Package ‘rearrr’

January 18, 2023

Title Rearranging Data

Version 0.3.3

Description Arrange data by a set of methods. Use rearrangers to reorder data points and mutators to change their values. From basic utilities, to centering the greatest value, to swirling in 3-dimensional space, ‘rearrr’ enables creativity when plotting and experimenting with data.

Calculate the angle to an origin

Description

[Experimental]

Calculates the angle between each data point \((x_2, y_2)\) and the origin \((x_1, y_1)\) with:

\[
\text{atan2}(y_2 - y_1, x_2 - x_1)
\]

And converts to degrees \([0\text{--}360)\), measured counterclockwise from the \(\{x > x_1, y = y_1\}\) line.

The origin can be supplied as coordinates or as a function that returns coordinates. The latter can be useful when supplying a grouped `data.frame` and finding the angle to e.g. the centroid of each group.

Usage

\[
\text{angle}(\text{data}, \ x_{-}\text{col} = \text{NULL}, \ y_{-}\text{col} = \text{NULL}, \ \text{origin} = \text{NULL}, \ \text{origin}_{-}\text{fn} = \text{NULL}, \ \text{degrees}_{-}\text{col}\_\text{name} = ".degrees", \ \text{origin}_{-}\text{col}\_\text{name} = ".origin", \ \text{overwrite} = \text{FALSE})
\]

Arguments

- `data` data.frame or vector.
- `x_col` Name of x column in `data`. If NULL and `data` is a vector, the index of `data` is used. If `data` is a data.frame, it must be specified.
- `y_col` Name of y column in `data`. If `data` is a data.frame, it must be specified.
- `origin` Coordinates of the origin to calculate angle to. A scalar to use in all dimensions or a vector with one scalar per dimension. **N.B.** Ignored when `origin_fn` is not NULL.
- `origin_fn` Function for finding the origin coordinates. **Input**: Each column will be passed as a vector in the order of `cols`. **Output**: A vector with one scalar per dimension. Can be created with `create_origin_fn()` if you want to apply the same function to each dimension. E.g. `create_origin_fn(median)` would find the median of each column. **Built-in functions** are `centroid()`, `most_centered()`, and `midrange()`
- `degrees_col_name` Name of new column with the degrees.
- `origin_col_name` Name of new column with the origin coordinates. If NULL, no column is added.
- `overwrite` Whether to allow overwriting of existing columns. (Logical)
Value

data.frame (tibble) with the additional columns (degrees and origin coordinates).

has_ggplot <- require(ggplot2) # Attach if installed

# Set seed
set.seed(1)

# Create a data frame
df <- data.frame("x" = runif(20), "y" = runif(20), "g" = rep(1:4, each = 5))

df_angles <- angle(
data = df, 
x_col = "x", 
y_col = "y", 
origin = c(0.5, 0.5)
)
df_angles

# Plot points with degrees
# Degrees are measured counterclockwise around the positive side of the x-axis
if (has_ggplot){
df_angles %>%
ggplot(aes(x = x, y = y, color = .degrees)) +
  geom_segment(aes(x = 0.5, xend = 1, y = 0.5, yend = 0.5), color = "magenta") +
  geom_point() +
  theme_minimal()
}

# Calculate angles to the centroid for each group in 'g'
angle(
data = dplyr::group_by(df, g), 
x_col = "x", 
y_col = "y", 
origin_fn = centroid
)
apply_transformation_matrix

Apply transformation matrix to a set of columns

Description

[Experimental]
Perform matrix multiplication with a transformation matrix and a set of data.frame columns.

The data points in `data` are moved prior to the transformation, to bring the origin to 0 in all dimensions. After the transformation, the inverse move is applied to bring the origin back to its original position. See `Details` section.

The columns in `data` are transposed, making the operation (without the origin movement):

\[ matdata[, \text{cols}]^T \]

The origin can be supplied as coordinates or as a function that returns coordinates. The latter can be useful when supplying a grouped data.frame and transforming around e.g. the centroid of each group.

Usage

apply_transformation_matrix(
  data,  
  mat,  
  cols,  
  origin = NULL,  
  origin_fn = NULL,  
  suffix = "_transformed",  
  keep_original = TRUE,  
  origin_col_name = ".origin",  
  overwrite = FALSE
)

Arguments

data data.frame or vector.
mat Transformation matrix. Must have the same number of columns as `cols`.
cols Columns to mutate values of. Must be specified when `data` is a data.frame.
origin Coordinates of the origin. Vector with the same number of elements as `cols` (i.e. origin_x, origin_y, ...). Ignored when `origin_fn` is not NULL.
origin_fn Function for finding the origin coordinates.

Input: Each column will be passed as a vector in the order of `cols`.
Output: A vector with one scalar per dimension.

Can be created with create_origin_fn() if you want to apply the same function to each dimension.
E.g. `create_origin_fn(median)` would find the median of each column.

Built-in functions are centroid(), most_centered(), and midrange()
apply_transformation_matrix

suffix
  Suffix to add to the names of the generated columns.
  Use an empty string (i.e. "") to overwrite the original columns.

keep_original
  Whether to keep the original columns. (Logical)
  Some columns may have been overwritten, in which case only the newest versions are returned.

origin_col_name
  Name of new column with the origin coordinates. If NULL, no column is added.

overwrite
  Whether to allow overwriting of existing columns. (Logical)

Details

Example with 2 columns (x, y) and a 2x2 transformation matrix:

  • Move origin to (0, 0):
    \[
    x = x - \text{origin\_x} \\
    y = y - \text{origin\_y}
    \]
  • Convert to transposed matrix:
    \[
    \text{data\_mat} = \text{rbind}(x, y)
    \]
  • Matrix multiplication:
    \[
    \text{transformed} = \text{mat} \times \text{data\_mat}
    \]
  • Move origin to original position (after extraction from \text{transformed}):
    \[
    x = x + \text{origin\_x} \\
    y = y + \text{origin\_y}
    \]

Value

data.frame (tibble) with the new, transformed columns and the origin coordinates.

  data = dplyr::group_by(df, g),
  mat = mat,
  cols = c("x", "y", "z"),
  origin_fn = centroid
)

# Plot the rotation
if (has_ggplot){
  res %>%
    ggplot(aes(x = x, y = y, color = g)) +
    geom_point() +
    geom_point(aes(x = x_transformed, y = y_transformed)) +
    theme_minimal()
}
center_max

Centers the highest value with values decreasing around it

Description

[Experimental]
The highest value is positioned in the middle with the other values decreasing around it.

Example:
The column values:
c(1, 2, 3, 4, 5)
are ordered as:
c(1, 3, 5, 4, 2)

Usage

center_max(data, col = NULL, shuffle_sides = FALSE)

Arguments

data data.frame or vector.
col Column to create sorting factor by. When `NULL` and `data` is a data.frame, the row numbers are used.
shuffle_sides Whether to shuffle which elements are left and right of the center. (Logical)

Value

The sorted data.frame (tibble)/vector.

# Grouped by G
df %>%
dplyr::select(G, A) %>% # For clarity
dplyr::group_by(G) %>%
center_max(col = "A")

# Plot the centered values
plot(x = 1:10, y = center_max(df, col = "B")$B)
plot(x = 1:10, y = center_max(df, col = "B", shuffle_sides = TRUE)$B)

---

**center_min**

Centers the lowest value with values increasing around it

**Description**

[Experimental]
The lowest value is positioned in the middle with the other values increasing around it.

**Example:**
The column values:
c(1, 2, 3, 4, 5)
are ordered as:
c(5, 3, 1, 2, 4)

**Usage**

center_min(data, col = NULL, shuffle_sides = FALSE)
center_min

Arguments

- **data**: data.frame or vector.
- **col**: Column to create sorting factor by. When `NULL` and `data` is a data.frame, the row numbers are used.
- **shuffle_sides**: Whether to shuffle which elements are left and right of the center. (Logical)

Value

The sorted data.frame (tibble)/vector.

Author(s)

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

# Center by each of the columns
center_min(df, col = "A")
center_min(df, col = "B")
center_min(df, col = "C")

# Randomize which elements are left and right of the center
center_min(df, col = "A", shuffle_sides = TRUE)

# Grouped by G
df %>%
```

```r
dplyr::select(G, A) %>% # For clarity
dplyr::group_by(G) %>%
center_min(col = "A")

# Plot the centered values
plot(x = 1:10, y = center_min(df, col = "B")$B)
plot(x = 1:10, y = center_min(df, col = "B", shuffle_sides = TRUE)$B)
```

---

**centroid**

Find the coordinates for the centroid

**Description**

[Experimental]

Calculates the mean of each passed vector/column.

**Usage**

```r
centroid(..., cols = NULL, na.rm = FALSE)
```

**Arguments**

- `...`: Numeric vectors or a single `data.frame`.
- `cols`: Names of columns to use when `...` is a single `data.frame`.
- `na.rm`: Whether to ignore missing values when calculating means. (Logical)

**Value**

Means of the supplied vectors/columns. Either as a vector or a data.frame.

**Author(s)**

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

**See Also**

Other coordinate functions: `create_origin_fn()`, `is_most_centered()`, `midrange()`, `most_centered()`

**Examples**

```r
# Attach packages
library(rearrr)
library(dplyr)

# Set seed
set.seed(1)

# Create three vectors
x <- runif(10)
y <- runif(10)
z <- runif(10)

# Find centroid coordinates
```
# Aka. the means of each vector
centro$\text{id}(x, y, z)$

# For data.frames

# Create data frame
df <- data.frame(
  "x" = x,
  "y" = y,
  "z" = z,
  "g" = rep(1:2, each = 5)
)

# Find centroid coordinates
# Aka. the means of each column
centro$\text{id}(\text{df}, \text{cols} = c("x", "y", "z"))$

# When ‘df’ is grouped
df %>%
  dplyr::group_by(g) %>%
  centro$\text{id}(\text{cols} = c("x", "y", "z"))$

circularize

Create x-coordinates so the points form a circle

Description

[Experimental]

Create the x-coordinates for a vector of y-coordinates such that they form a circle.

This will likely look most like a circle when the y-coordinates are somewhat equally distributed, e.g. a uniform distribution.

Usage

```
circularize(
  data,
  y_col = NULL,
  .min = NULL,
  .max = NULL,
  offset_x = 0,
  keep_original = TRUE,
  x_col_name = ".circle_x",
  degrees_col_name = ".degrees",
  origin_col_name = ".origin",
  overwrite = FALSE
)
```
circularize

Arguments

- **data**: data.frame or vector.
- **y_col**: Name of column in `data` with y-coordinates to create x-coordinates for.
- **.min**: Minimum y-coordinate. If NULL, it is inferred by the given y-coordinates.
- **.max**: Maximum y-coordinate. If NULL, it is inferred by the given y-coordinates.
- **offset_x**: Value to offset the x-coordinates by.
- **keep_original**: Whether to keep the original columns. (Logical)
  - Some columns may have been overwritten, in which case only the newest versions are returned.
- **x_col_name**: Name of new column with the x-coordinates.
- **degrees_col_name**: Name of new column with the angles in degrees. If NULL, no column is added.
  - Angling is counterclockwise around (0, 0) and starts at (max(x), 0).
- **origin_col_name**: Name of new column with the origin coordinates (center of circle). If NULL, no column is added.
- **overwrite**: Whether to allow overwriting of existing columns. (Logical)

Value

data.frame (tibble) with the added x-coordinates and the angle in degrees.

Author(s)

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

    )) +
    geom_point() +
    theme_minimal()
}

---

**closest_to**

*Orders values by shortest distance to an origin*

**Description**

[Experimental]

Values are ordered by how close they are to the origin.

In 1d (when `cols` has length 1), the origin can be thought of as a target value. In n dimensions, the origin can be thought of as coordinates.

The origin can be supplied as coordinates or as a function that returns coordinates. The latter can be useful when supplying a grouped `data.frame` and ordering the rows by their distance to the centroid of each group.

The `*_vec()` version takes and returns a vector.

**Example:**

The column values:

```
c(1, 2, 3, 4, 5)
```

and origin = 2

are ordered as:

```
c(2, 1, 3, 4, 5)
```
Usage

closest_to(
  data, 
  cols = NULL, 
  origin = NULL, 
  origin_fn = NULL, 
  shuffle_ties = FALSE, 
  origin_col_name = ".origin", 
  distance_col_name = ".distance", 
  overwrite = FALSE
)

closest_to_vec(data, origin = NULL, origin_fn = NULL, shuffle_ties = FALSE)

Arguments

data  data.frame or vector.

cols  Column(s) to create sorting factor by. When `NULL` and `data` is a data.frame, the row numbers are used.

origin  Coordinates of the origin to calculate distances to. A scalar to use in all dimensions or a vector with one scalar per dimension.

  N.B. Ignored when `origin_fn` is not `NULL`.

origin_fn  Function for finding the origin coordinates.

  Input: Each column will be passed as a vector in the order of `cols`.

  Output: A vector with one scalar per dimension.

  Can be created with `create_origin_fn()` if you want to apply the same function to each dimension.

  E.g. `create_origin_fn(median)` would find the median of each column.

  Built-in functions are `centroid()`, `most_centered()`, and `midrange()`

shuffle_ties  Whether to shuffle elements with the same distance to the origin. (Logical)

origin_col_name  Name of new column with the origin coordinates. If `NULL`, no column is added.

distance_col_name  Name of new column with the distances to the origin. If `NULL`, no column is added.

overwrite  Whether to allow overwriting of existing columns. (Logical)

Value

The sorted data.frame (tibble) / vector.

)$A

# Grouped by G
df %>%
dplyr::select(G, A) %>% # For clarity
dplyr::group_by(G) %>%
closest_to(
  cols = "A",
  origin_fn = create_origin_fn(median)
)
# Plot the rearranged values
plot(
  x = 1:10,
  y = closest_to(df,
    cols = "B",
    origin_fn = create_origin_fn(median)
  )$B,
  xlab = "Position",
  ylab = "B"
)

plot(
  x = 1:10,
  y = closest_to(df,
    cols = "A",
    origin_fn = create_origin_fn(median),
    shuffle_ties = TRUE
  )$A,
  xlab = "Position",
  ylab = "A"
)

# In multiple dimensions
df %>%
closest_to(cols = c("A", "B"), origin_fn = most_centered)

---

**cluster_groups**

*Move data points into clusters*

**Description**

*[Experimental]*

Transform values such that the elements in each group move closer to their centroid.

**Usage**

```r
cluster_groups(
  data,
  cols,
  group_cols = NULL,
  scale_min_fn = function(x) {
    quantile(x, 0.025)
  },
  scale_max_fn = function(x) {
    quantile(x, 0.975)
  },
  keep_centroids = FALSE,
  multiplier = 0.05,
  suffix = ".clustered",
  keep_original = TRUE,
  overwrite = FALSE
)
```
cluster_groups

Arguments

data data.frame. If `group_cols` is NULL, it must be grouped with `dplyr::group_by()`.
cols Names of columns in `data` to mutate. Each column is considered a dimension to contract distances in.
group_cols Names of grouping columns in `data`. Must be distinct from the names in `cols`.
If NULL and `data` is grouped, those groups are used instead.
scale_min_fn, scale_max_fn Function to find the minimum/maximum value in the original data when rescaling the contracted data.
    Input: A numeric vector.
    Output: A numeric scalar.
keep_centroids Whether to ensure the clusters have their original centroids. (Logical)
multiplier Numeric constant to multiply the distance to the group centroid by. A smaller value makes the clusters more compact and vice versa.
suffix Suffix to add to the names of the generated columns.
Use an empty string (i.e. "") to overwrite the original columns.
keep_original Whether to keep the original columns. (Logical)
Some columns may have been overwritten, in which case only the newest versions are returned.
overwrite Whether to allow overwriting of existing columns. (Logical)

Details

• Contracts the distance from each data point to the centroid of its group.
• Performs MinMax scaling such that the scale of the data points is similar to the original data.
• If enabled (not default), the centroids are moved to the original centroids.

Value
data.frame (tibble) with the clustered columns.

    color = df_clustered$g
)

## End(Not run)
```

create_dimming_fn  
Create dimming_fn function
create_dimming_fn

Description

[Experimental]

Creates a function that takes 2 inputs (`x`, `d`) and performs the operation:

\[ x \times \left( \frac{\text{numerator}}{(\text{add_to_distance} + d)^{\text{exponent}}} \right) \]

Here, `x` is the current value and `d` is its distance to an origin. The greater the distance, the more we will dim the value of `x`.

With the default values, the returned function is:

```r
function(x, d) {
  x * (1 / ((1 + d)^2))
}
```

Usage

`create_dimming_fn(numerator = 1, exponent = 2, add_to_distance = 1)`

Arguments

- **numerator**: The numerator. Defaults to 1.
- **exponent**: The exponent. Defaults to 2.
- **add_to_distance**: Constant to add to the distance before exponentiation. Ensures dimming even when the distance (d) is below 1. Defaults to 1.

Value

Function with the arguments `x` and `d`, with both expected to be numeric vectors. More specifically:

```r
function(x, d) {
  x * (numerator / ((add_to_distance + d)^exponent))
}
```

Author(s)

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

Examples

```r
# Attach packages
library(rearrr)
has_ggplot <- require(ggplot2) # Attach if installed

# Set seed
set.seed(1)

# Create two vectors
x <- runif(10)
```
d <- runif(10, max = 0.5)

# Create dimming_fn with an add_to_distance of 0
# Note: In practice this risks zero-division
non_smoothed_dimming_fn <- create_dimming_fn(add_to_distance = 0)
non_smoothed_dimming_fn
as.list(environment(non_smoothed_dimming_fn))

# Use median_origin_fn
non_smoothed_dimming_fn(x, d)

# Plotting the dimming

# Create data.frame with distance-based dimming
df <- data.frame(
  "x" = 1,
  "d" = 1:10
)
df$x_dimmed <- non_smoothed_dimming_fn(df$x, df$d)

# Plot the dimming
if (has_ggplot){
geeplot(df, aes(x=d, y=x_dimmed)) +
  geom_point() +
  geom_line() +
  theme_minimal()
}

---

create_n_fn 

Create n_fn function

Description

[Experimental]

Creates a function that applies a supplied function to all input vectors, or their indices, and rounds the results.

As used with `roll_elements()`. E.g. to find the the median index in a subset of a grouped data.frame.

Usage

`create_n_fn(fn, use_index = FALSE, negate = FALSE, round_fn = round, ...)`

Arguments

- **fn**: Function to apply to each dimension. Should return a numeric scalar.
- **use_index**: Whether to apply `fn` to the indices of the vectors. (Logical)
  The indices are created with `seq_along(x)`.
- **negate**: Whether to negate the result. I.e. to multiply it with -1. (Logical)
Function for rounding results of `fn`.
Rounding is done prior to negation.
E.g. `round`, `floor`, or `ceiling`.
To avoid rounding, supply `identity`.
Arguments for `fn`. E.g. `na.rm = TRUE`.

Value
Function with the dots (`...`) argument that applies the `fn` function to each element in `...` (or indices thereof) (usually one vector per dimension). The results are rounded with `round_fn`.
Note: The dots argument in the generated function should not to be confused with the dots argument in `create_n_fn()`.

#### create_origin_fn

Create origin_fn function

**Description**

[Experimental]

Creates a function that applies a supplied function to all input vectors.

**Usage**

create_origin_fn(fn, ...)

**Arguments**

- `fn`
  
  Function to apply to each dimension. Should return a numeric scalar.

- `...`
  
  Arguments for `fn`. E.g. `na.rm = TRUE`.

**Value**

Function with the dots (...) argument that applies the `fn` function to each element in ... (usually one vector per dimension).

**Author(s)**

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

**See Also**

  mean(y, na.rm = TRUE),
  mean(z, na.rm = TRUE)
  )

---

**degrees_to_radians**  
*Conversion between radians and degrees*

**Description**

*[Experimental]*  
Convert degrees to radians or radians to degrees.

**Usage**

`degrees_to_radians(degrees)`

`radians_to_degrees(radians)`

**Arguments**

`degrees`  
vector of degrees to convert to radians with

`'degrees' * (π/180)`

`radians`  
vector of radians to convert to degrees with

`'radians'/(π/180)`
dim_values

Value

vector with converted degrees/radians.

Missing values (NAs) are returned as they are.

Author(s)

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

Examples

# Attach packages
library(rearrr)
library(dplyr)

# Degrees to radians
degrees_to_radians(c(90, 180, 270))

# Radians to degrees
radians_to_degrees(c(pi / 2, pi, 1.5 * pi))

# Get back the original degrees
radians_to_degrees(degrees_to_radians(c(90, 180, 270)))

dim_values Dim values of a dimension based on the distance to an n-dimensional origin

Description

[Experimental]

Dims the values in the dimming dimension (last by default) based on the data point’s distance to the origin.

Distance is calculated as:

\[ d(P1, P2) = \sqrt{(x2 - x1)^2 + (y2 - y1)^2 + (z2 - z1)^2 + ...} \]

The default `dimming_fn` multiplies by the inverse-square of 1 + distance and is calculated as:

\[ dimming_fn(x, d) = x \times (1/(1 + d)^2) \]

Where \( x \) is the value in the dimming dimension. The +1 is added to ensure that values are dimmed even when the distance is below 1. The quickest way to change the exponent or the +1 is with `create_dimming_fn()`.

The origin can be supplied as coordinates or as a function that returns coordinates. The latter can be useful when supplying a grouped data.frame and dimming around e.g. the centroid of each group.
dim_values

dim_values(
  data,
  cols,
  dimming_fn = create_dimming_fn(numerator = 1, exponent = 2, add_to_distance = 1),
  origin = NULL,
  origin_fn = NULL,
  dim_col = tail(cols, 1),
  suffix = "_dimmed",
  keep_original = TRUE,
  origin_col_name = ".origin",
  overwrite = FALSE
)

Arguments

data  data.frame or vector.

cols  Names of columns in `data` to calculate distances from. The dimming column (`dim_col`) is dimmed based on all the columns. Each column is considered a dimension. **N.B.** when the dimming dimension is included in `cols`, it is used in the distance calculation as well.

dimming_fn  Function for calculating the dimmed values.
  **Input:** Two (2) input arguments:
  1. A numeric vector with the values in the dimming dimension.
  2. A numeric vector with corresponding distances to the origin.
  **Output:** A numeric vector with the same length as the input vectors.
  E.g.:
  ```
  function(x, d){
    x * (1 / ((1 + d) ^ 2))
  }
  ```
  This kind of dimming function can be created with `create_dimming_fn()`, which for instance makes it easy to change the exponent (the 2 above).

origin  Coordinates of the origin to dim around. A scalar to use in all dimensions or a vector with one scalar per dimension. **N.B.** Ignored when `origin_fn` is not NULL.

origin_fn  Function for finding the origin coordinates.
  **Input:** Each column will be passed as a vector in the order of `cols`.
  **Output:** A vector with one scalar per dimension.
  Can be created with `create_origin_fn()` if you want to apply the same function to each dimension.
  E.g. `create_origin_fn(median)` would find the median of each column.

Built-in functions are `centroid()`, `most_centered()`, and `midrange()`

dim_col  Name of column to dim. Default is the last column in `cols`.
  When the `dim_col` is not present in `cols`, it is not used in the distance calculation.

suffix  Suffix to add to the names of the generated columns.
  Use an empty string (i.e. "") to overwrite the original columns.
`dim_values`  

keep_original  Whether to keep the original columns. (Logical) Some columns may have been overwritten, in which case only the newest versions are returned.

origin_col_name  Name of new column with the origin coordinates. If `NULL`, no column is added.

overwrite  Whether to allow overwriting of existing columns. (Logical)

Details

- Calculates distances to origin with:

\[
d(P_1, P_2) = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2 + ...}
\]

- Applies the `dimming_fn` to the `dim_col` based on the distances.

Value

data.frame (tibble) with the dimmed column, along with the origin coordinates.

Author(s)

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

origin_fn = centroid
)

# Plot the dimmed data such that the alpha (opacity) is
# controlled by the dimming
# (Note: This works because the 'o' column is 1 for all values)
if (has_ggplot){
ggplot(
data = df_dimmed,
aes(x = x, y = y, alpha = o_dimmed, color = .cluster)
) +
geom_point() +
theme_minimal() +
labs(x = "x", y = "y", color = "Cluster", alpha = "o_dimmed")

}
Description

[Experimental]

Calculates the distance to the specified origin with:

\[ d(P_1, P_2) = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2 + ...} \]

The origin can be supplied as coordinates or as a function that returns coordinates. The latter can be useful when supplying a grouped data.frame and finding the distance to e.g. the centroid of each group.

Usage

```r
distance(
  data, 
  cols = NULL, 
  origin = NULL, 
  origin_fn = NULL, 
  distance_col_name = ".distance", 
  origin_col_name = ".origin", 
  overwrite = FALSE
)
```

Arguments

data data.frame or vector.

cols Names of columns in `data` to measure distance in. Each column is considered a dimension.

origin Coordinates of the origin to calculate distances to. A scalar to use in all dimensions or a vector with one scalar per dimension. 

N.B. Ignored when `origin_fn` is not NULL.

origin_fn Function for finding the origin coordinates.

Input: Each column will be passed as a vector in the order of `cols`.

Output: A vector with one scalar per dimension.

Can be created with `create_origin_fn()` if you want to apply the same function to each dimension.

E.g. `create_origin_fn(median)` would find the median of each column.

Built-in functions are `centroid()`, `most_centered()`, and `midrange()`

distance_col_name Name of new column with the distances.

origin_col_name Name of new column with the origin coordinates. If NULL, no column is added.

overwrite Whether to allow overwriting of existing columns. (Logical)

Value

data.frame (tibble) with the additional columns (distances and origin coordinates).

Examples

# Attach packages
library(rearrr)
library(dplyr)

# Set seed
set.seed(1)

# Create a data frame
df <- data.frame(
  "x" = runif(20),
  "y" = runif(20),
  "g" = rep(1:4, each = 5)
)

# Calculate distances in the two dimensions (x and y)
# With the origin at x=0.5, y=0.5
distance(
  data = df,
  cols = c("x", "y"),
  origin = c(0.5, 0.5)
)

# Calculate distances to the centroid for each group in 'g'
distance(
  data = dplyr::group_by(df, g),
  cols = c("x", "y"),
  origin_fn = centroid
)

-------------------------------------------------------------------

expand_distances  Expand the distances to an origin

Description

[Experimental]

Moves the data points in n-dimensional space such that their distance to a specified origin is increased/decreased. A `multiplier` greater than 1 leads to expansion, while a positive `multiplier` lower than 1 leads to contraction.

The origin can be supplied as coordinates or as a function that returns coordinates. The latter can be useful when supplying a grouped data.frame and expanding around e.g. the centroid of each group.

The multiplier/exponent can be supplied as a constant or as a function that returns a constant. The latter can be useful when supplying a grouped data.frame and the multiplier/exponent depends on the data in the groups.
For expansion in each dimension separately, use `expand_distances_each()`.

**NOTE:** When exponentiating, the default is to first add 1 to the distances, to ensure expansion even when the distance is between 0 and 1. If you need the purely exponentiated distances, disable `add_one_exp`.

### Usage

```r
expand_distances(
  data,
  cols = NULL,
  multiplier = NULL,
  multiplier_fn = NULL,
  origin = NULL,
  origin_fn = NULL,
  exponentiate = FALSE,
  add_one_exp = TRUE,
  suffix = "_expanded",
  keep_original = TRUE,
  mult_col_name = ifelse(isTRUE(exponentiate), ".exponent", ".multiplier"),
  origin_col_name = ".origin",
  overwrite = FALSE
)
```

### Arguments

- **data**
  - `data.frame` or `vector`.`
- **cols**
  - Names of columns in `data` to expand coordinates of. Each column is considered a dimension.
- **multiplier**
  - Constant to multiply/exponentiate the distances to the origin by. N.B. When `exponentiate` is TRUE, the `multiplier` becomes an exponent.
- **multiplier_fn**
  - Function for finding the `multiplier`. **Input:** Each column will be passed as a vector in the order of `cols`. **Output:** A numeric scalar.
- **origin**
  - Coordinates of the origin to expand around. A scalar to use in all dimensions or a vector with one scalar per dimension. N.B. Ignored when `origin_fn` is not NULL.
- **origin_fn**
  - Function for finding the origin coordinates. **Input:** Each column will be passed as a vector in the order of `cols`. **Output:** A vector with one scalar per dimension. Can be created with `create_origin_fn()` if you want to apply the same function to each dimension. E.g. `create_origin_fn(median)` would find the median of each column. **Built-in functions** are `centroid()`, `most_centered()`, and `midrange()`

- **exponentiate**
  - Whether to exponentiate instead of multiplying. (Logical)
- **add_one_exp**
  - Whether to add 1 to the distances before exponentiating to ensure they don’t contract when between 0 and 1. The added value is subtracted after the exponentiation. (Logical)

The distances to the origin (`d`) are exponentiated as such:

\[ d \leftarrow d + 1 \]
\[ d \leftarrow d \cdot \text{multiplier} \]
\[ d \leftarrow d - 1 \]

**N.B.** Ignored when `exponentiate` is FALSE.

- **suffix**: Suffix to add to the names of the generated columns. Use an empty string (i.e. `""`) to overwrite the original columns.
- **keep_original**: Whether to keep the original columns. (Logical) Some columns may have been overwritten, in which case only the newest versions are returned.
- **mult_col_name**: Name of new column with the `multiplier`. If NULL, no column is added.
- **origin_col_name**: Name of new column with the origin coordinates. If NULL, no column is added.
- **overwrite**: Whether to allow overwriting of existing columns. (Logical)

**Details**

Increases the distance to the origin in \(n\)-dimensional space by multiplying or exponentiating it by the multiplier.

We first move the origin to the zero-coordinates (e.g. \(\mathbf{c}(0, \theta, \theta)\)) and normalize each vector to unit length. We then multiply this unit vector by the multiplied/exponentiated distance and moves the origin back to its original coordinates.

The distance to the specified origin is calculated with:

\[
d(P_1, P_2) = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2 + \ldots}
\]

Note: By default (when `add_one_exp` is TRUE), we add 1 to the distance before the exponentiation and subtract it afterwards. See `add_one_exp`.

**Value**

data.frame (tibble) with the expanded columns, along with the applied multiplier/exponent and origin coordinates.

### Description

**[Experimental]**

Moves the data points in n-dimensional space such that their distance to the specified origin is increased/decreased in each dimension separately. A `multiplier` greater than 1 leads to expansion, while a positive `multiplier` lower than 1 leads to contraction.

The origin can be supplied as coordinates or as a function that returns coordinates. The latter can be useful when supplying a grouped data.frame and expanding around e.g. the centroid of each group.

The multipliers/exponents can be supplied as constant(s) or as a function that returns constants. The latter can be useful when supplying a grouped data.frame and the multiplier/exponent depends on the data in the groups. If supplying multiple constants, there must be one per dimension (length of `cols`).

For expansion of the multidimensional distance, use `expand_distances()`.  
**NOTE:** When exponentiating, the default is to first add 1 or -1 (depending on the sign of the distance) to the distances, to ensure expansion even when the distance is between -1 and 1. If you need the purely exponentiated distances, disable `add_one_exp`. 
Usage

expand_distances_each(
  data,
  cols = NULL,
  multipliers = NULL,
  multipliers_fn = NULL,
  origin = NULL,
  origin_fn = NULL,
  exponentiate = FALSE,
  add_one_exp = TRUE,
  suffix = "._expanded",
  keep_original = TRUE,
  mult_col_name = ifelse(isTRUE(exponentiate), ".exponents", ".multipliers"),
  origin_col_name = ".origin",
  overwrite = FALSE
)

Arguments

data data.frame or vector.

cols Names of columns in `data` to expand. Each column is considered a dimension to expand in.

multipliers Constant(s) to multiply/exponentiate the distance to the origin by. A scalar to use in all dimensions or a vector with one scalar per dimension. N.B. When `exponentiate` is TRUE, the `multipliers` become exponents.

multipliers_fn Function for finding the `multipliers`.

`Input`: Each column will be passed as a vector in the order of `cols`.

`Output`: A numeric vector with one element per dimension. Just as for `origin_fn`, it can be created with `create_origin_fn()` if you want to apply the same function to each dimension. See `origin_fn`.

origin Coordinates of the origin to expand around. A scalar to use in all dimensions or a vector with one scalar per dimension. N.B. Ignored when `origin_fn` is not NULL.

origin_fn Function for finding the origin coordinates.

`Input`: Each column will be passed as a vector in the order of `cols`.

`Output`: A vector with one scalar per dimension. Can be created with `create_origin_fn()` if you want to apply the same function to each dimension. E.g. `create_origin_fn(median)` would find the median of each column. Built-in functions are `centroid()`, `most_centered()`, and `midrange()`

exponentiate Whether to exponentiate instead of multiplying. (Logical)

add_one_exp Whether to add the sign (either 1 or -1) before exponentiating to ensure the values don’t contract. The added value is subtracted after the exponentiation. (Logical)

Exponentiation becomes:

\[ x \leftarrow x + \text{sign}(x) \]
\[ x \leftarrow \text{sign}(x) \times \text{abs}(x) \times \text{multiplier} \]
\[ x \leftarrow x - \text{sign}(x) \]

N.B. Ignored when `exponentiate` is FALSE.
**expand_distances_each**

- **suffix**
  - Suffix to add to the names of the generated columns.
  - Use an empty string (i.e. "") to overwrite the original columns.

- **keep_original**
  - Whether to keep the original columns. (Logical)
  - Some columns may have been overwritten, in which case only the newest versions are returned.

- **mult_col_name**
  - Name of new column with the multiplier(s). If NULL, no column is added.

- **origin_col_name**
  - Name of new column with the origin coordinates. If NULL, no column is added.

- **overwrite**
  - Whether to allow overwriting of existing columns. (Logical)

**Details**

For each value of each dimension (column), either multiply or exponentiate by the multiplier:

- **Multiplication**
  - \[ x \leftarrow x \times \text{multiplier} \]

- **Exponentiation**
  - \[ x \leftarrow \text{sign}(x) \times \text{abs}(x) ^ \text{multiplier} \]

  Note: By default (when `add_one_exp` is TRUE), we add the sign (1 / −1) of the value before the exponentiation and subtract it afterwards. See `add_one_exp`.

**Value**

data.frame (tibble) with the expanded columns, along with the applied multiplier/exponent and origin coordinates.

**FixedGroupsPipeline**  
*Chain multiple transformations with different argument values per group*

**Description**

*[Experimental]*  
Build a pipeline of transformations to be applied sequentially.  
Specify different argument values for each group in a fixed set of groups. E.g. if your data.frame contains 5 groups, you provide 5 argument values for each of the non-constant arguments (see `var_args`).
The number of expected groups is specified during initialization and the input `data` must be grouped such that it contains that exact number of groups. Transformations are applied to groups separately, why the given transformation function only receives the subset of `data` belonging to the current group.

**Standard workflow:** Instantiate pipeline -> Add transformations -> Apply to data

To apply the same arguments to all groups, see `Pipeline`. To apply generated argument values to an arbitrary number of groups, see `GeneratedPipeline`.

**Super class**

`rearrr::Pipeline` -> `FixedGroupsPipeline`

**Public fields**

- `transformations` list of transformations to apply.
- `names` Names of the transformations.
- `num_groups` Number of groups the pipeline will be applied to.

**Methods**

**Public methods:**

- `FixedGroupsPipeline$new()`  
- `FixedGroupsPipeline$add_transformation()`  
- `FixedGroupsPipeline$apply()`  
- `FixedGroupsPipeline$print()`  
- `FixedGroupsPipeline$clone()`

**Method** `new()`: Initialize the pipeline with the number of groups the pipeline will be applied to.

**Usage:**

`FixedGroupsPipeline$new(num_groups)`

**Arguments:**

- `num_groups` Number of groups the pipeline will be applied to.

**Method** `add_transformation()`: Add a transformation to the pipeline.

**Usage:**

`FixedGroupsPipeline$add_transformation(fn, args, var_args, name)`

**Arguments:**

- `fn` Function that performs the transformation.
- `args` Named list with arguments for the `fn` function.
- `var_args` Named list of arguments with list of differing values for each group.
  
  E.g. `list("a" = list(1, 2, 3), "b" = list("a", "b", "c"))` given 3 groups.
  
  By adding `".apply"` with a list of TRUE/FALSE flags, the transformation can be disabled for a specific group.
  
  E.g. `list(".apply" = list(TRUE, FALSE, TRUE), ....

  `name` Name of the transformation step. Must be unique.

**Returns:** The pipeline. To allow chaining of methods.

**Method** `apply()`: Apply the pipeline to a data.frame.
**Usage:**

`FixedGroupsPipeline$apply(data, verbose = FALSE)`

**Arguments:**

- `data` data.frame with the same number of groups as pre-registered in the pipeline. You can find the number of groups in `data` with `dplyr::n_groups(data)`. The number of groups expected by the pipeline can be accessed with `pipe$num_groups`.
- `verbose` Whether to print the progress.

**Returns:** Transformed version of `data`.

**Method print():** Print an overview of the pipeline.

**Usage:**

`FixedGroupsPipeline$print(...)`

**Arguments:**

- `...` further arguments passed to or from other methods.

**Returns:** The pipeline. To allow chaining of methods.

**Method clone():** The objects of this class are cloneable with this method.

**Usage:**

`FixedGroupsPipeline$clone(deep = FALSE)`

**Arguments:**

- `deep` Whether to make a deep clone.

**Author(s)**

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

**See Also**

Other pipelines: `GeneratedPipeline, Pipeline`

**Examples**

```r
# Attach package
library(rearrr)
library(dplyr)

# Create a data frame
# We group it by G so we have 3 groups
df <- data.frame(
  "Index" = 1:12,
  "A" = c(1:4, 9:12, 15:18),
  "G" = rep(1:3, each = 4)
) %>%
dplyr::group_by(G)

# Create new pipeline
pipe <- FixedGroupsPipeline$new(num_groups = 3)

# Add 2D rotation transformation
pipe$add_transformation(
  fn = rotate_2d,
)```
FixedGroupsTransformation

```
args = list(
  x_col = "Index",
  y_col = "A",
  suffix = "",
  overwrite = TRUE
),
var_args = list(
  degrees = list(45, 90, 180),
  origin = list(c(0, 0), c(1, 2), c(-1, 0))
),
name = "Rotate"
)

# Add the `cluster_group` transformation
# As the function is fed an ungrouped subset of `data`,
# i.e. the rows of that group, we need to specify `group_cols` in `args`
# That is specific to `cluster_groups()` though
# Also note `.apply` in `var_args` which tells the pipeline *not*
# to apply this transformation to the second group
pipe$add_transformation(
  fn = cluster_groups,
  args = list(
    cols = c("Index", "A"),
    suffix = "",
    overwrite = TRUE,
    group_cols = "G"
  ),
  var_args = list(
    multiplier = list(0.5, 1, 5),
    .apply = list(TRUE, FALSE, TRUE)
  ),
  name = "Cluster"
)

# Check pipeline object
pipe

# Apply pipeline to already grouped data.frame
# Enable `verbose` to print progress
pipe$apply(df, verbose = TRUE)
```

---

**Description**

[Experimental]

Container for the type of transformation used in `FixedGroupsPipeline`

**Note:** For internal use.

**Super class**

`rearrr::Transformation` -> `FixedGroupsTransformation`
Public fields

- `name` Name of transformation.
- `fn` Transformation function.
- `args` list of constant arguments for `fn`.
- `var_args` list of arguments for `fn` with different values per group.
- `num_groups` Number of groups that the transformation expects.
- `apply_arg` list of TRUE/FALSE flags indicating whether the transformation should be applied to each of the groups. When `NULL`, the transformation is applied to all groups.

Methods

Public methods:

- `FixedGroupsTransformation$new()`
- `FixedGroupsTransformation$get_group_args()`
- `FixedGroupsTransformation$apply()`
- `FixedGroupsTransformation$print()`
- `FixedGroupsTransformation$clone()`

Method `new()`: Initialize transformation.

Usage:
`FixedGroupsTransformation$new(fn, args, var_args, name = NULL)`

Arguments:
- `fn` Transformation function.
- `args` list of constant arguments for `fn`.
- `var_args` list of arguments for `fn` with different values per group. Each argument should have a list of values (one per group).
  - By adding ".apply" with a list of TRUE/FALSE flags, the transformation can be disabled for a specific group.
  - E.g. `list(".apply" = list(TRUE, FALSE, TRUE), ...`
- `name` Name of transformation.

Method `get_group_args()`: Get arguments for specific group ID.

Usage:
`FixedGroupsTransformation$get_group_args(group_id)`

Arguments:
- `group_id` ID of the group to get arguments for.

Returns: list of arguments.

Method `apply()`: Apply the transformation to a data.frame.

Usage:
`FixedGroupsTransformation$apply(data)`

Arguments:
- `data` data.frame with the expected number of groups.

Returns: Transformed version of `data`.
**Method** print(): Print an overview of the transformation.

*Usage:*
FixedGroupsTransformation$print(...) indent = 0, show_class = TRUE)

*Arguments:*
... further arguments passed to or from other methods.
indent How many spaces to indent when printing.
show_class Whether to print the transformation class name.

*Returns:* The pipeline. To allow chaining of methods.

**Method** clone(): The objects of this class are cloneable with this method.

*Usage:*
FixedGroupsTransformation$clone(deep = FALSE)

*Arguments:*
deep Whether to make a deep clone.

**Author(s)**
Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

**See Also**
Other transformation classes: GeneratedTransformation, Transformation

---

**flip_values**

*Flip the values around an origin*

**Description**

[Experimental]
The values are flipped with the formula \(x = 2 \ast c - x\) where \(x\) is the value and \(c\) is the origin coordinate to flip the values around.

The origin can be supplied as coordinates or as a function that returns coordinates. The latter can be useful when supplying a grouped data.frame and flipping around e.g. the centroid of each group.

By default the median value in each dimension is used.

The *_vec()* version take and return a vector.

**Example:**
The column values:
c(5, 2, 7, 4, 3, 1)
and the origin_fn = create_origin_fn(median)
Changes the values to:
c(2, 5, 0, 3, 4, 6)
Usage

```r
flip_values(
  data,
  cols = NULL,
  origin = NULL,
  origin_fn = create_origin_fn(median),
  suffix = "_flipped",
  keep_original = TRUE,
  origin_col_name = ".origin",
  overwrite = FALSE
)
```

```r
flip_values_vec(data, origin = NULL, origin_fn = create_origin_fn(median))
```

Arguments

data  data.frame or vector.
cols  Names of columns in `data` to flip values of.
origin  Coordinates of the origin to flip around. A scalar to use in all dimensions (columns) or a vector with one scalar per dimension.
          **N.B.** Ignored when `origin_fn` is not NULL. Remember to set it to NULL when passing origin coordinates manually!
origin_fn  Function for finding the origin coordinates.
          **Input:** Each column will be passed as a vector in the order of `cols`.
          **Output:** A vector with one scalar per dimension.
          Can be created with `create_origin_fn()` if you want to apply the same function to each dimension.
          E.g. `create_origin_fn(median)` would find the median of each column.
          **Built-in functions** are `centroid()`, `most_centered()`, and `midrange()`
suffix  Suffix to add to the names of the generated columns.
          Use an empty string (i.e. `""`) to overwrite the original columns.
keep_original  Whether to keep the original columns. (Logical)
          Some columns may have been overwritten, in which case only the newest versions are returned.
origin_col_name  Name of new column with the origin coordinates. If NULL, no column is added.
overwrite  Whether to allow overwriting of existing columns. (Logical)

    origin_fn = NULL, origin_col_name = NULL)

# Plot A and A flipped around its median
if (has_ggplot){
  ggplot(df, aes(x = Index, y = A)) +
    geom_line(aes(color = "A")) +

furthest_from

Orders values by longest distance to an origin

Description

[Experimental]

Values are ordered by how far they are from the origin.

In 1d (when `cols` has length 1), the origin can be thought of as a target value. In n dimensions, the origin can be thought of as coordinates.

The origin can be supplied as coordinates or as a function that returns coordinates. The latter can be useful when supplying a grouped data.frame and ordering the rows by their distance to the centroid of each group.

The _vec() version takes and returns a vector.

Example:

The column values:

```r
c(1, 2, 3, 4, 5)
```

and origin = 2

are ordered as:

```r
c(5, 4, 1, 3, 2)
```

Usage

```r
furthest_from(
  data,
  cols = NULL,
  origin = NULL,
  origin_fn = NULL,
  shuffle_ties = FALSE,
  origin_col_name = ".origin",
  distance_col_name = ".distance",
  overwrite = FALSE
)
```

```r
furthest_from_vec(data, origin = NULL, origin_fn = NULL, shuffle_ties = FALSE)
```
Arguments

- **data**: data.frame or vector.
- **cols**: Column(s) to create sorting factor by. When ``NULL` and `data` is a data.frame, the row numbers are used.
- **origin**: Coordinates of the origin to calculate distances to. A scalar to use in all dimensions or a vector with one scalar per dimension. **N.B.** Ignored when ``origin_fn` is not ``NULL`.
- **origin_fn**: Function for finding the origin coordinates. **Input**: Each column will be passed as a vector in the order of ``cols`.
  **Output**: A vector with one scalar per dimension. Can be created with `create_origin_fn()` if you want to apply the same function to each dimension. E.g. `create_origin_fn(median)` would find the median of each column. **Built-in functions** are `centroid()`, `most_centered()`, and `midrange()`
- **shuffle_ties**: Whether to shuffle elements with the same distance to the origin. (Logical)
- **origin_col_name**: Name of new column with the origin coordinates. If ``NULL`, no column is added.
- **distance_col_name**: Name of new column with the distances to the origin. If ``NULL`, no column is added.
- **overwrite**: Whether to allow overwriting of existing columns. (Logical)

Value

The sorted data.frame (tibble) / vector.

)

# In multiple dimensions
df %>%
  furthest_from(cols = c("A", "B"), origin_fn = most_centered)

---

### Description

**[Experimental]**

Build a pipeline of transformations to be applied sequentially.

Generate argument values for selected arguments with a given set of generators. E.g. randomly generate argument values for each group in a `data.frame`.

Groupings are reset between each transformation. See `group_cols`.

**Standard workflow:** Instantiate pipeline -> Add transformations -> Apply to data

To apply the same arguments to all groups, see `Pipeline`.

To apply different but specified argument values to a fixed set of groups, see `FixedGroupsPipeline`.

### Super class

`rearrr::Pipeline` -> `GeneratedPipeline`

### Public fields

- `transformations` list of transformations to apply.
- `names` Names of the transformations.

### Methods

**Public methods:**

- `GeneratedPipeline$add_transformation()`
- `GeneratedPipeline$print()`
- `GeneratedPipeline$clone()`

**Method** `add_transformation()`: Add a transformation to the pipeline.

**Usage:**

```r
GeneratedPipeline$add_transformation(
  fn,
  args,
  generators,
  name,
  group_cols = NULL
)
```

**Arguments:**

- `fn` Function that performs the transformation.
- `args` Named list with arguments for the `fn` function.
Named list of functions for generating argument values for a single call of `fn`.

It is possible to include an apply generator for deciding whether the transformation should be applied to the current group or not. This is done by adding a function with the name `.apply` to the `generators` list. E.g. `.apply` = function(){sample(c(TRUE, FALSE), 1)}.

Name of the transformation step. Must be unique.

Names of the columns to group the input data by before applying the transformation.

Note that the transformation function is applied separately to each group (subset). If the `fn` function requires access to the entire data.frame, the grouping columns should be specified as part of `args` and handled by the `fn` function.

Returns: The pipeline. To allow chaining of methods.

Examples:

```r
generators = list(degrees = function(){sample.int(360, 1)},
                  origin = function(){rnorm(2)},
                  .apply = function(){sample(c(TRUE, FALSE), 1)})
```

Method print(): Print an overview of the pipeline.

Usage:

```r
GeneratedPipeline$print(...) 
```

Arguments:

... further arguments passed to or from other methods.

Returns: The pipeline. To allow chaining of methods.

Method clone(): The objects of this class are cloneable with this method.

Usage:

```r
GeneratedPipeline$clone(deep = FALSE) 
```

Arguments:

deep Whether to make a deep clone.

Other pipelines: FixedGroupsPipeline, Pipeline

Examples

```r
# Attach package
library(rearr)

# Create a data frame
df <- data.frame(
  "Index" = 1:12,
  "A" = c(1:4, 9:12, 15:18),
)
"G" = rep(1:3, each = 4)
)

# Create new pipeline
pipe <- GeneratedPipeline$new()

# Add 2D rotation transformation
# Note that we specify the grouping via `group_cols`
pipe$add_transformation(
  fn = rotate_2d,
  args = list(
    x_col = "Index",
    y_col = "A",
    suffix = "",
    overwrite = TRUE
  ),
  generators = list(degrees = function(){sample.int(360, 1)},
                    origin = function(){rnorm(2)}),
  name = "Rotate",
  group_cols = "G"
)

# Add the `cluster_group` transformation
# Note that this function requires the entire input data
# to properly scale the groups. We therefore specify `group_cols`
# as part of `args`. This works as `cluster_groups()` accepts that
# argument.
# Also note the `.apply` generator which generates a TRUE/FALSE scalar
# for whether the transformation should be applied to the current group
pipe$add_transformation(
  fn = cluster_groups,
  args = list(
    cols = c("Index", "A"),
    suffix = "",
    overwrite = TRUE,
    group_cols = "G"
  ),
  generators = list(
    multiplier = function() {
      0.1 * runif(1) * 3 ^ sample.int(5, 1)
    },
    .apply = function(){sample(c(TRUE, FALSE), 1)}
  ),
  name = "Cluster"
)

# Check pipeline object
pipe

# Apply pipeline to data.frame
# Enable `verbose` to print progress
pipe$apply(df, verbose = TRUE)

# Method `GeneratedPipeline$add_transformation`
```
# `generators` is a list of functions for generating
# argument values for a chosen set of arguments
# `.apply` can be used to disable the transformation
generators = list(degrees = function(){sample.int(360, 1)},
                  origin = function(){rnorm(2)},
                  .apply = function(){sample(c(TRUE, FALSE), 1)})
```

---

**Description**

[Experimental]

Container for the type of transformation used in `GeneratedPipeline`.

**Note**: For internal use.

**Super class**

`rearrr::Transformation` -> `GeneratedTransformation`

**Public fields**

- `name` Name of transformation.
- `fn` Transformation function.
- `args` list of constant arguments for `fn`.
- `generators` list of generator functions for generating argument values.
- `apply_generator` Generator function for deciding whether to apply the transformation to the current group.

**Methods**

**Public methods:**
- `GeneratedTransformation$new()`
- `GeneratedTransformation$get_group_args()`
- `GeneratedTransformation$generate_args()`
- `GeneratedTransformation$print()`
- `GeneratedTransformation$clone()`

**Method** `new()`: Initialize transformation.

*Usage:*

```
GeneratedTransformation$new(
    fn,
    args,
    generators,
    name = NULL,
    group_cols = NULL
)
```
Arguments:

fn Transformation function.

args list of constant arguments for `fn`.

generators Named list of functions for generating argument values for a single call of `fn`.

It is possible to include an *apply generator* for deciding whether the transformation should be applied to the current group or not. This is done by adding a function with the name `.apply` to the `generators` list. E.g. `.apply` = function() { sample(c(TRUE, FALSE), 1) }

name Name of transformation.

group_cols Names of columns to group data.frame by before applying `fn`.

When `NULL`, the data.frame is not grouped.

**Method** `get_group_args()`: Get arguments for a group.

**Usage:**

GeneratedTransformation$get_group_args()

**Returns:** list of arguments (both constant and generated).

**Method** `generate_args()`: Generate arguments for a group with the `generators`.

**Usage:**

GeneratedTransformation$generate_args()

**Returns:** list of generated arguments.

Does not include the constant arguments.

**Method** `print()`: Print an overview of the transformation.

**Usage:**

GeneratedTransformation$print(..., indent = 0, show_class = TRUE)

**Arguments:**

... further arguments passed to or from other methods.

indent How many spaces to indent when printing.

show_class Whether to print the transformation class name.

**Returns:** The pipeline. To allow chaining of methods.

**Method** `clone()`: The objects of this class are cloneable with this method.

**Usage:**

GeneratedTransformation$clone(deep = FALSE)

**Arguments:**

deep Whether to make a deep clone.

**Author(s)**

Other transformation classes: `FixedGroupsTransformation`, `Transformation`
generate_clusters  Generate n-dimensional clusters

Description

[Experimental]
Generates data.frame (tibble) with clustered groups.

Usage

generate_clusters(
  num_rows,
  num_cols,
  num_clusters,
  compactness = 1.6,
  generator = runif,
  name_prefix = "D",
  cluster_col_name = ".cluster"
)

Arguments

- num_rows  Number of rows.
- num_cols  Number of columns (dimensions).
- num_clusters  Number of clusters.
- compactness  How compact the clusters should be. A larger value leads to more compact clusters (on average). Technically, it is passed to the `multiplier` argument in cluster_groups() as `0.1/compactness`.
- generator  Function to generate the numeric values. Must have the number of values to generate as its first (and only required) argument, as that is the only argument we pass to it.
- name_prefix  Prefix string for naming columns.
- cluster_col_name  Name of cluster factor.

Details

- Generates data.frame with random values using the `generator`.
- Divides the rows into groups (the clusters).
- Contracts the distance from each data point to the centroid of its group.
- Performs MinMax scaling such that the scale of the data points is similar to the generated data.

Value

data.frame (tibble) with the clustered columns and the cluster grouping factor.

# Attach packages
library(rearrr)
library(dplyr)
has_ggplot <- require(ggplot2) # Attach if installed

# Set seed
set.seed(10)

# Generate clusters
generate_clusters(num_rows = 20, num_cols = 3, num_clusters = 3, compactness = 1.6)
generate_clusters(num_rows = 20, num_cols = 5, num_clusters = 6, compactness = 2.5)

# Generate clusters and plot them
# Tip: Call this multiple times
# to see the behavior of `generate_clusters()`
if (has_ggplot){
  generate_clusters(
    num_rows = 50, num_cols = 2,
    num_clusters = 5, compactness = 1.6
  ) %>%
  ggplot(
    aes(x = D1, y = D2, color = .cluster)
  ) +
  geom_point() +
  theme_minimal() +
  labs(x = "D1", y = "D2", color = "Cluster")
}

# Plot clusters in 3d view
#

# Generate clusters
clusters <- generate_clusters(
  num_rows = 50, num_cols = 3,
  num_clusters = 5, compactness = 1.6
)

## Not run:
# Plot 3d with plotly
plotly::plot_ly(
  x = clusters$D1,
  y = clusters$D2,
  z = clusters$D3,
  type = "scatter3d",
  mode = "markers",
  color = clusters$.cluster
)```
hexagonalize

Create x-coordinates so the points form a hexagon

Description

[Experimental]
Create the x-coordinates for a vector of y-coordinates such that they form a hexagon. This will likely look most like a hexagon when the y-coordinates are somewhat equally distributed, e.g. a uniform distribution.

Usage

hexagonalize(
  data,
  y_col = NULL,
  .min = NULL,
  .max = NULL,
  offset_x = 0,
  keep_original = TRUE,
  x_col_name = ".hexagon_x",
  edge_col_name = ".edge",
  overwrite = FALSE
)

Arguments

data data.frame or vector.
y_col Name of column in `data` with y-coordinates to create x-coordinates for.
.min Minimum y-coordinate. If NULL, it is inferred by the given y-coordinates.
.max Maximum y-coordinate. If NULL, it is inferred by the given y-coordinates.
.offset_x Value to offset the x-coordinates by.
.keep_original Whether to keep the original columns. (Logical)
Some columns may have been overwritten, in which case only the newest versions are returned.
x_col_name Name of new column with the x-coordinates.
.edge_col_name Name of new column with the edge identifiers. If NULL, no column is added.
Numbering is clockwise and starts at the upper-right edge.
.overwrite Whether to allow overwriting of existing columns. (Logical)

Value

data.frame (tibble) with the added x-coordinates and an identifier for the edge the data point is a part of.

}
is_most_centered  Find which data point is closest to the centroid

Description

[Experimental]
Finds the data point with the shortest distance to the centroid.
To get the coordinates of the most centered data point, use most_centered() instead.

Usage

is_most_centered(..., na.rm = FALSE)

Arguments

... Numeric vectors.
na.rm Whether to ignore missing values. At least one data point must be complete.
(Logical)

Value

Logical vector (TRUE/FALSE) indicating if a data point is the most centered.

df %>%
dplyr::group_by(g) %>%
dplyr::mutate(mc = is_most_centered(x, y, z))

---

**median_index**

*Find index of interest for each vector*

**Description**

[Experimental]

Applies function to the indices of each vector in `...`.

These functions were created with `create_n_fn()`.

**Usage**

```r
median_index(..., negate = FALSE, round_fn = round)
quantile_index(..., prob, type = 7, negate = FALSE, round_fn = round)
```

**Arguments**

- `...` Numeric vectors.
- `negate`Whether to negate the result. I.e. to multiply it with -1. (Logical)
- `round_fn`Function for rounding output. Rounding is done prior to negation. E.g. `round`, `floor`, or `ceiling`.
- `prob`Probability in [0,1] for `quantile()`.
- `type`Quantile algorithm to use. See `quantile()`.
**midrange**

Value

numeric vector with one element per supplied vector.

Author(s)

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

See Also

Other n functions: `create_n_fn()`

Examples

```r
# Attach packages
library(rearrr)

# Set seed
set.seed(1)

# Create three vectors
x <- runif(10)
y <- runif(15)
z <- runif(20)

median_index(x, y, z)
quantile_index(x, y, z, prob = 0.2)

# Negate result
median_index(x, y, z, negate = TRUE)
```

---

**midrange**

Find the midrange values

---

**Description**

[Experimental]

Calculates the midrange for each of the passed vectors/columns.

Midrange is defined as:

\[
\frac{\text{max} + \text{min}}{2}
\]

**Usage**

`midrange(..., cols = NULL, na.rm = FALSE)`

**Arguments**

- `...`: Numeric vectors or a single data.frame.
- `cols`: Names of columns to use when `...` is a single data.frame.
- `na.rm`: Whether to ignore missing values when calculating min and max values. (Logical)
Value

Either a vector with the midrange of each supplied vector or a data.frame with the midrange of each supplied column along with any grouping variables.

Author(s)

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

See Also

Other coordinate functions: `centroid()`, `create_origin_fn()`, `is_most_centered()`, `most_centered()`

Examples

```r
# Attach packages
library(rearr)
library(dplyr)

# Set seed
set.seed(1)

# Create three vectors
x <- runif(10)
y <- runif(10)
z <- runif(10)

# Find midrange for each vector
midrange(x, y, z)

# For data.frames

# Create data frame
df <- data.frame(
  "x" = x,
  "y" = y,
  "z" = z,
  "g" = rep(1:2, each = 5)
)

# Find midrange for each column
midrange(df, cols = c("x", "y", "z"))

# When 'df' is grouped
df %>%
dplyr::group_by(g) %>%
midrange(cols = c("x", "y", "z"))
```

### min_max_scale

Scale to a range
Description

[Experimental]
Scales the values to a range with MinMax scaling.

Usage

```r
min_max_scale(
  x,
  new_min,
  new_max,
  old_min = NULL,
  old_max = NULL,
  na.rm = FALSE
)
```

Arguments

- `x`  
  Numeric vector to scale.
- `new_min`  
  Minimum value of target range.
- `new_max`  
  Maximum value of target range.
- `old_min`  
  Minimum value of original range.
  If `NULL`, this is the minimum value in `x`.
- `old_max`  
  Maximum value of original range.
  If `NULL`, this is the maximum value in `x`.
- `na.rm`  
  Whether missing values should be removed when calculating `old_min` and/or `old_max`.

**N.B.** Ignored when both `old_min` and `old_max` are `NULL`.

Value

Scaled version of `x`.

Author(s)

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

See Also

Other scaling functions: `to_unit_length()`

Examples

```r
# Attach packages
library(rearrr)

# Set seed

# Create numeric vector
x <- runif(10)

# Scale
```
most_centered

min_max_scale(x, new_min = -1, new_max = 0)
min_max_scale(x, new_min = -1, new_max = 0, old_max = 3)

---

most_centered  Find the coordinates for the data point closest to the centroid

Description

[Experimental]
Returns the coordinates for the data point with the shortest distance to the centroid.
To get a logical vector (TRUE/FALSE) indicating whether a data point is the most centered, use is_most_centered().

Usage

most_centered(..., cols = NULL, na.rm = FALSE)

Arguments

...  Numeric vectors or a single data.frame.
cols  Names of columns to use when `...` is a single data.frame.
na.rm  Whether to ignore missing values. At least one data point must be complete. (Logical)

Value

The coordinates for the data point closest to the centroid. Either as a vector or a data.frame.

Author(s)

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

See Also

Other coordinate functions: centroid(), create_origin_fn(), is_most_centered(), midrange()

Examples

# Attach packages
library(rearrr)
library(dplyr)

# Set seed
set.seed(1)

# Create three vectors
x <- runif(10)
y <- runif(10)
z <- runif(10)

# Find coordinates of the data point
# closest to the centroid
pair_extremes

```r
most_centered(x, y, z)

# Compare to centroid coordinates
centroid(x, y, z)

#
# For data.frames
#

# Create data frame
def <- data.frame(
  "x" = x,
  "y" = y,
  "z" = z,
  "g" = rep(1:2, each = 5)
)

# Find coordinates of the data point
# closest to the centroid
most_centered(def, cols = c("x", "y", "z"))

# When 'df' is grouped
def %>%
  dplyr::group_by(g) %>%
  most_centered(cols = c("x", "y", "z"))

# Filter to only include most centered data points
def %>%
  dplyr::group_by(g) %>%
  dplyr::filter(is_most_centered(x, y, z))
```

**Description**

[Experimental] The values are paired/grouped such that the lowest and highest values form the first group, the second lowest and the second highest values form the second group, and so on. The values are then sorted by these groups/pairs. When `data` has an uneven number of rows, the `unequal_method` determines which group should have only 1 element.

The *vec() version takes and returns a vector.

**Example:**
The column values:
c(1, 2, 3, 4, 5, 6)

Creates the **sorting factor:**
c(1, 2, 3, 3, 2, 1)

And are **ordered as:**
c(1, 6, 2, 5, 3, 4)
Usage

```r
pair_extremes(
  data,
  col = NULL,
  unequal_method = "middle",
  num_pairings = 1,
  balance = "mean",
  order_by_aggregates = FALSE,
  shuffle_members = FALSE,
  shuffle_pairs = FALSE,
  factor_name = ifelse(num_pairings == 1, ".pair", ".pairing"),
  overwrite = FALSE
)
```

```r
pair_extremes_vec(
  data,
  unequal_method = "middle",
  num_pairings = 1,
  balance = "mean",
  order_by_aggregates = FALSE,
  shuffle_members = FALSE,
  shuffle_pairs = FALSE
)
```

Arguments

- `data` data.frame or vector.
- `col` Column to create sorting factor by. When `NULL` and `data` is a data.frame, the row numbers are used.
- `unequal_method` Method for dealing with an unequal number of rows/elements in `data`.
  
  One of: `first`, `middle` or `last`

  - **first**: The first group will have size 1.
    **Example**:
    The ordered column values: 
    `c(1, 2, 3, 4, 5)`
    Creates the **sorting factor**:
    `c(1, 2, 3, 3, 2)`
    And are **ordered as**:
    `c(1, 5, 3, 2, 4)`

  - **middle**: The middle group will have size 1.
    **Example**:
    The ordered column values: 
    `c(1, 2, 3, 4, 5)`
    Creates the **sorting factor**:
    `c(1, 3, 2, 3, 1)`
    And are **ordered as**:
    `c(1, 5, 3, 2, 4)`

  - **last**: The last group will have size 1.
    **Example**:
    The ordered column values:
c(1, 2, 3, 4, 5)
Creates the sorting factor:
c(1, 2, 2, 1, 3)
And are ordered as:
c(1, 4, 2, 3, 5)

`num_pairings` Number of pairings to perform (recursively). At least 1.
Based on `balance`, the secondary pairings perform extreme pairing on either
the sum, absolute difference, min, or max of the pair elements.

`balance` What to balance pairs for in a given secondary pairing. Either "mean", "spread",
"min", or "max". Can be a single string used for all secondary pairings or one
for each secondary pairing (`num_pairings` - 1).
The first pairing always pairs the actual element values.

- **mean**: Pairs have similar means. The values in the pairs from the previous
  pairing are aggregated with `sum()` and paired.
- **spread**: Pairs have similar spread (e.g. standard deviations). The values in
  the pairs from the previous pairing are aggregated with `sum(abs(diff()))`
  and paired.
- **min / max**: Pairs have similar minimum / maximum values. The values in the
  pairs from the previous pairing are aggregated with `min()` / `max()` and
  paired.

`order_by_aggregates` Whether to order the pairs from initial pairings (first `num_pairings` - 1)
by their aggregate values instead of their pair identifiers.
N.B. Only used when `num_pairings` > 1.

`shuffle_members` Whether to shuffle the order of the group members within the groups. (Logical)

`shuffle_pairs` Whether to shuffle the order of the pairs. Pair members remain together. (Logical)

`factor_name` Name of new column with the sorting factor. If `NULL`, no column is added.

`overwrite` Whether to allow overwriting of existing columns. (Logical)

**Value**
The sorted data.frame (tibble) / vector. Optionally with the sorting factor added.
When `data` is a vector and `keep_factors` is FALSE, the output will be a vector. Otherwise,
a data.frame.

Examples

```r
# Attach packages
library(rearrr)
library(dplyr)

# Set seed
set.seed(1)

# Create a data frame
df <- data.frame(
  "index" = 1:10,
  "A" = sample(1:10),
  "B" = runif(10),
  "C" = LETTERS[1:10],
  "G" = c(1, 1, 1, 2, 2, 2, 3, 3, 3, 3),
  stringsAsFactors = FALSE
)

# Pair extreme indices (row numbers)
pair_extremes(df)

# Pair extremes in each of the columns
pair_extremes(df, col = "A")$A
pair_extremes(df, col = "B")$B
pair_extremes(df, col = "C")$C

# Shuffle the members pair-wise
# The rows within each pair are shuffled
# while the `.pair` column maintains its order
pair_extremes(df, col = "A", shuffle_members = TRUE)

# Shuffle the order of the pairs
# The rows within each pair maintain their order
# and stay together but the `.pair` column is shuffled
pair_extremes(df, col = "A", shuffle_pairs = TRUE)

# Use recursive pairing
# Mostly meaningful with much larger datasets
# Order initial grouping by pair identifiers
pair_extremes(df, col = "A", num_pairings = 2)
# Order initial grouping by aggregate values
pair_extremes(df, col = "A", num_pairings = 2, order_by_aggregates = TRUE)

# Grouped by G
# Each G group only has 3 elements
# so it only creates 1 pair and a group
# with the single excessive element
# per G group
df %>%
  dplyr::select(G, A) %>% # For clarity
dplyr::group_by(G) %>%
pair_extremes(col = "A")
```
Pipeline

Chain multiple transformations

Description

[Experimental]
Build a pipeline of transformations to be applied sequentially.
Uses the same arguments for all groups in `data`.
Groupings are reset between each transformation. See `group_cols`.

Standard workflow: Instantiate pipeline -> Add transformations -> Apply to data

To apply different argument values to each group, see `GeneratedPipeline` for generating argument values for an arbitrary number of groups and `FixedGroupsPipeline` for specifying specific values for a fixed set of groups.

Public fields

 transformations list of transformations to apply.
 names Names of the transformations.

Methods

Public methods:

- `Pipeline$add_transformation()`
- `Pipeline$apply()`
- `Pipeline$print()`
- `Pipeline$clone()`

Method `add_transformation()`: Add a transformation to the pipeline.

Usage:

`Pipeline$add_transformation(fn, args, name, group_cols = NULL)`
Pipeline

Arguments:

fn Function that performs the transformation.
args Named list with arguments for the `fn` function.
name Name of the transformation step. Must be unique.
group_cols Names of the columns to group the input data by before applying the transformation.

Note that the transformation function is applied separately to each group (subset). If the `fn` function requires access to the entire `data.frame`, the grouping columns should be specified as part of `args` and handled by the `fn` function.

Returns: The pipeline. To allow chaining of methods.

Method apply(): Apply the pipeline to a `data.frame`.

Usage:
Pipeline$apply(data, verbose = FALSE)

Arguments:
data `data.frame`.

A grouped `data.frame` will raise a warning and the grouping will be ignored. Use the `group_cols` argument in the `add_transformation` method to specify how `data` should be grouped for each transformation.

verbose Whether to print the progress.

Returns: Transformed version of `data`.

Method print(): Print an overview of the pipeline.

Usage:
Pipeline$print(...)

Arguments:
...

... further arguments passed to or from other methods.

Returns: The pipeline. To allow chaining of methods.

Method clone(): The objects of this class are cloneable with this method.

Usage:
Pipeline$clone(deep = FALSE)

Arguments:
deep Whether to make a deep clone.

Examples

```r
# Attach package
library(rearr)

# Create a data frame
df <- data.frame(
  "Index" = 1:12,
  "A" = c(1:4, 9:12, 15:18),
  "G" = rep(1:3, each = 4)
)

# Create new pipeline
pipe <- Pipeline$new()

# Add 2D rotation transformation
# Note that we specify the grouping via `group_cols`
pipe$add_transformation(
  fn = rotate_2d,
  args = list(
    x_col = "Index",
    y_col = "A",
    origin = c(0, 0),
    degrees = 45,
    suffix = "",
    overwrite = TRUE
  ),
  name = "Rotate",
  group_cols = "G"
)

# Add the `cluster_group` transformation
# Note that this function requires the entire input data
# to properly scale the groups. We therefore specify `group_cols`
# as part of `args`. This works as `cluster_groups()` accepts that
# argument.
pipe$add_transformation(
  fn = cluster_groups,
  args = list(
    cols = c("Index", "A"),
    suffix = "",
    overwrite = TRUE,
    multiplier = 0.05,
    group_cols = "G"
  ),
  name = "Cluster"
)

# Check pipeline object
pipe

# Apply pipeline to data.frame
# Enable `verbose` to print progress
pipe$apply(df, verbose = TRUE)
```
position_max

Positions the highest values with values decreasing around it

Description

[Experimental]

The highest value is positioned at the given index/quantile with the other values decreasing around it.

Example:
The column values:
c(1, 2, 3, 4, 5)
and position = 2
are ordered as:
c(3, 5, 4, 2, 1)

Usage

position_max(data, col = NULL, position = NULL, shuffle_sides = FALSE)

Arguments

data    data.frame or vector.
col     Column to create sorting factor by. When `NULL` and `data` is a data.frame, the row numbers are used.
position Index or quantile (in 0-1) at which to position the element of interest.
shuffle_sides  Whether to shuffle which elements are left and right of the position. (Logical)

Value

The sorted data.frame (tibble) / vector.

plot(x = 1:10, y = position_max(df, col = "B", position = 3, shuffle_sides = TRUE)$B)

position_min

Positions the lowest value with values increasing around it

Description

[Experimental]
The lowest value is positioned at the given index/quantile with the other values increasing around it.

Example:
The column values:
c(1, 2, 3, 4, 5)
and position = 2
are ordered as:
c(3, 1, 2, 4, 5)

Usage

position_min(data, col = NULL, position = NULL, shuffle_sides = FALSE)

Arguments

data data.frame or vector.
col Column to create sorting factor by. When `NULL` and `data` is a data.frame, the row numbers are used.
position Index or quantile (in 0-1) at which to position the element of interest.
shuffle_sides Whether to shuffle which elements are left and right of the position. (Logical)

Value

The sorted data.frame (tibble)/vector.

plot(x = 1:10, y = position_min(df, col = "B", position = 3, shuffle_sides = TRUE)$B)

---

**Description**

**[Experimental]**

The values are windowed and reversed within windows.

The *_vec()* version takes and returns a vector.

**Example:**

The column values:

```r
c(1, 2, 3, 4, 5, 6)
```

With `window_size = 3`

Are ordered as:

```r
c(3, 2, 1, 6, 4, 5)
```

**Usage**

```r
rev_windows(data, window_size, factor_name = ".window", overwrite = FALSE)
```

```r
rev_windows_vec(data, window_size)
```

**Arguments**

- `data` data.frame or vector.
- `window_size` Size of the windows. (Logical)
- `factor_name` Name of the factor with window identifiers. If `"NULL"`, no column is added.
- `overwrite` Whether to allow overwriting of existing columns. (Logical)
Value

The sorted data.frame (tibble) / vector. Optionally with the windows factor added.
When `data` is a vector and `keep_windows` is FALSE, the output will be a vector. Otherwise, a data.frame.

# Plot the extreme pairs
plot(
  x = 1:10,
  y = rev_windows_vec(1:10, window_size = 3)
)
**Roll elements**

### Description

[Experimental]
Rolls positions of elements.

Example:
Rolling `c(1, 2, 3, 4, 5)` with `n = 2` becomes:
`c(3, 4, 5, 1, 2)`

`roll_elements_vec()` takes and returns a vector.

Should not be confused with `roll_values()`, which changes the values of the elements and wraps to a given range.

### Usage

```r
roll_elements(
  data,
  cols = NULL,
  n = NULL,
  n_fn = NULL,
  n_col_name = ".n",
  overwrite = FALSE,
  ...
)

roll_elements_vec(data, n = NULL, n_fn = NULL, ...)
```

### Arguments

- **data**: vector or data.frame to roll elements of. When a data.frame is grouped, the rolling is applied group-wise.
- **cols**: Names of columns in `data` to roll. If NULL, the index is rolled and used to reorder `data`.
  
  N.B. only used when `data` is a data.frame.
- **n**: Number of positions to roll. A positive number rolls left/up. A negative number rolls right/down.
- **n_fn**: Function to find `n`. Useful when `data` is a grouped data.frame and `n` should depend on the rows in the group.
  
  **Input**: Each specified vector/column in `data` is passed to the function as a separate argument.
  
  **Output**: It should return either a vector with one integer-like scalar per column or a single integer-like scalar to use for all columns.
  
  Can be created with `create_n_fn()`. See also `median_index()` and `quantile_index()`.
- **n_col_name**: Name of new column with the applied `n` values. If NULL, no column is added.
- **overwrite**: Whether to allow overwriting of columns with the same name as `n_col_name`.
  
  (Logical)
- **...**: Extra arguments for `n_fn`. 
Value

Rolled `data`.

Examples

# Attach packages
library(rearrr)
library(dplyr)

# Roll vector left
roll_elements(1:10, n = 2)

# Roll vector right and return the vector
roll_elements_vec(1:10, n = -2)

# Roll vector left by median index (rounded to 6)
roll_elements(3:12, n_fn = median_index)

# Roll vector right by median value (rounded to 8)
roll_elements(3:12, n_fn = create_n_fn(median, negate = TRUE))

# Pass extra arguments (here 'prob') to 'n_fn' via '...' 
roll_elements(1:10,
  n_fn = quantile_index,
  prob = 0.2)

# Roll data.frame

# Set seed
set.seed(1)

# Create a data frame
df <- data.frame(
  "x" = 1:20,
  "y" = runif(20) * 10,
  "g" = rep(1:4, each = 5)
)

# Roll rows left/up
roll_elements(df, n = 2)
roll_values

# Roll rows right/down
roll_elements(df, n = -2)

# Roll 'x' column right/down
roll_elements(df, cols = "x", n = -2)

# Roll rows right by median index in each group
# Specify 'negate' for the 'median_index' function
roll_elements(
  df %>% dplyr::group_by(g),
  n_fn = median_index,
  negate = TRUE
)

roll_values Shift values and wrap to range

Description

[Experimental]
Adds a specified value to each element in the vector and wraps the values around the min-max range with:

\[(x - \text{.min}) \% (\text{.max} - \text{.min} + \text{between}) + \text{.min}\]

Useful when adding to the degrees of a circle, where the values should remain in the 0-360 range. A value larger than 360 will start over from 0, e.g. 365 -> 5, while a value smaller than 0 would become e.g. -5 -> 355. Here, 0 and 360 are considered the same angle. If we were instead adding days to the weekdays 1-7, where 1 and 7 are separate days, we can set `between = 1` to have one day in-between them.

wrap_to_range() is a wrapper with `add = 0`.

The *_vec() versions take and return a vector.

Should not be confused with roll_elements(), which changes the positions of the elements.

Usage

roll_values(
  data,
  cols = NULL,
  add = 0,
  .min = NULL,
  .max = NULL,
  between = 0,
  na.rm = FALSE,
  suffix = ".rolled",
  keep_original = TRUE,
  range_col_name = ".range",
  overwrite = FALSE
)

wrap_to_range(
  data,
roll_values

roll_values_vec(
    data,
    add = 0,
    .min = NULL,
    .max = NULL,
    between = 0,
    na.rm = FALSE
)

wrap_to_range_vec(data, .min = NULL, .max = NULL, between = 0, na.rm = FALSE)

Arguments

data vector or data.frame to roll/wrap values of. When a data.frame is grouped, the rolling/wrapping is applied group-wise.
cols Names of columns to roll/wrap in `data`. Must be specified when `data` is a data.frame.
add Amount to add to each element. (numeric scalar) When 0, the wrapping is applied without any rolling.
.min Minimum value allowed. If NULL, the minimum value in the vector/column is used.
.max Maximum value allowed. If NULL, the maximum value in the vector/column is used.
between The wrapping distance between `.max` and `.min`. When 0, they are considered the same. I.e. `.max == .min`.
na.rm Whether to remove missing values (NAs) when finding the `.min` and `.max` values.
suffix Suffix to add to the names of the generated columns. Use an empty string (i.e. `""`) to overwrite the original columns.
keep_original Whether to keep the original columns. (Logical) Some columns may have been overwritten, in which case only the newest versions are returned.
range_col_name Name of new column with the min-max range. If NULL, no column is added.
N.B. Ignored when `data` is a vector.
overwrite Whether to allow overwriting of existing columns. (Logical)
`roll_values`

Value

`data` with new columns with values in the specified min-max range(s) and columns with the applied ranges.
The `*vec()` versions return a vector.

    cols = c("w", "d"),
    add = 1
)

# Wrap weekdays to 2-5 range
wrap_to_range(
    df,
    cols = "w",
    .min = 2,
    .max = 5,
    between = 1
)

---

**rotate_2d**

**Rotate the values around an origin in 2 dimensions**

**Description**

[Experimental]

The values are rotated counterclockwise around a specified origin.

The origin can be supplied as coordinates or as a function that returns coordinates. The latter can be useful when supplying a grouped data.frame and rotating around e.g. the centroid of each group.
rotate_2d

Usage

rotate_2d(
data,
degrees,
x_col = NULL,
y_col = NULL,
suffix = "_rotated",
origin = NULL,
origin_fn = NULL,
keep_original = TRUE,
degrees_col_name = ".degrees",
origin_col_name = ".origin",
overwrite = FALSE
)

Arguments

data data.frame or vector.
degrees Degrees to rotate values counterclockwise. In \([-360, 360]\). Can be a vector with multiple degrees.
x_col Name of x column in `data`. If NULL and `data` is a vector, the index of `data` is used. If `data` is a data.frame, it must be specified.
y_col Name of y column in `data`. If `data` is a data.frame, it must be specified.
suffix Suffix to add to the names of the generated columns.
Use an empty string (i.e. "") to overwrite the original columns.
origin Coordinates of the origin to rotate around. A vector with 2 elements (i.e. origin_x, origin_y). Ignored when `origin_fn` is not NULL.
origin_fn Function for finding the origin coordinates.
Input: Each column will be passed as a vector in the order of `cols`.
Output: A vector with one scalar per dimension.
Can be created with `create_origin_fn()` if you want to apply the same function to each dimension.
E.g. `create_origin_fn(median)` would find the median of each column.
Built-in functions are `centroid()`, `most_centered()`, and `midrange()`
keep_original Whether to keep the original columns. (Logical)
Some columns may have been overwritten, in which case only the newest versions are returned.
degrees_col_name Name of new column with the degrees. If NULL, no column is added.
origin_col_name Name of new column with the origin coordinates. If NULL, no column is added.
overwrite Whether to allow overwriting of existing columns. (Logical)

Details

Applies the following rotation matrix:

\[
\begin{bmatrix}
\cos \theta & -\sin \theta \\
\end{bmatrix}
\]
That is:
\[ x' = x \cos \theta - y \sin \theta \]
\[ y' = x \sin \theta + y \cos \theta \]

Where \( \theta \) is the angle in radians.

As specified at Wikipedia/Rotation_matrix.

Value

data.frame (tibble) with seven new columns containing the rotated x-, y- and z-values and the degrees, radiuses and origin coordinates.

---

**rotate_3d**

Rotate the values around an origin in 3 dimensions

---

**Description**

*[Experimental]*

The values are rotated counterclockwise around a specified origin.

The origin can be supplied as coordinates or as a function that returns coordinates. The latter can be useful when supplying a grouped dataframe and rotating around e.g. the centroid of each group.

**Usage**

rotate_3d(
  data,
  x_col,
  y_col,
  z_col,
  x_deg = 0,
  y_deg = 0,
  z_deg = 0,
  suffix = "_rotated",
  origin = NULL,
origin_fn = NULL,
keep_original = TRUE,
degrees_col_name = ".degrees",
origin_col_name = ".origin",
overwrite = FALSE
)

Arguments

data data.frame or vector.
x_col, y_col, z_col
   Name of x/y/z column in `data`. All must be specified.

x_deg, y_deg, z_deg
   Degrees to rotate values around the x/y/z-axis counterclockwise. In [-360, 360]. Can be vectors with multiple degrees.
   `x_deg` is roll. `y_deg` is pitch. `z_deg` is yaw.

suffix Suffix to add to the names of the generated columns.
   Use an empty string (i.e. "") to overwrite the original columns.

origin Coordinates of the origin to rotate around. Vector with 3 elements (i.e. origin_x, origin_y, origin_z). Ignored when `origin_fn` is not NULL.

origin_fn Function for finding the origin coordinates.
   Input: Each column will be passed as a vector in the order of `cols`.
   Output: A vector with one scalar per dimension.
   Can be created with `create_origin_fn()` if you want to apply the same function to each dimension.
   E.g. `create_origin_fn(median)` would find the median of each column.
   Built-in functions are `centroid()`, `most_centered()`, and `midrange()`

keep_original Whether to keep the original columns. (Logical)
   Some columns may have been overwritten, in which case only the newest versions are returned.

degrees_col_name Name of new column with the degrees. If NULL, no column is added.
   Also adds a string version with the same name + ".str", making it easier to group by the degrees when plotting multiple rotations.

origin_col_name Name of new column with the origin coordinates. If NULL, no column is added.

overwrite Whether to allow overwriting of existing columns. (Logical)

Details

Applies the following rotation matrix:

\[
\begin{bmatrix}
\cos \alpha \cos \beta & \cos \alpha \sin \beta \sin \gamma - \sin \alpha \cos \gamma & \cos \alpha \sin \beta \cos \gamma + \sin \alpha \sin \gamma \\
\sin \alpha \cos \beta & \sin \alpha \sin \beta \sin \gamma + \cos \alpha \cos \gamma & \sin \alpha \sin \beta \cos \gamma - \cos \alpha \sin \gamma \\
-\sin \beta & \cos \beta \sin \gamma & \cos \beta \cos \gamma
\end{bmatrix}
\]

Where $\alpha = \`z\_deg`$ in radians, $\beta = \`y\_deg`$ in radians, $\gamma = \`x\_deg`$ in radians.

As specified at Wikipedia/Rotation_matrix.
**Value**

data.frame (tibble) with six new columns containing the rotated x-, y- and z-values and the degrees and origin coordinates.

shear_2d

Shear the values around an origin in 2 dimensions

Description

[Experimental]

Shear a set of 2d points around an origin. The shearing formulas (excluding the origin movements) is:

\[
x' = x + x_{hear} \times y \\
y' = y + y_{hear} \times x
\]

The data points in `data` are moved prior to the shearing, to bring the origin to 0 in all dimensions. After the shearing, the inverse move is applied to bring the origin back to its original position.

The origin can be supplied as coordinates or as a function that returns coordinates. The latter can be useful when supplying a grouped data frame and shearing around e.g. the centroid of each group.
Usage

shear_2d(
  data,
  x_shear,
  y_shear = 0,
  x_col = NULL,
  y_col = NULL,
  suffix = "_sheared",
  origin = NULL,
  origin_fn = NULL,
  keep_original = TRUE,
  shear_col_name = ".shear",
  origin_col_name = ".origin",
  overwrite = FALSE
)

Arguments

data data.frame or vector.
x_shear Shear factor for the x dimension (numeric). Decides the amount of shearing. Can be a vector with multiple shear factors.
y_shear Shear factor for the y dimension (numeric). Decides the amount of shearing. Can be a vector with multiple shear factors.
x_col Name of x column in `data`.
y_col Name of y column in `data`.
suffix Suffix to add to the names of the generated columns. Use an empty string (i.e. "") to overwrite the original columns.
origin Coordinates of the origin to shear around. Vector with 2 elements (origin_x, origin_y). Ignored when `origin_fn` is not NULL.
origin_fn Function for finding the origin coordinates. Input: Each column will be passed as a vector in the order of `cols`. Output: A vector with one scalar per dimension. Can be created with `create_origin_fn()` if you want to apply the same function to each dimension. E.g. `create_origin_fn(median)` would find the median of each column. Built-in functions are `centroid()`, `most_centered()`, and `midrange()`
keep_original Whether to keep the original columns. (Logical) Some columns may have been overwritten, in which case only the newest versions are returned.
shear_col_name Name of new column with the shearing factors. If NULL, no column is added. Also adds a string version with the same name + "_str", making it easier to group by the shearing factors when plotting multiple shearings.
origin_col_name Name of new column with the origin coordinates. If NULL, no column is added.
overwrite Whether to allow overwriting of existing columns. (Logical)

Value
data.frame (tibble) with sheared columns, the shearing factors and the origin coordinates.

# Plot sheared data
shear_3d

Shear values around an origin in 3 dimensions

Description

[Experimental]

Shears points around an origin in 3-dimensional space. See applied shearing matrices under Details.

The data points in `data` are moved prior to the shearing, to bring the origin to 0 in all dimensions. After the shearing, the inverse move is applied to bring the origin back to its original position.

The origin can be supplied as coordinates or as a function that returns coordinates. The latter can be useful when supplying a grouped data.frame and shearing around e.g. the centroid of each group.
shear_3d

Usage

shear_3d(
  data,
  x_col,  
  y_col,  
  z_col,  
  x_shear = NULL,  
  y_shear = NULL,  
  z_shear = NULL,  
  suffix = "_sheared",  
  origin = NULL,  
  origin_fn = NULL,  
  keep_original = TRUE,  
  shear_col_name = ".shear",  
  origin_col_name = ".origin",  
  overwrite = FALSE
)

Arguments

data data.frame or vector.
x_col, y_col, z_col
  Name of x/y/z column in `data`. All must be specified.
x_shear, y_shear, z_shear
  Shear factor for the x/y/z dimension (numeric). Decides the amount of shearing. Can be vectors with multiple shear factors. N.B. Exactly 2 of the dimensions must have shear factors specified.
suffix
  Suffix to add to the names of the generated columns. Use an empty string (i.e. "") to overwrite the original columns.
origin
  Coordinates of the origin to shear around. Vector with 3 elements (i.e. origin_x, origin_y, origin_z). Ignored when `origin_fn` is not NULL.
origin_fn
  Function for finding the origin coordinates. Input: Each column will be passed as a vector in the order of `cols`. Output: A vector with one scalar per dimension. Can be created with `create_origin_fn()` if you want to apply the same function to each dimension. E.g. `create_origin_fn(median)` would find the median of each column. Built-in functions are `centroid()`, `most_centered()`, and `midrange()`
keep_original
  Whether to keep the original columns. (Logical)
  Some columns may have been overwritten, in which case only the newest versions are returned.
shear_col_name
  Name of new column with the shearing amounts. If NULL, no column is added. Also adds a string version with the same name + ".str", making it easier to group by the shearing amounts when plotting multiple shears.
origin_col_name
  Name of new column with the origin coordinates. If NULL, no column is added.
overwrite
  Whether to allow overwriting of existing columns. (Logical)
Details

Applies one of the following transformation matrices, depending on which two shearing amounts are specified:

Given \( x_{\text{shear}} \) and \( y_{\text{shear}} \):

\[
\begin{bmatrix}
1 & 0 & x_{\text{shear}} \\
0 & 1 & y_{\text{shear}} \\
0 & 0 & 1
\end{bmatrix}
\]

Given \( x_{\text{shear}} \) and \( z_{\text{shear}} \):

\[
\begin{bmatrix}
1 & x_{\text{shear}} & 0 \\
0 & 1 & 0 \\
0 & z_{\text{shear}} & 1
\end{bmatrix}
\]

Given \( y_{\text{shear}} \) and \( z_{\text{shear}} \):

\[
\begin{bmatrix}
1 & 0 & 0 \\
y_{\text{shear}} & 1 & 0 \\
z_{\text{shear}} & 0 & 1
\end{bmatrix}
\]

Value

data.frame (tibble) with six new columns containing the sheared x-, y- and z-values and the shearing amounts and origin coordinates.

**shuffle_hierarchy**

Shuffle multi-column hierarchy of groups
Description

[Experimental]
Shuffles a tree/hierarchy of groups, one column at a time. The levels in the last ("leaf") column are shuffled first, then the second-last column, and so on. Elements of the same group are ordered sequentially.

Usage

shuffle_hierarchy(
  data,
  group_cols,
  cols_to_shuffle = group_cols,
  leaf_has_groups = TRUE
)

Arguments

data data.frame.
group_cols Names of columns making up the group hierarchy. The last column is the leaf and is shuffled first (if also in `cols_to_shuffle`).
cols_to_shuffle Names of columns to shuffle hierarchically. By default, all the `group_cols` are shuffled.
leaf_has_groups Whether the leaf column contains groups or values. (Logical)
  When the elements are group identifiers, they are ordered sequentially and shuffled together.
  When the elements are values, they are simply shuffled.

Value

The shuffled data.frame (tibble).

Author(s)

Ludvig Renbo Olsen, <r-pkgs@ludvig Olsen.dk>

Examples

# Attach packages
library(rearrr)
library(dplyr)

df <- data.frame(
  'a' = rep(1:4, each = 4),
  'b' = rep(1:8, each = 2),
  'c' = 1:16
)
# Set seed for reproducibility
set.seed(2)

# Shuffle all columns
shuffle_hierarchy(df, group_cols = c('a', 'b', 'c'))

# Don't shuffle 'b' but keep grouping by it
# So 'c' will be shuffled within each group in 'b'
shuffle_hierarchy(
  data = df,
  group_cols = c('a', 'b', 'c'),
  cols_to_shuffle = c('a', 'c')
)

# Shuffle 'b' as if it's not a group column
# so elements are independent within their group
# (i.e. same-valued elements are not necessarily ordered sequentially)
shuffle_hierarchy(df, group_cols = c('a', 'b'), leaf_has_groups = FALSE)

---

### square

Create x-coordinates so the points form a square

**Description**

*[Experimental]*

Create the x-coordinates for a vector of y-coordinates such that they form a rotated square.

This will likely look most like a square when the y-coordinates are somewhat equally distributed, e.g. a uniform distribution.

**Usage**

```r
square(
  data,
  y_col = NULL,
  .min = NULL,
  .max = NULL,
  offset_x = 0,
  keep_original = TRUE,
  x_col_name = ".square_x",
  edge_col_name = ".edge",
  overwrite = FALSE
)
```

**Arguments**

- `data` data.frame or vector.
- `y_col` Name of column in `data` with y-coordinates to create x-coordinates for.
- `min` Minimum y-coordinate. If `NULL`, it is inferred by the given y-coordinates.
- `max` Maximum y-coordinate. If `NULL`, it is inferred by the given y-coordinates.
- `offset_x` Value to offset the x-coordinates by.
Whether to keep the original columns. (Logical)

Some columns may have been overwritten, in which case only the newest versions are returned.

Name of new column with the x-coordinates.

Name of new column with the edge identifiers. If NULL, no column is added.

Numbering is clockwise and starts at the upper-right edge.

Whether to allow overwriting of existing columns. (Logical)

data.frame (tibble) with the added x-coordinates and an identifier for the edge the data point is a part of.

---

**swirl_2d**  
*Swirl the values around an origin in 2 dimensions*

**Description**

[Experimental]

The values are swirled counterclockwise around a specified origin. The swirling is done by rotating around the origin with the degrees based on the distances to the origin as so:

\[
\text{degrees} = \frac{\text{scale}_\text{fn}(\text{distances})}{(2 \times \text{radius})} \times 360
\]

The origin can be supplied as coordinates or as a function that returns coordinates. The latter can be useful when supplying a grouped data frame and swirling around e.g. the centroid of each group.

**Usage**

```r
swirl_2d(
data,
  radius,
  x_col = NULL,
  y_col = NULL,
  suffix = "_swirled",
  origin = NULL,
  origin_fn = NULL,
  scale_fn = identity,
  keep_original = TRUE,
  degrees_col_name = ".degrees",
  radius_col_name = ".radius",
  origin_col_name = ".origin",
  overwrite = FALSE
)
```

**Arguments**

- `data` data.frame or vector.
radius

Radius of the most-inner swirl on the x-axis in the simplest case. A negative number changes the direction to clockwise rotation. Can be a vector with multiple radiiues.

Note: With a custom `scaling_fn`, this might not be the actual swirl radius anymore. Think of it more as a width setting where a larger number leads to fewer full rotations.

x_col

Name of x column in `data`. If NULL and `data` is a vector, the index of `data` is used. If `data` is a data.frame, it must be specified.

y_col

Name of y column in `data`. If `data` is a data.frame, it must be specified.

suffix

Suffix to add to the names of the generated columns. Use an empty string (i.e. `""`) to overwrite the original columns.

origin

Coordinates of the origin to swirl around. Vector with 2 elements (i.e. origin_x, origin_y). Ignored when `origin_fn` is not NULL.

origin_fn

Function for finding the origin coordinates.

Input: Each column will be passed as a vector in the order of `cols`.

Output: A vector with one scalar per dimension.

Can be created with `create_origin_fn()` if you want to apply the same function to each dimension.

E.g. `create_origin_fn(median)` would find the median of each column.

Built-in functions are `centroid()`, `most_centered()`, and `midrange()`

scale_fn

Function for scaling the distances before calculating the degrees.

Input: A numeric vector (the distances).

Output: A numeric vector (the scaled distances) of the same length.

E.g.:

```r
function(d){
  d ^ 1.5
}
```

keep_original

Whether to keep the original columns. (Logical)

Some columns may have been overwritten, in which case only the newest versions are returned.

degrees_col_name

Name of new column with the degrees. If NULL, no column is added.

radius_col_name

Name of new column with the radius. If NULL, no column is added.

origin_col_name

Name of new column with the origin coordinates. If NULL, no column is added.

overwrite

Whether to allow overwriting of existing columns. (Logical)

Value

data.frame (tibble) with three new columns containing the swirled x- and y-values, the degrees, the radius, and the origin coordinates.

  theme_minimal() +
  labs(x = "r1", y = "r2")
}

swirl_3d

Swirl the values around an origin in 3 dimensions

Description

[Experimental]

The values are swirled counterclockwise around a specified origin. The swirling is done by rotating around the origin, basing the degrees for each rotation-axis on the distances to the origin as so:

\[ x_{\text{degrees}} = \frac{\text{scale\_fn(distances)}}{2 \times x_{\text{radius}}} \times 360 \]

The origin can be supplied as coordinates or as a function that returns coordinates. The latter can be useful when supplying a grouped data.frame and swirling around e.g. the centroid of each group.

Usage

swirl_3d(
  data,
  x_col,
  y_col,
  z_col,
  x_radius = 0,
y_radius = 0,
z_radius = 0,
suffix = "_swirled",
origin = NULL,
origin_fn = NULL,
scale_fn = identity,
keep_original = TRUE,
degrees_col_name = ".degrees",
radius_col_name = ".radius",
origin_col_name = ".origin",
overwrite = FALSE)

Arguments
data data.frame or vector.
x_col, y_col, z_col
   Name of x/y/z column in `data`. All must be specified.
x_radius, y_radius, z_radius
   Radiuses of the most-inner swirls around each axis (in the simplest case). Can be
   vectors with multiple radiuses.
   E.g. the `x_radius` specifies the radius when rotating around the x-axis, not
   the radius on the x-axis.
   Note: With a custom `scaling_fn`, these might not be the actual swirl radiuses
   anymore. Think of them more as width settings where a larger number leads to
   fewer full rotations.
suffix
   Suffix to add to the names of the generated columns.
   Use an empty string (i.e. "") to overwrite the original columns.
origin
   Coordinates of the origin to swirl around. Vector with 3 elements (i.e. origin_x,
   origin_y, origin_z). Ignored when `origin_fn` is not NULL.
origin_fn
   Function for finding the origin coordinates.
   **Input**: Each column will be passed as a vector in the order of `cols`.
   **Output**: A vector with one scalar per dimension.
   Can be created with `create_origin_fn()` if you want to apply the same function
to each dimension.
   E.g. `create_origin_fn(median)` would find the median of each column.
   **Built-in functions** are `centroid()`, `most_centered()`, and `midrange()`
scale_fn
   Function for scaling the distances before calculating the degrees.
   **Input**: A numeric vector (the distances).
   **Output**: A numeric vector (the scaled distances) of the same length.
   E.g.:
   function(d){
     d ^ 1.5
   }
keep_original
   Whether to keep the original columns. (Logical)
   Some columns may have been overwritten, in which case only the newest
   versions are returned.
swirl_3d

degrees_col_name
Name of new column with the degrees. If NULL, no column is added.
Also adds a string version with the same name + "_str", making it easier to
group by the degrees when plotting multiple rotations.

radius_col_name
Name of new column with the radiuses. If NULL, no column is added.

origin_col_name
Name of new column with the origin coordinates. If NULL, no column is added.

overwrite
Whether to allow overwriting of existing columns. (Logical)

Value
data.frame (tibble) with new columns containing the swirled x- and y-values, the degrees, the
radiuses, and the origin coordinates.

to_unit_length  Scale to unit length

Description

[Experimental]
Scales the vectors to unit length row-wise or column-wise.
The *_vec() version take and return a vector.

Usage

to_unit_length(
  data, 
  cols = NULL, 
  by_row = is.data.frame(data),
  suffix = ifelse(isTRUE(by_row), "_row_unit", "_col_unit"),
  overwrite = FALSE
)
to_unit_length_vec(data)

Arguments

data data.frame or vector.

cols Names of columns in `data` to scale.

by_row Whether to scale row vectors instead of column vectors. (Logical)

Note: Disable when `data` is a vector.

suffix Suffix to add to the names of the generated columns.

Use an empty string (i.e. "") to overwrite the original columns.

overwrite Whether to allow overwriting of existing columns. (Logical)

Value

Scaled vector or data.frame (tibble) with the scaled columns.

**transfer_centroids**  
Transfer centroids from one data frame to another

Description

[Experimental]

Given two data.frames with the same columns (and groupings), transfer the centroids from one to the other.

This is commonly used to restore the centroids after transforming the columns.

Usage

transfer_centroids(to_data, from_data, cols, group_cols = NULL)

Arguments

to_data  
data.frame.

Existing `dplyr` groups are ignored. Specify in `group_cols` instead.
transfer_centroids

from_data data.frame with the same columns (and groupings) as `to_data`.
Existing `dplyr` groups are ignored. Specify in `group_cols` instead.
cols Names of numeric columns to transfer centroids to. Must exist in both `to_data` and `from_data`.
group_cols Names of grouping columns.

Value
The `to_data` data.frame (tibble) with the centroids from the `from_data` data.frame.

Author(s)
Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

Examples
# Attach packages
library(rearrr)
library(dplyr)

# Set seed
set.seed(1)

# Create a data frame
df <- data.frame(
  "x" = runif(20),
  "y" = runif(20),
  "g" = rep(1:4, each = 5)
)

# Create another data frame with different x and y values
df2 <- df
df2$x <- runif(20)
df2$y <- runif(20)

# Check centroids before transfer
df %>%
dplyr::group_by(g) %>%
dplyr::summarize_all(mean)
df2 %>%
dplyr::group_by(g) %>%
dplyr::summarize_all(mean)

# Now let's transfer the centroids from df to df2
df3 <- transfer_centroids(
  to_data = df2,
  from_data = df,
  cols = c("x", "y"),
group_cols = "g"
# Check that the transfer gave us the same centroids as df
df3 %>%
  dplyr::group_by(g) %>%
  dplyr::summarize_all(mean)

### Description

**[Experimental]**

Container for the type of transformation used in Pipeline.

**Note:** For internal use.

### Public fields

- **name** Name of transformation.
- **fn** Transformation function.
- **args** List of arguments for `fn`.
- **group_cols** Names of columns to group data.frame by before applying `fn`.

When `NULL`, the data.frame is not grouped.

### Methods

#### Public methods:

- `Transformation$new()`
- `Transformation$apply()`
- `Transformation$print()`
- `Transformation$clone()`

#### Method `new()`: Initialize transformation.

**Usage:**

```
Transformation$new(fn, args, name = NULL, group_cols = NULL)
```

**Arguments:**

- **fn** Transformation function.
- **args** List of arguments for `fn`.
- **name** Name of transformation.
- **group_cols** Names of columns to group data.frame by before applying `fn`.

When `NULL`, the data.frame is not grouped.

#### Method `apply()`: Apply the transformation to a data.frame.

**Usage:**

```
Transformation$apply(data)
```

**Arguments:**
data data.frame.
   A grouped data.frame will first be ungrouped. If `group_cols` is specified, it will then
   be grouped by those columns.

*Returns:* Transformed version of `data`.

**Method** print(): Print an overview of the transformation.

*Usage:*

```
Transformation$print(..., indent = 0, show_class = TRUE)
```

*Arguments:*

- ... further arguments passed to or from other methods.
- indent How many spaces to indent when printing.
- show_class Whether to print the transformation class name.

*Returns:* The pipeline. To allow chaining of methods.

**Method** clone(): The objects of this class are cloneable with this method.

*Usage:*

```
Transformation$clone(deep = FALSE)
```

*Arguments:*

- deep Whether to make a deep clone.

Other transformation classes: `FixedGroupsTransformation, GeneratedTransformation`

---

**triangularize**

*Create x-coordinates so the points form a triangle*

**Description**

*[Experimental]*

Create the x-coordinates for a vector of y-coordinates such that they form a triangle.

The data points are stochastically distributed based on edge lengths, why it might be preferable to
set a random seed.

This will likely look most like a triangle when the y-coordinates are somewhat equally distributed,
e.g. a uniform distribution.
triangularize

Usage

triangularize(
  data,
  y_col = NULL,
  .min = NULL,
  .max = NULL,
  offset_x = 0,
  keep_original = TRUE,
  x_col_name = ".triangle_x",
  edge_col_name = ".edge",
  overwrite = FALSE
)

Arguments

data data.frame or vector.
ya_col Name of column in `data` with y-coordinates to create x-coordinates for.
.min Minimum y-coordinate. If NULL, it is inferred by the given y-coordinates.
.max Maximum y-coordinate. If NULL, it is inferred by the given y-coordinates.
.offset_x Value to offset the x-coordinates by.
keep_original Whether to keep the original columns. (Logical)
x_col_name Name of new column with the x-coordinates.
edge_col_name Name of new column with the edge identifiers. If NULL, no column is added.
Numbering is clockwise and starts at the upper-right edge.
.overwrite Whether to allow overwriting of existing columns. (Logical)

Value

data.frame (tibble) with the added x-coordinates and an identifier for the edge the data point is a part of.

Author(s)

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

}
```

---

**triplet_extremes**  
*Makes triplets of extreme values and sort by them*

---

**Description**

**[Experimental]**

The values are grouped in three such that the first group is formed by the lowest and highest values and the value closest to the median, the second group is formed by the second lowest and second highest values and the value second closest to the median, and so on. The values are then sorted by these groups and their actual value.

When the number of rows/elements in `data` is not evenly divisible by three, the `unequal_method_1` (single excessive element) and `unequal_method_2` (two excessive elements) determines which
triplet_extremes

Element(s) should form a smaller group. This group will be the first group in a given grouping (see `num_groupings`) with the identifier 1.
The *_vec()* version takes and returns a vector.

**Example:**
The column values:
c(1, 2, 3, 4, 5, 6)
Are sorted in triplets as:
c(1, 3, 6, 2, 4, 5)

**Usage**

```r
triplet_extremes(
  data,
  col = NULL,
  middle_is = "middle",
  unequal_method_1 = "middle",
  unequal_method_2 = c("middle", "middle"),
  num_groupings = 1,
  balance = "mean",
  order_by_aggregates = FALSE,
  shuffle_members = FALSE,
  shuffle_triplets = FALSE,
  factor_name = ifelse(num_groupings == 1, ".triplet", ".tripleting"),
  overwrite = FALSE
)

triplet_extremes_vec(
  data,
  middle_is = "middle",
  unequal_method_1 = "middle",
  unequal_method_2 = c("middle", "middle"),
  num_groupings = 1,
  balance = "mean",
  order_by_aggregates = FALSE,
  shuffle_members = FALSE,
  shuffle_triplets = FALSE
)
```

**Arguments**

- `data` : data.frame or vector.
- `col` : Column to create sorting factor by. When `NULL` and `data` is a data.frame, the row numbers are used.
- `middle_is` : Whether the middle element in the triplet is the nth closest element to the median value or the nth+1 lowest/highest value. One of: middle (default), min, or max.

  Triplet grouping is performed greedily from the most extreme values to the least extreme values. E.g. c(1, 6, 12) is created before c(2, 5, 11) which is made before c(3, 7, 10).

**Examples:**
When `middle_is` == 'middle', a 1:12 sequence is grouped into:
c(c(1, 6, 12), c(2, 7, 11), c(3, 5, 10), c(4, 8, 9))
When `middle_is` == 'min', a 1:12 sequence is grouped into:
c(c(1, 2, 12), c(3, 4, 11), c(5, 6, 10), c(7, 8, 9))
When `middle_is` == 'max', a 1:12 sequence is grouped into:
c(c(1, 11, 12), c(2, 9, 10), c(3, 7, 8), c(4, 5, 6))

unequal_method_1, unequal_method_2
Method for dealing with either a single excessive element (`unequal_method_1`) or two excessive elements (`unequal_method_2`) when the number of rows/elements in `data` are not evenly divisible by three.

`unequal_method_1`: One of: min, middle or max.
`unequal_method_2`: Vector with two of: min, middle or max. Can be the same value twice.

Note: The excessive element(s) are extracted before triplet grouping. These elements are put in their own group and given group identifier 1.

E.g. When `unequal_method_2` is c("middle", "middle") the two elements closest to the median are extracted.

num_groupings
Number of times to group into triplets (recursively). At least 1.

Based on `balance`, the secondary groupings perform extreme triplet grouping on either the sum, absolute difference, min, or max of the triplet elements.

balance
What to balance triplets for in a given secondary triplet grouping. Either "mean", "spread", "min", or "max". Can be a single string used for all secondary groupings or one for each secondary grouping (`num_groupings` - 1).

The first triplet grouping always groups the actual element values.

**mean**: Triplets have similar means. The values in the triplets from the previous grouping are aggregated with `sum()` and extreme triplet grouped.

**spread**: Triplets have similar spread (e.g. standard deviations). The values in the triplets from the previous triplet grouping are aggregated with `sum(abs(diff()))` and extreme triplet grouped.

**min / max**: Triplets have similar minimum / maximum values. The values in the triplets from the previous triplet grouping are aggregated with `min()` / `max()` and extreme triplet grouped.

order_by_aggregates
Whether to order the groups from initial groupings (first `num_groupings` - 1) by their aggregate values instead of their group identifiers.

N.B. Only used when `num_groupings` > 1.

shuffle_members
Whether to shuffle the order of the group members within the groups. (Logical)

shuffle_triplets
Whether to shuffle the order of the triplets. Triplet members remain together. (Logical)

factor_name
Name of new column with the sorting factor. If `NULL`, no column is added.

overwrite
Whether to allow overwriting of existing columns. (Logical)

Value
The sorted data.frame (tibble) / vector. Optionally with the sorting factor added.

When `data` is a vector and `keep_factors` is `FALSE`, the output will be a vector. Otherwise, a data.frame.

# Attach packages
library(rearrr)
library(dplyr)

# Set seed
collect.seed()

# Create a data frame
df <- data.frame(
  "index" = 1:12,
  "A" = sample(1:12),
  "B" = runif(12),
  "C" = LETTERS[1:12],
  "G" = c(1, 1, 1, 1, 2, 2, 2, 2, 3, 3, 3, 3),
  stringsAsFactors = FALSE
)

# Triplet group extreme indices (row numbers)
triplet_extremes(df)

# Triplet group extremes in each of the columns
triplet_extremes(df, col = "A")$A
triplet_extremes(df, col = "B")$B
triplet_extremes(df, col = "C")$C

# Shuffle the members triplet-wise
# The triplets maintain their order
# but the rows within each triplet are shuffled
triplet_extremes(df, col = "A", shuffle_members = TRUE)

# Shuffle the order of the triplets
# The triplets are shuffled but
# the rows within each triplet maintain their order
triplet_extremes(df, col = "A", shuffle_triplets = TRUE)

# Use recursive grouping
# Mostly meaningful with much larger datasets
# Order initial grouping by group identifiers
triplet_extremes(df, col = "A", num_groupings = 2)
# Order initial grouping by aggregate values
triplet_extremes(df, col = "A", num_groupings = 2, order_by_aggregates = TRUE)

# Grouped by G

```r
# Each G group only has 4 elements
# so it only creates 1 triplet and a group
# with the single excessive element
# per G group
df %>%
dplyr::select(G, A) %>% # For clarity
dplyr::group_by(G) %>%
triplet_extremes(col = "A")

# Plot the extreme triplets
plot(
x = 1:12,
y = triplet_extremes(df, col = "A")$A,
col = as.character(rep(1:4, each = 3))
)

# With shuffled triplet members (run a few times)
plot(
x = 1:12,
y = triplet_extremes(df, col = "A", shuffle_members = TRUE)$A,
col = as.character(rep(1:4, each = 3))
)

# With shuffled triplets (run a few times)
plot(
x = rep(1:6, each = 2),
y = triplet_extremes(df, col = "A", shuffle_triplets = TRUE)$A,
col = as.character(rep(1:4, each = 3))
)
```

---

**vector_length**

*Calculate vector length(s)*

**Description**

*Experimental*

Calculates vector lengths/magnitudes row- or column-wise with

```
\text{sqrt}(\text{sum}(x^2))
```

Where \( x \) is the vector to get the length/magnitude of.

Should not be confused with `length()`, which counts the elements.

**Usage**

```
vector_length(
  data,
  cols = NULL,
  by_row = is.data.frame(data),
  len_col_name = ".vec_len",
  overwrite = FALSE
)
```
vector_length

Arguments

- **data**
  - data.frame or vector.
- **cols**
  - Names of columns in `data` to measure vector length of.
- **by_row**
  - Whether to measure length of row vectors instead of column vectors. (Logical)
  - Note: Disable when `data` is a vector.
- **len_col_name**
  - Name of new column with the row vector lengths when `data` is a data.frame and `by_row` is TRUE.
- **overwrite**
  - Whether to allow overwriting of existing columns. (Logical)

Value

Vector length(s).

When `data` is a vector: scalar

When `data` is a data.frame and `by_row` is TRUE: `data` with an extra column with row vector lengths.

When `data` is a data.frame and `by_row` is FALSE: A data.frame with the summarized column vector lengths.
