Package ‘ranger’

November 12, 2023

Type Package

Title A Fast Implementation of Random Forests

Version 0.16.0

Date 2023-11-09

Author Marvin N. Wright [aut, cre], Stefan Wager [ctb], Philipp Probst [ctb]

Maintainer Marvin N. Wright <cran@wrig.de>

Description A fast implementation of Random Forests, particularly suited for high dimensional data. Ensembles of classification, regression, survival and probability prediction trees are supported. Data from genome-wide association studies can be analyzed efficiently. In addition to data frames, datasets of class 'gwaa.data' (R package 'GenABEL') and 'dgCMatrix' (R package 'Matrix') can be directly analyzed.

License GPL-3

Imports Rcpp (>= 0.11.2), Matrix

LinkingTo Rcpp, RcppEigen

Depends R (>= 3.1)

Suggests survival, testthat

Encoding UTF-8

csrf

Case-specific random forests.

Description

In case-specific random forests (CSRF), random forests are built specific to the cases of interest. Instead of using equal probabilities, the cases are weighted according to their difference to the case of interest.

Usage

csrft(
  formula,
  training_data,
  test_data,
  params1 = list(),
  params2 = list(),
  verbose = FALSE
)
Arguments

- `formula`: Object of class `formula` or character describing the model to fit.
- `training_data`: Training data of class `data.frame`.
- `test_data`: Test data of class `data.frame`.
- `params1`: Parameters for the proximity random forest grown in the first step.
- `params2`: Parameters for the prediction random forests grown in the second step.
- `verbose`: Logical indicating whether or not to print computation progress.

Details

The algorithm consists of 3 steps:

1. Grow a random forest on the training data
2. For each observation of interest (test data), the weights of all training observations are computed by counting the number of trees in which both observations are in the same terminal node.
3. For each test observation, grow a weighted random forest on the training data, using the weights obtained in step 2. Predict the outcome of the test observation as usual.

In total, n+1 random forests are grown, where n is the number observations in the test dataset. For details, see Xu et al. (2014).

Value

Predictions for the test dataset.

Author(s)

Marvin N. Wright

References

Examples

```r
## Split in training and test data
train.idx <- sample(nrow(iris), 2/3 * nrow(iris))
iris.train <- iris[train.idx, ]
iris.test <- iris[-train.idx, ]

## Run case-specific RF
csr(Species ~ ., training_data = iris.train, test_data = iris.test, 
   params1 = list(num.trees = 50, mtry = 4),
   params2 = list(num.trees = 5))
```
Deforesting a random forest

Description

The main purpose of this function is to allow for post-processing of ensembles via L2 regularized regression (i.e., the LASSO), as described in Friedman and Popescu (2003). The basic idea is to use the LASSO to post-process the predictions from the individual base learners in an ensemble (i.e., decision trees) in the hopes of producing a much smaller model without sacrificing much in the way of accuracy, and in some cases, improving it. Friedman and Popescu (2003) describe conditions under which tree-based ensembles, like random forest, can potentially benefit from such post-processing (e.g., using shallower trees trained on much smaller samples of the training data without replacement). However, the computational benefits of such post-processing can only be realized if the base learners "zeroed out" by the LASSO can actually be removed from the original ensemble, hence the purpose of this function. A complete example using \texttt{ranger} can be found at https://github.com/imbs-hl/ranger/issues/568.

Usage

deforest(object, which.trees = NULL, ...)  

## S3 method for class 'ranger'  
deforest(object, which.trees = NULL, warn = TRUE, ...)

Arguments

- \textbf{object}  
  A fitted random forest (e.g., a \texttt{ranger} object).
- \textbf{which.trees}  
  Vector giving the indices of the trees to remove.
- \textbf{warn}  
  Logical indicating whether or not to warn users that some of the standard output of a typical \texttt{ranger} object or no longer available after deforestation. Default is \texttt{TRUE}.
- \textbf{...}  
  Additional (optional) arguments. (Currently ignored.)

Value

An object of class "deforest.ranger"; essentially, a \texttt{ranger} object with certain components replaced with NAs (e.g., out-of-bag (OOB) predictions, variable importance scores (if requested), and OOB-based error metrics).

Note

This function is a generic and can be extended by other packages.

Author(s)

Brandon M. Greenwell
getTerminalNodeIDs

References

Examples

## Example of deforesting a random forest
rfo <- ranger(Species ~ ., data = iris, probability = TRUE, num.trees = 100)
dfo <- deforest(rfo, which.trees = c(1, 3, 5))
dfo  # same as `rfo` but with trees 1, 3, and 5 removed

## Sanity check
preds.rfo <- predict(rfo, data = iris, predict.all = TRUE)$predictions
preds.dfo <- predict(dfo, data = iris, predict.all = TRUE)$predictions
identical(preds.rfo[, , -c(1, 3, 5)], y = preds.dfo)

getTerminalNodeIDs  Get terminal node IDs (deprecated)

Description

This function is deprecated. Please use predict() with type = "terminalNodes" instead. This function calls predict() now.

Usage

getTerminalNodeIDs(rf, dat)

Arguments

rf  ranger object.
dat  New dataset. Terminal node IDs for this dataset are obtained.

Value

Matrix with terminal node IDs for all observations in dataset and trees.

Examples

rf <- ranger(Species ~ ., data = iris, num.trees = 5, write.forest = TRUE)
getTerminalNodeIDs(rf, iris)
**holdoutRF**

*Hold-out random forests*

**Description**

Grow two random forests on two cross-validation folds. Instead of out-of-bag data, the other fold is used to compute permutation importance. Related to the novel permutation variable importance by Janitza et al. (2015).

**Usage**

`holdoutRF(...)`

**Arguments**

...  

All arguments are passed to `ranger()` (except `importance`, `case.weights`, `replace` and `holdout`).

**Value**

Hold-out random forests with variable importance.

ranger

importance_pvalues

ranger variable importance p-values

Description

Compute variable importance with p-values. For high dimensional data, the fast method of Janitza et al. (2016) can be used. The permutation approach of Altmann et al. (2010) is computationally intensive but can be used with all kinds of data. See below for details.

Usage

importance_pvalues(
  x,
  method = c("janitza", "altmann"),
  num.permutations = 100,
  formula = NULL,
  data = NULL,
  ...
)
Arguments

x ranger or holdoutRF object.

method Method to compute p-values. Use "janitza" for the method by Janitza et al. (2016) or "altmann" for the non-parametric method by Altmann et al. (2010).

num.permutations Number of permutations. Used in the "altmann" method only.

formula Object of class formula or character describing the model to fit. Used in the "altmann" method only.

data Training data of class data.frame or matrix. Used in the "altmann" method only.

Details

The method of Janitza et al. (2016) uses a clever trick: With an unbiased variable importance measure, the importance values of non-associated variables vary randomly around zero. Thus, all non-positive importance values are assumed to correspond to these non-associated variables and they are used to construct a distribution of the importance under the null hypothesis of no association to the response. Since only the non-positive values of this distribution can be observed, the positive values are created by mirroring the negative distribution. See Janitza et al. (2016) for details.

The method of Altmann et al. (2010) uses a simple permutation test: The distribution of the importance under the null hypothesis of no association to the response is created by several replications of permuting the response, growing an RF and computing the variable importance. The authors recommend 50-100 permutations. However, much larger numbers have to be used to estimate more precise p-values. We add 1 to the numerator and denominator to avoid zero p-values.

Value

Variable importance and p-value for each variable.

Author(s)

Marvin N. Wright

Examples

```r
## Janitza's p-values with corrected Gini importance
n <- 50
p <- 400
dat <- data.frame(y = factor(rbinom(n, 1, .5)), replicate(p, runif(n)))
rf.sim <- ranger(y ~ ., dat, importance = "impurity_corrected")
importance_pvalues(rf.sim, method = "janitza")

## Permutation p-values
## Not run:
rf.iris <- ranger(Species ~ ., data = iris, importance = "permutation")
importance_pvalues(rf.iris, method = "altermann", formula = Species ~ ., data = iris)
## End(Not run)
```

parse.formula

Parse formula

Description

Parse formula and return dataset containing selected columns. Interactions are supported for numerical columns only. An interaction column is the product of all interacting columns.

Usage

```r
parse.formula(formula, data, env = parent.frame())
```

Arguments

- **formula**: Object of class formula or character describing the model to fit.
- **data**: Training data of class data.frame.
- **env**: The environment in which the left hand side of formula is evaluated.

Value

Dataset including selected columns and interactions.
predict.ranger

Ranger prediction

Description

Prediction with new data and a saved forest from Ranger.

Usage

```r
## S3 method for class 'ranger'
predict(
  object,
  data = NULL,
  predict.all = FALSE,
  num.trees = object$num.trees,
  type = "response",
  se.method = "infjack",
  quantiles = c(0.1, 0.5, 0.9),
  what = NULL,
  seed = NULL,
  num.threads = NULL,
  verbose = TRUE,
  ...
)
```

Arguments

- `object`: Ranger ranger object.
- `data`: New test data of class `data.frame` or `gwaa.data` (GenABEL).
- `predict.all`: Return individual predictions for each tree instead of aggregated predictions for all trees. Return a matrix (sample x tree) for classification and regression, a 3d array for probability estimation (sample x class x tree) and survival (sample x time x tree).
- `num.trees`: Number of trees used for prediction. The first `num.trees` in the forest are used.
- `type`: Type of prediction. One of 'response', 'se', 'terminalNodes', 'quantiles' with default 'response'. See below for details.
- `se.method`: Method to compute standard errors. One of 'jack', 'infjack' with default 'infjack'. Only applicable if type = 'se'. See below for details.
- `quantiles`: Vector of quantiles for quantile prediction. Set type = 'quantiles' to use.
- `what`: User specified function for quantile prediction used instead of `quantile`. Must return numeric vector, see examples.
- `seed`: Random seed. Default is NULL, which generates the seed from R. Set to 0 to ignore the R seed. The seed is used in case of ties in classification mode.
- `num.threads`: Number of threads. Default is number of CPUs available.
- `verbose`: Verbose output on or off.
- `...`: further arguments passed to or from other methods.
Details

For type = 'response' (the default), the predicted classes (classification), predicted numeric values (regression), predicted probabilities (probability estimation) or survival probabilities (survival) are returned. For type = 'se', the standard error of the predictions are returned (regression only). The jackknife-after-bootstrap or infinitesimal jackknife for bagging is used to estimate the standard errors based on out-of-bag predictions. See Wager et al. (2014) for details. For type = 'terminalNodes', the IDs of the terminal node in each tree for each observation in the given dataset are returned. For type = 'quantiles', the selected quantiles for each observation are estimated. See Meinshausen (2006) for details.

If type = 'se' is selected, the method to estimate the variances can be chosen with se.method. Set se.method = 'jack' for jackknife-after-bootstrap and se.method = 'infjack' for the infinitesimal jackknife for bagging.

For classification and predict.all = TRUE, a factor levels are returned as numerics. To retrieve the corresponding factor levels, use rf$forest$levels, if rf is the ranger object.

Value

Object of class ranger.prediction with elements

- predictions: Predicted classes/values (only for classification and regression)
- unique.death.times: Unique death times (only for survival).
- chf: Estimated cumulative hazard function for each sample (only for survival).
- survival: Estimated survival function for each sample (only for survival).
- num.trees: Number of trees.
- num.independent.variables: Number of independent variables.
- treetype: Type of forest/tree. Classification, regression or survival.
- num.samples: Number of samples.

ranger
**Examples**

```r
## Classification forest
ranger(Species ~ ., data = iris)
train.idx <- sample(nrow(iris), 2/3 * nrow(iris))
iris.train <- iris[train.idx ,]
iris.test <- iris[-train.idx ,]
rg.iris <- ranger(Species ~ ., data = iris.train)
pred.iris <- predict(rg.iris, data = iris.test)
table(iris.test$Species, pred.iris$predictions)

## Quantile regression forest
rf <- ranger(mpg ~ ., mtcars[1:26, ], quantreg = TRUE)
pred <- predict(rf, mtcars[27:32, ], type = "quantiles", quantiles = c(0.1, 0.5, 0.9))
pred$predictions

## Quantile regression forest with user-specified function
rf <- ranger(mpg ~ ., mtcars[1:26, ], quantreg = TRUE)
pred <- predict(rf, mtcars[27:32, ], type = "quantiles",
what = function(x) sample(x, 10, replace = TRUE))
pred$predictions
```

**Description**

Prediction with new data and a saved forest from Ranger.

**Usage**

```r
## S3 method for class 'ranger.forest'
predict(
  object,
  data,
  predict.all = FALSE,
  num.trees = object$num.trees,
  type = "response",
  se.method = "infjack",
  seed = NULL,
  num.threads = NULL,
  verbose = TRUE,
  inbag.counts = NULL,
  ...
)
```
**predict.ranger.forest**

**Arguments**

- **object**  
  Ranger `ranger.forest` object.

- **data**  
  New test data of class `data.frame` or `gwaa.data` (GenABEL).

- **predict.all**  
  Return individual predictions for each tree instead of aggregated predictions for all trees. Return a matrix (sample x tree) for classification and regression, a 3d array for probability estimation (sample x class x tree) and survival (sample x time x tree).

- **num.trees**  
  Number of trees used for prediction. The first `num.trees` in the forest are used.

- **type**  
  Type of prediction. One of 'response', 'se', 'terminalNodes', 'quantiles' with default 'response'. See below for details.

- **se.method**  
  Method to compute standard errors. One of 'jack', 'infjack' with default 'infjack'. Only applicable if `type` = 'se'. See below for details.

- **seed**  
  Random seed. Default is `NULL`, which generates the seed from R. Set to 0 to ignore the R seed. The seed is used in case of ties in classification mode.

- **num.threads**  
  Number of threads. Default is number of CPUs available.

- **verbose**  
  Verbose output on or off.

- **inbag.counts**  
  Number of times the observations are in-bag in the trees.

- **...**  
  Further arguments passed to or from other methods.

**Details**

For `type` = 'response' (the default), the predicted classes (classification), predicted numeric values (regression), predicted probabilities (probability estimation) or survival probabilities (survival) are returned. For `type` = 'se', the standard error of the predictions are returned (regression only). The jackknife-after-bootstrap or infinitesimal jackknife for bagging is used to estimate the standard errors based on out-of-bag predictions. See Wager et al. (2014) for details. For `type` = 'terminalNodes', the IDs of the terminal node in each tree for each observation in the given dataset are returned.

If `type` = 'se' is selected, the method to estimate the variances can be chosen with `se.method`. Set `se.method = 'jack'` for jackknife after bootstrap and `se.method = 'infjack'` for the infinitesimal jackknife for bagging.

For classification and predict.all = TRUE, a factor levels are returned as numerics. To retrieve the corresponding factor levels, use `rf$forest$levels`, if `rf` is the ranger object.

**Value**

Object of class `ranger.prediction` with elements

- **predictions**  
  Predicted classes/values (only for classification and regression)

- **unique.death.times**  
  Unique death times (only for survival).

- **chf**  
  Estimated cumulative hazard function for each sample (only for survival).

- **survival**  
  Estimated survival function for each sample (only for survival).

- **num.trees**  
  Number of trees.

- **num.independent.variables**  
  Number of independent variables.

- **treetype**  
  Type of forest/tree. Classification, regression or survival.

- **num.samples**  
  Number of samples.

Description

Ranger is a fast implementation of random forests (Breiman 2001) or recursive partitioning, particularly suited for high dimensional data. Classification, regression, and survival forests are supported. Classification and regression forests are implemented as in the original Random Forest (Breiman 2001), survival forests as in Random Survival Forests (Ishwaran et al. 2008). Includes implementations of extremely randomized trees (Geurts et al. 2006) and quantile regression forests (Meinshausen 2006).

Usage

```r
ranger(formula = NULL, data = NULL, num.trees = 500, mtry = NULL, importance = "none", write.forest = TRUE, probability = FALSE, min.node.size = NULL, min.bucket = NULL, max.depth = NULL, replace = TRUE, sample.fraction = ifelse(replace, 1, 0.632), case.weights = NULL, class.weights = NULL, splitrule = NULL, num.random.splits = 1, alpha = 0.5, minprop = 0.1, split.select.weights = NULL, always.split.variables = NULL, respect.unordered.factors = NULL, scale.permutation.importance = FALSE, local.importance = FALSE, regularization.factor = 1, regularization.usedepth = FALSE, keep.inbag = FALSE, inbag = NULL, holdout = FALSE, quantreg = FALSE, time.interest = NULL, oob.error = TRUE, num.threads = NULL,
```
save.memory = FALSE,
verbose = TRUE,
node.stats = FALSE,
seed = NULL,
dependent.variable.name = NULL,
status.variable.name = NULL,
classification = NULL,
x = NULL,
y = NULL,
...)

Arguments

formula Object of class formula or character describing the model to fit. Interaction terms supported only for numerical variables.
data Training data of class data.frame, matrix, dgCMatrix (Matrix) or gwaa.data (GenABEL).
num.trees Number of trees.
mtry Number of variables to possibly split at in each node. Default is the (rounded down) square root of the number variables. Alternatively, a single argument function returning an integer, given the number of independent variables.
importance Variable importance mode, one of 'none', 'impurity', 'impurity_corrected', 'permutation'. The 'impurity' measure is the Gini index for classification, the variance of the responses for regression and the sum of test statistics (see splitrule) for survival.
write.forest Save ranger.forest object, required for prediction. Set to FALSE to reduce memory usage if no prediction intended.
probability Grow a probability forest as in Malley et al. (2012).
min.node.size Minimal node size to split at. Default 1 for classification, 5 for regression, 3 for survival, and 10 for probability.
min.bucket Minimal terminal node size. No nodes smaller than this value can occur. Default 3 for survival and 1 for all other tree types.
max.depth Maximal tree depth. A value of NULL or 0 (the default) corresponds to unlimited depth, 1 to tree stumps (1 split per tree).
replace Sample with replacement.
sample.fraction Fraction of observations to sample. Default is 1 for sampling with replacement and 0.632 for sampling without replacement. For classification, this can be a vector of class-specific values.
case.weights Weights for sampling of training observations. Observations with larger weights will be selected with higher probability in the bootstrap (or subsampled) samples for the trees.
class.weights Weights for the outcome classes (in order of the factor levels) in the splitting rule (cost sensitive learning). Classification and probability prediction only. For classification the weights are also applied in the majority vote in terminal nodes.
splitrule  Splitting rule. For classification and probability estimation "gini", "extratrees" or "hellinger" with default "gini". For regression "variance", "extratrees", "maxstat" or "beta" with default "variance". For survival "logrank", "extratrees", "C" or "maxstat" with default "logrank".

num.random.splits  For "extratrees" splitrule: Number of random splits to consider for each candidate splitting variable.

alpha  For "maxstat" splitrule: Significance threshold to allow splitting.

minprop  For "maxstat" splitrule: Lower quantile of covariate distribution to be considered for splitting.

split.select.weights  Numeric vector with weights between 0 and 1, used to calculate the probability to select variables for splitting. Alternatively, a list of size num.trees, containing split select weight vectors for each tree can be used.

always.split.variables  Character vector with variable names to be always selected in addition to the mtry variables tried for splitting.

respect.unordered.factors  Handling of unordered factor covariates. One of 'ignore', 'order' and 'partition'. For the "extratrees" splitrule the default is "partition" for all other splitrules 'ignore'. Alternatively TRUE (= 'order') or FALSE (= 'ignore') can be used. See below for details.

scale.permutation.importance  Scale permutation importance by standard error as in (Breiman 2001). Only applicable if permutation variable importance mode selected.

local.importance  Calculate and return local importance values as in (Breiman 2001). Only applicable if importance is set to 'permutation'.

regularization.factor  Regularization factor (gain penalization), either a vector of length p or one value for all variables.

regularization.usedepth  Consider the depth in regularization.

keep.inbag  Save how often observations are in-bag in each tree.

inbag  Manually set observations per tree. List of size num.trees, containing inbag counts for each observation. Can be used for stratified sampling.

holdout  Hold-out mode. Hold-out all samples with case weight 0 and use these for variable importance and prediction error.

quantreg  Prepare quantile prediction as in quantile regression forests (Meinshausen 2006). Regression only. Set keep.inbag = TRUE to prepare out-of-bag quantile prediction.

time.interest  Time points of interest (survival only). Can be NULL (default, use all observed time points), a vector of time points or a single number to use as many time points (grid over observed time points).
oob.error Compute OOB prediction error. Set to FALSE to save computation time, e.g. for large survival forests.

num.threads Number of threads. Default is number of CPUs available.

save.memory Use memory saving (but slower) splitting mode. No effect for survival and GWAS data. Warning: This option slows down the tree growing, use only if you encounter memory problems.

verbose Show computation status and estimated runtime.

node.stats Save node statistics. Set to TRUE to save prediction, number of observations and split statistics for each node.

seed Random seed. Default is NULL, which generates the seed from R. Set to 0 to ignore the R seed.

dependent.variable.name Name of dependent variable, needed if no formula given. For survival forests this is the time variable.

status.variable.name Name of status variable, only applicable to survival data and needed if no formula given. Use 1 for event and 0 for censoring.

classification Set to TRUE to grow a classification forest. Only needed if the data is a matrix or the response numeric.

x Predictor data (independent variables), alternative interface to data with formula or dependent.variable.name.

y Response vector (dependent variable), alternative interface to data with formula or dependent.variable.name. For survival use a Surv() object or a matrix with time and status.

... Further arguments passed to or from other methods (currently ignored).

Details

The tree type is determined by the type of the dependent variable. For factors classification trees are grown, for numeric values regression trees and for survival objects survival trees. The Gini index is used as default splitting rule for classification. For regression, the estimated response variances or maximally selected rank statistics (Wright et al. 2016) can be used. For Survival the log-rank test, a C-index based splitting rule (Schmid et al. 2015) and maximally selected rank statistics (Wright et al. 2016) are available. For all tree types, forests of extremely randomized trees (Geurts et al. 2006) can be grown.

With the probability option and factor dependent variable a probability forest is grown. Here, the node impurity is used for splitting, as in classification forests. Predictions are class probabilities for each sample. In contrast to other implementations, each tree returns a probability estimate and these estimates are averaged for the forest probability estimate. For details see Malley et al. (2012).

Note that nodes with size smaller than min.node.size can occur because min.node.size is the minimal node size to split at, as in original Random Forests. To restrict the size of terminal nodes, set min.bucket. Variables selected with always.split.variables are tried additionally to the mtry variables randomly selected. In split.select.weights, weights do not need to sum up to 1, they will be normalized later. The weights are assigned to the variables in the order they appear in the formula or in the data if no formula is used. Names of the split.select.weights vector are
ignored. Weights assigned by \texttt{split.select.weights} to variables in \texttt{always.split.variables} are ignored. The usage of \texttt{split.select.weights} can increase the computation times for large forests.

Unordered factor covariates can be handled in 3 different ways by using \texttt{respect.unordered.factors}: For 'ignore' all factors are regarded ordered, for 'partition' all possible 2-partitions are considered for splitting. For 'order' and 2-class classification the factor levels are ordered by their proportion falling in the second class, for regression by their mean response, as described in Hastie et al. (2009), chapter 9.2.4. For multiclass classification the factor levels are ordered by the first principal component of the weighted covariance matrix of the contingency table (Coppersmith et al. 1999), for survival by the median survival (or the largest available quantile if the median is not available). The use of 'order' is recommended, as it computationally fast and can handle an unlimited number of factor levels. Note that the factors are only reordered once and not again in each split.

The 'impurity_corrected' importance measure is unbiased in terms of the number of categories and category frequencies and is almost as fast as the standard impurity importance. It is a modified version of the method by Sandri & Zuccolotto (2008), which is faster and more memory efficient. See Nembrini et al. (2018) for details. This importance measure can be combined with the methods to estimate p-values in \texttt{importance.pvalues}. We recommend not to use the 'impurity_corrected' importance when making predictions since the feature permutation step might reduce predictive performance (a warning is raised when predicting on new data).

Note that ranger has different default values than other packages. For example, our default for \texttt{mtry} is the square root of the number of variables for all tree types, whereas other packages use different values for regression. Also, changing one hyperparameter does not change other hyperparameters (where possible). For example, \texttt{splitrule=extratrees} uses randomized splitting but does not disable bagging as in Geurts et al. (2006). To disable bagging, use \texttt{replace = \false, sample.fraction = 1}. This can also be used to grow a single decision tree without bagging and feature subsetting: \texttt{ranger(\ldots, num.trees = 1, mtry = p, replace = \false, sample.fraction = 1)}, where \texttt{p} is the number of independent variables.

While random forests are known for their robustness, default hyperparameters not always work well. For example, for high dimensional data, increasing the \texttt{mtry} value and the number of trees \texttt{num.trees} is recommended. For more details and recommendations, see Probst et al. (2019). To find the best hyperparameters, consider hyperparameter tuning with the \texttt{tuneRanger} or \texttt{mlr3} packages.

Out-of-bag prediction error is calculated as accuracy (proportion of misclassified observations) for classification, as Brier score for probability estimation, as mean squared error (MSE) for regression and as one minus Harrell's C-index for survival. Harrell's C-index is calculated based on the sum of the cumulative hazard function (CHF) over all timepoints, i.e., \texttt{rowSums(chf)}, where \texttt{chf} is the the out-of-bag CHF; for details, see Ishwaran et al. (2008). Calculation of the out-of-bag prediction error can be turned off with \texttt{oob.error = \false}.

Regularization works by penalizing new variables by multiplying the splitting criterion by a factor, see Deng & Runger (2012) for details. If \texttt{regularization.usedepth=\true}, \texttt{f^d} is used, where \texttt{f} is the regularization factor and \texttt{d} the depth of the node. If regularization is used, multithreading is deactivated because all trees need access to the list of variables that are already included in the model.

For a large number of variables and data frames as input data the formula interface can be slow or impossible to use. Alternatively dependent \texttt{variable.name} (and \texttt{status.variable.name} for survival) or \texttt{x} and \texttt{y} can be used. Use \texttt{x} and \texttt{y} with a matrix for \texttt{x} to avoid conversions and save
memory. Consider setting `save.memory = TRUE` if you encounter memory problems for very large datasets, but be aware that this option slows down the tree growing.

For GWAS data consider combining `ranger` with the GenABEL package. See the Examples section below for a demonstration using Plink data. All SNPs in the GenABEL object will be used for splitting. To use only the SNPs without sex or other covariates from the phenotype file, use `0` on the right hand side of the formula. Note that missing values are treated as an extra category while splitting.

See https://github.com/imbs-hl/ranger for the development version.

With recent R versions, multithreading on Windows platforms should just work. If you compile yourself, the new RTools toolchain is required.

**Value**

Object of class `ranger` with elements

- **forest**: Saved forest (If `write.forest` set to `TRUE`). Note that the variable IDs in the `split.varIDs` object do not necessarily represent the column number in R.
- **predictions**: Predicted classes/values, based on out-of-bag samples (classification and regression only).
- **variable.importance**: Variable importance for each independent variable.
- **variable.importance.local**: Variable importance for each independent variable and each sample, if `local.importance` is set to `TRUE` and `importance` is set to `permutation`.
- **prediction.error**: Overall out-of-bag prediction error. For classification this is accuracy (proportion of misclassified observations), for probability estimation the Brier score, for regression the mean squared error and for survival one minus Harrell's C-index.
- **r.squared**: R squared. Also called explained variance or coefficient of determination (regression only). Computed on out-of-bag data.
- **confusion.matrix**: Contingency table for classes and predictions based on out-of-bag samples (classification only).
- **unique.death.times**: Unique death times (survival only).
- **chf**: Estimated cumulative hazard function for each sample (survival only).
- **survival**: Estimated survival function for each sample (survival only).
- **call**: Function call.
- **num.trees**: Number of trees.
- **num.independent.variables**: Number of independent variables.
- **mtry**: Value of mtry used.
- **min.node.size**: Value of minimal node size used.
- **treetype**: Type of forest/tree. classification, regression or survival.
importance.mode

Importance mode used.

num.samples

Number of samples.

inbag.counts

Number of times the observations are in-bag in the trees.

dependent.variable.name

Name of the dependent variable. This is NULL when x/y interface is used.

status.variable.name

Name of the status variable (survival only). This is NULL when x/y interface is used.

Examples

```r
## Classification forest with default settings
ranger(Species ~ ., data = iris)

## Prediction
train.idx <- sample(nrow(iris), 2/3 * nrow(iris))
iris.train <- iris[train.idx, ]
iris.test <- iris[-train.idx, ]
rg.iris <- ranger(Species ~ ., data = iris.train)
pred.iris <- predict(rg.iris, data = iris.test)
table(iris.test$Species, pred.iris$predictions)

## Quantile regression forest
rf <- ranger(mpg ~ ., mtcars[1:26, ], quantreg = TRUE)
pred <- predict(rf, mtcars[27:32, ], type = "quantiles")
pred$predictions

## Variable importance
rg.iris <- ranger(Species ~ ., data = iris, importance = "impurity")
rg.iris$variable.importance

## Survival forest
require(survival)
rg.veteran <- ranger(Surv(time, status) ~ ., data = veteran)
plot(rg.veteran$unique.death.times, rg.veteran$survival[1,])

## Alternative interfaces (same results)
ranger(dependent.variable.name = "Species", data = iris)
ranger(y = iris[, 5], x = iris[, -5])

## Not run:
## Use GenABEL interface to read Plink data into R and grow a classification forest
## The ped and map files are not included
library(GenABEL)
convert.snp.ped("data.ped", "data.map", "data.raw")
dat.gwaa <- load.gwaa.data("data.pheno", "data.raw")
phdata(dat.gwaa)$trait <- factor(phdata(dat.gwaa)$trait)
ranger(trait ~ ., data = dat.gwaa)

## End(Not run)
```
Description
Extract unique death times of Ranger Survival forest

Usage
```
## S3 method for class 'ranger'
timepoints(x, ...)
```

Arguments
- `x` Ranger Survival forest object.
- `...` Further arguments passed to or from other methods.

Value
Unique death times

ranger

treeInfo

Tree information in human readable format

Description

Extract tree information of a ranger object.

Usage

treeInfo(object, tree = 1)

Arguments

object ranger object.
tree Number of the tree of interest.

Details

Node and variable ID's are 0-indexed, i.e., node 0 is the root node. If the formula interface is used in the ranger call, the variable ID's are usually different to the original data used to grow the tree. Refer to the variable name instead to be sure.

Splitting at unordered factors (nominal variables) depends on the option respect.unordered.factors in the ranger call. For the "ignore" and "order" approaches, all values smaller or equal the splitval value go to the left and all values larger go to the right, as usual. However, with "order" the values correspond to the order in object$forest$covariate.levels instead of the original order (usually alphabetical). In the "partition" mode, the splitval values for unordered factor are comma separated lists of values, representing the factor levels (in the original order) going to the right.

Value

A data.frame with the columns

<table>
<thead>
<tr>
<th>nodeID</th>
<th>The nodeID, 0-indexed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>leftChild</td>
<td>ID of the left child node, 0-indexed.</td>
</tr>
<tr>
<td>rightChild</td>
<td>ID of the right child node, 0-indexed.</td>
</tr>
<tr>
<td>splitvarID</td>
<td>ID of the splitting variable, 0-indexed. Caution, the variable order changes if the formula interface is used.</td>
</tr>
<tr>
<td>splitvarName</td>
<td>Name of the splitting variable.</td>
</tr>
<tr>
<td>splitval</td>
<td>The splitting value. For numeric or ordinal variables, all values smaller or equal go to the left, larger values to the right.</td>
</tr>
<tr>
<td>terminal</td>
<td>Logical, TRUE for terminal nodes.</td>
</tr>
</tbody>
</table>
prediction One column with the predicted class (factor) for classification and the predicted numerical value for regression.
numSamples Number of samples in the node (only if ranger called with node.stats = TRUE).
splitStat Split statistics, i.e., value of the splitting criterion (only if ranger called with node.stats = TRUE).
