Package ‘ranger’

April 3, 2023

Type Package
Title A Fast Implementation of Random Forests
Version 0.15.1
Date 2023-04-03
Author Marvin N. Wright [aut, cre], Stefan Wager [ctb], Philipp Probst [ctb]
Maintainer Marvin N. Wright <cran@wrig.de>
Description A fast implementation of Random Forests, particularly suited for high
dimensional data. Ensembles of classification, regression, survival and
probability prediction trees are supported. Data from genome-wide association
studies can be analyzed efficiently. In addition to data frames, datasets of
class 'gwa.data' (R package 'GenABEL') and 'dgCMatrix' (R package 'Matrix')
can be directly analyzed.
License GPL-3
Imports Rcpp (>= 0.11.2), Matrix
LinkingTo Rcpp, RcppEigen
Depends R (>= 3.1)
Suggests survival, testthat
Encoding UTF-8
RoxygenNote 7.2.2

NeedsCompilation yes
Repository CRAN
Date/Publication 2023-04-03 09:20:03 UTC

R topics documented:

csrf ........................................ 2
deforest ..................................... 3
In case-specific random forests (CSRF), random forests are built specific to the cases of interest. Instead of using equal probabilities, the cases are weighted according to their difference to the case of interest.

Usage

csf(formula, training_data, test_data, params1 = list(), params2 = list(), verbose = FALSE)

Arguments

formula Object of class formula or character describing the model to fit.
training_data Training data of class data.frame.
test_data Test data of class data.frame.
params1 Parameters for the proximity random forest grown in the first step.
params2 Parameters for the prediction random forests grown in the second step.
verbose Logical indicating whether or not to print computation progress.
deforest

Details

The algorithm consists of 3 steps:

1. Grow a random forest on the training data
2. For each observation of interest (test data), the weights of all training observations are computed by counting the number of trees in which both observations are in the same terminal node.
3. For each test observation, grow a weighted random forest on the training data, using the weights obtained in step 2. Predict the outcome of the test observation as usual.

In total, n+1 random forests are grown, where n is the number observations in the test dataset. For details, see Xu et al. (2014).

Value

Predictions for the test dataset.

Author(s)

Marvin N. Wright

References

Examples

```r
## Split in training and test data
train.idx <- sample(nrow(iris), 2/3 * nrow(iris))
iris.train <- iris[train.idx, ]
iris.test <- iris[-train.idx, ]

## Run case-specific RF
csf(Species ~ ., training_data = iris.train, test_data = iris.test,
   params1 = list(num.trees = 50, mtry = 4),
   params2 = list(num.trees = 5))
```

---

deforest  
Deforesting a random forest
Description

The main purpose of this function is to allow for post-processing of ensembles via L2 regularized regression (i.e., the LASSO), as described in Friedman and Popescu (2003). The basic idea is to use the LASSO to post-process the predictions from the individual base learners in an ensemble (i.e., decision trees) in the hopes of producing a much smaller model without sacrificing much in the way of accuracy, and in some cases, improving it. Friedman and Popescu (2003) describe conditions under which tree-based ensembles, like random forest, can potentially benefit from such post-processing (e.g., using shallower trees trained on much smaller samples of the training data without replacement). However, the computational benefits of such post-processing can only be realized if the base learners "zeroed out" by the LASSO can actually be removed from the original ensemble, hence the purpose of this function. A complete example using \texttt{ranger} can be found at https://github.com/imbs-hl/ranger/issues/568.

Usage

deforest(object, which.trees = NULL, ...)  
## S3 method for class 'ranger'
deforest(object, which.trees = NULL, warn = TRUE, ...)

Arguments  

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object</td>
<td>A fitted random forest (e.g., a \texttt{ranger} object).</td>
</tr>
<tr>
<td>which.trees</td>
<td>Vector giving the indices of the trees to remove.</td>
</tr>
<tr>
<td>...</td>
<td>Additional (optional) arguments. (Currently ignored.)</td>
</tr>
<tr>
<td>warn</td>
<td>Logical indicating whether or not to warn users that some of the standard output of a typical \texttt{ranger} object or no longer available after deforestation. Default is TRUE.</td>
</tr>
</tbody>
</table>

Value

An object of class "deforest.ranger"; essentially, a \texttt{ranger} object with certain components replaced with NAs (e.g., out-of-bag (OOB) predictions, variable importance scores (if requested), and OOB-based error metrics).

Note

This function is a generic and can be extended by other packages.

getTerminalNodeIDs

Examples

```r
## Example of deforesting a random forest
rfo <- ranger(Species ~ ., data = iris, probability = TRUE, num.trees = 100)
dfo <- deforest(rfo, which.trees = c(1, 3, 5))
dfo # same as 'rfo' but with trees 1, 3, and 5 removed

## Sanity check
preds.rfo <- predict(rfo, data = iris, predict.all = TRUE)$predictions
preds.dfo <- predict(dfo, data = iris, predict.all = TRUE)$predictions
identical(preds.rfo[, , -c(1, 3, 5)], y = preds.dfo)
```

---

getTerminalNodeIDs

Get terminal node IDs (deprecated)

Description

This function is deprecated. Please use predict() with type = "terminalNodes" instead. This function calls predict() now.

Usage

```r
getTerminalNodeIDs(rf, dat)
```

Arguments

- `rf` ranger object.
- `dat` New dataset. Terminal node IDs for this dataset are obtained.

Value

Matrix with terminal node IDs for all observations in dataset and trees.

Examples

```r
rf <- ranger(Species ~ ., data = iris, num.trees = 5, write.forest = TRUE)
getTerminalNodeIDs(rf, iris)
```
holdoutRF

Hold-out random forests

Description

Grow two random forests on two cross-validation folds. Instead of out-of-bag data, the other fold is used to compute permutation importance. Related to the novel permutation variable importance by Janitza et al. (2015).

Usage

holdoutRF(...)

Arguments

... All arguments are passed to ranger() (except importance, case.weights, replace and holdout.).

Value

Hold-out random forests with variable importance.

Author(s)

Marvin N. Wright

References

See Also

ranger
importance.ranger  

ranger variable importance

Description

Extract variable importance of ranger object.

Usage

## S3 method for class 'ranger'
importance(x, ...)

Arguments

x  
ranger object.

...  
Further arguments passed to or from other methods.

Value

Variable importance measures.

Author(s)

Marvin N. Wright

ranger

importance_pvalues  

counter-ranger variable importance p-values

Description

Compute variable importance with p-values. For high dimensional data, the fast method of Janitza et al. (2016) can be used. The permutation approach of Altmann et al. (2010) is computationally intensive but can be used with all kinds of data. See below for details.

Usage

importance_pvalues(
  x,
  method = c("janitza", "altmann"),
  num.permutations = 100,
  formula = NULL,
  data = NULL,
  ...
)
importance_pvalues

Arguments

x ranger or holdoutRF object.

method Method to compute p-values. Use "janitza" for the method by Janitza et al. (2016) or "altmann" for the non-parametric method by Altmann et al. (2010).

num.permutations Number of permutations. Used in the "altmann" method only.

formula Object of class formula or character describing the model to fit. Used in the "altmann" method only.

data Training data of class data.frame or matrix. Used in the "altmann" method only.

... Further arguments passed to ranger(). Used in the "altmann" method only.

Details

The method of Janitza et al. (2016) uses a clever trick: With an unbiased variable importance measure, the importance values of non-associated variables vary randomly around zero. Thus, all non-positive importance values are assumed to correspond to these non-associated variables and they are used to construct a distribution of the importance under the null hypothesis of no association to the response. Since only the non-positive values of this distribution can be observed, the positive values are created by mirroring the negative distribution. See Janitza et al. (2016) for details.

The method of Altmann et al. (2010) uses a simple permutation test: The distribution of the importance under the null hypothesis of no association to the response is created by several replications of permuting the response, growing an RF and computing the variable importance. The authors recommend 50-100 permutations. However, much larger numbers have to be used to estimate more precise p-values. We add 1 to the numerator and denominator to avoid zero p-values.

Value

Variable importance and p-value for each variable.

Author(s)

Marvin N. Wright

ranger
Examples

```r
## Janitza's p-values with corrected Gini importance
n <- 50
p <- 400
dat <- data.frame(y = factor(rbinom(n, 1, .5)), replicate(p, runif(n)))
rf.sim <- ranger(y ~ ., dat, importance = "impurity_corrected")
importance_pvalues(rf.sim, method = "janitza")

## Permutation p-values
## Not run:
rf.iris <- ranger(Species ~ ., data = iris, importance = 'permutation')
importance_pvalues(rf.iris, method = "altmann", formula = Species ~ ., data = iris)

## End(Not run)
```

### parse.formula

**Parse formula**

**Description**

Parse formula and return dataset containing selected columns. Interactions are supported for numerical columns only. An interaction column is the product of all interacting columns.

**Usage**

```r
parse.formula(formula, data, env = parent.frame())
```

**Arguments**

- `formula`: Object of class formula or character describing the model to fit.
- `data`: Training data of class data.frame.
- `env`: The environment in which the left hand side of formula is evaluated.

**Value**

Dataset including selected columns and interactions.
## Description

Prediction with new data and a saved forest from Ranger.

## Usage

```r
## S3 method for class 'ranger'
predict(  
object,  
data = NULL,  
predict.all = FALSE,  
num.trees = object$num.trees,  
type = "response",  
se.method = "infjack",  
quantiles = c(0.1, 0.5, 0.9),  
what = NULL,  
seed = NULL,  
num.threads = NULL,  
verbose = TRUE,  
...  
)
```

## Arguments

- **object**: Ranger ranger object.
- **data**: New test data of class `data.frame` or `gwaa.data` (GenABEL).
- **predict.all**: Return individual predictions for each tree instead of aggregated predictions for all trees. Return a matrix (sample x tree) for classification and regression, a 3d array for probability estimation (sample x class x tree) and survival (sample x time x tree).
- **num.trees**: Number of trees used for prediction. The first `num.trees` in the forest are used.
- **type**: Type of prediction. One of 'response', 'se', 'terminalNodes', 'quantiles' with default 'response'. See below for details.
- **se.method**: Method to compute standard errors. One of 'jack', 'infjack' with default 'infjack'. Only applicable if type = 'se'. See below for details.
- **quantiles**: Vector of quantiles for quantile prediction. Set type = 'quantiles' to use.
- **what**: User specified function for quantile prediction used instead of `quantile`. Must return numeric vector, see examples.
- **seed**: Random seed. Default is NULL, which generates the seed from R. Set to 0 to ignore the R seed. The seed is used in case of ties in classification mode.
- **num.threads**: Number of threads. Default is number of CPUs available.
- **verbose**: Verbose output on or off.
- **...**: further arguments passed to or from other methods.
predict.ranger

Details

For type = 'response' (the default), the predicted classes (classification), predicted numeric values (regression), predicted probabilities (probability estimation) or survival probabilities (survival) are returned. For type = 'se', the standard error of the predictions are returned (regression only). The jackknife-after-bootstrap or infinitesimal jackknife for bagging is used to estimate the standard errors based on out-of-bag predictions. See Wager et al. (2014) for details. For type = 'terminalNodes', the IDs of the terminal node in each tree for each observation in the given dataset are returned. For type = 'quantiles', the selected quantiles for each observation are estimated. See Meinshausen (2006) for details.

If type = 'se' is selected, the method to estimate the variances can be chosen with se.method. Set se.method = 'jack' for jackknife-after-bootstrap and se.method = 'infjack' for the infinitesimal jackknife for bagging.

For classification and predict.all = TRUE, a factor levels are returned as numerics. To retrieve the corresponding factor levels, use rf$forest$levels, if rf is the ranger object.

Value

Object of class ranger.prediction with elements

- predictions: Predicted classes/values (only for classification and regression)
- unique.death.times: Unique death times (only for survival).
- chf: Estimated cumulative hazard function for each sample (only for survival).
- survival: Estimated survival function for each sample (only for survival).
- num.trees: Number of trees.
- num.independent.variables: Number of independent variables.
- treetype: Type of forest/tree. Classification, regression or survival.
- num.samples: Number of samples.

predict.ranger.forest

Description

Prediction with new data and a saved forest from Ranger.

Usage

```r
## S3 method for class 'ranger.forest'
predict(
  object,
  data,
  predict.all = FALSE,
  num.trees = object$num.trees,
  type = "response",
  se.method = "infjack",
  seed = NULL,
  num.threads = NULL,
  verbose = TRUE,
  inbag.counts = NULL,
  ...
)
```
Arguments

object Ranger ranger.forest object.
data New test data of class data.frame or gwaa.data (GenABEL).
predict.all Return individual predictions for each tree instead of aggregated predictions for all trees. Return a matrix (sample x tree) for classification and regression, a 3d array for probability estimation (sample x class x tree) and survival (sample x time x tree).
num.trees Number of trees used for prediction. The first num.trees in the forest are used.
type Type of prediction. One of 'response', 'se', 'terminalNodes', 'quantiles' with default 'response'. See below for details.
se.method Method to compute standard errors. One of 'jack', 'infjack' with default 'infjack'. Only applicable if type = 'se'. See below for details.
seed Random seed. Default is NULL, which generates the seed from R. Set to 0 to ignore the R seed. The seed is used in case of ties in classification mode.
um.threads Number of threads. Default is number of CPUs available.
verbose Verbose output on or off.
inbag.counts Number of times the observations are in-bag in the trees.
... further arguments passed to or from other methods.

details

For type = 'response' (the default), the predicted classes (classification), predicted numeric values (regression), predicted probabilities (probability estimation) or survival probabilities (survival) are returned. For type = 'se', the standard error of the predictions are returned (regression only). The jackknife-after-bootstrap or infinitesimal jackknife for bagging is used to estimate the standard errors based on out-of-bag predictions. See Wager et al. (2014) for details. For type = 'terminalNodes', the IDs of the terminal node in each tree for each observation in the given dataset are returned.

If type = 'se' is selected, the method to estimate the variances can be chosen with se.method. Set se.method = 'jack' for jackknife after bootstrap and se.method = 'infjack' for the infinitesimal jackknife for bagging.

For classification and predict.all = TRUE, a factor levels are returned as numerics. To retrieve the corresponding factor levels, use rf$forest$levels, if rf is the ranger object.

Value

Object of class ranger.prediction with elements

predictions Predicted classes/values (only for classification and regression)
unique.death.times Unique death times (only for survival).
chf Estimated cumulative hazard function for each sample (only for survival).
survival Estimated survival function for each sample (only for survival).
um.trees Number of trees.
um.independent.variables Number of independent variables.
treetype Type of forest/tree. Classification, regression or survival.
um.samples Number of samples.

Marvin N. Wright
Description

Ranger is a fast implementation of random forests (Breiman 2001) or recursive partitioning, particularly suited for high dimensional data. Classification, regression, and survival forests are supported. Classification and regression forests are implemented as in the original Random Forest (Breiman 2001), survival forests as in Random Survival Forests (Ishwaran et al. 2008). Includes implementations of extremely randomized trees (Geurts et al. 2006) and quantile regression forests (Meinshausen 2006).

Usage

ranger(
  formula = NULL,
  data = NULL,
  num.trees = 500,
  mtry = NULL,
  importance = "none",
  write.forest = TRUE,
  probability = FALSE,
  min.node.size = NULL,
  min.bucket = NULL,
  max.depth = NULL,
  replace = TRUE,
  sample.fraction = ifelse(replace, 1, 0.632),
  case.weights = NULL,
  class.weights = NULL,
  splitrule = NULL,
  num.random.splits = 1,
  alpha = 0.5,
  minprop = 0.1,
  split.select.weights = NULL,
  always.split.variables = NULL,
  respect.unordered.factors = NULL,
  scale.permutation.importance = FALSE,
  local.importance = FALSE,
  regularization.factor = 1,
  regularization.usedepth = FALSE,
  keep.inbag = FALSE,
  inbag = NULL,
  holdout = FALSE,
  quantreg = FALSE,
  oob.error = TRUE,
  num.threads = NULL,
  save.memory = FALSE,
```
verbose = TRUE,
seed = NULL,
dependent.variable.name = NULL,
status.variable.name = NULL,
classification = NULL,
x = NULL,
y = NULL,
```

Arguments

- **formula**: Object of class `formula` or character describing the model to fit. Interaction terms supported only for numerical variables.
- **data**: Training data of class `data.frame`, `matrix`, `dgCMatrix` (Matrix) or `gwaa.data` (GenABEL).
- **num.trees**: Number of trees.
- **mtry**: Number of variables to possibly split at in each node. Default is the (rounded down) square root of the number variables. Alternatively, a single argument function returning an integer, given the number of independent variables.
- **importance**: Variable importance mode, one of 'none', 'impurity', 'impurity_corrected', 'permutation'. The 'impurity' measure is the Gini index for classification, the variance of the responses for regression and the sum of test statistics (see `splitrule`) for survival.
- **write.forest**: Save `ranger.forest` object, required for prediction. Set to FALSE to reduce memory usage if no prediction intended.
- **probability**: Grow a probability forest as in Malley et al. (2012).
- **min.node.size**: Minimal node size to split at. Default 1 for classification, 5 for regression, 3 for survival, and 10 for probability.
- **min.bucket**: Minimal terminal node size. No nodes smaller than this value can occur. Default 3 for survival and 1 for all other tree types.
- **max.depth**: Maximal tree depth. A value of NULL or 0 (the default) corresponds to unlimited depth, 1 to tree stumps (1 split per tree).
- **replace**: Sample with replacement.
- **sample.fraction**: Fraction of observations to sample. Default is 1 for sampling with replacement and 0.632 for sampling without replacement. For classification, this can be a vector of class-specific values.
- **case.weights**: Weights for sampling of training observations. Observations with larger weights will be selected with higher probability in the bootstrap (or subsampled) samples for the trees.
- **class.weights**: Weights for the outcome classes (in order of the factor levels) in the splitting rule (cost sensitive learning). Classification and probability prediction only. For classification the weights are also applied in the majority vote in terminal nodes.
splitrule   Splitting rule. For classification and probability estimation "gini", "extratrees" or "hellinger" with default "gini". For regression "variance", "extratrees", "maxstat" or "beta" with default "variance". For survival "logrank", "extratrees", "C" or "maxstat" with default "logrank".

num.random.splits   For "extratrees" splitrule.: Number of random splits to consider for each candidate splitting variable.

alpha   For "maxstat" splitrule: Significance threshold to allow splitting.

minprop   For "maxstat" splitrule: Lower quantile of covariate distribution to be considered for splitting.

split.select.weights   Numeric vector with weights between 0 and 1, used to calculate the probability to select variables for splitting. Alternatively, a list of size num.trees, containing split select weight vectors for each tree can be used.

always.split.variables   Character vector with variable names to be always selected in addition to the mtry variables tried for splitting.

respect.unordered.factors   Handling of unordered factor covariates. One of 'ignore', 'order' and 'partition'. For the "extratrees" splitrule the default is 'partition' for all other splitrules 'ignore'. Alternatively TRUE (= 'order') or FALSE (= 'ignore') can be used. See below for details.

scale.permutation.importance   Scale permutation importance by standard error as in (Breiman 2001). Only applicable if permutation variable importance mode selected.

local.importance   Calculate and return local importance values as in (Breiman 2001). Only applicable if importance is set to 'permutation'.

regularization.factor   Regularization factor (gain penalization), either a vector of length p or one value for all variables.

regularization.usedepth   Consider the depth in regularization.

keep.inbag   Save how often observations are in-bag in each tree.

inbag   Manually set observations per tree. List of size num.trees, containing inbag counts for each observation. Can be used for stratified sampling.

holdout   Hold-out mode. Hold-out all samples with case weight 0 and use these for variable importance and prediction error.

quantreg   Prepare quantile prediction as in quantile regression forests (Meinshausen 2006). Regression only. Set keep.inbag = TRUE to prepare out-of-bag quantile prediction.

oob.error   Compute OOB prediction error. Set to FALSE to save computation time, e.g. for large survival forests.

num.threads   Number of threads. Default is number of CPUs available.
save.memory  Use memory saving (but slower) splitting mode. No effect for survival and
GWAS data. Warning: This option slows down the tree growing, use only if you
encounter memory problems.

verbose  Show computation status and estimated runtime.

seed  Random seed. Default is NULL, which generates the seed from R. Set to 0 to
ignore the R seed.

dependent.variable.name  Name of dependent variable, needed if no formula given. For survival forests
this is the time variable.

status.variable.name  Name of status variable, only applicable to survival data and needed if no for-
mula given. Use 1 for event and 0 for censoring.

classification  Set to TRUE to grow a classification forest. Only needed if the data is a matrix or
the response numeric.

x  Predictor data (independent variables), alternative interface to data with formula
or dependent.variable.name.

y  Response vector (dependent variable), alternative interface to data with formula
or dependent.variable.name. For survival use a Surv() object or a matrix with
time and status.

...  Further arguments passed to or from other methods (currently ignored).

Details

The tree type is determined by the type of the dependent variable. For factors classification trees are
grown, for numeric values regression trees and for survival objects survival trees. The Gini index is
used as default splitting rule for classification. For regression, the estimated response variances or
maximally selected rank statistics (Wright et al. 2016) can be used. For Survival the log-rank test,
a C-index based splitting rule (Schmid et al. 2015) and maximally selected rank statistics (Wright
et al. 2016) are available. For all tree types, forests of extremely randomized trees (Geurts et al.
2006) can be grown.

With the probability option and factor dependent variable a probability forest is grown. Here,
the node impurity is used for splitting, as in classification forests. Predictions are class probabilities
for each sample. In contrast to other implementations, each tree returns a probability estimate and
these estimates are averaged for the forest probability estimate. For details see Malley et al. (2012).

Note that nodes with size smaller than min.node.size can occur because min.node.size is the
minimal node size to split at, as in original Random Forests. To restrict the size of terminal nodes,
set min.bucket. Variables selected with always.split.variables are tried additionally to the
mtry variables randomly selected. In split.select.weights, weights do not need to sum up to 1,
they will be normalized later. The weights are assigned to the variables in the order they appear in
the formula or in the data if no formula is used. Names of the split.select.weights vector are
ignored. Weights assigned by split.select.weights to variables in always.split.variables
are ignored. The usage of split.select.weights can increase the computation times for large
forests.

Unordered factor covariates can be handled in 3 different ways by using respect.unordered.factors:
For ‘ignore’ all factors are regarded ordered, for ‘partition’ all possible 2-partitions are considered
for splitting. For 'order' and 2-class classification the factor levels are ordered by their propor-
tion falling in the second class, for regression by their mean response, as described in Hastie et al. (2009), chapter 9.2.4. For multiclass classification the factor levels are ordered by the first principal
component of the weighted covariance matrix of the contingency table (Coppersmith et al. 1999),
for survival by the median survival (or the largest available quantile if the median is not available).
The use of 'order' is recommended, as it computationally fast and can handle an unlimited number
of factor levels. Note that the factors are only reordered once and not again in each split.

The 'impurity_corrected' importance measure is unbiased in terms of the number of categories and
category frequencies and is almost as fast as the standard impurity importance. It is a modified
version of the method by Sandri & Zuccolotto (2008), which is faster and more memory efficient.
See Nembrini et al. (2018) for details. This importance measure can be combined with the methods
to estimate p-values in importance_pvalues. We recommend not to use the 'impurity_corrected'
importance when making predictions since the feature permutation step might reduce predictive
performance (a warning is raised when predicting on new data).

Regularization works by penalizing new variables by multiplying the splitting criterion by a factor,
see Deng & Runger (2012) for details. If regularization.usedepth=TRUE, \( f^d \) is used, where \( f \)
is the regularization factor and \( d \) the depth of the node. If regularization is used, multithreading
is deactivated because all trees need access to the list of variables that are already included in the
model.

For a large number of variables and data frames as input data the formula interface can be slow
or impossible to use. Alternatively dependent.variable.name (and status.variable.name for
survival) or x and y can be used. Use x and y with a matrix for x to avoid conversions and save
memory. Consider setting save.memory = TRUE if you encounter memory problems for very large
datasets, but be aware that this option slows down the tree growing.

For GWAS data consider combining ranger with the GenABEL package. See the Examples section
below for a demonstration using Plink data. All SNPs in the GenABEL object will be used for
splitting. To use only the SNPs without sex or other covariates from the phenotype file, use \( y \)
on the right hand side of the formula. Note that missing values are treated as an extra category while
splitting.

See https://github.com/imbs-hl/ranger for the development version.

With recent R versions, multithreading on Windows platforms should just work. If you compile
yourself, the new RTools toolchain is required.

Value

Object of class ranger with elements

forest Saved forest (If write.forest set to TRUE). Note that the variable IDs in the
split.varIDs object do not necessarily represent the column number in R.
predictions Predicted classes/values, based on out of bag samples (classification and regres-
sion only).
variable.importance Variable importance for each independent variable.
variable.importance.local Variable importance for each independent variable and each sample, if local.importance
is set to TRUE and importance is set to 'permutation'.
prediction.error
Overall out of bag prediction error. For classification this is the fraction of misclassified samples, for probability estimation the Brier score, for regression the mean squared error and for survival one minus Harrell’s C-index.

r.squared
R squared. Also called explained variance or coefficient of determination (regression only). Computed on out of bag data.

confusion.matrix
Contingency table for classes and predictions based on out of bag samples (classification only).

unique.death.times
Unique death times (survival only).

chf
Estimated cumulative hazard function for each sample (survival only).

survival
Estimated survival function for each sample (survival only).

call
Function call.

num.trees
Number of trees.

num.independent.variables
Number of independent variables.

mtry
Value of mtry used.

min.node.size
Value of minimal node size used.

treetype
Type of forest/tree. classification, regression or survival.

importance.mode
Importance mode used.

num.samples
Number of samples.

inbag.counts
Number of times the observations are in-bag in the trees.

predict.ranger

Examples

```r
## Classification forest with default settings
ranger(Species ~ ., data = iris)

## Prediction
train.idx <- sample(nrow(iris), 2/3 * nrow(iris))
iris.train <- iris[train.idx, ]
iris.test <- iris[-train.idx, ]
rg.iris <- ranger(Species ~ ., data = iris.train)
pred.iris <- predict(rg.iris, data = iris.test)
table(iris.test$Species, pred.iris$predictions)

## Quantile regression forest
rf <- ranger(mpg ~ ., mtcars[1:26, ], quantreg = TRUE)
pred <- predict(rf, mtcars[27:32, ], type = "quantiles")
pred$predictions

## Variable importance
rg.iris <- ranger(Species ~ ., data = iris, importance = "impurity")
rg.iris$variable.importance

## Survival forest
require(survival)
rg.veteran <- ranger(Surv(time, status) ~ ., data = veteran)
plot(rg.veteran$unique.death.times, rg.veteran$survival[1,])

## Alternative interfaces (same results)
```
ranger(dependent.variable.name = "Species", data = iris)
ranger(y = iris[, 5], x = iris[, -5])

## Not run:
## Use GenABEL interface to read Plink data into R and grow a classification forest
## The ped and map files are not included
library(GenABEL)
convert.snp.ped("data.ped", "data.map", "data.raw")
dat.gwaa <- load.gwaa.data("data.pheno", "data.raw")
phdata(dat.gwaa)$trait <- factor(phdata(dat.gwaa)$trait)
ranger(trait ~ ., data = dat.gwaa)

## End(Not run)

timepoints.ranger  Ranger timepoints

Description

Extract unique death times of Ranger Survival forest

Usage

## S3 method for class 'ranger'
timepoints(x, ...)

Arguments

x  Ranger Survival forest object.
...	Further arguments passed to or from other methods.

Value

Unique death times

Author(s)

Marvin N. Wright

ranger
### timepoints.ranger.prediction

*Ranger timepoints*

## Description

Extract unique death times of Ranger Survival prediction object.

## Usage

```r
## S3 method for class 'ranger.prediction'
timepoints(x, ...)
```

## Arguments

- `x` Ranger Survival prediction object.
- `...` Further arguments passed to or from other methods.

## Value

Unique death times

## Author(s)

Marvin N. Wright

## See Also

- `ranger`

### treeInfo

*Tree information in human readable format*

## Description

Extract tree information of a ranger object.

## Usage

```r
treeInfo(object, tree = 1)
```

## Arguments

- `object` ranger object.
- `tree` Number of the tree of interest.
Details

Node and variable ID’s are 0-indexed, i.e., node 0 is the root node. If the formula interface is used in the ranger call, the variable ID’s are usually different to the original data used to grow the tree. Refer to the variable name instead to be sure.

Splitting at unordered factors (nominal variables) depends on the option `respect.unordered.factors` in the ranger call. For the "ignore" and "order" approaches, all values smaller or equal the `splitval` value go to the left and all values larger go to the right, as usual. However, with "order" the values correspond to the order in `object$forest$covariate.levels` instead of the original order (usually alphabetical). In the "partition" mode, the `splitval` values for unordered factor are comma separated lists of values, representing the factor levels (in the original order) going to the right.

Value

A data.frame with the columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nodeID</td>
<td>The nodeID, 0-indexed.</td>
</tr>
<tr>
<td>leftChild</td>
<td>ID of the left child node, 0-indexed.</td>
</tr>
<tr>
<td>rightChild</td>
<td>ID of the right child node, 0-indexed.</td>
</tr>
<tr>
<td>splitvarID</td>
<td>ID of the splitting variable, 0-indexed. Caution, the variable order changes if the formula interface is used.</td>
</tr>
<tr>
<td>splitvarName</td>
<td>Name of the splitting variable.</td>
</tr>
<tr>
<td>splitval</td>
<td>The splitting value. For numeric or ordinal variables, all values smaller or equal go to the left, larger values to the right.</td>
</tr>
<tr>
<td>terminal</td>
<td>Logical, TRUE for terminal nodes.</td>
</tr>
<tr>
<td>prediction</td>
<td>One column with the predicted class (factor) for classification and the predicted numerical value for regression.</td>
</tr>
</tbody>
</table>
