Package ‘rTensor’

March 22, 2020

Type Package

Title Tools for Tensor Analysis and Decomposition

Version 1.4.1

Author James Li and Jacob Bien and Martin Wells

Maintainer James Li <jamesyili@gmail.com>

Description A set of tools for creation, manipulation, and modeling of tensors with arbitrary number of modes. A tensor in the context of data analysis is a multidimensional array. rTensor does this by providing a S4 class 'Tensor' that wraps around the base 'array' class. rTensor provides common tensor operations as methods, including matrix unfolding, summing/averaging across modes, calculating the Frobenius norm, and taking the inner product between two tensors. Familiar array operations are overloaded, such as index subsetting via '[', and element-wise operations. rTensor also implements various tensor decomposition, including CP, GLRAM, MPCA, PVD, and Tucker. For tensors with 3 modes, rTensor also implements transpose, t-product, and t-SVD, as defined in Kilmer et al. (2013). Some auxiliary functions include the Khatri-Rao product, Kronecker product, and the Hadamard product for a list of matrices.

Description

This package is centered around the **Tensor-class**, which defines a S4 class for tensors of arbitrary number of modes. A vignette and/or a possible paper will be included in a future release of this package.

Details

This page will summarize the full functionality of this package. Note that since all the methods associated with S4 class **Tensor-class** are documented there, we will not duplicate it here.

The remaining functions can be split into two groups: the first is a set of tensor decompositions, and the second is a set of helper functions that are useful in tensor manipulation.

**rTensor** implements the following tensor decompositions:

- **cp**: Canonical Polyadic (CP) decomposition
- **tucker**: General Tucker decomposition
- **mpca**: Multilinear Principal Component Analysis; note that for 3-Tensors this is also known as Generalized Low Rank Approximation of Matrices (GLRAM)
- **hosvd**: (Truncated-)Higher-order singular value decomposition
- **t_svd**: Tensor singular value decomposition; 3-Tensors only; also note that there is an associated reconstruction function **t_svd_reconstruct**
- **pvd**: Population value decomposition of images; 3-Tensors only

**rTensor** also provides a set functions for tensors multiplication:

- **ttm**: Tensor times matrix, aka m-mode product
- **ttl**: Tensor times list (of matrices)
- **t_mult**: Tensor product based on block circulant unfolding; only implemented for a pair of 3-Tensors

...as well as for matrices:

- **hadamard_list**: Computes the Hamadard (element-wise) product of a list of matrices
- **kronecker_list**: Computes the Kronecker product of a list of matrices
- **khatri_rao**: Computes the Khatri-Rao product of two matrices
- **khatri_rao_list**: Computes the Khatri-Rao product of a list of matrices
- **fold**: General folding of a matrix into a tensor
- **k_fold**: Inverse operation for **k_unfold**
- **unmatvec**: Inverse operation for **matvec**

For more information on any of the functions, please consult the individual man pages.

---

**as.tensor**

**Tensor Conversion**

**Description**

Create a **Tensor-class** object from an array, matrix, or vector.

**Usage**

```
as.tensor(x, drop = FALSE)
```

**Arguments**

- `x` an instance of array, matrix, or vector
- `drop` whether or not modes of 1 should be dropped

**Value**

a **Tensor-class** object

**Examples**

```r
#From vector
evec <- runif(100); evecT <- as.tensor(evec); evecT
#From matrix
emat <- matrix(runif(1000), nrow=100, ncol=10)
ematT <- as.tensor(emat); ematT
#From array
indices <- c(10,20,30,40)
earn <- array(runif(prod(indices)), dim = indices)
earnT <- as.tensor(earn); earnT
```

---

**cp**

**Canonical Polyadic Decomposition**

**Description**

Canonical Polyadic (CP) decomposition of a tensor, aka CANDECOMP/PARAFAC. Approximate a K-Tensor using a sum of `num_components` rank-1 K-Tensors. A rank-1 K-Tensor can be written as an outer product of K vectors. There are a total of `num_components` *tnsr@num_modes` vectors in the output, stored in `tnsr@num_modes` matrices, each with `num_components` columns. This is an iterative algorithm, with two possible stopping conditions: either relative error in Frobenius norm has gotten below `tol`, or the `max_iter` number of iterations has been reached. For more details on CP decomposition, consult Kolda and Bader (2009).
Usage

```r
cp(tnsr, num_components = NULL, max_iter = 25, tol = 1e-05)
```

Arguments

- **tnsr**: Tensor with K modes
- **num_components**: the number of rank-1 K-Tensors to use in approximation
- **max_iter**: maximum number of iterations if error stays above tol
- **tol**: relative Frobenius norm error tolerance

Details

Uses the Alternating Least Squares (ALS) estimation procedure. A progress bar is included to help monitor operations on large tensors.

Value

A list containing the following:

- **lambdas**: a vector of normalizing constants, one for each component
- **U**: a list of matrices - one for each mode - each matrix with num_components columns
- **conv**: whether or not resid < tol by the last iteration
- **norm_percent**: the percent of Frobenius norm explained by the approximation
- **est**: estimate of tnsr after compression
- **fnorm_resid**: the Frobenius norm of the error fnorm(est-tnsr)
- **all_resids**: vector containing the Frobenius norm of error for all the iterations

References

See Also

tucker

Examples

```r
subject <- faces_tnsr[,,14]
cpD <- cp(subject, num_components=10)
cpD$conv
cpD$norm_percent
plot(cpD$all_resids)
```
### cs_fold

**Column Space Folding of Matrix**

**Description**

DEPRECATED. Please see `unmatvec`.

**Usage**

```r
cs_fold(mat, m = NULL, modes = NULL)
```

**Arguments**

- `mat`: matrix to be folded
- `m`: the mode corresponding to `cs_unfold`
- `modes`: the original modes of the tensor

---

### cs_unfold-methods

**Tensor Column Space Unfolding**

**Description**

DEPRECATED. Please see `matvec-methods` and `unfold-methods`.

**Usage**

```r
cs_unfold(tnsr, m)
```

**Details**

```r
## S4 method for signature 'Tensor'
cs_unfold(tnsr, m = NULL)
```

**Arguments**

- `tnsr`: Tensor instance
- `m`: mode to be unfolded on
dim-methods

Mode Getter for Tensor

Description

Return the vector of modes from a tensor

Usage

```r
## S4 method for signature 'Tensor'
dim(x)
```

Arguments

- `x` the Tensor instance

Details

```r
dim(x)
```

Value

an integer vector of the modes associated with `x`

Examples

```r
tnsr <- rand_tensor()
dim(tnsr)
```

faces_tnsr

ORL Database of Faces

Description

A dataset containing pictures of 40 individuals under 10 different lightings. Each image has 92 x 112 pixels. Structured as a 4-tensor with modes 92 x 112 x 40 x 10.

Usage

`faces_tnsr`

Format

A Tensor object with modes 92 x 112 x 40 x 10. The first two modes correspond to the image pixels, the third mode corresponds to the individual, and the last mode corresponds to the lighting.
Description

Returns the Frobenius norm of the Tensor instance.

Usage

fnorm(tnsr)

## S4 method for signature 'Tensor'
fnorm(tnsr)

Arguments

tnsr the Tensor instance

Details

fnorm(tnsr)

Value

numeric Frobenius norm of x

Examples

```r
tnsr <- rand_tensor()
fnorm(tnsr)
```
fold

General Folding of Matrix

Description

General folding of a matrix into a Tensor. This is designed to be the inverse function to `unfold-methods`, with the same ordering of the indices. This amounts to following: if we were to unfold a Tensor using a set of row_idx and col_idx, then we can fold the resulting matrix back into the original Tensor using the same row_idx and col_idx.

Usage

```r
fold(mat, row_idx = NULL, col_idx = NULL, modes = NULL)
```

Arguments

- `mat`: matrix to be folded into a Tensor
- `row_idx`: the indices of the modes that are mapped onto the row space
- `col_idx`: the indices of the modes that are mapped onto the column space
- `modes`: the modes of the output Tensor

Details

This function uses `aperm` as the primary workhorse.

Value

Tensor object with modes given by `modes`

References

See Also

`unfold-methods, k_fold, unmatvec`

Examples

```r
tnsr <- new("Tensor",3L,c(3L,4L,5L),data=runif(60))
matT3<-unfold(tnsr,row_idx=2,col_idx=c(3,1))
identical(fold(matT3,row_idx=2,col_idx=c(3,1),modes=c(3,4,5)),tnsr)
```
**hadamard_list**  
*List hadamard Product*

**Description**

Returns the hadamard (element-wise) product from a list of matrices or vectors. Commonly used for n-mode products and various Tensor decompositions.

**Usage**

```r
hadamard_list(L)
```

**Arguments**

- `L` list of matrices or vectors

**Value**

matrix that is the hadamard product

**Note**

The modes/dimensions of each element in the list must match.

**See Also**

`kronecker_list`, `khatri_rao_list`

**Examples**

```r
lizt <- list('mat1' = matrix(runif(40), ncol=4),
             'mat2' = matrix(runif(40), ncol=4),
             'mat3' = matrix(runif(40), ncol=4))
dim(hadamard_list(lizt))
```

---

**head-methods**  
*Head for Tensor*

**Description**

Extend head for Tensor

**Usage**

```r
## S4 method for signature 'Tensor'
head(x, ...)
```
Arguments

\begin{itemize}
\item \texttt{x} \quad \text{the Tensor instance}
\item \ldots \quad \text{additional parameters to be passed into head()}
\end{itemize}

Details

\texttt{head(x,\ldots)}

See Also

tail-methods

Examples

\begin{verbatim}
 tnsr <- rand_tensor()
 head(tnsr)
\end{verbatim}

Description

Higher-order SVD of a K-Tensor. Write the K-Tensor as a (m-mode) product of a core Tensor (possibly smaller modes) and K orthogonal factor matrices. Truncations can be specified via ranks (making them smaller than the original modes of the K-Tensor will result in a truncation). For the mathematical details on HOSVD, consult Lathauwer et. al. (2000).

Usage

\texttt{hosvd(tnsr, ranks = NULL)}

Arguments

\begin{itemize}
\item \texttt{tnsr} \quad \text{Tensor with K modes}
\item \texttt{ranks} \quad \text{a vector of desired modes in the output core tensor, default is tnsr@modes}
\end{itemize}

Details

A progress bar is included to help monitor operations on large tensors.

Value

a list containing the following:

\begin{itemize}
\item \texttt{Z} \quad \text{core tensor with modes specified by ranks}
\item \texttt{U} \quad \text{a list of orthogonal matrices, one for each mode}
\item \texttt{est} \quad \text{estimate of tnsr after compression}
\item \texttt{fnorm_resid} \quad \text{the Frobenius norm of the error fnorm(est-tnsr) - if there was no truncation, then this is on the order of mach_eps * fnorm.}
\end{itemize}
Note

The length of ranks must match tnsr@num_modes.

References

See Also

tucker

Examples

```r
tnsr <- rand_tensor(c(6,7,8))
hosvdD <- hosvd(tnsr)
hosvdD$fnorm_resid
hosvdD2 <- hosvd(tnsr,ranks=c(3,3,4))
hosvdD2$fnorm_resid
```

### initialize-methods

*Initializes a Tensor instance*

Description

Not designed to be called by the user. Use as.tensor instead.

Usage

```r
## S4 method for signature 'Tensor'
initialize(.Object, num_modes = NULL, modes = NULL,
          data = NULL)
```

Arguments

- `.Object` the tensor object
- `num_modes` number of modes of the tensor
- `modes` modes of the tensor
- `data` can be vector, matrix, or array

See Also

as.tensor
**innerProd-methods**

---

### Tensors Inner Product

**Description**

Returns the inner product between two Tensors

**Usage**

```r
innerProd(tnsr1, tnsr2)
```

#### ## S4 method for signature 'Tensor, Tensor'

```r
innerProd(tnsr1, tnsr2)
```

**Arguments**

- `tnsr1`: first Tensor instance
- `tnsr2`: second Tensor instance

**Details**

```r
innerProd(tnsr1, tnsr2)
```

**Value**

Inner product between `x1` and `x2`

**Examples**

```r
tnsr1 <- rand_tensor()
tnsr2 <- rand_tensor()
innerProd(tnsr1, tnsr2)
```

---

### khatri_rao

---

#### Khatri-Rao Product

**Description**

Returns the Khatri-Rao (column-wise Kronecker) product of two matrices. If the inputs are vectors then this is the same as the Kronecker product.

**Usage**

```r
khatri_rao(x, y)
```
Arguments

x  first matrix
y  second matrix

Value

matrix that is the Khatri-Rao product

Note

The number of columns must match in the two inputs.

See Also

kronecker, khatrao_list

Examples

dim(khatri_rao(matrix(runif(12), ncol=4), matrix(runif(12), ncol=4)))

---

khatri_rao_list  List Khatri-Rao Product

Description

Returns the Khatri-Rao product from a list of matrices or vectors. Commonly used for n-mode products and various Tensor decompositions.

Usage

khatri_rao_list(L, reverse = FALSE)

Arguments

L  list of matrices or vectors
reverse  whether or not to reverse the order

Value

matrix that is the Khatri-Rao product

Note

The number of columns must match in every element of the input list.

See Also

khatri_rao
Examples

```r
going <- list('mat1' = matrix(runif(12), ncol=4),
      'mat2' = matrix(runif(12), ncol=4),
      'mat3' = matrix(runif(12), ncol=4))
dim(khatri_rao_list(going))
```
k_fold

k-mode Folding of Matrix

Description

k-mode folding of a matrix into a Tensor. This is the inverse function to k_unfold in the m mode. In particular, k_fold(k_unfold(tnsr,m),m,getModes(tnsr)) will result in the original Tensor.

Usage

k_fold(mat, m = NULL, modes = NULL)

Arguments

mat        matrix to be folded into a Tensor
m          the index of the mode that is mapped onto the row indices
modes      the modes of the output Tensor

Details

This is a wrapper function to fold.

Value

Tensor object with modes given by modes

References

See Also

k_unfold-methods, fold, unmatvec

Examples

tnsr <- new("Tensor",3L,c(3L,4L,5L),data=runif(60))
matT2<-k_unfold(tnsr,m=2)
identical(k_fold(matT2,m=2,modes=c(3,4,5)),tnsr)
Description

Unfolding of a tensor by mapping the kth mode (specified through parameter m), and all other modes onto the column space. This the most common type of unfolding operation for Tucker decompositions and its variants. Also known as k-mode matricization.

Usage

k_unfold(tnsr, m)

## S4 method for signature 'Tensor'

k_unfold(tnsr, m = NULL)

Arguments

- tnsr: the Tensor instance
- m: the index of the mode to unfold on

Details

k_unfold(tnsr,m=NULL)

Value

matrix with x@modes[m] rows and prod(x@modes[-m]) columns

References

See Also

matvec-methods and unfold-methods

Examples

tnsr <- rand_tensor()
matT2<-rs_unfold(tnsr,m=2)
**Description**
For 3-tensors only. Stacks the slices along the third mode. This is the prevalent unfolding for T-SVD and T-MULT based on block circulant matrices.

**Usage**
matvec(tnsr)

```r
## S4 method for signature 'Tensor'
matvec(tnsr)
```

**Arguments**
tnsr

the Tensor instance

**Details**
matvec(tnsr)

**Value**
matrix with prod(x@modes[-m]) rows and x@modes[m] columns

**References**

**See Also**
k_unfold-methods and unfold-methods

**Examples**
```r
tnsr <- rand_tensor(c(2,3,4))
matT1 <- matvec(tnsr)
```
Description

Given a mode for a K-tensor, this returns the K-1 tensor resulting from taking the mean across that particular mode.

Usage

```
modeMean(tnsr, m, drop)
```

```
## S4 method for signature 'Tensor'
modeMean(tnsr, m = NULL, drop = FALSE)
```

Arguments

- `tnsr`: the Tensor instance
- `m`: the index of the mode to average across
- `drop`: whether or not mode m should be dropped

Details

```
modeMean(tnsr,m=NULL,drop=FALSE)
```

Value

K-1 or K Tensor, where K = x@num_modes

See Also

`modeSum`

Examples

```
tnsr <- rand_tensor()
modeMean(tnsr,1,drop=TRUE)
```
Description

Given a mode for a K-tensor, this returns the K-1 tensor resulting from summing across that particular mode.

Usage

modeSum(tnsr, m, drop)

## S4 method for signature 'Tensor'
modeSum(tnsr, m = NULL, drop = FALSE)

Arguments

- tnsr: the Tensor instance
- m: the index of the mode to sum across
- drop: whether or not mode m should be dropped

Details

modeSum(tnsr,m=NULL,drop=FALSE)

Value

K-1 or K tensor, where K = x@num_modes

See Also

modeMean

Examples

tnsr <- rand_tensor()
modeSum(tnsr,3,drop=TRUE)
**Description**

This is basically the Tucker decomposition of a K-Tensor, `tucker`, with one of the modes uncompressed. If K = 3, then this is also known as the Generalized Low Rank Approximation of Matrices (GLRAM). This implementation assumes that the last mode is the measurement mode and hence uncompressed. This is an iterative algorithm, with two possible stopping conditions: either relative error in Frobenius norm has gotten below `tol`, or the `max_iter` number of iterations has been reached. For more details on the MPCA of tensors, consult Lu et al. (2008).

**Usage**

```r
mpca(tnsr, ranks = NULL, max_iter = 25, tol = 1e-05)
```

**Arguments**

- `tnsr`: Tensor with K modes
- `ranks`: a vector of the compressed modes of the output core Tensor, this has length K-1
- `max_iter`: maximum number of iterations if error stays above `tol`
- `tol`: relative Frobenius norm error tolerance

**Details**

Uses the Alternating Least Squares (ALS) estimation procedure. A progress bar is included to help monitor operations on large tensors.

**Value**

A list containing the following:

- `Z_ext`: the extended core tensor, with the first K-1 modes given by `ranks`
- `U`: a list of K-1 orthogonal factor matrices - one for each compressed mode, with the number of columns of the matrices given by `ranks`
- `conv`: whether or not `resid < tol` by the last iteration
- `est`: estimate of `tnsr` after compression
- `norm_percent`: the percent of Frobenius norm explained by the approximation
- `fnorm_resid`: the Frobenius norm of the error `fnorm(est-tnsr)`
- `all_resids`: vector containing the Frobenius norm of error for all the iterations

**Note**

The length of `ranks` must match `tnsr@num_modes-1`. 
References

See Also
tucker, hosvd

Examples

subject <- faces_tnsr[,,21]
mpcaD <- mpca(subject, ranks=c(10,10))
mpcaD$conv
mpcaD$norm_percent
plot(mpcaD$all_resids)

Ops-methods

Conformable elementwise operators for Tensor

Description

Overloads elementwise operators for tensors, arrays, and vectors that are conformable (have the same modes).

Usage

## S4 method for signature 'Tensor,Tensor'
Ops(e1, e2)

Arguments

e1 left-hand object
e2 right-hand object

Examples

tnsr <- rand_tensor(c(3,4,5))
tnsr2 <- rand_tensor(c(3,4,5))
tnsrsun <- tnsr + tnsr2
tnsrdiff <- tnsr - tnsr2
tnsrelemprod <- tnsr * tnsr2
tnsrelemquot <- tnsr / tnsr2
for (i in 1:3L)
  for (j in 1:4L)
    for (k in 1:5L)
      stopifnot(tnsrsun@data[i,j,k]==tnsr@data[i,j,k]+tnsr2@data[i,j,k])
      stopifnot(tnsrdiff@data[i,j,k]==(tnsr@data[i,j,k]-tnsr2@data[i,j,k]))
      stopifnot(tnsrelemprod@data[i,j,k]==tnsr@data[i,j,k]*tnsr2@dta[i,j,k])
plot_orl

Function to plot the ORL Database of Faces

Description

A wrapper function to image() to allow easy visualization of faces_tnsr, the ORL Face Dataset.

Usage

plot_orl(subject = 1, condition = 1)

Arguments

subject which subject to plot (1-40)
condition which lighting condition (1-10)

References

See Also

faces_tnsr

Examples

plot_orl(subject=5,condition=4)
plot_orl(subject=2,condition=7)
### Description

Extend print for Tensor

### Usage

```r
## S4 method for signature 'Tensor'
print(x, ...)
```

### Arguments

- `x`: the Tensor instance
- `...`: additional parameters to be passed into print()

### Details

```r
print(x, ...)
```

### See Also

- `show`

### Examples

```r
tnsr <- rand_tensor()
print(tnsr)
```

---

### Description

The default Population Value Decomposition (PVD) of a series of 2D images. Constructs population-level matrices $P$, $V$, and $D$ to account for variances within as well as across the images. Structurally similar to Tucker (`tucker`) and GLRAM (`mpca`), but retains crucial differences. Requires $2n^3 + 2$ parameters to specified the final ranks of $P$, $V$, and $D$, where $n^3$ is the third mode (how many images are in the set). Consult Crainiceanu et al. (2013) for the construction and rationale behind the PVD model.

### Usage

```r
pvd(tnsr, uranks = NULL, wranks = NULL, a = NULL, b = NULL)
```
Arguments

- `tnsr`: 3-Tensor with the third mode being the measurement mode
- `uranks`: ranks of the U matrices
- `wranks`: ranks of the W matrices
- `a`: rank of $P = U\%\times t(U)$
- `b`: rank of $D = W\%\times t(W)$

Details

The PVD is not an iterative method, but instead relies on $n^3 + 2$ separate PCA decompositions. The third mode is for how many images are in the set.

Value

A list containing the following:

- `P`: population-level matrix $P = U\%\times t(U)$, where $U$ is constructed by stacking the truncated left eigenvectors of slicewise PCA along the third mode
- `V`: a list of image-level core matrices
- `D`: population-level matrix $D = W\%\times t(W)$, where $W$ is constructed by stacking the truncated right eigenvectors of slicewise PCA along the third mode
- `est`: estimate of `tnsr` after compression
- `norm_percent`: the percent of Frobenius norm explained by the approximation
- `fnorm_resid`: the Frobenius norm of the error $\|\|f\|\|_{\text{norm}}(\text{est}-\text{tnsr})$

References

Examples

```r
subject <- faces_tnsr[, , 8]
pvdD <- pvd(subject, uranks = rep(46, 10), wranks = rep(56, 10), a = 46, b = 56)
```
**rand_tensor**  
*Tensor with Random Entries*

**Description**
Generate a Tensor with specified modes with iid normal(0,1) entries.

**Usage**
`rand_tensor(modes = c(3, 4, 5), drop = FALSE)`

**Arguments**
- **modes**: the modes of the output Tensor
- **drop**: whether or not modes equal to 1 should be dropped

**Value**
a Tensor object with modes given by `modes`

**Note**
Default `rand_tensor()` generates a 3-Tensor with modes c(3,4,5).

**Examples**
- `rand_tensor()`
- `rand_tensor(c(4,4,4))`
- `rand_tensor(c(10,2,1),TRUE)`

---

**rs_fold**  
*Row Space Folding of Matrix*

**Description**
DEPRECATED. Please see `k_fold`.

**Usage**
`rs_fold(mat, m = NULL, modes = NULL)`

**Arguments**
- **mat**: matrix to be folded
- **m**: the mode corresponding to `rs_unfold`
- **modes**: the original modes of the tensor
rs_unfold-methods  Tensor Row Space Unfolding

Description

DEPRECATED. Please see k_unfold-methods and unfold-methods.

Usage

rs_unfold(tnsr, m)

## S4 method for signature 'Tensor'
rs_unfold(tnsr, m = NULL)

Arguments

tnsr Tensor instance
m mode to be unfolded on

Details

rs_unfold(tnsr,m=NULL)

show-methods  Show for Tensor

Description

Extend show for Tensor

Usage

## S4 method for signature 'Tensor'
show(object)

Arguments

object the Tensor instance

Details

show(object)

See Also

print
Examples

```r
tnsr <- rand_tensor()
tnsr
```

---

t-methods  

Tensor Transpose

Description

Implements the tensor transpose based on block circulant matrices (Kilmer et al. 2013) for 3-tensors.

Usage

```r
## S4 method for signature 'Tensor'
t(x)
```

Arguments

- `x`: a 3-tensor

Details

`t(x)`

Value

Tensor transpose of `x`

References

Examples

```r
tnsr <- rand_tensor()
identical(t(tnsr)@data[,1],t(tnsr@data[,1]))
identical(t(tnsr)@data[,2],t(tnsr@data[,5]))
identical(t(t(tnsr)),tnsr)
```
**Description**

Extend tail for Tensor

**Usage**

```r
## S4 method for signature 'Tensor'
tail(x, ...)
```

**Arguments**

- `x`: the Tensor instance
- `...`: additional parameters to be passed into tail()

**Details**

```r
tail(x, ...)
```

**See Also**

`head-methods`

**Examples**

```r
tnsr <- rand_tensor()
tail(tnsr)
```

---

**Tensor-class**

*S4 Class for a Tensor*

**Description**

An S4 class for a tensor with arbitrary number of modes. The Tensor class extends the base 'array' class to include additional tensor manipulation (folding, unfolding, reshaping, subsetting) as well as a formal class definition that enables more explicit tensor algebra.
Tensor-class

Details

This can be seen as a wrapper class to the base array class. While it is possible to create an instance using new, it is also possible to do so by passing the data into as.tensor.

Each slot of a Tensor instance can be obtained using @.

The following methods are overloaded for the Tensor class: dim-methods, head-methods, tail-methods, print-methods, show-methods, element-wise array operations, array subsetting (extract via ‘[]’), array subset replacing (replace via ‘[:]’), and tperm-methods, which is a wrapper around the base aperm method.

To sum across any one mode of a tensor, use the function modeSum-methods. To compute the mean across any one mode, use modeMean-methods.

You can always unfold any Tensor into a matrix, and the unfold-methods, k_unfold-methods, and matvec-methods methods are for that purpose. The output can be kept as a Tensor with 2 modes or a matrix object. The vectorization function is also provided as vec. See the attached vignette for a visualization of the different unfoldings.

Conversion from array/matrix to Tensor is facilitated via as.tensor. To convert from a Tensor instance, simply invoke @data.

The Frobenius norm of the Tensor is given by fnorm-methods, while the inner product between two Tensors (of equal modes) is given by innerProd-methods. You can also sum through any one mode to obtain the K-1 Tensor sum using modeSum-methods. modeMean-methods provides similar functionality to obtain the K-1 Tensor mean. These are primarily meant to be used internally but may be useful in doing statistics with Tensors.

For Tensors with 3 modes, we also overloaded t (transpose) defined by Kilmer et.al (2013). See t-methods.

To create a Tensor with i.i.d. random normal(0, 1) entries, see rand_tensor.

Slots

- num_modes  number of modes (integer)
- modes  vector of modes (integer), aka sizes/extent/dimensions
- data  actual data of the tensor, which can be ’array’ or ’vector’

**tperm-methods**

*Mode Permutation for Tensor*

**Description**
Overloads `aperm` for `Tensor` class for convenience.

**Usage**

```r
 tperm(tnsr, perm, ...)
```

```r
tperm(tnsr, perm, ...)
```

**Arguments**

- `tnsr` : the `Tensor` instance
- `perm` : the new permutation of the current modes
- `...` : additional parameters to be passed into `aperm`

**Details**

```r
tperm(tnsr, perm=NULL, ...)
```

**Examples**

```r
tnsr <- rand_tensor(c(3,4,5))
dim(tperm(tnsr, perm=c(2,1,3)))
dim(tperm(tnsr, perm=c(1,3,2)))
```

---

**ttl**

*Tensor Times List*

**Description**
Contracted (m-Mode) product between a `Tensor` of arbitrary number of modes and a list of matrices. The result is folded back into `Tensor`.

**Usage**

```r
ttl(tnsr, list_mat, ms = NULL)
```

**Arguments**

- `tnsr` : Tensor object with K modes
- `list_mat` : a list of matrices
- `ms` : a vector of modes to contract on (order should match the order of `list_mat`)
Details

Performs ttm repeated for a single Tensor and a list of matrices on multiple modes. For instance, suppose we want to do multiply a Tensor object tnsr with three matrices mat1, mat2, mat3 on modes 1, 2, and 3. We could do ttm(ttm(ttm(tnsr,mat1,1),mat2,2),3), or we could do ttl(tnsr,list(mat1,mat2,mat3),c(1,2,3)). The order of the matrices in the list should obviously match the order of the modes. This is a common operation for various Tensor decompositions such as CP and Tucker. For the math on the m-Mode Product, see Kolda and Bader (2009).

Value

Tensor object with K modes

Note

The returned Tensor does not drop any modes equal to 1.

References

See Also

ttm

Examples

tnsr <- new("Tensor",3L,c(3L,4L,5L),data=runif(60))
lizt <- list('mat1' = matrix(runif(30),ncol=3),
               'mat2' = matrix(runif(40),ncol=4),
               'mat3' = matrix(runif(50),ncol=5))
rtl(tnsr,lizt,ms=c(1,2,3))

ttm

Tensor Times Matrix (m-Mode Product)

Description

Contracted (m-Mode) product between a Tensor of arbitrary number of modes and a matrix. The result is folded back into Tensor.

Usage

ttm(tnsr, mat, m = NULL)
**Arguments**

- `tnsr`: Tensor object with K modes
- `mat`: input matrix with same number columns as the mth mode of `tnsr`
- `m`: the mode to contract on

**Details**

By definition, `rs_unfold(ttm(tnsr,mat),m) = mat%*%rs_unfold(tnsr,m)`, so the number of columns in `mat` must match the mth mode of `tnsr`. For the math on the m-Mode Product, see Kolda and Bader (2009).

**Value**

a Tensor object with K modes

**Note**

The mth mode of `tnsr` must match the number of columns in `mat`. By default, the returned Tensor does not drop any modes equal to 1.

**References**

**See Also**

- `ttl.rs_unfold-methods`

**Examples**

```r
tnsr <- new("Tensor",3L,c(3L,4L,5L),data=runif(60))
mat <- matrix(runif(50),ncol=5)
ttm(tnsr,mat,m=3)
```

---

**Description**

The Tucker decomposition of a tensor. Approximates a K-Tensor using a n-mode product of a core tensor (with modes specified by `ranks`) with orthogonal factor matrices. If there is no truncation in one of the modes, then this is the same as the MPCA, `mpca`. If there is no truncation in all the modes (i.e. `ranks = tnsr@modes`), then this is the same as the HOSVD, `hosvd`. This is an iterative algorithm, with two possible stopping conditions: either relative error in Frobenius norm has gotten below `tol`, or the `max_iter` number of iterations has been reached. For more details on the Tucker decomposition, consult Kolda and Bader (2009).
tucker

Usage

tucker(tnsr, ranks = NULL, max_iter = 25, tol = 1e-05)

Arguments

tnsr Tensor with K modes
ranks a vector of the modes of the output core Tensor
max_iter maximum number of iterations if error stays above tol
tol relative Frobenius norm error tolerance

Details

Uses the Alternating Least Squares (ALS) estimation procedure also known as Higher-Order Orthogonal Iteration (HOOI). Initialized using a (Truncated-)HOSVD. A progress bar is included to help monitor operations on large tensors.

Value

a list containing the following:

Z the core tensor, with modes specified by ranks
U a list of orthogonal factor matrices - one for each mode, with the number of columns of the matrices given by ranks
conv whether or not resid < tol by the last iteration
est estimate of tnsr after compression
norm_percent the percent of Frobenius norm explained by the approximation
fnorm_resid the Frobenius norm of the error fnorm(est-tnsr)
all_resids vector containing the Frobenius norm of error for all the iterations

Note

The length of ranks must match tnsr@num_modes.

References

Examples

tnsr <- rand_tensor(c(4,4,4,4))
tuckerD <- tucker(tnsr,ranks=c(2,2,2,2))
tuckerD$conv
tuckerD$norm_percent
plot(tuckerD$all_resids)
t_mult Tensor Multiplication (T-MULT)

Description

Implements T-MULT based on block circulant matrices (Kilmer et al. 2013) for 3-tensors.

Usage

```r
t_mult(x, y)
```

Arguments

- `x` a 3-tensor
- `y` another 3-tensor

Details

Uses the Fast Fourier Transform (FFT) speed up suggested by Kilmer et al. 2013 instead of explicitly constructing the block circulant matrix. For the mathematical details of T-MULT, see Kilmer et al. (2013).

Value

tensor product between x and y

Note

This only works (so far) between 3-Tensors.

References

Examples

```r
tnsr <- new("Tensor", 3L, c(3L,4L,5L), data=runif(60))
tnsr2 <- new("Tensor", 3L, c(4L,3L,5L), data=runif(60))
t_mult(tnsr, tnsr2)
```
Description
TSVD for a 3-Tensor. Constructs 3-Tensors $U, S, V$ such that $\text{tnsr} = \text{t_mult}(\text{t_mult}(U, S), t(V))$. 
$U$ and $V$ are orthogonal 3-Tensors with orthogonality defined in Kilmer et al. (2013), and $S$ is a 3-
Tensor consists of facewise diagonal matrices. For more details on the TSVD, consult Kilmer et al. 
(2013).

Usage
\[ \text{t_svd}(\text{tnsr}) \]

Arguments
\[ \text{tnsr} \quad \text{3-Tensor to decompose via TSVD} \]

Value
a list containing the following:
\[ \text{U} \quad \text{the left orthogonal 3-Tensor} \]
\[ \text{V} \quad \text{the right orthogonal 3-Tensor} \]
\[ \text{S} \quad \text{the middle 3-Tensor consisting of face-wise diagonal matrices} \]

Note
Computation involves complex values, but if the inputs are real, then the outputs are also real. Some 
loss of precision occurs in the truncation of the imaginary components during the FFT and inverse 
FFT.

**t_svd_reconstruct**  
*Reconstruct Tensor From TSVD*

**Description**

Reconstruct the original 3-Tensor after it has been decomposed into $U, S, V$ via `t_svd`.

**Usage**

```r
 t_svd_reconstruct(L)
```

**Arguments**

- **L** list that is an output from `t_svd`

**Value**

a 3-Tensor

**See Also**

- `t_svd`

**Examples**

```r
 tnsr <- rand_tensor(c(10, 10, 10))
 tsvdD <- t_svd(tnsr)
 1 - fnorm(t_svd_reconstruct(tsvdD) - tnsr) / fnorm(tnsr)
```

---

**unfold-methods**  
*Tensor Unfolding*

**Description**

Unfolds the tensor into a matrix, with the modes in `rs` onto the rows and modes in `cs` onto the columns. Note that `c(rs, cs)` must have the same elements (order doesn't matter) as `x@modes`. Within the rows and columns, the order of the unfolding is determined by the order of the modes. This convention is consistent with Kolda and Bader (2009).

**Usage**

```r
 unfold(tnsr, row_idx, col_idx)
```

```
## S4 method for signature 'Tensor'
 unfold(tnsr, row_idx = NULL, col_idx = NULL)
```
Arguments

- tnsr: the Tensor instance
- row_idx: the indices of the modes to map onto the row space
- col_idx: the indices of the modes to map onto the column space

Details

For Row Space Unfolding or m-mode Unfolding, see `rs_unfold-methods`. For Column Space Unfolding or matvec, see `cs_unfold-methods`.

`vec-methods` returns the vectorization of the tensor.

`unfold(tnsr, row_idx=NULL, col_idx=NULL)`

Value

matrix with `prod(row_idx)` rows and `prod(col_idx)` columns

References

See Also

- `k_unfold-methods` and `matvec-methods`

Examples

```r
tnsr <- rand_tensor()
matT3<-unfold(tnsr,row_idx=2,col_idx=c(3,1))
```

unmatvec

Unmatvec Folding of Matrix

Description

The inverse operation to `matvec-methods`, turning a matrix into a Tensor. For a full account of matrix folding/unfolding operations, consult Kolda and Bader (2009).

Usage

```
unmatvec(mat, modes = NULL)
```

Arguments

- mat: matrix to be folded into a Tensor
- modes: the modes of the output Tensor
vec-methods

Value

Tensor object with modes given by modes

References

See Also

matvec-methods, fold, k_fold

Examples

tnsr <- new("Tensor", 3L, c(3L, 4L, 5L), data=runif(60))
matT1<-matvec(tnsr)
identical(unmatvec(matT1,modes=c(3,4,5)),tnsr)

vec-methods

Tensor Vec

Description

Turns the tensor into a single vector, following the convention that earlier indices vary slower than later indices.

Usage

vec(tnsr)

## S4 method for signature 'Tensor'
vec(tnsr)

Arguments

tnsr the Tensor instance

Details

vec(tnsr)

Value

vector with length prod(x@modes)

References

Examples

```r
tnsr <- rand_tensor(c(4,5,6,7))
vec(tnsr)
```

Description

Extends '['] and '[:>' from the base array class for the Tensor class. Works exactly as it would for the base 'array' class.

Usage

```r
## S4 method for signature 'Tensor'
x[i, j, ..., drop = TRUE]

## S4 replacement method for signature 'Tensor'
x[i, j, ...] <- value
```

Arguments

- `x`: Tensor to be subset
- `i, j, ...`: indices that specify the extents of the sub-tensor
- `drop`: whether or not to reduce the number of modes to exclude those that have '1' as the mode
- `value`: either vector, matrix, or array that will replace the subtensor

Details

```r
x[i,j,...,drop=TRUE]
```

Value

an object of class Tensor

Examples

```r
tnsr <- rand_tensor()
tnsr[1,2,3]
tnsr[3,1,]
tnsr[,5]
tnsr[,5,drop=FALSE]

tnsr[1,2,3] <- 3; tnsr[1,2,3]
tnsr[3,1,] <- rep(0,5); tnsr[3,1,]
tnsr[,2,] <- matrix(0,nrow=3,ncol=5); tnsr[,2,]
```
