upper and lower bounds.

Value
returns an object of class "rq", which can be passed to summary.rq to obtain standard errors, etc.
References

See Also
rq, rq.fit.br, rq.fit.pfn

Description
This is a lower level routine called by rq() to compute quantile regression methods using the Frisch-Newton algorithm. It allows the call to specify linear inequality constraints to which the fitted coefficients will be subjected. The constraints are assumed to be formulated as Rb >= r.

Usage
rq.fit.fnc(x, y, R, r, tau=0.5, beta=0.9995, eps=1e-06)

Arguments
x The design matrix
y The response vector
R The matrix describing the inequality constraints
r The right hand side vector of inequality constraints
tau The quantile of interest, must lie in (0,1)
beta technical step length parameter – alter at your own risk!
eps tolerance parameter for convergence. In cases of multiple optimal solutions there may be some discrepancy between solutions produced by method "fn" and method "br". This is due to the fact that "fn" tends to converge to a point near the centroid of the solution set, while "br" stops at a vertex of the set.

Details
The details of the algorithm are explained in Koenker and Ng (2002). The basic idea can be traced back to the log-barrier methods proposed by Frisch in the 1950's for constrained optimization. But the current implementation is based on proposals by Mehrotra and others in the recent (explosive) literature on interior point methods for solving linear programming problems. See "rq" helpfile for an example. It is an open research problem to provide an inference apparatus for inequality constrained quantile regression.

Value
returns an object of class "rq", which can be passed to summary.rq to obtain standard errors, etc.

`rq.fit.hogg`  
**weighted quantile regression fitting**

Description

Function to estimate a regression model by minimizing the weighted sum of several quantile regression functions. See Koenker(1984) for an asymptotic look at these estimators. This is a slightly generalized version of what Zou and Yuan (2008) call composite quantile regression in that it permits weighting of the components of the objective function and also allows further linear inequality constraints on the coefficients.

Usage

```r
rq.fit.hogg(x, y, taus = c(0.1, 0.3, 0.5), weights = c(0.7, 0.2, 0.1),  
R = NULL, r = NULL, beta = 0.99995, eps = 1e-06)
```

Arguments

- **x**: design matrix
- **y**: response vector
- **taus**: quantiles getting positive weight
- **weights**: weights assigned to the quantiles
- **R**: optional matrix describing linear inequality constraints
- **r**: optional vector describing linear inequality constraints
- **beta**: step length parameter of the Frisch Newton Algorithm
- **eps**: tolerance parameter for the Frisch Newton Algorithm

Details

Minimizes a weighted sum of quantile regression objective functions using the specified taus. The model permits distinct intercept parameters at each of the specified taus, but the slope parameters are constrained to be the same for all taus. This estimator was originally suggested to the author by Bob Hogg in one of his famous blue notes of 1979. The algorithm used to solve the resulting linear programming problems is either the Frisch Newton algorithm described in Portnoy and Koenker (1997), or the closely related algorithm described in Koenker and Ng(2002) that handles linear inequality constraints. See `qrisk` for illustration of its use in portfolio allocation.

Linear inequality constraints of the form $Rb \geq r$ can be imposed with the convention that $b$ is a $m + p$ where $m$ is the length(taus) and $p$ is the column dimension of x without the intercept.
Value

coefficients estimated coefficients of the model

Author(s)

Roger Koenker

References

**Rq.fit.lasso**  
**Lasso Penalized Quantile Regression**

**Description**

The fitting method implements the lasso penalty of Tibshirani for fitting quantile regression models. When the argument lambda is a scalar the penalty function is the l1 norm of the last (p-1) coefficients, under the presumption that the first coefficient is an intercept parameter that should not be subject to the penalty. When lambda is a vector it should have length equal the column dimension of the matrix x and then defines a coordinatewise specific vector of lasso penalty parameters. In this case lambda entries of zero indicate covariates that are not penalized. There should be a sparse version of this, but isn’t (yet).

**Usage**

rq.fit.lasso(x, y, tau = 0.5, lambda = 1, beta = .9995, eps = 1e-06)

**Arguments**

- **x** the design matrix
- **y** the response variable
- **tau** the quantile desired, defaults to 0.5.
- **lambda** the value of the penalty parameter(s) that determine how much shrinkage is done. This should be either a scalar, or a vector of length equal to the column dimension of the x matrix.
beta       step length parameter for Frisch-Newton method.
eps        tolerance parameter for convergence.

Value

Returns a list with a coefficient, residual, tau and lambda components. When called from "rq" (as intended) the returned object has class "lassorqs".

Preprocessing Algorithm for Quantile Regression

Description

A preprocessing algorithm for the Frisch Newton algorithm for quantile regression. This is one possible method for rq().

Usage

rq.fit.pfn(x, y, tau=0.5, Mm.factor=0.8, max.bad.fixup=3, eps=1e-06)
Arguments

- **x**: design matrix usually supplied via `rq()`
- **y**: response vector usually supplied via `rq()`
- **tau**: quantile of interest
- **Mm.factor**: constant to determine sub sample size m
- **max.bad.fixup**: number of allowed mispredicted signs of residuals
- **eps**: convergence tolerance

Details

Preprocessing algorithm to reduce the effective sample size for QR problems with (plausibly) iid samples. The preprocessing relies on subsampling of the original data, so situations in which the observations are not plausibly iid, are likely to cause problems. The tolerance eps may be relaxed somewhat.

Value

Returns an object of type `rq`

Author(s)

Roger Koenker <rkoenker@uiuc.edu>

References

See Also

- `rq`

**Description**

The fitting method implements the smoothly clipped absolute deviation penalty of Fan and Li for fitting quantile regression models. When the argument `lambda` is a scalar the penalty function is the scad modified l1 norm of the last (p-1) coefficients, under the presumption that the first coefficient is an intercept parameter that should not be subject to the penalty. When `lambda` is a vector it should have length equal the column dimension of the matrix x and then defines a coordinatewise specific vector of scad penalty parameters. In this case `lambda` entries of zero indicate covariates that are not penalized. There should be a sparse version of this, but isn’t (yet).
Usage

\[
\text{rq.fit.scad}(x, y, \tau = 0.5, \alpha = 3.2, \lambda = 1, \text{start} = \text{"rq"}, \\
\beta = .9995, \epsilon = 1e-06)
\]

Arguments

\begin{itemize}
  \item \textbf{x} \hspace{1cm} \text{the design matrix}
  \item \textbf{y} \hspace{1cm} \text{the response variable}
  \item \textbf{tau} \hspace{1cm} \text{the quantile desired, defaults to 0.5.}
  \item \textbf{alpha} \hspace{1cm} \text{tuning parameter of the scad penalty.}
  \item \textbf{lambda} \hspace{1cm} \text{the value of the penalty parameter that determines how much shrinkage is done.}
    \text{This should be either a scalar, or a vector of length equal to the column dimension of the } x \text{ matrix.}
  \item \textbf{start} \hspace{1cm} \text{starting method, default method 'rq' uses the unconstrained rq estimate, while}
    \text{method 'lasso' uses the corresponding lasso estimate with the specified lambda.}
  \item \textbf{beta} \hspace{1cm} \text{step length parameter for Frisch-Newton method.}
  \item \textbf{eps} \hspace{1cm} \text{tolerance parameter for convergence.}
\end{itemize}

Details

The algorithm is an adaptation of the "difference convex algorithm" described in Wu and Liu (2008).
\text{It solves a sequence of (convex) QR problems to approximate solutions of the (non-convex) scad problem.}

Value

\text{Returns a list with a coefficient, residual, tau and lambda components. When called from "rq" as intended the returned object has class "scadrqs".}

**rq.fit.sfn**  
Sparse Regression Quantile Fitting

Description

Fit a quantile regression model using a sparse implementation of the Frisch-Newton interior-point algorithm.

Usage

```r
rq.fit.sfn(a, y, tau = 0.5, rhs = (1-tau)*c(t(a) %*% rep(1,length(y))), control)
```

Arguments

- **a**: structure of the design matrix $X$ stored in csr format
- **y**: response vector
- **tau**: desired quantile
- **rhs**: the right-hand-side of the dual problem; regular users shouldn’t need to specify this, but in special cases can be quite usefully altered to meet special needs. See e.g. Section 6.8 of Koenker (2005).
- **control**: control parameters for fitting routines: see sfn.control

Details

This is a sparse implementation of the Frisch-Newton algorithm for quantile regression described in Portnoy and Koenker (1997). The sparse matrix linear algebra is implemented through the functions available in the R package **SparseM**.

try(rq.o <- rq.fit.sfnc(sX, y, sR, r)) #> not enough tmp memory

(tmpmax <- floor(1e5 + exp(-12.1)*(sX@ia[p+1]-1)^2.35))
## now ok:
rq.o <- rq.fit.sfnc(sX, y, sR, r, control = list(tmpmax = tmpmax))
Description

These are objects of class "rq". They represent the fit of a linear conditional quantile function model.

Details

The coefficients, residuals, and effects may be extracted by the generic functions of the same name, rather than by the $ operator. For pure rq objects this is less critical than for some of the inheritor classes. In particular, for fitted rq objects using "lasso" and "scad" penalties, loglik and AIC functions compute degrees of freedom of the fitted model as the number of estimated parameters whose absolute value exceeds a threshold edfThresh. By default this threshold is 0.0001, but this can be passed via the AIC function if this value is deemed unsatisfactory. The function AIC is a generic function in R, with parameter k that controls the form of the penalty: the default value of k is 2 which yields the classical Akaike form of the penalty, while k <= 0 yields the Schwarz (BIC) form of the penalty. Note that the extractor function coef returns a vector with missing values omitted.

Generation

This class of objects is returned from the rq function to represent a fitted linear quantile regression model.

Methods

The "rq" class of objects has methods for the following generic functions: coef, effects, formula, labels, model.frame, model.matrix, plot, logLik, AIC, extractAIC, predict, print, print.summary, residuals, summary

Structure

The following components must be included in a legitimate rq object.

- coefficients: the coefficients of the quantile regression fit. The names of the coefficients are the names of the single-degree-of-freedom effects (the columns of the model matrix). If the model was fitted by method "br" with ci=TRUE, then the coefficient component consists of a matrix whose first column consists of the vector of estimated coefficients and the second and third columns are the lower and upper limits of a confidence interval for the respective coefficients.
- residuals: the residuals from the fit.
- dual: the vector dual variables from the fit.
- rho: The value(s) of objective function at the solution.
contrasts a list containing sufficient information to construct the contrasts used to fit any factors occurring in the model. The list contains entries that are either matrices or character vectors. When a factor is coded by contrasts, the corresponding contrast matrix is stored in this list. Factors that appear only as dummy variables and variables in the model that are matrices correspond to character vectors in the list. The character vector has the level names for a factor or the column labels for a matrix.

model optionally the model frame, if model=TRUE.
x optionally the model matrix, if x=TRUE.
y optionally the response, if y=TRUE.

rq, coefficients.

rq.process.object Linear Quantile Regression Process Object

Description
These are objects of class rq.process. They represent the fit of a linear conditional quantile function model.

Details
These arrays are computed by parametric linear programming methods using using the exterior point (simplex-type) methods of the Koenker–d’Orey algorithm based on Barrodale and Roberts median regression algorithm.

Generation
This class of objects is returned from the rq function to represent a fitted linear quantile regression model.

Methods
The "rq.process" class of objects has methods for the following generic functions: effects, formula, labels, model.frame, model.matrix, plot, predict, print, print.summary, summary

Structure
The following components must be included in a legitimate rq.process object.

sol The primal solution array. This is a (p+3) by J matrix whose first row contains the 'breakpoints' \(tau_1, tau_2, \ldots, tau_J\), of the quantile function, i.e. the values in [0,1] at which the solution changes, row two contains the corresponding quantiles evaluated at the mean design point, i.e. the inner product of xbar and \(b(tau_i)\), the third row contains the value of the objective function evaluated at the corresponding \(tau_j\), and the last p rows of the matrix give \(b(tau_i)\). The solution \(b(tau_i)\) prevails from \(tau_i\) to \(tau_i + 1\). Portnoy (1991) shows that \(J = O_p(n \log n)\).
dsol. The dual solution array. This is a \( n \) by \( J \) matrix containing the dual solution corresponding to sol, the \( ij \)-th entry is 1 if \( y_i > x_i b(\tau_j) \), is 0 if \( y_i < x_i b(\tau_j) \), and is between 0 and 1 otherwise, i.e. if the residual is zero. See Gutenbrunner and Jureckova (1991) for a detailed discussion of the statistical interpretation of dsol. The use of dsol in inference is described in Gutenbrunner, Jureckova, Koenker, and Portnoy (1994).

**rq.wfit**

Function to choose method for Weighted Quantile Regression

Description

Weight the data and then call the chosen fitting algorithm.

Usage

\[
\text{rq.wfit}(x, y, \text{tau}=0.5, \text{weights}, \text{method}="br", \ldots)
\]

Arguments

- \( x \) the design matrix
- \( y \) the response variable
- \( \text{tau} \) the quantile desired, if \( \text{tau} \) lies outside \((0,1)\) the whole process is estimated.
- \( \text{weights} \) weights used in the fitting
- \( \text{method} \) method of computation: "br" is Barrodale and Roberts exterior point "fn" is the Frisch-Newton interior point method.
- \( \ldots \) Optional arguments passed to fitting routine.

rq rq.fit.br rq.fit.fnb
rqProcess

Compute Standardized Quantile Regression Process

Description
Computes a standardized quantile regression process for the model specified by the formula, on the partition of [0,1] specified by the taus argument, and standardized according to the argument nullH. Intended for use in KhmaladzeTest.

Usage
rqProcess(formula, data, taus, nullH = "location", ...)

Arguments
- formula: model formula
- data: data frame to be used to interpret formula
- taus: quantiles at which the process is to be evaluated, if any of the taus lie outside (0,1) then the full process is computed for all distinct solutions.
- nullH: Null hypothesis to be used for standardization
- ...: optional arguments passed to summary.rq

Details
The process computes standardized estimates based on the hypothesis specified in the nullH argument. The Vhat component is rescaled by the Cholesky decomposition of the tau specific covariance matrix, the vhat component is rescaled by the marginal standard errors. The nature of the covariance matrix used for the standardization is controlled arguments passed via the ... argument to summary.rq. If the full process is estimated then these covariance options aren’t available and only a simple iid-error form of the covariance matrix is used.

Value
- taus: The points of evaluation of the process
- qtaus: Values of xbar’betahat(taus)
- Vhat: Joint parametric QR process
- vhat: Marginal parametric QR processes

*Function to fit multiple response quantile regression models*

**Description**

Function intended for multiple response quantile regression called from boot.rq for wild bootstrap option.

**Usage**

```r
rqs.fit(x, y, tau=0.5, tol = 0.0001)
```

**Arguments**

- `x` the design matrix an n by p matrix.
- `y` the response variable as a n by m matrix
- `tau` the quantile desired, if tau lies outside (0,1)
- `tol` tolerance parameter for Barrodale and Roberts exterior point method.

**See Also**

- boot.rq

---

**rqss**

*Additive Quantile Regression Smoothing*

**Description**

Fitting function for additive quantile regression models with possible univariate and/or bivariate nonparametric terms estimated by total variation regularization.

**Usage**

```r
rqss(formula, tau = 0.5, data = parent.frame(), weights, na.action, method = "sfn", lambda = NULL, contrasts = NULL, ztol = 1e-5, control, ...)
```

**Arguments**

- `formula` a formula object, with the response on the left of a ‘~’ operator, and terms, separated by ‘+’ operators, on the right. The terms may include qss terms that represent additive nonparametric components. These terms can be univariate or bivariate. See qss for details on how to specify these terms.
- `tau` the quantile to be estimated, this must be a number between 0 and 1,
data  a data.frame in which to interpret the variables named in the formula, or in the
subset and the weights argument.

weights  vector of observation weights; if supplied, the algorithm fits to minimize the sum
of the weights multiplied into the absolute residuals. The length of weights must
be the same as the number of observations. The weights must be nonnegative
and it is strongly recommended that they be strictly positive, since zero weights
are ambiguous.

na.action  a function to filter missing data. This is applied to the model.frame after any
subset argument has been used. The default (with na.fail) is to create an error
if any missing values are found. A possible alternative is na.omit, which deletes
observations that contain one or more missing values.

method  the algorithmic method used to compute the fit. There are currently two options.
Both are implementations of the Frisch–Newton interior point method described
in detail in Portnoy and Koenker(1997). Both are implemented using sparse
Cholesky decomposition as described in Koenker and Ng (2003).

Option "sfnc" is used if the user specifies inequality constraints. Option "sfn"
is used if there are no inequality constraints. Linear inequality constraints on the
fitted coefficients are specified by a matrix $\mathbf{R}$ and a vector $\mathbf{r}$, specified inside the
qss terms, representing the constraints in the form $\mathbf{R}\mathbf{b} \geq \mathbf{r}$.

The option method = "lasso" allows one to penalize the coefficients of the
covariates that have been entered linearly as in `rq.fit.lasso`; when this is
specified then there should be an additional lambda argument specified that de-
termines the amount of shrinkage.

lambda  can be either a scalar, in which case all the slope coefficients are assigned this
value, or alternatively, the user can specify a vector of length equal to the number
of linear covariates plus one (for the intercept) and these values will be used as
coordinate dependent shrinkage factors.

contrasts  a list giving contrasts for some or all of the factors default = NULL appearing in
the model formula. The elements of the list should have the same name as the
variable and should be either a contrast matrix (specifically, any full-rank matrix
with as many rows as there are levels in the factor), or else a function to compute
such a matrix given the number of levels.

ztol  A zero tolerance parameter used to determine the number of zero residuals in
the fitted object which in turn determines the effective dimensionality of the fit.

control  control argument for the fitting routines (see sfn.control

...  Other arguments passed to fitting routines

Details

Total variation regularization for univariate and bivariate nonparametric quantile smoothing is de-
scribed in Koenker, Ng and Portnoy (1994) and Koenker and Mizera(2003) respectively. The add-
tive model extension of this approach depends crucially on the sparse linear algebra implement-
tion for R described in Koenker and Ng (2003). There are extractor methods logLik and AIC
that is relevant to lambda selection. A more detailed description of some recent developments of
these methods is available from within the package with vignette("rqss"). Since this function
uses sparse versions of the interior point algorithm it may also prove to be useful for fitting linear
models without \texttt{qss} terms when the design has a sparse structure, as for example when there is a complicated factor structure.

If the \texttt{MatrixModels} and \texttt{Matrix} packages are both loadable then the linear in parameters portion of the design matrix is made in sparse matrix form, this is helpful in large applications with many factor variables for which dense formation of the design matrix would take too much space.

\textbf{Value}

The function returns a fitted object representing the estimated model specified in the formula. See \texttt{rqss.object} for further details on this object, and references to methods to look at it.

\textbf{Examples}

\begin{verbatim}
 n <- 200 x <- sort(rchisq(n,4)) z <- x + rnorm(n) y <- log(x)+ .1*(log(x))^2 + log(x)*rnorm(n)/4 + z plot(x, y-z) f.N <- rqss(y ~ qss(x, constraint= "N") + z) f.I <- rqss(y ~ qss(x, constraint= "I") + z) f.CI <- rqss(y ~ qss(x, constraint= "CI") + z) lines(x[-1], f.N $coef[1] + f.N $coef[-(1:2)]) lines(x[-1], f.I $coef[1] + f.I $coef[-(1:2)], col="blue") lines(x[-1], f.CI$coef[1] + f.CI$coef[-(1:2)], col="red")

## A bivariate example data(CobarOre) fCO <- rqss(z ~ qss(cbind(x,y), lambda= .08), data=CobarOre) plot(fCO)
\end{verbatim}
**Description**

Functions to reveal the inner meaning of objects created by `rqss` fitting.

**Usage**

```r
## S3 method for class 'rqss'
logLik(object, ...)
## S3 method for class 'rqss'
AIC(object, ..., k=2)
## S3 method for class 'rqss'
print(x, ...)
## S3 method for class 'rqss'
resid(object, ...)
## S3 method for class 'rqss'
fitted(object, ...)
```

**Arguments**

- `object`: an object returned from `rqss` fitting, describing an additive model estimating a conditional quantile function. See `qss` for details on how to specify these terms.
- `x`: an `rqss` object, as above.
- `k`: a constant factor governing the weight attached to the penalty term on effective degrees of freedom of the fit. By default `k=2` corresponding to the Akaike version of the penalty, negative values indicate that the `k` should be set to `log(n)` as proposed by Schwarz (1978).
- `...`: additional arguments

**Details**

Total variation regularization for univariate and bivariate nonparametric quantile smoothing is described in Koenker, Ng and Portnoy (1994) and Koenker and Mizera(2003) respectively. The additive model extension of this approach depends crucially on the sparse linear algebra implementation for R described in Koenker and Ng (2003). Eventually, these functions should be expanded to provide an automated lambda selection procedure.

**Value**

The function `summary.rqss` returns a list consisting of the following components:

- `fidelity`: Value of the quantile regression objective function.
- `penalty`: A list consisting of the values of the total variation smoothing penalty for each of additive components.
rqss.object

```
edf                     Effective degrees of freedom of the fitted model, defined as the number of zero residuals of the fitted model, Koenker Mizera (2003) for details.
qssedfs                 A list of effective degrees of freedom for each of the additive components of the fitted model, defined as the number of non-zero elements of each penalty component of the residual vector.
1amdas                  A list of the lambdas specified for each of the additive components of the model.
```

```
Description

Auxiliary function for setting storage dimensions and other parameters rq.fit.sfn[c]

Usage

sfn.control(nsubmax = NULL, tmpmax = NULL, nnz1max = NULL, cachsz = 64,
small = 1e-06, maxiter = 100, warnMesg = TRUE)

Arguments

nsubmax upper bound for dimension of lindx
tmpmax upper bound for dimension of tmpvec
nnz1max upper bound for non-zero entries of L stored in lnz, including diagonal
cachsz size of cache in kbytes on target machine
small convergence tolerance for interior point algorithm
maxiter maximal number of interior point iterations.
warnMesg logical flag controlling printing of warnings.

Details

Sparse fitting requires a number of temporary storage arrays whose size depends on problem specific
features in somewhat mysterious ways, parameters controlling these sizes and some other fitting
aspects can be controlled by specifying elements of this control object.

Value

List with components named as the arguments given above.

**srisk**

*Markowitz (Mean-Variance) Portfolio Optimization*

**Description**

This function estimates optimal mean-variance portfolio weights from a matrix of historical or simulated asset returns.

**Usage**

srisk(x, mu = 0.07, lambda = 1e+08, alpha = 0.1, eps = 1e-04)

**Arguments**

- **x**: Matrix of asset returns
- **mu**: Required mean rate of return for the portfolio
- **lambda**: Lagrange multiplier associated with mean return constraint
- **alpha**: Choquet risk parameter, unimplemented
- **eps**: Tolerance parameter for mean return constraint

**Details**

The portfolio weights are estimated by solving a constrained least squares problem.

**Value**

- **pihat**: Optimal portfolio weights
- **muhat**: Mean return in sample
- **sighat**: Standard deviation of returns in sample

**Author(s)**

qrisk
Summary methods for Censored Quantile Regression

Description

Returns a summary object for a censored quantile regression fit. A null value will be returned if printing is invoked.

Usage

```r
## S3 method for class 'crq'
summary(object, taus = 1:4/5, alpha = .05, se="boot", covariance=TRUE, ...)  
## S3 method for class 'summary.crq'
print(x, digits = max(5, .Options$digits - 2), ...)  
## S3 method for class 'summary.cpons'
print(x, ...)  
## S3 method for class 'summary.crons'
plot(x, nrow = 3, ncol = 3, CoxPHit = NULL, ...)
```

Arguments

- `object`: An object of class "crq" produced by a call to `crq()`.
- `x`: An object of class "crq" produced by a call to `crq()`.
- `se`: Specifies the method used to compute standard standard errors. but the only available method (so far) is "boot". Further arguments to `boot.crq` and `boot.rq` can be passed with the ... argument.
- `covariance`: Logical flag to indicate whether the full covariance matrix of the estimated parameters should be returned.
- `nrow`: Number of rows of the plot layout.
- `ncol`: Number of columns of the plot layout.
- `taus`: Quantiles to be summarized.
- `alpha`: Confidence level for summary intervals.
- `digits`: Number of digits to be printed in summary display.
- `CoxPHit`: An object of class coxph produced by coxph.
- `...`: Optional arguments to summary, e.g. to specify bootstrap methods sample sizes, etc. see `boot.rq` and `boot.crq`

Details

For the Powell method the resampling strategy used by the se = "boot" method is based on the Bilias, Chen and Ying (2000) proposal. For the Portnoy and Peng-Huang methods the bootstrapping is by default actually based on a delete-d jackknife, as described in Portnoy (2013), but resampling xy pairs using either conventional multinomial resampling or using exponential weighting as in Bose and Chatterjee (2003) can be used by specifying the bmethod argument. Note that the default
number of replications is set at \( R = 100 \) a value that is obviously too small for most applications. This is done merely to speed up the examples in the documentation and facilitate testing. Larger, more appropriate values of \( R \) can be passed to the bootstrapping functions via the \( \ldots \) argument of the summary method. It is important to recognize that when some of the bootstrap replications are NA they are simply ignored in the computation of the confidence bands and standard errors as currently reported. The number of these NAs is returned as part of the \texttt{summary.crq} object, and when printed is also reported.

**Value**

For method "Powell" an object of class \texttt{summary.crq} is returned with the following components:

- **coefficients**: a p by 4 matrix consisting of the coefficients, their estimated standard errors, their t-statistics, and their associated p-values.
- **cov**: the estimated covariance matrix for the coefficients in the model, provided that \texttt{covariance = TRUE} appears in the calling sequence.
- **rdf**: the residual degrees of freedom
- **tau**: the quantile estimated

For the other methods an object of class \texttt{summary.crq} is returned with the following components:

- **coefficients**: a list of p by 6 matrix consisting of the coefficients, upper and lower bounds for a (1-alpha) level confidence interval, their estimated standard errors, their t-statistics, and their associated p-values, one component for each element of the specified \texttt{taus} vector.
- **cov**: the estimated covariance matrix for the coefficients in the model, provided that \texttt{covariance = TRUE} in the called sequence.

Summary methods for Quantile Regression

Description

Returns a summary list for a quantile regression fit. A null value will be returned if printing is invoked.

Usage

## S3 method for class 'rq'
summary(object, se = NULL, covariance=FALSE, hs = TRUE, U = NULL, gamma = 0.7, ...)
## S3 method for class 'rqs'
summary(object, ...)

Arguments

- **object**: This is an object of class "rq" or "rqs" produced by a call to rq(), depending on whether one or more tauds are specified.
- **se**: specifies the method used to compute standard standard errors. There are currently six available methods:
  1. "rank" which produces confidence intervals for the estimated parameters by inverting a rank test as described in Koenker (1994). This method involves solving a parametric linear programming problem, and for large sample sizes can be extremely slow, so by default it is only used when the sample size is less than 1000, see below. The default option assumes that the errors are iid, while the option iid = FALSE implements a proposal of Koenker Machado (1999). See the documentation for rq.fit.br for additional arguments.
  2. "iid" which presumes that the errors are iid and computes an estimate of the asymptotic covariance matrix as in KB(1978).
  3. "nid" which presumes local (in tau) linearity (in x) of the the conditional quantile functions and computes a Huber sandwich estimate using a local estimate of the sparsity.
  4. "ker" which uses a kernel estimate of the sandwich as proposed by Powell(1990).
  5. "boot" which implements one of several possible bootstrapping alternatives for estimating standard errors including a variate of the wild bootstrap for clustered response. See boot.rq for further details.
  6. "BLB" which implements the bad of little bootstraps method proposed in Kleiner, et al (2014). The sample size of the little bootstraps is controlled by the parameter gamma, see below. At present only bmethod = "xy" is sanction, and even that is experimental. This option is intended for applications with very large n where other flavors of the bootstrap can be slow.
If \( \text{se} = \text{NULL} \) (the default) and \( \text{covariance} = \text{FALSE} \), and the sample size is less than 1001, then the "rank" method is used, otherwise the "nid" method is used.

**covariance**
logical flag to indicate whether the full covariance matrix of the estimated parameters should be returned.

**hs**
Use Hall Sheather bandwidth for sparsity estimation if false revert to Bofinger bandwidth.

**U**
Resampling indices or gradient evaluations used for bootstrap, see \texttt{boot.rq}.

**gamma**
parameter controlling the effective sample size of the 'bag of little bootstrap samples' that will be \( \hat{b} = n \gamma \) where \( n \) is the sample size of the original model.

**...**
Optional arguments to \texttt{summary}, e.g. \texttt{bsmethod} to use bootstrapping. see \texttt{boot.rq}.

When using the "rank" method for confidence intervals, which is the default method for sample sizes less than 1000, the type I error probability of the intervals can be controlled with the \texttt{alpha} parameter passed via "...", thereby controlling the width of the intervals plotted by \texttt{plot.summary.rqs}.

**Details**
When the default summary method is used, it tries to estimate a sandwich form of the asymptotic covariance matrix and this involves estimating the conditional density at each of the sample observations, negative estimates can occur if there is crossing of the neighboring quantile surfaces used to compute the difference quotient estimate. A warning message is issued when such negative estimates exist indicating the number of occurrences -- if this number constitutes a large proportion of the sample size, then it would be prudent to consider an alternative inference method like the bootstrap. If the number of these is large relative to the sample size it is sometimes an indication that some additional nonlinearity in the covariates would be helpful, for instance quadratic effects. Note that the default \texttt{se} method is rank, unless the sample size exceeds 1001, in which case the \texttt{rank} method is used. There are several options for alternative resampling methods. When \texttt{summary.rqs} is invoked, that is when \texttt{summary} is called for a \texttt{rqs} object consisting of several \texttt{taus}, the \texttt{B} components of the returned object can be used to construct a joint covariance matrix for the full object.

**Value**
a list is returned with the following components, when \texttt{object} is of class "\texttt{rqs}" then there is a list of such lists.

- **coefficients**
a \( p \) by 4 matrix consisting of the coefficients, their estimated standard errors, their t-statistics, and their associated p-values.

- **cov**
the estimated covariance matrix for the coefficients in the model, provided that \texttt{cov=TRUE} in the called sequence.

- **Hinv**
inverse of the estimated Hessian matrix returned if \texttt{cov=TRUE} and \texttt{se %in% c("nid","ker")}, note that for \texttt{se = "boot"} there is no way to split the estimated covariance matrix into its sandwich constituent parts.

- **J**
Unscaled Outer product of gradient matrix returned if \texttt{cov=TRUE} and \texttt{se != "iid"}. The Huber sandwich is \texttt{cov = tau (1-tau) Hinv %*% J %*% Hinv}, as for the \texttt{Hinv} component, there is no \texttt{J} component when \texttt{se == "boot"}. (Note that to make the Huber sandwich you need to add the tau (1-tau) mayonnaise yourself.)
Matrix of bootstrap realizations.

U Matrix of bootstrap randomization draws.

Examples

data(stackloss)
y <- stack.loss
x <- stack.x
summary(rq(y ~ x, method="fn")) # Compute se's for fit using "nid" method.
summary(rq(y ~ x, ci=FALSE), se="ker")
# default "br" alg, and compute kernel method se's

---

summary.rqss | Summary of rqss fit

Description

Summary Method for a fitted rqss model.

Usage

```r
## S3 method for class 'rqss'
summary(object, cov = FALSE, ztol = 1e-5, ...)  
```

Arguments

- `object` an object returned from rqss fitting, describing an additive model estimating a conditional quantile function. See qss for details on how to specify these terms.
- `cov` if TRUE return covariance matrix for the parametric components as Vcov and a list of covariance matrices for the nonparametric components as Vqss.
- `ztol` Zero tolerance parameter used to determine the number of zero residuals indicating the estimated parametric dimension of the model, the so-called effective degrees of freedom.
- `...` additional arguments
Details

This is a highly experimental function intended to explore inferential methods for rqss fitting. The function is modeled after summary.gam in Simon Wood's (2006) mgcv package. (Of course, Simon should not be blamed for any deficiencies in the current implementation. The basic idea is to condition on the lambda selection and construct quasi-Bayesian credibility intervals based on normal approximation of the "posterior," as computed using the Powell kernel estimate of the usual quantile regression sandwich. See summary.rq for further details and references. The function produces a conventional coefficient table with standard errors t-statistics and p-values for the coefficients on the parametric part of the model, and another table for additive nonparametric effects. The latter reports F statistics intended to evaluate the significance of these components individually. In addition the fidelity (value of the QR objective function evaluated at the fitted model), the effective degrees of freedom, and the sample size are reported.

Value

- **coef**: Table of estimated coefficients and their standard errors, t-statistics, and p-values for the parametric components of the model
- **qsstab**: Table of approximate F statistics, effective degrees of freedom and values of the penalty terms for each of the additive nonparametric components of the model, and the lambda values assigned to each.
- **fidelity**: Value of the quantile regression objective function.
- **tau**: Quantile of the estimated model
- **formula**: formula of the estimated model
- **edf**: Effective degrees of freedom of the fitted model, defined as the number of zero residuals of the fitted model, see Koenker Mizera (2003) for details.
- **n**: The sample size used to fit the model.
- **Vcov**: Estimated covariance matrix of the fitted parametric component
- **Vqss**: List of estimated covariance matrices of the fitted nonparametric component

Examples

```r
n <- 200
x <- sort(rchisq(n,4))
z <- x + rnorm(n)
y <- log(x) + .1*(log(x))^2 + log(x)*rnorm(n)/4 + z
f <- rqss(y ~ qss(x) + z)
summary(f)
```

```r
table.rq

Table of Quantile Regression Results
```

Description

Defunct Function to produce a table of quantile regression results for a group of specified quantiles. See `rq` which now permits multiple `taus`.

Usage

`table.rq(x, ...)`

Arguments

- `x` : input
- `...` : other optional arguments

Value

None.

See Also

`rq`.

```r
uis

UIS Drug Treatment study data
```
Description

There are 628 data points in the original data, 575 of which have no missing values.
