Package ‘reproducer’

February 6, 2023

Title Reproduce Statistical Analyses and Meta-Analyses
Version 0.5.1
Date 2023-02-05
Maintainer Lech Madeyski <lech.madeyski@gmail.com>
Description Includes data analysis functions (e.g., to calculate effect sizes and 95% Confidence Intervals (CI) on Standardised Effect Sizes (d) for AB/BA cross-over repeated-measures experimental designs), data presentation functions (e.g., density curve overlaid on histogram), and the data sets analyzed in different research papers in software engineering (e.g., related to software defect prediction or multi-site experiment concerning the extent to which structured abstracts were clearer and more complete than conventional abstracts) to streamline reproducible research in software engineering.

aggregateIndividualDocumentStatistics

Description

This function assumes an ABBA crossover experiment has reported means and variances for each technique in each time period. We calculate the weighted mean and pooled within group variance for the observations arising from the two different sets of materials for a specific technique.

Usage

Arguments

- **D1.M** is a vector of mean values from a set of experiments in a family reporting observations from participants using a specific document in the first time period with either the control or the treatment technique.
- **D1.SD** is a vector of results from the set of experiment in a family reporting the standard deviations of observations from participants using the same document in the first time period with the same technique.
- **D1.N** is a vector of the numbers of participants in each experiment in a family, using the same document for participants using either the same technique.
- **D2.M** is a vector of mean values of observations from participants using the alternative document in the second time period, but using the same technique.
- **D2.SD** is a vector of the standard deviations of observations from participants using the alternative document in the second time period with the same technique.
- **D2.N** is a vector of the numbers of participants using the same document in the second time period for participants using the same technique.

Value

data frame incl. the overall weighted mean and pooled standard deviation

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

aggregateIndividualDocumentStatistics(10, 2, 20, 15, 2, 20)

#   M  SD
# 1 12.5 2
AnalyseResiduals

Description
The function calculates sample statistics based on the residuals from a specified experiment.

Usage
AnalyseResiduals(Residuals, ExperimentName = "ExpName")

Arguments
- Residuals: a vector of residuals
- ExperimentName: a character string identifying the data set

Value
A dataframe identifying the ExperimentName and its associated sample parameter: Length, Mean, Median, Variance, Standard deviation, skewness, kurtosis, the outcome of the Shapiro and Anderson-Darling normality test and the number of outliers.

Author(s)
Barbara Kitchenham and Lech Madeyski

Examples
ExpData=rnorm(30,0,1)
sample.seed(123)
AnalyseResiduals(Residuals=ExpData,ExperimentName='ExpName')

Example output:

```
# ExperimentName  Mean  Median  Variance  Skewness  Kurtosis  ShapiroTest  AndersonDarling
# ExpName          -0.1396192  -0.01943395  0.8424521  -0.1964175  4.559587  0.1608315  0.1316835
# NumOut
# 1
```

boxplotAndDensityCurveOnHistogram

Description
Boxplot and density curve overlaid on histogram

Usage
boxplotAndDensityCurveOnHistogram(df, columnName, limLow, limHigh)
**Arguments**

- **df**: Data frame with data to be displayed
- **colName**: Name of the selected column in a given data frame
- **limLow**: the limit on the lower side of the displayed range
- **limHigh**: the limit on the higher side of the displayed range

**Value**

A figure being a density curve overlaid on histogram

**Author(s)**

Lech Madeyski

**Examples**

```r
library(ggplot2)
library(grid)
library(gridExtra)
boxplotAndDensityCurveOnHistogram(Madeyski15EISEJ.PropProjects, "STUD", 0, 100)
boxplotAndDensityCurveOnHistogram(Madeyski15SQJ.NDC, "simple", 0, 100)
```

---

**Description**

Box plot

**Usage**

```r
boxplotHV(df, colName, limLow, limHigh, isHorizontal)
```

**Arguments**

- **df**: Data frame with data to be displayed
- **colName**: Name of the selected column in a given data frame
- **limLow**: the limit on the lower side of the displayed range
- **limHigh**: the limit on the higher side of the displayed range
- **isHorizontal**: Boolean value to control whether the box plot should be horizontal or not (i.e., vertical)

**Value**

A box plot
### Description

This function is a helper function that calculates one element of the standardized mean difference effect size variance based on Hedges and Olkin p128-131.

### Usage

```r
calc.a(f, A)
```

### Arguments

- `f`: a vector defining the degrees of freedom for the effect sizes
- `A`: a vector defining the constants that relate each StdMD to its related t-variable where \( t^2 = Ad^2 \)

### Value

The value of a.

### Examples

```r
reproducer:::calc.a(10, 2/10)
# [1] 0.2128649
```
calc.b

calc.b

description
This function is a helper function that calculates one element of the standardized mean difference
effect size variance based on Hedges and Olkin p128-131.

Usage
calc.b(f)

Arguments
f a vector defining the degrees of freedom for the effect sizes

Value
The value of b.

Author(s)
Barbara Kitchenham and Lech Madeyski

Examples
reproducer:::calc.b(8)
#0.08649774

Calc4GroupNPStats
Calc4GroupNPStats

description
This function does a non-parametric analysis of a randomized blocks experiment assuming 2 blocks
and 2 treatment conditions.

Usage
Calc4GroupNPStats(
  x1,
  x2,
  x3,
  x4,
  sigfig = -1,
  alpha = 0.05,
  alternative = "two.sided"
)

Arguments

- \( x_1 \) is the data associated with treatment A in one block 1
- \( x_2 \) is the data associated with treatment B in block 1
- \( x_3 \) is the data associated with treatment A in block 2
- \( x_4 \) is the data associated with treatment B in block 2

- `sigfig` is the number of significant digits in the data. If >0 the data will be appropriately truncated.

- `alpha` is the significance level for all statistical tests

- `alternative` The type of statistical test. Valid values are one of c('two.sided', 'greater', 'less')

Value

The function returns the Cliff’s d and its variance, the probability of superiority, phat, and its variance for the 4 group experiment experiment.

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

```r
set.seed(123)
x <- list()
x[[1]] <- rnorm(10, 0, 1)
x[[2]] <- rnorm(10, 0.8, 1)
x[[3]] <- rnorm(10, 0.5, 1)
x[[4]] <- rnorm(10, 1.3, 1)
as.data.frame(Calc4GroupNPStats(x[[1]], x[[2]], x[[3]], x[[4]], sigfig = -1, alpha = 0.05))
```

```r

# 0.005990797 20 20 TRUE
```

```r
as.data.frame(Calc4GroupNPStats(x[[2]], x[[1]], x[[4]], x[[3]], sigfig = -1, alpha = 0.05, alternative = "greater")
```
calcCliffdConfidenceIntervals

calcCliffdConfidenceIntervals

description
This function is a helper function. It assesses the significance one-sided and two-sided statistical of Cliff’s d based on its confidence interval. The type of test is determined by the parameter One.Sided.Tests, the direction of one-sided tests is determined by the parameter Positive.MD.

Usage

calcCliffdConfidenceIntervals(
  d.value,  
  d.variance,  
  d.df,  
  alpha = 0.05,  
  alternative = "two.sided"
)

Arguments

d.value  This is the value of Cliff’s d.
d.variance  This is the estimated variance of Cliff’s d
d.df  The degrees of freedom.
alpha  This is the alpha level required for the statistical tests (default 0.05)
alternative  This defines whether a one-sided test or a two-sided (default) test is required. For a one-sided test use parameter values greater ‘ or ‘less’ to define whether the d-value should be greater or less than zero.

Value
The function returns a Boolean variable identifying whether the effect size is significant and the confidence interval bounds.
**Author(s)**

Barbara Kitchenham and Lech Madeyski

**Examples**

```r
reproducer:::calcCliffdConfidenceIntervals(d.value=0.5, d.variance=0.04,d.df=18)
# A tibble: 1 x 5
#  d.tvalue d.pvalue d.ci.lower d.ci.upper d.sig
#1 2.5     0.0223   0.0479    0.782  TRUE
```

```r
reproducer:::calcCliffdConfidenceIntervals(d.value=0.5,d.variance=0.04,d.df=18,alternative='greater')
# A tibble: 1 x 5
#  d.tvalue d.pvalue d.ci.lower d.ci.upper d.sig
#1 2.5     0.0112   0.123      1       TRUE
```

```r
reproducer:::calcCliffdConfidenceIntervals(d.value=0.2,d.variance=0.04,d.df=18,alternative='greater')
# A tibble: 1 x 3
#  d.tvalue d.pvalue d.ci.lower d.ci.upper d.sig
#1 1       0.165    -0.133     1       FALSE
```

```r
reproducer:::calcCliffdConfidenceIntervals(d.value=-0.5,d.variance=0.04,d.df=18,alternative='less')
# A tibble: 1 x 5
#  d.tvalue d.pvalue d.ci.lower d.ci.upper d.sig
#1 -2.5    0.0112   -1          -0.123 TRUE
```

**Description**

This function provides single-sided and two-sided confidence interval of an effect size (assuming that the null hypothesis value is zero).

**Usage**

```r
calcEffectSizeConfidenceIntervals(
effectsize,
effectsize.variance,
effectsize.df = 0,
alpha = 0.05,
alternative = "two.sided",
```
calcEffectSizeConfidenceIntervals

UpperValue = Inf,
LowerValue = -Inf

Arguments

effectsize The effect size
effectsize.variance The effect size variance
effectsize.df The degrees of freedom for confidence intervals based on the t-distribution. If df=0 (default), the confidence interval is based on the normal distribution
alpha The significance level of the confidence interval (default 0.05).
alternative This defines whether a one-sided test or a two-sided (default) test is required. For a one-sided test use parameter values greater or 'less' to define whether the d-value should be greater or less than zero.
UpperValue The maximum legal value of the effect size (default Inf). Used to ensure that confidence intervals of effect sizes such as correlation coefficients are restricted to sensible values.
LowerValue The minimum legal value of the effect size (default -Inf). Used to ensure that confidence intervals of effect sizes such as correlation coefficients are restricted to sensible values.

Value

The value of the test statistic, the p.value of test statistic, the upper and lower confidence interval of the effect size, a logical value specifying whether the effect size is significantly different from zero based on the confidence interval and the lower and upper confidence interval bounds.

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

reproducer:::calcEffectSizeConfidenceIntervals(
effectsize=0.37,effectsize.variance=0.00847,effectsize.df=11.1,
alpha=0.05,alternative='two.sided',UpperValue=0.5,LowerValue=-0.5)
# A tibble: 1 x 5
#  ES.test ES.pvalue ES.sig ES.ci.lower ES.ci.upper
#  <dbl> <dbl> <lgl>   <dbl>     <dbl>
#1 4.02 0.00198 TRUE  0.168      0.5
Description

This function is a helper function. It assesses the significance one-sided and two-sided statistical
doing the probability of superiority based on its confidence interval. The type of test and the direction
of the test is determined by the parameter alternative which takes one of the values 'two.sided',
'greater' or 'less'.

Usage

calcPHatConfidenceIntervals(
  phat,       
  phat.variance,  
  phat.df,      
  alpha = 0.05,  
  alternative = "two.sided"  
)

Arguments

  phat   This is the value of the probability of superiority.
  phat.variance   This is the estimated variance of the probability of superiority.
  phat.df   The degrees of freedom associated with phat value.
  alpha   This is the alpha level required for the statistical tests (default 0.05)
  alternative   This defines whether a one-sided test or a two-sided (i.e. default) test is required.
                For a one-sided test use parameter values greater' or 'less' to define whether the
                phat-value should be greater or less than 0.5.

Value

The function returns a Boolean variable identifying whether the effect size is significant and the
confidence interval bounds.

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

reproducer::calcPHatConfidenceIntervals(.65,0.005,8)
# A tibble: 1 x 5
# phat.test pvalue phat.sig phat.ci.lower phat.ci.upper
# <dbl> <dbl> <lgl> <dbl> <dbl>
# 1 2.12 0.0667 FALSE 0.487 0.813

# A tibble: 1 x 5
# phat.test pvalue phat.sig phat.ci.lower phat.ci.upper
# <dbl> <dbl> <lgl> <dbl> <dbl>
# 1 2.12 0.0333 TRUE 0.519 1

calculate2GMdMRE

**Description**

The function uses simulations assess the accuracy and power of parametric and non-parametric effect sizes for two group designs and four different distributions.

**Usage**

```r
calculate2GMdMRE(
  mean = 0,
  sd = 1,
  N,
  reps,
  diff = c(0.2, 0.5, 0.8),
  type = "n",
  seed = 123,
  StdAdj = 0,
  AlwaysTwoSidedTests = FALSE,
  LargeSampleSize = 5e+06
)
```

**Arguments**

- **mean**: The mean (or rate for gamma data) of the baseline distribution.
- **sd**: The standard deviation or shape of the baseline distribution.
- **N**: The number of observations per group in each of the simulated experiment.
- **reps**: The number of experiments (i.e. two-group datasets) to be simulated.
- **diff**: A list identifying the mean group differences being assessed.
- **type**: A string parameter defining the distribution being simulated i.e. 'n' for normal data, 'l' for log-normal data, 'g' for gamma data and 'lap' for Laplace data.
- **seed**: A starting value for the simulations.
- **StdAdj**: A value that can be used to add additional variance for normal, lognormal and Laplace data and to change the shape parameter for gamma data.
- **AlwaysTwoSidedTests**: A boolean variable. If TRUE the simulation always used two-sided tests otherwise the simulations use one-sided tests.
- **LargeSampleSize**: Size of the large sample (default 5000000) used in each of the two groups used to obtain expected values of the non-parametric effect sizes (the expected value of the standardized mean difference are always known).
Value

Tibble identifying the accuracy i.e. MdMRE of three effect sizes Cliff’s d, CentralPHat, and StdMD estimates found in each sample, the variance of each of effect sizes, the mean of the observed values, the expected values of the effect sizes based on a single large sample and the power of each effect size based on the proportion of samples for which the effect sizes were significant.

```
Description

The function uses simulation to assess the accuracy and power of parametric and non-parametric effect sizes for four group randomized block designs and four different distributions.

Usage

```r
calculate4GMdMRE(
  mean = 0,
  sd = 1,
  N = 10,
  reps = 10,
  diff = c(0.2, 0.5, 0.8),
  type = "n",
  seed = 123,
  StdAdj = 0,
  Blockmean = 0.5,
  AlwaysTwoSidedTests = FALSE,
  LargeSampleSize = 2500000
)
```

Arguments

- **mean**: The mean (or rate for gamma data) of the baseline distribution
- **sd**: The standard deviation or shape of the baseline distribution
- **N**: The number of observations per group
- **reps**: The number of replications (i.e. two-group datasets) to be simulated
- **diff**: A list identifying the mean group differences being assessed
- **type**: A string parameter defining the distribution being simulated i.e. 'n' for normal data, 'l' for log-normal data, 'g' for gamma data and 'lap' for Laplace data.
- **seed**: A starting value for the simulations
- **StdAdj**: A numerical parameter that can be used to add additional variance for normal, lognormal and Laplace data and to change the shape parameter for gamma data.
- **Blockmean**: A numerical parameter used to introduce a fixed Block effect
- **AlwaysTwoSidedTests**: A boolean variable. If TRUE the simulations always used two-sided tests otherwise the simulations use one-sided tests.
- **LargeSampleSize**: Size of the large sample (default 2500000) in each of the four groups used to obtain expected values of the non-parametric effect sizes for four group experiments (the expected value of the standardized mean difference is always known) return Tibble identifying the accuracy i.e. MdMRE of three effect sizes Cliff's d, CentralPHat, and StdMD estimates found in each simulation, the variance of each of effect sizes, the mean of the observed values, the expected values of the effect sizes based on a single large sample and the power of each effect size based on the proportion of samples for which the effect sizes were significant.

Example:

```r
as.data.frame(calculate4GMdMRE(mean=0,sd=1,N=10,reps=100,diff=c(0.2,0.5,0.8),type='n',seed=123,StdAdj=0,Blockmean=0.5,AlwaysTwoSidedTests=FALSE,LargeSampleSize=2500000))
```
calculateBasicStatistics

describe a function that calculates the following statistics for a set of data: length, mean, median, variance, standard error of the mean, and confidence interval bounds. The input data must be a vector of 2 or more numerical values.

Usage

calculateBasicStatistics(x, alpha = 0.05)

Arguments

x The data to be summarized
alpha The probability level to be used when constructing the confidence interval bounds.

Value

A dataframe comprising the length, mean, variance, standard error and confidence limit bounds of the input data x.

Author(s)

Barbara Kitchenham and Lech Madeyski
Examples

```r
ShortExperimentNames <- c("E1", "E2", "E3", "E4")
FullExperimentNames <- c("EUBAS", "R1UCLM", "R2UCLM", "R3UCLM")
Metrics <- c("Comprehension", "Modification")
Groups <- c("A", "B", "C", "D")
Type <- c(rep("4G", 4))
StudyID <- "S2"
Control <- "SC"
ReshapedData <- ExtractExperimentData(
  KitchenhamEtAl.CorrelationsAmongParticipants.Scanniello14TOSEM,
  ExperimentNames = FullExperimentNames, idvar = "ParticipantID",
  timevar = "Period", ConvertToWide = TRUE
)
NewTable <- ConstructLevel1ExperimentRData(
  ReshapedData, StudyID, ShortExperimentNames, Groups,
  Metrics, Type, Control
)
calculateBasicStatistics(NewTable$r)
  # N  Mean Median Variance SE  LowerBound  UpperBound
  # 1 32 0.06175 0.1688 0.2482 0.08808 -0.1109  0.2344
```

Description

This function implements finds Cliff’s d and its confidence intervals. The null hypothesis is that for two independent group, \(P(X<Y)=P(X>Y)\). The function reports a 1-alpha confidence interval for \(P(X>Y)-P(X<Y)\). The algorithm computes a confidence interval for Cliff’s d using the method in Cliff, 1996, p. 140, eq 5.12. The function is based on code produce by Rand Wilcox but has been amended. The plotting function has been removed and the dependency on Wilcox’s binomci function has been removed. Construction of confidence intervals if values in one group are all larger than values in the other group has been amended to use the smallest non-zero variance method. Upper and lower confidence interval bounds cannot assume invalid values, i.e. values <-1 or >1.

Usage

```r
calculateCliffd(x, y, alpha = 0.05, sigfig = -1)
```

Arguments

- `x` is a vector of values from group 1
- `y` is a vector of values from group 2
- `alpha` is the Type 1 error level for statistical tests
- `sigfig` is the number of significant digit. If sigfig>0 the data in x and y is truncated to the specified value.
Value

list including the value of Cliffs d its consistent variance and confidence intervals and the equivalent probability of superiority value and its confidence intervals.

```r
x <- c(1.2, 3.2, 2.4, 2.5, 3) y <- c(3.4, 2.4, 6.7, 5.9)
# calculateCliffD(x, y)
# $n1 # [1] 6 # $n2 # [1] 6 # $d # [1] -0.8611111 # $sqse.d # [1] 0.02017931
# $p # [1] 0.06944444
z <- c(1, 2, 3, 4) y <- c(5, 6, 7, 8)
calculateCliffD(z, y)
```

describeGroupSummaryStatistics

describeGroupSummaryStatistics

Description

This function calculates the following statistics data within groups: length, mean, median, variance, standard error of the mean, and confidence interval bounds.

Usage

calculateGroupSummaryStatistics(x, Group)

Arguments

x
The data to be summarized. This must be a vector of 2 or more numerical values

Group
The categorical data defining the groups. This must be a vector of the same length as x containing factors specifying the data groups

Value

A dataframe comprising the number, mean, variance, standard error and confidence limit bounds of the data in each category

Author(s)

Barbara Kitchenham and Lech Madeyski

calculateHg

description
calculateHg

This function calculates Hedges g and Hedges g adjusted given the basic experimental statistics -
the mean values for participants, number of observations (participants), and standard deviation in
both the control group and the treatment group. Hence, the function assumes the data is held
as summary statistics including the control group mean, standard deviation and sample size and
equivalent values for treatment group.

Usage
calculateHg(Mc, Mt, Nc, Nt, SDc, SDt)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mc</td>
<td>is a vector containing the mean value of the control group for each experiment.</td>
</tr>
<tr>
<td>Mt</td>
<td>is a vector containing the mean value of the treatment group for each experiment.</td>
</tr>
<tr>
<td>Nc</td>
<td>is a vector containing the number of observations (participants) in the control group for each experiment.</td>
</tr>
<tr>
<td>Nt</td>
<td>is a vector of the number of observations (participants) in the treatment group for each experiment.</td>
</tr>
<tr>
<td>SDc</td>
<td>is a vector of the standard deviations of the control group for each experiment.</td>
</tr>
<tr>
<td>SDt</td>
<td>is a vector of the standard deviations of the treatment group for each experiment.</td>
</tr>
</tbody>
</table>
**Value**

data frame composed of Hedges’ g and Hedges’ g adjusted effect sizes

**Author(s)**

Barbara Kitchenham and Lech Madeyski

**Examples**

calculateHg(10, 15, 20, 20, 2, 2)

# Hg  HgAdjusted
# 1  2.5  2.450276

calculateKendalltaupb

@title calculateKendalltaupb @description Computes point bi-serial version of Kendall’s tau plus a 1-alpha confidence interval using the method recommended by Long and Cliff (1997). The algorithm is based on Wilcox’s code but was extended to return the consistent variance and the confidence intervals based on the t-distribution. Also added a Diagnostic parameter to output internal calculations.

**Description**

@title calculateKendalltaupb @description Computes point bi-serial version of Kendall’s tau plus a 1-alpha confidence interval using the method recommended by Long and Cliff (1997). The algorithm is based on Wilcox’s code but was extended to return the consistent variance and the confidence intervals based on the t-distribution. Also added a Diagnostic parameter to output internal calculations.

**Usage**

calculateKendalltaupb(x, y = NULL, alpha = 0.05, alternative = "two.sided")

**Arguments**

x  either a matrix with two columns containing two correlated variables or a vector of variables

y  if y=NULL, assume x is a matrix with two columns, otherwise y is a vector of variables with x[i] and y[i] being from the same experimental unit

alpha  the Type 1 error level used for statistical tests (default 0.05)

alternative  The type of statistical test. Valid values are one of c("two.sided", "greater", "less")

**Value**

list containing the estimate of Kendall’s tau, the consistent variance of tau and its confidence intervals based on the t-test (recommended by Long and Cliff)
**Author(s)**

Rand Wilcox, Barbara Kitchenham and Lech Madeyski

**Examples**

```r
set.seed(123)
a <- c(1.2, 3, 1.8, 2, 0.5, 0.5, 1, 3, 1)
b <- c(1, 1, 1, 1, 0, 0, 0, 0)

```
Description

The function uses a simulates a large experiment to estimate the asymptotic values of the probability of superiority, Cliff’s d and the standardized mean difference data for a four group randomized blocks experiment for four different distributions: Normal (i.e. type='n'), log-normal (i.e. type='l'), gama (i.e. type='g') and Laplace (i.e., type='lap').

Usage

```r
calculateLargeSampleRandomizedBlockDesignEffectSizes(
  meanC = 0,
  sdC = 1,
  diff,
  N = 5e+06,
  type = "n",
  Blockmean = 0,
  StdAdj = 0
)
```

Arguments

- `meanC`: to act as the mean of the distribution (default 0) used to generate the control group data (note for the gamma distribution this is the rate parameter and must not be zero)
- `sdC`: the variance/spread of the distribution (default 1) used to generate the control group data.
- `diff`: a value added to meanC to generate the treatment group data (default 0).
- `N`: the size of each group (default 5000000)
- `type`: the distribution of the data to be generated. One of: 'n' for normal (default), 'l' for log-normal, 'g' for gamma, and 'lap' for Laplace.
- `Blockmean`: a value that can be added one of the blocks to represent a fixed block effect (default 0).
- `StdAdj`: a value that can be added to sdC to introduce heterogeneity into the tretament group (default 0).

Value

A tibble identifying the sample statistics and the values of the probability of superiority, Cliff’s d and StdMD (labelled StdES)
Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

```r
set.seed=400
calculateLargeSampleRandomizedDesignEffectSizes(
  meanC=0, sdC=1, diff=.5, N=100000, type='n', Blockmean=0.5, StdAdj = 0)
# MeanC  SdC  MeanT  SdT  BE  Phat  Cliffd  UES  Var  StdES
# 1  0  1  0.5  1  0.638  0.277  0.501  0.998  0.502
```

Description

The function uses a simulates a large experiment to estimate the asymptotic values of the probability of superiority, Cliff’s d and the standardized mean difference data for a two group randomized experiment for four different distributions: Normal (i.e. type='n'), log-normal (i.e. type='l'), gamma (i.e. type='g') and Laplace (i.e., type='lap').

Usage

```r
calculateLargeSampleRandomizedDesignEffectSizes(
  meanC = 0,
  sdC = 1,
  diff = 0,
  N = 5e+06,
  type = "n",
  StdAdj = 0
)
```

Arguments

- **meanC**: to act as the mean of the distribution (default 0) used to generate the control group data (note for the gamma distribution this is the rate parameter and must not be zero)
- **sdC**: the variance/spread of the distribution (default 1) used to generate the control group data.
- **diff**: a value (default 0) added to meanC to generate the treatment group data.
- **N**: the size of each group (default 500000)
- **type**: the distribution of the data to be generated (default ‘n’)
- **StdAdj**: a value (default 0) that can be added to sdC to introduce heterogeneity into the treatment group
Value

A tibble identifying the sample statistics and the values of the probability of superiority, Cliff’s d and StdMD (labelled StdES)

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

```r
set.seed=400
calculateLargeSampleRandomizedDesignEffectSizes(
    meanC=0, sdC=1, diff=.5, N=100000, type='n', StdAdj = 0)
# A tibble: 1 x 9
#  MeanC SdC MeanT SdT Phat Cliffd UES Var StdES
#1  0    1    0.5 1.037 0.275 0.499 1.01 0.497
```

Description

This function analyses data on r values obtained in the format obtained from the ConstructLevel1ExperimentRData function and finds the r-value for each metric for each experiment.

Usage

```r
CalculateLevel2ExperimentRData(
    Level1Data, Groups, StudyID, ExperimentNames, Metrics, Type
)
```

Arguments

- **Level1Data**: a tibble in the format produced by the ConstructLevel1ExperimentRData function which has r-values for each sequence group in a crossover experiment.
- **Groups**: This is a list that defines the sequence group labels used in the dataset.
- **StudyID**: This holds an identifier used to identify the origin of the experimental data in the output from this function.
ExperimentNames
This a list of identifiers used to define each experiment in the output from this function.

Metrics
This is a list of of character strings identifying each outcome metric reported in each of the experiments in the set of replicated experiments.

Type
this is a list of character strings specifying for each experiment whether the experiment is a two sequence group ’2G’ or four sequence group ’4G’ experiment.

return RExp.Table This is a table containing the pooled data variance and the pooled difference variance for the experiment and the value r for the experiment for each metric

calculateNullESAccuracy

Description

The function uses simulation to assess the accuracy when the mean difference is zero, and the type 1 error rates of parametric and non-parametric effect sizes for both two group randomized designs and four group randomized block designs, for each of four different distributions.

Usage

```r
calculateNullESAccuracy(
  mean = 0,
  sd = 1,
  N = 10,
  reps = 10,
  type = "n",
  seed = 123,
  StdAdj = 0,
  Blockmean = 0.5
)
```

Arguments

- `mean`: The mean of the baseline distribution.
- `sd`: The standard deviation or shape of the baseline distribution.
- `N`: The number of observations per group for two group experiments and N/2 the sample sizes for four group experiments. N must be even to ensure equal N/2 defines appropriate sample sizes per group for 4 group experiments.
- `reps`: The number of replications (i.e. two-group and four group experiments) to be simulated.
- `type`: A string parameter defining the distribution being simulated i.e. 'n' for normal data, 'l' for log-normal data, 'g' for gamma data and 'lap' for Laplace data.
- `seed`: A starting value for the simulations.
- `StdAdj`: A numerical parameter that can be used to add additional variance for normal, lognormal and Laplace data and to change the shape parameter for gamma data.
- `Blockmean`: A numerical parameter used to introduce a fixed Block effect for four group experiments.

Value

A tibble identifying the median absolute error for the effect sizes Cliff’s d, phat and StdMD and the Type 1 error rate, estimated from the proportion of significant effect sizes in the simulated experiments.
Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

```r

```

Description

This function calculates the probability of superiority (i.e., Phat) and its confidence interval based on Brunner and Munzel (2000) heteroscedastic analog of WMW test. It is based on Wilcox’x bmp function with some amendments. It does not include a plotit facility. It uses the smallest non-zero variance to identify confidence intervals and statistical significance for values of Phat=0 and Phat=1. It ensure that confidence intervals do not take on invalid values such as values <0 or >1.

Usage

```r
calculatePhat(x, y, alpha = 0.05, sigfig = -1)
```

Arguments

- **x** is a vector of values from group 1
- **y** is a vector of values from group 2
- **alpha** is the Type 1 error level for statistical tests
- **sigfig** is the number of significant digits. If sigfig>0 the data in x and y is truncated to the specified number of significant digits.
Value

list including the value of the t-test for PHat, the estimate of PHat and Cliff’s d, and the confidence
intervals for PHat.

Author(s)

Rand Wilcox amendments by Barbara Kitchenham and Lech Madeyski

Examples

```r
x <- c(1.2, 3.0, 2.2, 4.0, 2.5, 3.0)
y <- c(3, 4.2, 4, 6, 7, 5.9)

CalculateRLevel1

Description
This helper function constructs the theoretical effect sizes and distribution statistics for four (normal, lognormal, Laplace & gamma) given specific parameter values for the distributions and is used to support the calculation of population statistics for two and four group experiments.

Usage
calculatePopulationStatistics(mean, std, type = "n")

Arguments
mean    The theoretical central location parameter for the distribution specified by the type parameter.
std     The theoretical spread parameter for the distribution specified by the type parameter.
type    String identifying the distribution, 'n' for normal, 'ln' for lognormal, 'lap' for Laplace, 'g' for Gamm

Value
dataframe containing the expected standardized effect size, mean, variance, skewness and kurtosis statistics for samples from the specific distribution

Author(s)
Barbara Kitchenham and Lech Madeyski

Examples
reproducer:::calculatePopulationStatistics(mean=0, std=1, type='n')

CalculateRLevel1

Description
This function calculates the r value for a 2-group (2G) or 4-Group (4G) Crossover experiment for each sequence group and each outcome metric. The function returns both the exact r value and the r value based on pooled variances for each sequence group and outcome metric.
CalculateRLevel1

Usage

CalculateRLevel1(
    Dataset,
    StudyID,
    Groups = c("A", "B", "C", "D"),
    ExperimentName,
    Metrics,
    Type,
    Control
)

Arguments

Dataset This holds the data for each participant in a 2-group or 4-group crossover experiment in the 'wide' format. I.e., there is only one entry per participant. The data set should have been generated from a long version of the data based on a variable labelled 'Period' which is used to define which participant data was collected in the first period of the experiment - see function ExtractLevel1ExperimentRData.

StudyID This holds an identifier used to identify the origin of the experimental data in the output from this function.

Groups This is a list that defined the sequence group identifiers used in the dataset.

ExperimentName This an identifiers used to define the specific experiment in the output from this function.

Metrics This is a list of metrics, e.g., ('Correctness','Time','Efficiency').

Type this is a character string specifying whether the experiment is a two sequence group or four sequence group experiment.

Control this is a character string that defines the control treatment in the experiment.

Details

script to obtain correlation coefficients

Value

table this is a tibble holding information identifying for each metric and sequence group the first time period and second time period variance, the pooled variance, the variance of the difference values and the exact r and pooled r. # importFrom stats # importFrom var # importFrom tibble

calculateSmallSampleSizeAdjustment
calculateSmallSampleSizeAdjustment

description

Function calculates the Hedges small sample size adjustment for standardized mean effect sizes. It calculates the exact value unless the caller sets the parameter exact to FALSE, or the degrees of freedom is too large.

Function calculates the small sample size adjustment for standardized mean effect sizes

Usage

calculateSmallSampleSizeAdjustment(df, exact = TRUE)
calculateSmallSampleSizeAdjustment(df, exact = TRUE)
calculateSmallSampleSizeAdjustment

Arguments

- **df**: A vector of degrees of freedom
- **exact**: Default value=TRUE, if `exact==TRUE` the function returns the exact value of the adjustment(s) which is suitable for small values of `df`, if `exact==FALSE` the function returns the approximate version of the adjustment(s). See Hedges and Olkin 'Statistical methods for Meta-Analysis' Academic Press 1985.

Value

- small sample size adjustment value

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

```r
df <- 2
c <- calculateSmallSampleSizeAdjustment(df)

df <- c(5, 10, 17)
adjexact <- calculateSmallSampleSizeAdjustment(df)
# adjexact=0.8407487 0.9227456 0.9551115
# Hedges and Olkin values 0.8408, 0.9228, 0.9551
adjapprox <- calculateSmallSampleSizeAdjustment(df, FALSE)
# adjapprox=0.8421053 0.9230769 0.9552239

df <- 2
a <- calculateSmallSampleSizeAdjustment(df)
# > a
# [1] 0.5641896

df <- c(5, 10, 17)
adjexact <- calculateSmallSampleSizeAdjustment(df)
# > adjexact
# [1] 0.8407487 0.9227456 0.9551115
# Hedges and Olkin values 0.8408, 0.9228, 0.9551
adjapprox <- calculateSmallSampleSizeAdjustment(df, FALSE)
# > adjapprox
# [1] 0.8421053 0.9230769 0.9552239

# Another example:
df <- c(10, 25, 50)
calculateSmallSampleSizeAdjustment(df, exact = TRUE)
# [1] 0.9227456 0.9696456 0.9849119

calculateSmallSampleSizeAdjustment(df, exact = FALSE)
# [1] 0.9230769 0.9696970 0.9849246
```
**CatchError**

**Description**

This is a helper function to stop simulations failing if the metafor function rma fails for example cannot converge properly for a specific dataset.

**Usage**

```r
CatchError(expr)
```

**Arguments**

- `expr` The expression that is being monitored

**Value**

A message confirming whether the expression has performed successfully

**Author(s)**

Barbara Kitchenham and Lech Madeyski

**Examples**

```r
ES=c(0.2,0.3)
ESvar=c(0.04,0.03)
outcome=reproducer::CatchError(metafor::rma(ES,ESvar,method='Meth'))
outcome
# [1] 'Failure'
```

---

**checkIfValidDummyVariable**

**Description**

This helper function checks whether a vector variable comprises only zeros and 1’s.

**Usage**

```r
checkIfValidDummyVariable(vector)
```

**Arguments**

- `vector` Vector variable
Value

The logical value: TRUE - if a vector variable passed as the function’s parameter represents a valid dummy variable, i.e., comprises only zeros and 1’s. FALSE - if a vector variable passed as the function’s parameter does not represent a valid dummy variable.

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

```r
print(reproducer:::checkIfValidDummyVariable(c(0, 1, 0, 0)))
# [1] TRUE
print(reproducer:::checkIfValidDummyVariable(c(0, 1, 2, 0)))
# [1] FALSE
```

Description

Data form a set of primary studies on reading methods for software inspections. They were reported and analysed by M. Ciolkowski (‘What do we know about perspective-based reading? an approach for quantitative aggregation in software engineering’, in Proceedings of the 3rd International Symposium on Empirical Software Engineering and Measurement, ESEM’09, pp. 133-144, IEEE Computer Society, 2009), corrected and re-analysed by Madeyski and Kitchenham (‘How variations in experimental designs impact the construction of comparable effect sizes for meta-analysis’ (to be submitted)).

Usage

Ciolkowski09ESEM.MetaAnalysis.PBRvsCBRorAR

Format

A data frame with 21 rows and 7 variables:

- **Study** Name of empirical study
- **Ref.** Reference to the paper reporting primary study or experimental run where data were originally reported
- **Control** Control treatment: Check-Based Reading (CBR) or Ad-hoc Reading (AR)
- **Within-subjects** Yes - if the primary study used the within-subjects experimental design, No - if the primary study did not use the within-subjects experimental design
- **Cross-over** Yes - if the primary study used the cross-over experimental design, No - if the primary study did not use the cross-over experimental design
- **d_ByCiolkowski** d effect size calculated by Ciolkowski
- **d_ByOriginalAuthors** d effect size as reported by the original authors
Details

If you use this data set please cite: Lech Madeyski and Barbara Kitchenham, 'How variations in experimental designs impact the construction of comparable effect sizes for meta-analysis', 2015.

Examples

Ciolkowski09ESEM.MetaAnalysis.PBRvsCBRorAR

| Cliffd.test | Cliffd.test |

Description

This function provides single-sided and two-sided tests of Cliff's d

Usage

Cliffd.test(x, y, alpha = 0.05, alternative = "two.sided", sigfig = -1)

Arguments

x The data from one group
y The data from the alternative group
alpha The significance level of tests which also controls the values of the confidence interval (default 0.05)
alternative This defines whether a one-sided test or a two-sided test is required (default "two.sided"). For a one-sided test use parameter values 'greater' or 'less' to define whether the d-value should be greater or less than zero.
sigfig is the number of significant digits. If sigfig>0 the data in x and y is truncated to the specified number of significant digits.

Value

The values of Cliff's d and its standard error, the t-value, its p-value and the upper and lower confidence interval.

Author(s)

Barbara Kitchenham and Lech Madeyski
Examples

```
a = c(1.2, 3, 2.2, 4, 2.5, 3)
b = c(3, 4.2, 4, 6, 7, 5.9)
Cliffd.test(a, b, alpha = .05, alternative = 'two.sided', sigfig = -1)
# A tibble: 1 x 7
# d sqse.d d.tvalue d.pvalue d.ci.lower d.ci.upper d.sig
#1 -0.861 0.0202 -42.7 1.20e-12 -0.896 -0.816 TRUE

Cliffd.test(b, a, alpha = .05, alternative = 'greater', sigfig = -1)
# A tibble: 1 x 7
# d sqse.d d.tvalue d.pvalue d.ci.lower d.ci.upper d.sig
#1 0.861 0.0202 42.7 5.99e-13 0.824 1 TRUE
```

Description

The function constructs various different d-style effect sizes for a set of different experiments given basic statistics from each experiment (the mean value of the control group Mc, the mean value of the treatment group Mt, the standard deviation of the control group SDc, standard deviation of the the treatment group SDt, the number of observations (participants) in the control group Nc, and the number of observations (participants) in the treatment group Nt). The input variables can be vectors or individual numbers but all input vectors must be of the same length. The function returns Glass’s Delta, Cohen’s D, point bi-serial r (based on Hedges’g unadjusted), Hedges’g and Hedges’g adjusted for small sample size.

Usage

```
constructEffectSizes(Mc, Mt, SDc, SDt, Nc, Nt)
```

Arguments

- **Mc**: is a vector containing the mean value of the control group for each experiment.
- **Mt**: is a vector containing the mean value of the treatment group for each experiment.
- **SDc**: is a vector of the standard deviations of the control group for each experiment.
- **SDt**: is a vector of the standard deviations of the the treatment group for each experiment.
- **Nc**: is a vector containing the the number of observations (participants) in the control group for each experiment.
- **Nt**: is a vector of the number of observations (participants) in the treatment group for each experiment.
ConstructLevel1ExperimentRData

Value

data frame composed of five effect sizes (Glass delta, Cohen’s d, Hedges’ g, r, Hedges’ g adjusted)

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

```r
constructEffectSizes(10, 15, 0.3, 0.2, 15, 15)

Mt <- c(0.633, 0.673, 0.423, 0.727, 0.631)
Mc <- c(0.612, 0.526, 0.356, 0.618, 0.534)
SDt <- c(0.198, 0.115, 0.172, 0.088, 0.122)
SDc <- c(0.159, 0.089, 0.111, 0.166, 0.119)
Nt <- c(12, 12, 14, 10, 8)
Nc <- c(12, 12, 14, 10, 8)
EffectSizes <- constructEffectSizes(Mc, Mt, SDc, SDt, Nt, Nc)
EffectSizes
# GlassDelta Cohend Hedgesg r HedgesgAdjusted
# 1 0.1320755 0.1221516 0.1169513 0.05837591 0.1129107
# 2 1.6516854 1.4931812 1.4296121 0.58151846 1.3802200

# 4 0.6566265 0.8648343 0.8204538 0.37953300 0.7857047
# 5 0.8151261 0.8604924 0.8049169 0.37335594 0.7608781
```

Description

This function returns the r value for a 2-group (2G) or 4-Group (4G) Crossover experiment for a group of 1 or more experiments for each sequence group and each outcome metric. For sets of 2 or more experiments, the experiments are assumed to be replicates and to report the same sets of Metrics and have the same Control treatment and use the same sequence Group identifiers, but are not necessarily the same Type. We return both the exact r value and the r value based on pooled variances for each sequence group and outcome metric.

Usage

```r
ConstructLevel1ExperimentRData(Data,
    StudyID,
    ExperimentNames,
    Groups,
    Metrics,
    Type,
)```
ConstructLevel1ExperimentRData

Arguments

Data This is a list parameter each entry in the list holds the data for each participant in a 2-group or 4-group crossover experiment in the 'wide' format. I.e., there is only one entry per participant. The data should have been generated from a long version of the data based on a variable labelled 'Period' which is used to define which participant data was collected in the first period of the experiment - see function ExtractLevel1ExperimentRData.

StudyID This holds an identifier used to identify the origin of the experimental data in the output from this function.

ExperimentNames This a list of identifiers used to define each experiment in the output from this function.

Groups This is a list that defined the sequence group identifiers used in the dataset.

Metrics This is a list of of character strings identifying each outcome metric reported in each of the experiments in the set of replicated experiments.

Type this is a list of character strings specifying for each experiment whether the experiment is a 2-group or 4-group experiment

Control this is a character string that defines the control treatment in the experiment.

Value

R.Data.Table this is a tibble holding information identifying for each metric and sequence group the first time period and second time period variance, the pooled variance, the variance of the difference values and the exact r and pooled r.

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

# ShortExperimentNames <- c("E1", "E2", "E3", "E4")

Control <- "SC"

# Obtain experimental data from each file and put in wide format
dataset2 <- KitchenhamEtAl.CorrelationsAmongParticipants.Scanniello14TOSEM
ReshapedData <- ExtractExperimentData(dataset2,
  ExperimentNames = FullExperimentNames,
  idvar = "ParticipantID", timevar = "Period", ConvertToWide = TRUE
)
crossoverResidualAnalysis

crossoverResidualAnalysis

description

This function analyses one or more crossover experiments where each experiment can be either a
two group or four group experiment as specified by Type parameter. The file parameter includes
a dataset comprising one or more experiments as defined by the ExperimentNames parameter and
each experiment includes values for every output variable defined in the Metrics parameter. After
being analysed using the linear modeling lmer function of the lme4 package, the residuals are
assessed for normality based on the Anderson-Darling test. Warning 1. This function should only
be used with data sets that include one or more individual crossover experiments in the format
used in the datasets reported in the reproducer package that were used in the paper B. Kitchenham,
L. Madeyski, G. Scanniello, and C. Gravino, “The importance of the correlation between results
from individual participants in crossover studies,” IEEE Transactions in SoftwareEngineering, 2021
The lmer function assumes that when experiments include multiple data from the same participant,
the correlation between measures for the same participant will be positive. If there is no positive
correlation, the function will deliver the warning: boundary (singular) fit: see ?isSingular. This
does not mean the analysis has failed. It means that the within participant and between participant
variance are set to the same value.

usage

crossoverResidualAnalysis(file, StudyID, ExperimentNames, Type, Metrics)
Arguments

- **file**
  The dataset to be analysed.
- **StudyID**
  A character string used to identify the origin of the dataset.
- **ExperimentNames**
  A vector of one or more strings variables identifying each experiment in the file.
- **Type**
  A vector of string variables identifying the design for each experiment. Each
element should have the value '2G' or '4G'.
- **Metrics**
  A vector of string variables identifying the variables to be analysed.

Value

The results of analysing the residuals for each experiment and metric using the Anderson-Darling
test (ADpval) and the number of outliers (NumOut).

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

```r
crossoverResidualAnalysis(
  File, StudyID='S1', ExperimentNames=c('USB2'), Type=c('4G'),
  Metrics=c('Correctness', 'Time', 'Efficiency'))
```

<table>
<thead>
<tr>

Description

Density curve overlaid on histogram

Usage

```r
densityCurveOnHistogram(df, colName, limLow, limHigh)
```

Arguments

- **df**
  Data frame with data to be displayed
- **colName**
  Name of the selected column in a given data frame
- **limLow**
  the limit on the lower side of the displayed range
- **limHigh**
  the limit on the higher side of the displayed range
**Value**

A figure being a density curve overlaid on histogram

**Author(s)**

Lech Madeyski

**Examples**

```r
densityCurveOnHistogram(Madeyski15EISEJ.PropProjects, "STUD", 0, 100)
# densityCurveOnHistogram(data.frame(x<-rnorm(50, mean=50, sd=5)), 'x', 0, 100)
```

**Description**

This helper function is called by the function 'crossoverResidualAnalysis' to perform either an AB/BA crossover analysis or a four-group crossover on the data set defined by the parameter DataSet depending on the value of the Type parameter.

**Usage**

```r
doLM(DataSet, Metric, Type)
```

**Arguments**

- **DataSet** The dataset to be analysed.
- **Metric** The name of the variable to be analysed
- **Type** Defines the experimental design

**Value**

The data analysis results provided by the lmer function of the lme4 package

**Author(s)**

Barbara Kitchenham and Lech Madeyski
effectSizeCI

**Description**

The procedure is based on finding the upper and lower 0.025 bounds for the related t-variable. The t-variable needs to be adjusted for bias by multiplying by \( c \). The upper and lower bounds on the t-variable are then used to calculate the upper and lower bounds on the repeated measures effect size (d\_RM) by multiplying the upper and lower bound of the t-variable by \( \sqrt{(n1+n2)/(2*(n1*n2))} \). Upper and lower bounds on the equivalent independent groups effect size (d\_IG) are found by multiplying the upper and lower bounds on d\_RM by \( \sqrt{1-r} \).

**Usage**

```r
effectSizeCI(
  expDesign,
  t,
  n1,
  n2,
  r = 0,
  epsilon = 1e-10,
  maxsteps = 1000,
  stepsize = 3
)
```

**Arguments**

- `expDesign` Experimental design: 1) crossover repeated measures (’CrossOverRM’), 2) before-after repeated measures (expDesign==’BeforeAfterRM’), 3) independent groups (’IG’)
- `t` t-statistics (t must be less than or equal to 37.62, the limit from the R function documentation)
- `n1` The number of observations in sequence group 1 (expDesign==’CrossOverRM’), or the total number of observations (expDesign==’BeforeAfterRM’)
- `n2` The number of observations in sequence group 2 (expDesign==’CrossOverRM’) or the number of observations in group 2 (expDesign==’IG’)
- `r` The correlation between outcomes for individual subject (the within subject correlation)
- `epsilon` The precision of the iterative procedure
- `maxsteps` The maximum number of steps of the iterative procedure (the procedure terminates at maxsteps or earlier if CI with enough precision have been calculated)
- `stepsize` The size of steps (influences the convergence of the calculations, i.e., the number of steps required to obtain the final result of precision defined by the epsilon)
Value

A list of Confidence Intervals for: t-statistic (t_LB and t_UB), repeated-measures effect size d_RM (d_RM_LB, d_RM_UB), independent groups effect size (d_IG_LB, d_IG_UB)

Author(s)

Lech Madeyski and Barbara Kitchenham

Examples

effectSizeCI(expDesign = "CrossOverRM", t = 14.4, n1 = 15, n2 = 15, r = 0.64011)
effectSizeCI(expDesign = "BeforeAfterRM", t = 14.16536, n1 = 15, n2 = 0, r = 0.6146771)
effectSizeCI(expDesign = "IG", t = -6.344175, n1 = 15, n2 = 15)
effectSizeCI(expDesign = "CrossOverRM", t = 0.5581, n1 = 6, n2 = 6, r = 0.36135)
effectSizeCI(expDesign = "CrossOverRM", r = 0.855, t = 4.33, n1 = 7, n2 = 6)

Description

This function reads datasets from a defined directory in the reproducer package that hold the results of a family crossover experiments in the long format. It converts the data to the wide format if required.

Usage

ExtractExperimentData(
  DataSet,
  ExperimentNames,
  idvar = "ParticipantID",
  timevar = "Period",
  ConvertToWide = TRUE
)

Arguments

DataSet

This is a tibble holding the data for each crossover experiment in a family (a family can include only one experiment).

ExperimentNames

This is a list with the full names of each experiment.

idvar

This is the name of the column that contains the data for specific participants. It is only assumed to be unique within an experiment (default idvar='ParticipantID').

timevar

This is the name of the table column that defines which data was collected in a specific time period. This function assumes that there are only two time periods (default timevar='Period').

ConvertToWide

This determine whether the function converts the data to the wide format (default ConvertToWide=TRUE).
**Value**

A list with an entry for the data for each experiment. If ConvertToWide is TRUE, it returns the data in the wide format otherwise it returns the data as it was read. Within each list item the data is returned as a tibble

```r
# importFrom stats # importFrom tibble # importFrom base
```

**Author(s)**

Barbara Kitchenham and Lech Madeyski

**Examples**

```r
ExperimentNames <- c("EUBAS", "R1UCLM", "R2UCLM", "R3UCLM")
Metrics <- c("Comprehension", "Modification")
Groups <- c("A", "B", "C", "D")
Type <- c(rep("4G", 4))
StudyID <- "S2"
Control <- "SC"

# Obtain experimental data from each file and put in wide format
dataset2 <- KitchenhamEtAl.CorrelationsAmongParticipants.Scanniello14TOSEM
ReshapedData <- ExtractExperimentData(dataset2, ExperimentNames = ExperimentNames, idvar = "ParticipantID", timevar = "Period", ConvertToWide = TRUE)

```

**Description**

This function constructs a table identifying the number of participants in each sequence group for a set of experiments each of which used a crossover design.
Usage

ExtractGroupSizeData(
  ExpDataWide,
  StudyID,
  ShortExperimentNames,
  Type,
  Groups = c("A", "B", "C", "D")
)

Arguments

ExpDataWide  this is a list of tibbles each comprising data from one experiment in its wide format
StudyID  an identifier for the group of related experiments (i.e., a family).
ShortExperimentNames  a list of character strings identifying each experiment.
Type  A list identifying the type of crossover '2G' or '4G' for each experiment in the family
Groups  a list of the terms used to specify sequence groups in the experiments.

Value

A tibble containing the number of participants in each sequence group in each experiment.

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

ExperimentNames <- c("EUBAS", "R1UCLM", "R2UCLM", "R3UCLM")
ShortExperimentNames <- c("E1", "E2", "E3", "E4")
Metrics <- c("Comprehension", "Modification")
Type <- c("4G", "4G", "4G", "4G")
Groups <- c("A", "B", "C", "D")
StudyID <- "S2"
Control <- "SC"
# Obtain experimental data from a file and put in wide format
dataset2 <- KitchenhamEtAl.CorrelationsAmongParticipants.Scanniello14TOSEM
ReshapedData <- ExtractExperimentData(dataset2,
  ExperimentNames = ExperimentNames,
  idvar = "ParticipantID", timevar = "Period", ConvertToWide = TRUE
)
ExtractGroupSizeData(ReshapedData, StudyID, ShortExperimentNames, Type, Groups = Groups)
# A tibble: 16 x 4
# Study Exp Group n
# <chr> <chr> <chr> <int>
# 1 S2 Exp1 A 6
# 2 S2 Exp1 B 6
Description
This function extracts summary statistics from meta-analysis results obtained from the rma function of the metafor R package. If required the function transform back to standardized mean difference (effect size type ‘d’ i.e. Hg) or point biserial correlations (effect size type ‘r’). Warning: the ‘ExtractMAStatistics’ function works with ‘metafor’ version 2.0-0, but changes to metafor’s method of providing access to its individual results may introduce errors into the function.

Usage
ExtractMAStatistics(
  mresults,
  Nc,
  Nt,
  Transform = TRUE,
  type = "d",
  sig = 4,
  returnse = FALSE
)

ExtractMAStatistics(
  mresults,
  Nc,
  Nt,
Transform = TRUE,
type = "d",
sig = 4,
returnse = FALSE
)

**Arguments**

- `maresults`: is the output from the `rma` function.
- `Nc`: is the number of participants in the control condition group.
- `Nt`: is the number of participants in the treatment condition group.
- `Transform`: is a boolean value indicating whether the outcome values need to be transformed back to standardized mean difference (‘d’ i.e. Hg or d) or point biserial correlations (‘r’). It is defaulted to TRUE. If this parameter is set to FALSE, no transformation will be applied.
- `type`: this indicates the type of transformation required - it defaults to ‘d’ which requests transformation from Zr to Hg, using ‘r’ requests transformation from Zr to r.
- `sig`: indicates the number of significant digits requested in the output, the default is 4; it rounds the values of mean, pvalue, upper and lower bound to the specified number of significant digits.
- `returnse`: if set to TRUE returns the standard error of the effect size (default: returnse=FALSE)

**Value**

data frame incl. summary statistics from meta-analysis results: overall mean value for the effect sizes, the p-value of the mean, the upper and lower confidence interval bounds (UB and LB), QE which is the heterogeneity test statistic and QEp which the the p-value of the heterogeneity statistic

data frame incl. summary statistics from meta-analysis results: overall mean value for the effect sizes, the p-value of the mean, the upper and lower confidence interval bounds (UB and LB), QE which is the heterogeneity test statistic and QEp which the the p-value of the heterogeneity statistic

Description

This function extracts data obtained from the lme4 package lmer function. It assumes a simple randomized experiment with each element having one or more repeated measures. It outputs the mean together with its standard error and confidence interval bounds.

Usage

ExtractSummaryStatisticsRandomizedExp(lmeRA, N, alpha = 0.05)

Arguments

lmeRA The output from the lmer function
N The total number of observations
alpha the probability level to be used when constructing the confidence interval bounds.

Value

REA.Summary A dataframe holding the number of observations N, the overall mean value as its standard error reported as by the lmer function, and its confidence interval bounds.
Examples

ShortExperimentNames <- c("E1", "E2", "E3", "E4")

Description

Formatting function to set decimal precision in labels
getEffectSizesABBA

Usage

fmt()

Author(s)

Lech Madeyski

description

Function to calculate both effect sizes (dIG, dRM), i.e., independent groups and repeated measures standardized effect sizes and variances, for AB/BA crossover design studies. Function is used in a paper 'Effect Sizes and their Variance for AB/BA Crossover Design Studies' by Lech Madeyski and Barbara Kitchenham.

Usage

getEffectSizesABBA(simulationData)

Arguments

simulationData - data set in a form required to calculate effect sizes in AB/BA crossover experimental designs

Value

data frame incl. calculated effect sizes and variances: # dIG - independent groups standardized effect size # var.dIG - variance of independent groups standardized effect size # dRM - repeated measures (within-subjects) standardized effect size # var.dRM - variance of repeated measures (within-subjects) standardized effect size # dIG.Fromt - independent groups standardized effect size calculated from t: dIG.Fromt=t*sqrt((N1+N2)/(2*N1*N2)) # var.dIG.Fromt - variance of independent groups standardized effect size calculated from t: var.dIG.Fromt=var.t*(1-r)*((N1+N2)/(2*N1*N2)) # dRM - dRM calculated from t: dRM.Fromt=t*sqrt((N1+N2)/(2*N1*N2)) # var.dRM - variance of dRM calculated from t: var.dRM=var.t*(1-r)*((N1+N2)/(2*N1*N2)) # var.dRM2 - var.dRM calculated from t or rather dRM: var.dRM2=(df/(df-2))*(1-r)((N1+N2)/(2*N1*N2)+dRM) # var.dRM2/c^2 - var.dRM.Approx - var.dRM calculated on a basis of Johnson and Welch (1940) report an approximate formula for the variance of a t variable: var.dRM.Approx=((N1+N2)/(2*N1*N2)) + (dRM^2)/(N1+N2-2)) # see paper and Equation 49 # var.dIG.Approx - var.dIG calculated on a basis of Johnson and Welch (1940) report an approximate formula for the variance of a t variable: var.dIG.Approx=(((N1+N2)*(1-r))/(2*N1*N2)) + (dIG^2)/(4*(N1+N2-2)) # see paper and Equation 50 # unstandardizedES - estimated unstandardized technique effect size # periodES - estimated period effect # var.sig - sum of within-subjects variance and between-subjects variance # var.within - within-subjects variance # var.between - between-subjects variance # t - t-value # var.t - variance of t-variable # gRM - Hedges and Olkin (1985) unbiased estimator of the repeated measures
effect size \( g_{RM} = d_{RM} \times c \) \# \( \text{var}_g = \frac{df}{(df-2)} \times \left( \frac{N1+N2}{2 \times N1 \times N2} \times c^2 + g^2 \right) \) # Equation 56 \# \( \text{var}_g^2 = \text{var}_d \times c^2 \) # \( g_{IG} \) - Hedges and Olkin (1985) unbiased estimator of the independent groups effect size \( g_{IG} = d_{IG} \times c \) \# \( \text{var}_g = \frac{df}{(df-2)} \times \left( \frac{N1+N2}{2 \times N1 \times N2} \times c^2 + g^2 \right) \) # Equation 57 \# \( \text{var}_g^2 = \text{var}_d \times c^2 \) # \( r \) - the correlation between the values observed for the same subject

Author(s)

Lech Madeyski and Barbara Kitchenham

Examples

```r
simulationData <- getSimulationData(25, 18.75, 50, 10, 5, 500) # generate simulated data set
es <- getEffectSizesABBA(simulationData) # return effect sizes and variances
OR
simulationData <- getSimulationData(25, 18.75, 50, 10, 5, 15)
es <- getEffectSizesABBA(simulationData) # return effect sizes and variances
```

Description

Function to calculate both effect sizes (\( d_{IG.ipe} \), \( d_{RM.ipe} \)), i.e., independent groups and repeated measures standardized effect sizes and variances, for AB/BA crossover design studies ignoring period effect (thus wrong). Function was removed in the revision of the paper 'Effect Sizes and their Variance for AB/BA Crossover Design Studies' by Lech Madeyski and Barbara Kitchenham.

Usage

```r
getEffectSizesABBAIgnoringPeriodEffect(simulationData)
```

Arguments

- `simulationData` - data set in a form required to calculate effect sizes in AB/BA crossover experimental designs

Value

data frame incl. calculated effect sizes and variances: # \( d_{IG.ipe} \) - independent groups standardized effect size # \( \text{var}d_{IG.ipe} \) - variance of independent groups standardized effect size # \( d_{RM.ipe} \) - repeated measures (within-subjects) standardized effect size # \( \text{var}d_{RM.ipe} \) - variance of repeated measures (within-subjects) standardized effect size # \( d_{IG.Fromt.ipe} \) - independent groups standardized effect size calculated from t: \( d_{IG.Fromt} = t \times \text{sqr}(1-r) \times \text{sqr}(N1+N2)/(2 \times N1 \times N2) \) # \( \text{var}d_{IG.Fromt.ipe} \)
- variance of independent groups standardized effect size calculated from t: \( \text{var.dIG.Fromt} = \frac{\text{var.t} 	imes (1-r)}{((N1+N2)/(2*N1*N2))} \)
- dRM calculated from t: \( \text{dRM.Fromt} = \text{t} \times \sqrt{\frac{(N1+N2)}{2*N1*N2}} \)
- \( \text{var.dRM.Fromt.ipe} - \text{var.dRM calculated from t or rather dRM.Fromt2.ipe} - \text{var.dRM calculated from t or rather dRM.Fromt} \)
- \( \text{var.dRM.Fromt2.ipe} - \text{var.dRM calculated from t or rather dRM.Fromt} \)
- \( \text{dRM.Fromt} = \text{t} \times \sqrt{\frac{(N1+N2)}{2*N1*N2}} \)
- \( \text{var.dRM.Fromt} = \text{var.t} \times \frac{(N1+N2)}{2*N1*N2} \)
- \( \text{var.dRM.Fromt2} = \frac{(df/(df-2)) \times ((N1+N2))/(2*N1*N2)+dRM.Fromt^2)}{c^2} \)
- estimated unstandardized technique effect size 
- \( \text{var.sig.ipe} - \text{sum of within-subjects variance and between-subjects variance} \)
- \( \text{var.within.ipe} - \text{within-subjects variance} \)
- \( \text{var.between.ipe} - \text{between-subjects variance} \)
- \( \text{t.ipe} - \text{t-value} \)
- \( \text{var.t.ipe} - \text{variance of t-variable} \)

**Author(s)**

Lech Madeyski and Barbara Kitchenham

**Examples**

```r
simulationData <- getSimulationData(25, 18.75, 50, 10, 5, 500) # generate simulated data set
es.ipe <- getEffectSizesABBAIgnoringPeriodEffect(simulationData) # return effect sizes and variances
```

---

**Description**

Function to generate the simulated data set used in a paper 'Effect Sizes and their Variance for AB/BA Crossover Design Studies' by Lech Madeyski and Barbara Kitchenham

**Usage**

```r
getSimulationData(
  var, 
  covar, 
  meanA1, 
  treatmentDiff, 
  periodEffect, 
  numOfSamples 
)
```

**Arguments**

- `var`: Variance among subjects is a sum of the between subjects variance and the within subjects variance
- `covar`: Covariance equal to the between subjects variance
- `meanA1`: Mean for treatment sequence A1
- `treatmentDiff`: Technique effect which is the difference between the effect of technique A and technique B
- `periodEffect`: Period effect which is the difference between period 1 and period 2
- `numOfSamples`: Number of samples ('rows' of data) required for each technique and period
**getTheoreticalEffectSizeVariancesABBA**

**Details**

Functions related to a paper 'Effect sizes and their variance for AB/BA crossover design studies' by Lech Madeyski and Barbara Kitchenham

**Value**

Data frame: `data.frame`: 4*numOfSamples obs. of 5 variables: `$ pid : int 1 2 3 4 5 6 7 8 9 10 ... $ technique: Factor w/ 2 levels 'T1','T2': ... $ period : Factor w/ 2 levels 'P1','P2': ... $ sequence : Factor w/ 2 levels 'S1','S2': ... $ result : num ...

**Author(s)**

Lech Madeyski and Barbara Kitchenham

**Examples**

```r
# generate the simulated data set from the paper
data <- getSimulationData(25, 18.75, 50, 10, 5, 500)
data <- getSimulationData(25, 18.75, 50, 10, 5, 15)
```

**Description**

Function provides the theoretical value of the t-statistic, variance of t, and variance of the effect sizes based on the parameters built into crossover model data simulated by the getSimulationData() function. Function is used in a paper 'Effect Sizes and their Variance for AB/BA Crossover Design Studies' by Lech Madeyski and Barbara Kitchenham.

**Usage**

```r
getTheoreticalEffectSizeVariancesABBA(
  theoreticalvarW,
  theoreticalTechniqueEffect,
  theoreticalrho,
  N1,
  N2
)
```
Arguments

- theoreticalvarW - The within subject variance used to construct the simulation, i.e., the built-in Variance - the built-in Covariance
- theoreticalTechniqueEffect - The technique effect built into the crossover model data
- theoreticalrho - The between subject correlation built into the crossover model simulation data
- N1 - The number of subjects in sequence group 1 in the crossover model simulation
- N2 - The number of subjects in sequence group 2 in the crossover model simulation

Value

data frame incl. calculated: theoreticalt - the theoretical value of the t-statistic theoreticalvart - variance of t theoreticalvardIG - variance of the effect size dIG based on the parameters built into crossover model data simulated by the getSimulationData function theoreticalvardRM - variance of the effect size dRM based on the parameters built into crossover model data simulated by the getSimulationData function

Author(s)

Lech Madeyski and Barbara Kitchenham

Examples

# Generates data used in Table 15 of the paper

Description

Usage

KitchenhamEtAl.CorrelationsAmongParticipants.Abrahao13TSE

Format

A data frame with 224 rows and 8 variables:

- **ExperimentID**<fct>|ExperimentID: A unique identifier for each of the five experiments in the data set.
- **ParticipantID**<fct>|Participant ID: An identifier for each participant, unique for a specific experiment.
- **SequenceGroup**<fct>|Experimental Sequence Group: A (DM-NODM,ECP-EPlat or MShop-Theatre), B (NODM-DM,ECP-EPlat or MShop-Theatre), C(DM-NODM,EPlat-ECP or Theatre-MShop), D(NODM-DM,EPlat-ECP or Theatre-MShop)
- **System**<fct>|Software systems used in the experiment: ECP an e-commerce platform from which CDs and books can be bought, EPlat a system for the management of courses, lectures and students of a university, M-Shop a system for managing sales at a music shop, Theatre a system for managing bookings for a theatre.
- **Period**<fct>|Time period of the cross-over experiment: 1 or 2
- **Treatment**<fct>|Experimental Treatment: A Dynamic Model (DM) vs No Dynamic Model (NODM)
- **Comprehension**<dbl>|Dependent variable: The comprehension level the software engineer achieved based on the F-measure
- **CrossOverID**<fct>|CrossOver category: For 4 group crossover designs, the crossover category specifies the matching pairs of sequence groups, CO1 and CO2. For a 2 group crossover, the category is set to CO1 only
- **Ability**<fct>|Ability: An assessment of the ability of participants: Low, High, NA (not available)

Examples

KitchenhamEtAl.CorrelationsAmongParticipants.Abrahao13TSE

Description

Data illustrate correlations between results from individual participants in a family of two cross-over experiments conducted by Gravino et al.: [1] C. Gravino, G. Scanniello, and G. Tortora, 'Source-code comprehension tasks supported by UML design models: Results from a controlled experiment and a differentiated replication,' Journal of Visual Languages and Computing, vol. 28, pp. 23–38, 2015. The experiments assess whether the comprehension of object oriented source-code increases used with UML class and sequence diagrams produced in the software design phase. If you use this
Usage

KitchenhamEtAl.CorrelationsAmongParticipants.Gravino15JVLC

Format

A data frame with 64 rows and 9 variables:

- **ExperimentID** <fct> | ExperimentID: A unique identifier for each of the three experiments in the data set.
- **ParticipantID** <fct> | Participant ID: An identifier for each participant, unique for a specific experiment.
- **SequenceGroup** <fct> | Experimental Sequence Group: A, B, C, D
- **System** <fct> | Software systems used in the experiment: Music shop, a system for handling the sales of a music shop. Theater ticket, a system for managing theatre reservations.
- **Period** <fct> | Time period of the cross-over experiment: 1 or 2
- **Treatment** <fct> | Experimental Treatment: Mo, design models were available, NOMo design models were not available
- **Comprehension** <dbl> | Dependent variable: The level of comprehension achieved by the software engineer.
- **Time** <dbl> | Dependent variable: The time [min] taken to complete the comprehension task.
- **CrossOverID** <fct> | CrossOver category: For 4 group crossover designs, the crossover category specifies the matching pairs of sequence groups, CO1 and CO2. For 2 group crossover, the category is set to CO1 only

Examples

KitchenhamEtAl.CorrelationsAmongParticipants.Gravino15JVLC

KitchenhamEtAl.CorrelationsAmongParticipants.Gravino15JVLC
Description

Usage

KitchenhamEtAl.CorrelationsAmongParticipants.Madeyski10

Format

‘KitchenhamEtAl.CorrelationsAmongParticipants.Madeyski10’: a data frame with 45 rows and 10 variables:

- **ExperimentID** <fct> | ExperimentID: This experiment is the only cross-over experiment in the family of TDD and Pair-Programming experiments conducted by Madeyski, so all values in this column are set to ‘P2007’.
- **ParticipantID** <fct> | Participant ID: An identifier for each participant, unique for a specific experiment.
- **SequenceGroup** <fct> | Experimental Sequence Group: A (TLSP-TFSP), B (TFSP-TLSP)
- **System** <fct> | Software system to develop: Smell (a tool for identifying bad code smells in Java source code through the use of a set of software metrics) or Library (a library application)
- **Period** <fct> | Time period of the cross-over experiment: 1 or 2
- **Treatment** <fct> | Experimental Treatment: Test-First Solo Programming (TFSP) vs Test-Last Solo Programming (TLSP)
- **PATP** <dbl> | Dependent variable: Percentage of Acceptance Tests Passed
- **NATPPH** <dbl> | Dependent variable: Number of Acceptance Tests Passed Per Hour
- **CBO** <dbl> | Dependent variable: Mean value of Coupling Between Objects (CBO), see CK set of metrics
- **WMC** <dbl> | Dependent variable: Mean value of Weighted Number of Methods in Class (WMC), see CK set of metrics
- **RFC** <dbl> | Dependent variable: Mean value of Response For a Class (RFC), see CK set of metrics
- **CrossOverID** <fct> | Cross-Over Code. This experiment is a simple two-group cross-over experiment with one cross-over code, so all values in this column are set to ‘CO1’. However, four-group experiments require a code to identify the linked sequence groups (although that can be deduced from the system used in the first time period). A crossover code is also essential for non-parametric analysis.

KitchenhamEtAl.CorrelationsAmongParticipants.Ricca10TSE

KitchenhamEtAl.CorrelationsAmongParticipants.Ricca10TSE data

Description

Data illustrate correlations between results from individual participants in a family of four cross-over experiments conducted by Ricca et al.: [1] F. Ricca, M. D. Penta, M. Torchiano, P. Tonella, and M. Ceccato ‘How developers’ experience and ability influence web application comprehension tasks supported by uml stereotypes: A series of four experiments’, IEEE Transactions on Software Engineering, vol. 36, no. 1, pp. 96-118, 2010. Although we present the full data set, only the first two experiments were used in the correlation study, because many of the observations in the final two studies were unpaired. The experiments assess whether participants performance comprehension tasks better when using source code complemented by standard UML diagrams (UML) or by diagrams stereotyped using the Conallen notation (Conallen). If you use this data set please cite: [1] F. Ricca, M. D. Penta, M. Torchiano, P. Tonella, and M. Ceccato ‘How developers’ experience and ability influence web application comprehension tasks supported by uml stereotypes: A series of four experiments’, IEEE Transactions on Software Engineering, vol. 36, no. 1, pp. 96—118, 2010. ### Description

### Usage

**KitchenhamEtAl.CorrelationsAmongParticipants.Romano18ESEM**

### Format

A data frame with 194 and 10 variables:

**ExperimentID** <fct> | ExperimentID: A unique identifier for each part of the experiment. Exp.1 identifies data from the first part of the experiment, Exp.2 identifies data from the second part of the experiment.

**ParticipantID** <fct> | Participant ID: An identifier for each participant, unique for both parts of the experiment.

**SequenceGroup** <fct> | Experimental Sequence Group: A, B
System <fct> Software systems used in the experiment: For the first part of the experiment, M-Shop (a system for managing a music shop) and Theater (a system for managing theatre reservations). For the second part of the experiment: AveCalc (a system that manages as electronic register and LaTazza (a system for a drinks vending machine)

Period <fct> Time period of the cross-over experiment: 1 or 2

Treatment <fct> Experimental Treatment: NOISE, participants were asked to perform a comprehension task in a noisy environment. NORMAL, participants were asked to perform a comprehension task under normal working conditions.

Fc <dbl> Dependent variable: the balanced F-measure which represents the trade-off between precision and recall, measured in the first part of the experiment.

Avg <dbl> Dependent variable: The average number of fully correct answers, measured in the first part of the experiment.

Ff <dbl> Dependent variable: Effectiveness of fault correction. Measured in the second part of the experiment.

CrossOverID <fct> CrossOver category: For 4 group crossovers, the crossover category specifies the matching pairs of sequence groups, CO1 and CO2. For 2 group crossover, the category is set to CO1 only.

KitchenhamEtAl.CorrelationsAmongParticipants.Scanniello14JVLC

Description

Usage

KitchenhamEtAl.CorrelationsAmongParticipants.Scanniello14JVLC

Format

A data frame with 36 rows and 12 variables:

**ExperimentID**<fct> | ExperimentID: A unique identifier for each experiment in the data set.

**ParticipantID**<fct> | Participant ID: An identifier for each team of four participants, unique for the specific experiment.

**SequenceGroup**<fct> | Experimental Sequence Group: A, B

**System**<fct> | Software systems used in the experiment: Library (a software system to manage books and users of a library) and FilmCollection (a software system for the selling and the rental of films in a shop) in ExperimentStage1 and Rent (a car rental software to manage cars, customers, and reservations) and ECP (an E-Commerce Platform to order CDs and books via the Internet from an on line catalogue), in ExperimentStage2.

**Treatment**<fct> | Experimental Treatment: TPS vs F2F.

**Period**<fct> | Time period of the cross-over experiment: 1 or 2 within each stage of the experiment

**Time**<fct> | Total time [min] to accomplish the requirement engineering task.

**Quality**<fct> | Dependent variable: The quality of the requirements engineering task.

**CrossOverID**<fct> | Crossover category: For a single 2 group crossover experiment, the value is set to CO1 for each experiment stage.

**ExperimentPeriod**<fct> | The time period across both stages of the experiment.

**ExperimentStage**<fct> | ExperimentStage: 1 first stage, 2 second stage.

Examples

KitchenhamEtAl.CorrelationsAmongParticipants.Scanniello14JVLC

Description

Data illustrate correlations between results from individual participants in a family of four cross-over experiments conducted by Scanniello et al: [1] G. Scanniello, C. Gravino, M. Genero, J.A. Cruz-Lemus, and G. Tortora, 'On the Impact of UML Analysis Models on Source-Code Comprehensibility and Modifiability', ACM Transactions on Software Engineering and Methodology, vol. 23, no. 2, pp. 13:1-13:26, 2014 The family of experiments investigated whether the availability of analysis models in addition to the source code made the code easier to understand and

Usage

KitchenhamEtAl.CorrelationsAmongParticipants.Scanniello14TOSEM

Format

‘KitchenhamEtAl.CorrelationsAmongParticipants.Scanniello14TOSEM’: a data frame with 172 rows and 9 variables:

ExperimentID <fct> | ExperimentID: A unique identifier for each experiment in the data set.
ParticipantID <fct> | Participant ID: An identifier for each participant, unique for a specific experiment.
Treatment <fct> | Experimental Treatment: AM an Analysis Model with source code (AM) vs Source Code only (SC)
SequenceGroup <fct> | Experimental Sequence Group: A (AM-SC,S1-S2), B (SC-AM,S1-S2), C(AM-SC,S2-S1), D(SC-AM,S2-S1)
System <fct> | Software systems used in the experiment: S1 A system to sell and manage CDs/DVDs in a music shop, S2 A system to book and by theater tickets.
Comprehension <dbl> | Dependent variable: The comprehension level the software engineer achieved based on the F-measure
Modification <dbl> | Dependent variable: The modifiability level the software engineer achieved based on the F-measure
Period <fct> | Time period of the cross-over experiment: 1 or 2
CrossOverID <fct> | CrossOver category: For 4 group the crossover category specifies the matching pairs of sequence groups, CO1 and CO2. For 2 group crossover, the category is set to CO1 only

Examples

KitchenhamEtAl.CorrelationsAmongParticipants.Scanniello14TOSEM
Data illustrate correlations between results from individual participants in cross-over experiment usb2 conducted by Scanniello et al: [1] G. Scanniello, A. Marcus, and D. Pascale, 'Link analysis algorithms for static concept location: an empirical assessment', Empirical Software Engineering, vol. 20, no. 6, pp. 1666–1720, 2015. The goal of the experiment is to assess whether a new technique (implemented as an Eclipse plug-in) for static concept location (proposed by the authors) supports users in identifying the places in the code where changes are to be made.

Usage

Format

‘KitchenhamEtAl.CorrelationsAmongParticipants.Scanniello15EMSE’: a data frame with 48 rows and 10 variables:

- **ExperimentID** <fct> | ExperimentID: A unique identifier for each experiment in the data set.
- **ParticipantID** <fct> | Participant ID: An identifier for each participant, unique for a specific experiment.
- **System** <fct> | Software systems used in the experiment: Jedit and Atunes
- **Treatment** <fct> | Experimental Treatment: Use of Concept Location plug-in (CL) vs no Concept Location plug-in (NOCL)
- **Period** <fct> | Time period of the cross-over experiment: 1 or 2
- **Correctness** <int> | Dependent variable: 0, 1, 2, 3, 4. The participants are asked to indicate a single change method for each of 4 bug reports. A change method is correctly identified if that method is in the change set of the bug report.
- **Time** <dbl> | Dependent variable: The total time [min] to accomplish concept location tasks, i.e., to identify (four) bugs given their reports
- **Efficiency** <dbl> | Dependent variable: The participants’ efficiency in the execution of concept location tasks. It is computed dividing correctness by time.
- **CrossOverID** <fct> | Crossover category: For 4 group crossover designs, the crossover category specifies the matching pairs of sequence groups, CO1 and CO2.

KitchenhamEtAl.CorrelationsAmongParticipants.Scanniello17TOSEM

Description

Usage

KitchenhamEtAl.CorrelationsAmongParticipants.Scanniello17TOSEM

Format

A data frame with 200 rows and 17 variables:

- **ExperimentID** <fct> | ExperimentID: A unique identifier for each of the experiments in the data set.
- **ParticipantID** <fct> | Participant ID: An identifier for each participant, unique for a specific experiment.
- **SequenceGroup** <fct> | Experimental Sequence Group: A, B, C, D
System <fct>Software systems used in the experiments: The Unibas experiment used Agenda (a system for tracking personal contacts) and Gas-Station (a system for managing a petrol station). The UniNa experiment used Financial (a system which is a command line option price calculator) and Hotel-Reservation. The POLINA and PROF experiments used AveCalc (a system that manages as electronic register and LaTazza (a system for a drinks vending machine).

Period <fct>Time period of the cross-over experiment: 1 or 2

Treatment <fct>Experimental Treatment: ABBR, abbreviated names. FULL, full names

Time <dbl>Dependent variable: The time each participant spent performing the SE task.

FMeasure <dbl>Dependent variable: The effectiveness of the participants taking into account correctness and completeness of the fault fixing tasks

Efficiency <dbl>Independent variable: The ratio of effectiveness to time.

CrossOverID <fct>CrossOver category: For 4 group crossover designs, the crossover category specifies the matching pairs of sequence groups, CO1 and CO2. For 2 group crossover, the category is set to CO1 only.

Language <fct>Java or C. The language was the same for all participants in a specific experiment. POLINA and PROF used Java, UNIBAS and UNINA used C.

Ident <dbl>Independent variable: The number of faults identified.

Fixed <dbl>Independent variable: The number of faults identified.

WrongIdent <dbl>Independent variable: The number of faults incorrectly identified

WronglyFixed <dbl>Independent variable: The number of faults incorrectly fixed.

precision <dbl>Independent variable: The ratio of number of faults correctly fixed to the number of faults correctly identified.

recall <dbl>Independent variable: The ratio of number of faults correctly fixed to the total number of fault.

KitchenhamEtAl.CorrelationsAmongParticipants.Scanniello17TOSEM

KitchenhamEtAl.CorrelationsAmongParticipants.Torchiano17JVLCData

Description

Data illustrate correlations between results from individual participants in a family of three cross-over experiments conducted by Torchiano et al: [1] M. Torchiano, G. Scanniello, F. Ricca, G. Reggio, and M. Leotta, 'Do UML object diagrams affect design comprehensibility? Results from a family of four controlled experiments.' Journal of Visual Languages and Computing, vol. 41, pp. 10–21, 2017. Although the paper reports four experiment, we only have data from three of

Usage

KitchenhamEtAl.CorrelationsAmongParticipants.Torchiano17JVLC

Format

A data frame with 214 rows and 8 variables:

- **ExperimentID**: A unique identifier for each of the three experiments in the data set.
- **ParticipantID**: An identifier for each participant, unique for a specific experiment.
- **SequenceGroup**: Experimental Sequence Group: A, B, C, D
- **System**: Software systems used in the experiment: File System manager (FS) for folders, files, links. Roads system (R) handles maps made up of cities connected by means of roads. Train (T) a system to manage timetables, trains, and paths. Catalogue system (C). It collects category of items (e.g., cars) and items (e.g., car models) based on a set of features (e.g., number of doors). In PoliTo2, only FS and T were administered to the participants, while in UniBas1 and UniGe1 all the four experimental objects were used.
- **Period**: Time period of the cross-over experiment: 1 or 2
- **Treatment**: Experimental Treatment: Object Diagram (OD) vs No Object Diagram (NoOD)
- **Comprehension**: Dependent variable: The comprehension level the software engineers. For PoliTo2 Comprehension was based on answering a set of 4 questions, for UniBas and UniGe comprehension was measured using the F metric.
- **CrossOverID**: CrossOver category: For 4 group crossover designs, the crossover category specifies the matching pairs of sequence groups, CO1 and CO2. For 2 group crossover, the category is set to CO1 only

KitchenhamMadeyski.SimulatedCrossoverDataSets
Description

This data is used in the paper: Barbara Kitchenham, Lech Madeyski and Pearl Brereton. Meta-analysis for Families of Experiments: A Systematic Review and Reproducibility Assessment, Empirical Software Engineering (2019) doi:10.1007/s10664-019-09747-0. This data set reports the meta-analysis results reported by the authors of the primary studies included in the systematic review that reported results on a per document basis which for S7 and S11 was equivalent to reporting the results for each time period.

Usage

KitchenhamMadeyskiBrereton.ABBAMetaAnalysisReportedResults

Format

A text file with variables:

- **Study**  This field includes the study identifier of each of the the 3 primary studies which reported results per document.
- **Type**  This identifies the type of effect size used by the study authors. d or g refer to d_IG and g_IG, P is the aggregated p values, if the repeated measures (RM) estimate was obtained it is appropriately specified.
- **Source** Always set to Rep. This identifies that the data was as reported by the primary study authors.
- **mean**  The overall mean effect size reported by the study authors
- **pvalue**  The one-sided p-value associated with the overall mean reported by the study authors. NA means the authors did not report this statistic.
- **UB**  The upper bound of the confidence interval of the overall mean as reported by the primary study authors. NA means the authors did not report this statistic.
- **LB**  The lower bound of the confidence interval of the overall mean as reported by the primary study authors. NA means the authors did not report this statistic.
- **QE**  The heterogeneity statistic associated with the meta-analysis as reported by the study authors. NA means the authors did not report this statistic.
- **Qep**  The p-value of the heterogeneity statistic associated with the meta-analysis as reported by the study authors. NA means the authors did not report this statistic.

KitchenhamMadeyskiBrereton.ABBAReportedEffectSizes

Description

This data is used in the paper: Barbara Kitchenham, Lech Madeyski and Pearl Brereton. Meta-analysis for Families of Experiments: A Systematic Review and Reproducibility Assessment. Empirical Software Engineering (2019) doi:10.1007/s10664-019-09747-0. This file holds the descriptive data for each document and each experiment for studies 3, 7 and 11 which include the mean, standard deviation and sample size for the control and treatment techniques. These studies performed ABBA crossover experiments and reported data for each document separately. Note Study 3 also undertook an independent groups study but data from that experiment is held in the ExpData file.

Usage

KitchenhamMadeyskiBrereton.DocData

Format

A text file with variables:

Study This field includes the study identifier of each of the 3 primary studies which reported their basic statistics on a time period & document basis.

Exp This identifies the experiment to which the descriptive data belongs.

Doc This identifies whether the data arose from the document used in the first or second time period. The value ‘Doc1’ identifies the data as coming from the first document or first time period. The value ‘Doc2’ identifies the data as coming from the second time period or document. Note for Study 3 we used the analysis of a specific document that was used in all 4 ABBA experiments. For studies 7 and 11, the authors identified which we used in r=each time period and Doc1 refers to data from the first time period.

Mc The mean value of the observations obtained using the control technique for the identified document.

SDc The standard deviation of the observations obtained using the control technique for the identified document.

Nc The number of participants using the control technique in the first time period for the identified document.
\textbf{Mt} The mean value of the observations obtained using the treatment technique for the identified document.

\textbf{SDT} The standard deviation of the observations obtained using the treatment technique for the identified document.

\textbf{Nt} The number of participants using the treatment technique in the first time period for the identified document.

Description

Usage

KitchenhamMadeyskiBudgen16.COCOMO

Format

A data frame with variables:

Project Project ID
Type A categorical variable describing the type of the project
Year The year the project was completed
Lang A categorical variable describing the development language used
Rely Ordinal value defining the required software reliability
Data Ordinal value defining the data complexity / Data base size
Cplx Ordinal value defining the complexity of the software / Process complexity
Aaf ??
**Time**  Ordinal value defining the stringency of timing constraints / Time constraint for cpu

**Stor**  Ordinal value defining the stringency of the data storage requirements / Main memory constraint

**Virt**  Virtual Machine volatility

**Turn**  Turnaround time

**Type2**  A categorical variable defining the hardware type: mini, max=mainframe, midi

**Acap**  Ordinal value defining the analyst capability

**Aexp**  Ordinal value defining the analyst experience / application experience

**Pcap**  Ordinal value defining the programming capability of the team / Programmers capability

**Vexp**  Ordinal value defining the virtual machine experience of the team

**Lexp**  Ordinal value defining the programming language experience of the team

**Cont ??**

**Modp**  / Modern programming practices

**Tool**  Ordinal value defining the extent of tool use / Use of software tools

**ToolCat**  Recoding of Tool to labelled ordinal scale

**Sced**  Ordinal value defining the stringency of the schedule requirements / Schedule constraint

**Rvol**  Ordinal value defining the requirements volatility of the project

**Select**  Categorical value calculated by BAK for an analysis example

**Rvolcat**  Recoding of Rvol to a labelled ordinal scale

**Modecat**  Mode of the projects: O=Organic, E=Embedded, SD-Semi-Detached

**Mode1**  Dummy variable calculated by BAK: 1 if the project is Organic, 0 otherwise

**Mode2**  Dummy variable calculated by BAK: 1 if the project is Semi-detached, 0 otherwise

**Mode3**  Dummy variable calculated by BAK: 1 if the project is Embedded, 0 otherwise

**KDSI**  Product Size Thousand of Source Instructions

**AKDSI**  Adjusted Product Size for Project in Thousand Source Instructions - differs from KDSI for enhancement projects

**Effort**  Project Effort in Man months

**Duration**  Duration in months

**Productivity**  Productivity of project calculated by BAK as AKDSI/Effort, so the the larger the value the better the productivity

Description

Usage

KitchenhamMadeyskiBudgen16.FINNISH
Format

A data frame with variables:

**Project**  Project ID

**DevEffort**  Development Effort measured in hours

**UserEffort**  Effort provided by the customer/user organisation measured in hours

**Duration**  Project duration measured in months

**HWType**  A categorical variable defining the hardware type

**AppType**  A categorical variable defining the application type

**FP**  Function Points measured using the TIEKE organisation method

**Co**  A categorical variable defining the company

Details

Data set collected from 9 Finish companies by Mr Hanna Maki from the TIEKE organisation see Barbara Kitchenham and Kari Kansala, Inter-item correlations among function points, Proceedings ICSE 15, 1983, pp 477-480

Description

Usage

KitchenhamMadeyskiBudgen16.PolishData
Format

A data frame with variables:

- **Abstract**  The abstract identifier
- **Site** Numeric identifier for the site
- **Treatment** The first three characters of the Abstract field which identifies the journal and time period of the abstract
- **Journal** An acronym for the journal from which the abstract was obtained: IST or JSS
- **Timeperiod** The Time period in which the abstract was found: 1 or 2
- **J1** The identifier for the judge who made the next 2 assessments
- **J1Completeness** The average completeness made by judge J1 based on the 8 completeness questions
- **J1Clarity** The clarity assessment made by judge J1
- **J2** The identifier for the judge who made the next 2 assessments
- **J2Completeness** The average completeness made by judge J2 based on the 8 completeness questions
- **J2Clarity** The clarity assessment made by judge J2
- **J3** The identifier for the judge who made the next 2 assessments
- **J3Completeness** The average completeness made by judge J3 based on the 8 completeness questions
- **J3Clarity** The clarity assessment made by judge J3
- **J4** The identifier for the judge who made the next 2 assessments
- **J4Completeness** The average completeness made by judge J4 based on the 8 completeness questions
- **J4Clarity** The clarity assessment made by judge J4
- **MedianCompleteness** The median of J1Completeness, J2Completeness, J3Completeness, J4Completeness
- **MedianClarity** The median of J1Clarity, J2Clarity, J3Clarity, J4Clarity

Details

Data set derived from PolishSubjects data set collected at Wroclaw University. It summarizes the completeness and clarity data collected from 4 judges about the same abstract.

**Description**

**Usage**

*KitchenhamMadeyskiBudgen16.PolishSubjects*

**Format**

A data frame with variables:

- **Judge**  The identifier for each subject
- **Abstract**  The identifier for each abstract - the code starts with a three alphanumeric string that defines the source of the abstract
- **OrderViewed**  Each judge assessed 4 abstracts in sequence, this data item identifies the order in which the subject viewed the specified abstract
- **Completness1**  Assessment by judge of question 1: Is the reason for the project clear? Can take values: Yes/No/Partly
- **Completness2**  Assessment by judge of question 2: Is the specific aim/purpose of the study clear? Can take values: Yes/No/Partly
- **Completness3**  Assessment by judge of question 3: If the aim is to describe a new or enhanced software technology (e.g. method, tool, procedure or process) is the method used to develop this technology defined? Can take values: Yes/No/Partly/NA
- **Completness4**  Assessment by judge of question 4: Is the form (e.g. experiment, general empirical study, data mining, case study, survey, simulation etc.) that was used to evaluate the technology made clear? Can take values: Yes/No/Partly
- **Completness5**  Assessment by judge of question 5: Is there a description of how the evaluation process was organised? Can take values: Yes/No/Partly
- **Completness6**  Assessment by judge of question 6: Are the results of the evaluation clearly described? Can take values: Yes/No/Partly
- **Completness7**  Assessment by judge of question 7: Are any limitations of the study reported?: Yes/No/Partly
- **Completness8**  Assessment by judge of question 8: Are any ideas for future research presented?: Yes/No/Partly
Clarity  Assessment by judge of question regarding the overall understandability of the abstract: Please give an assessment of the clarity of this abstract by circling a number on the scale of 1-10 below, where a value of 1 represents Very Obscure and 10 represents Extremely Clearly Written.

Completeness1NumValue  A numerical value for completeness question 1 where 0=No, Partly=0.5, yes =1
Completeness2NumValue  A numerical value for completeness question 2 where 0=No, Partly=0.5, yes =1, NA means not applicable
Completeness3NumValue  A numerical value for completeness question 3 where 0=No, Partly=0.5, yes =1, NA means not applicable or not answered
Completeness4NumValue  A numerical value for completeness question 4 where 0=No, Partly=0.5, yes =1, NA means not applicable
Completeness5NumValue  A numerical value for completeness question 5 where 0=No, Partly=0.5, yes =1, NA means not applicable
Completeness6NumValue  A numerical value for completeness question 6 where 0=No, Partly=0.5, yes =1, NA means not applicable
Completeness7NumValue  A numerical value for completeness question 7 where 0=No, Partly=0.5, yes =1, NA means not applicable
Completeness8NumValue  A numerical value for completeness question 8 where 0=No, Partly=0.5, yes =1, NA means not applicable

Sum  The sum of the numerical completeness questions excluding those labelled NA
TotalQuestions  The count of the number of question related to completeness excluding questions considered not applicable
Completeness  Sum/TotalQuestions

Details
Data set collected at Wroclaw University of Technology (POLAND) by Lech Madeyski includes separate entries for each abstract assessed by a judge, that is 4 entries for each judge. Data collected from 16 subjects recruited from Wroclaw University of Technology who were each asked to assess 4 abstracts.

Note Only completeness question 2 was expected to be context dependent and have a NA (not applicable) answer, if other completeness answers were left blank, BAK coded the answer as NA

Description

Usage

KitchenhamMadeyskiBudgen16.SubjectData

Format

A data frame with variables:

- **Judge**: Alphanumeric identifier for each judge
- **Institution**: Numerical value identifying each site from which data was collected
- **JudgeID**: Numerical value identifying each judge
- **Age**: Age of the judge in years
- **Eng1st**: Whether the judge's first language was English: Yes/No
- **YearsStudy**: The number of years have student been studying computing at University: 1, 2, 3, 4
- **AbstractsRead**: Number of abstracts the judge had read prior to the study: 0, 1 to 10, 10+
- **AbstractsWritten**: Whether the judge had ever written an abstract for a scientific report/article
- **AbstractID**: Alphanumeric identifier for an abstract. The first character identifies the journal, I=IST, J=JSS, the third digit identifies the time period as 1 or 2, the remaining digits identify the abstract number within the set of abstracts found for the specified journal and time period
- **Treat**: The initial 3 characters of AbstractID
- **TreatID**: A numeric identifier for the journal and time period, 1=IB1, 2=IB2, 3=JB1, 4=JB2
- **Order**: The order in which the judge should have viewed the specified abstract
- **Completness1NumValue**: The numeric answer to completeness question 1
- **Completness2NumValue**: The numeric answer to completeness question 2
- **Completness3NumValue**: The numeric answer to completeness question 3
- **Completness4NumValue**: The numeric answer to completeness question 4
- **Completness5NumValue**: The numeric answer to completeness question 5
- **Completness6NumValue**: The numeric answer to completeness question 6
- **Completness7NumValue**: The numeric answer to completeness question 7
### completeness8NumValue
The numeric answer to completeness question 8

### Clarity
The response to the clarity question or NA if not answered

### NumberOfAnsweredCompletenessQuestions
The number of completeness questions excluding those with NA

### TotalScore
Sum of the numeric values of the 8 completeness questions

### MeanScore
Sum of the completeness questions 1 to 8 divided by TotalScore

### Site
The name of the site which provided the data. HongKong refers to the Polytechnic University, HongKong.2 refers to the City University

#### LaplaceDist

**Description**

Returns a sample of N observations from a Laplace distribution with specified mean and spread.

**Usage**

LaplaceDist(N, mean, spread, max = 0.5, min = -0.5)

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>is the required sample size</td>
</tr>
<tr>
<td>mean</td>
<td>is the required mean</td>
</tr>
<tr>
<td>spread</td>
<td>is the spread of the function</td>
</tr>
<tr>
<td>max</td>
<td>the upper limit of the distribution. Must be finite.</td>
</tr>
<tr>
<td>min</td>
<td>the lower limit of the distribution. Must be finite.</td>
</tr>
</tbody>
</table>
Value

N values from a Laplace distribution

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

```r
set.seed(123)

# [8] 1.53636446 0.10855453 -0.09076809
```

Description

Usage

Madeyski15EISEJ.OpenProjects

Format

A data frame with variables:

- **PROP** The percentage of classes of proprietary (i.e., industrial) projects that must be tested in order to find 80% of defects in case of software defect prediction models built on open source projects.

- **NOTOPEN** The percentage of classes of projects which are not open source projects that must be tested in order to find 80% of defects in case of software defect prediction models built on open source projects.

- **STUD** The percentage of classes of student (i.e., academic) projects that must be tested in order to find 80% of defects in case of software defect prediction models built on open source projects.

- **OPEN** The percentage of classes of open source projects that must be tested in order to find 80% of defects in case of software defect prediction models built on open source projects.
Details

This paper presents an analysis of 84 versions of industrial, open-source and academic projects. We have empirically evaluated whether those project types constitute separate classes of projects with regard to defect prediction. The predictions obtained from the models trained on the data from the open source projects were compared with the predictions from the other models (built on proprietary, i.e. industrial, student, open source, and not open source projects).

Examples
Madeyski15EISEJ.StudProjects
Description

Usage

Madeyski15SQJ.NDC

Format

A data frame with variables:

- **Project** In case of open source projects this field includes the name of the project as well as its version. In case of industrial projects this field includes the string 'proprietary' (we were not allowed to disclose the names of the analyzed industrial software projects developed by Capgemini Polska).

- **simple** The percentage of classes that must be tested in order to find 80% of defects in case of simple defect prediction models, i.e., using only software product metrics as predictors.

- **advanced** The percentage of classes that must be tested in order to find 80% of defects in case of advanced defect prediction models, using not only software product metrics but also the NDC (Number of distinct committers) process metric.

Details

'This paper presents an empirical evaluation in which several process metrics were investigated in order to identify the ones which significantly improve the defect prediction models based on product metrics. Data from a wide range of software projects (both, industrial and open source) were collected. The predictions of the models that use only product metrics (simple models) were compared with the predictions of the models which used product metrics, as well as one of the process metrics under scrutiny (advanced models). To decide whether the improvements were significant or not, statistical tests were performed and effect sizes were calculated. The advanced defect prediction models trained on a data set containing product metrics and additionally Number of Distinct Committers (NDC) were significantly better than the simple models without NDC, while the effect size was medium and the probability of superiority (PS) of the advanced models over simple ones was high (p=.016, r=-.29, PS=.76), which is a substantial finding useful in defect prediction. A similar result with slightly smaller PS was achieved by the advanced models trained on a data set containing product metrics and additionally all of the investigated process metrics (p=.038, r=-.29, PS=.68). The advanced models trained on a data set containing product metrics and additionally Number of Modified Lines (NML) were significantly better than the simple models without NML, but the effect size was small (p=.038, r=.06). Hence, it is reasonable to recommend the NDC process metric in building the defect prediction models.' [https://dx.doi.org/10.1007/s11219-014-9241-7]

Description

If you use this data set please cite this R package and the paper where we analyze the data set:

Usage

MadeyskiKitchenham.EUBASdata

Format

A data frame with variables:

**ID**  Project ID

**TimePeriod**  Period of time (run): R1, R2

**SequenceGroup**  Sequence group: G1, G2, G3, G4

**System**  Software system identifier indicates the system (i.e., S1 or S2) used as the experimental object: S1. A software system to sell and manage CDs/DVDs in a music shop, S2. A software system to book and buy theater tickets

**Technique**  The independent variable. It is a nominal variable that can assume the following two values: AM (analysis models plus source code) and SC (source code alone)

**Comp_Level**  This denotes the comprehension level of the source code achieved by a software engineer

**Modi_Level**  This denotes the capability of a maintainer to modify source code
Details

Data set comes from an experiment conducted in Italy at the University of Basilicata (with 24 first-year students from the Master's Program in Computer Science) to answer the question 'Do the software models produced in the requirements analysis process aid in the comprehensibility and modifiability of source code?', see G. Scanniello, C. Gravino, M. Genero, J. A. Cruz-Lemus, and G. Tortora, 'On the Impact of UML Analysis Models on Source-code Comprehensibility and Modifiability,' ACM Transactions on Software Engineering and Methodology, vol. 23, pp. 13:1-13:26, Apr. 2014. However, the inconsistent subject data for subject 2 was removed, see the aforementioned paper by Madeyski and Kitchenham.

MadeyskiKitchenham.EUBASdata

MadeyskiKitchenham.MetaAnalysis.PBRvsCBRorAR data

Description

Data form a set of primary studies on reading methods for software inspections. They were analysed by Lech Madeyski and Barbara Kitchenham, 'How variations in experimental designs impact the construction of comparable effect sizes for meta-analysis', 2015.

Usage

MadeyskiKitchenham.MetaAnalysis.PBRvsCBRorAR

Format

A data frame with 17 rows and 26 variables:

Study Name of empirical study
Ref. Reference to the paper reporting primary study or experimental run where data were originally reported
Teams The number of teams including both, PBR and Control teams
DesignDesc Experimental design description: Before-after, Between-groups, Cross-over
ExpDesign Experimental design: between-groups (BG), within-subjects cross-over (WSCO), within-subjects before-after (WSBA)
M_PBR The average proportion of defects found by teams using PBR
M_C  The average proportion of defects found by teams using Control treatment: Check-Based Reading (CBR) or Ad-Hoc Reading (AR)

Diff  The difference between M_PBR and M_C, i.e. Diff = M_PBR - M_C

Inc  The percentage increase in defect rate detection, i.e. Inc=100*[\( \frac{M_{PBR}-M_C}{M_C} \)]

SD_C_ByAuthors  The standard deviation of the control group values reported by the original Authors, i.e., obtained from the papers/raw data

SD_C  The standard deviation of the control group values equals SD_C_ByAuthors for studies for which the data was available OR the weighted average of SD_C_ByAuthors (i.e., 0.169) for studies where SD_C_ByAuthors is missing.

V_C  The variance of the Control group observations, i.e., the variance obtained from the teams using the Control method V_C=SD_C^2

V_D  The variance of the unstandardized mean difference D (between the mean value for the treatment group and the mean value for the Control group)

SD_C_Alt  This is the equivalent of SD_C (the standard deviation of the control group) based on a different variance for the student studies or the practitioner studies depending on the subject type of the study with the missing value.

V_Alt  The variance of the mean difference in the meta-analysis based on SD_C_Alt

SS_C  The sum of squares of the Control group values. For within subjects studies SS=V_C*(n-1). For between subjects studies SS=V_C*(n_C-1)

n_PBR  The number of PBR teams

n_C  The number of Control (CBR or AR) teams

ControlType  Type of Control treatment: CRB or AR

ParticipantsType  Type of participants: Engineers or Students

TeamType  Type of team: Nominal or Real

TwoPersonTeamVsLargerTeam  Reflects size of the teams: 2-PersonTeam or LargerTeam

ArtefactType  The type of artefact: Requirements or Other

AssociatedWithBasili  Whether study is associated with Basili (the forerunner): Yes or No

ControlType_Basili  Combined ControlType and AssociatedWithBasili: AH_AssociatedWithBasili, CBR_AssociatedWithBasili, CBR_NotAssociatedWithBasili

Details

Description
Implements analysis of small sample size experiments based on Hedges and Olkin p128-131.

Usage
metaanalyseSmallSampleSizeExperiments(d, f, A)

Arguments
d  a vector of standardized mean differences for different experiments (not adjusted for small sample size)
f  a vector defining the degrees for each experiment
A  a vector defining the relationship between d and its related t value for each experiment
MetaAnalysisSimulations

**Value**

- **UnweightedMean** The unweighted mean of the small size adjusted standardized mean differences
- **WeightedMean** The weighted mean of the small size adjusted standardized mean differences
- **VarWeightedMean** The variance of the weighted mean

**Author(s)**

Barbara Kitchenham and Lech Madeyski

**Examples**

```r
d=c(0.461, 0.782, 0.513, -0.131, -0.018, 0.774, 0.138, -0.482, 0.333, 0.701, -0.222, 0.399, 0.538, -0.19, 0.833, 0.512, 0.001, -0.366, 0.510)

metaanalyseSmallSampleSizeExperiments(d,f,A)
```

**Description**

This function simulates data from many families of experiments. The number of families simulated is defined by the Replications parameter. The parameter Exp determines the number of experiments in each family. The function simulates data from one of four distributions and uses the data to construct two of groups of equal size (GroupSize). The experimental design of individual experiments in each family is determined by the FourGroup parameter. If FourGroup=FALSE, the basic experimental design is a balanced two group randomized experiment, otherwise the experimental design is a balanced four group experiment corresponding to a randomized blocks experiment. The function calls either NP2GMetaAnalysisSimulation or NP2GMetaAnalysisSimulation to generate and analyse data for each individual family. The function either returns the meta-analysed data from each experiment or provides summary statistics.

**Usage**

```r
MetaAnalysisSimulations(
  mean = 0,
  sd = 1,
  diff = 0.5,
  GroupSize = 10,
  type = "n",
  Replications = 50,
  Exp = 5,
  seed = 456,
  alpha = 0.05,
)```
FourGroup = FALSE,
StdAdj = 0,
BlockEffect = 0,
BlockStdAdj = 0,
StdExp = 0,
MAMethod = "PM",
returnES = FALSE,
AlwaysTwoSidedTests = FALSE
)

Arguments

mean  
the value used for the mean of control group in the simulated data. It can be any real number including zero.

sd  
the value used for the spread of the control group and the spread of the treatment group in the simulated data. The value must be a real value greater than 0.

diff  
mean+diff is the value used for the mean of the treatment group. It can be zero.

GroupSize  
is the size of each of the groups comprising one experiment. Groupsize should be an integer of 4 or more

type  
specifies the distribution being simulated. The permitted values are 'n' for the normal distribution (default), 'l' for the lognormal distribution, 'g' for the gamma distribution and 'lap' for the Laplace distribution.

Replications  
The number of times the set of experiments is simulated.

Exp  
is the number of experiments in each family of experiments being simulated. Exp should be an integer of 2 or more (default 5).

seed  
specifies the seed to be used to initiate the simulation, so the simulation is repeatable.

alpha  
The significance level used for tests and confidence intervals (default 0.05)

FourGroup  
is a Boolean variable that determines whether the experiment is a two group experiments or a 4-Group randomised block experiment. It defaults to FALSE which means a two-group experiment is the default condition

StdAdj  
If non-zero that can be used to introduced variability into the treatment spread/variance (default 0). Not appropriate for gamma data.

BlockEffect  
A factor used to change the mean difference between blocks (default 0.5)

BlockStdAdj  
if non-zero this can be used to change the BlockEffect from a fixed to random effect (default 0).

StdExp  
if non-zero it simulates a random effect between experiments in the same family (default 0).

MAMethod  
specifies the model to be used when experimental effect effect sizes ar aggregated using the R metafor package.

returnES  
if TRUE the function outputs the summary statistics otherwise it outputs the meta-analysis results for each family (default FALSE)
AlwaysTwoSidedTests

This parameter can be used to override the one-sided tests used as default if the
diff parameter is non-zero (default FALSE). This should only be set to TRUE
to check simulation reported in other papers that seem to have used two-sided
tests.

Value

The parameter either returns the meta-analysis values obtained from each family or the average
values of the meta-analysis over all replications.

Description

This function simulates data from a family of experiments. The parameter Exp determines the number of experiments in the family. The function simulates data from one of four distributions and uses the data to construct two of groups of equal size (GroupSize). The distribution for one of the groups corresponds to the control and is based on the given mean and spread, the distribution for the other group corresponds to the treatment group and is based on the mean+diff and the spread plus any variance adjustment requested (determined by the parameter StdAdj). The data from each experiment is analysed separately to estimate three non-parametric effect sizes: the Cliff’s d and the probability of superiority referred to as phat and their variances. Parametric effect sizes Cohen’s d (also known as the standardized means difference, SMD) and the small sample size adjusted standardized mean difference g are also calculated together with their variances. The effect sizes are then meta-analysed using various methods: the simple average of the effect size and the variance weighted averages (using the exact and approximate normal variance and the weighted and unweighted standardized mean difference). The function uses the metafor package for formal meta-analysis, and the specific method of formal meta-analysis used is determined by the MAMethod.
All tests of significance are done at the 0.05 level. If the parameter returnES is TRUE, the function returns the effect sizes for each experiment in the family, otherwise it returns the meta-analysis results.

**Usage**

```r
NP2GMetaAnalysisSimulation(
  mean,
  sd,
  diff,
  GroupSize,
  Exp = 5,
  type = "n",
  StdAdj = 0,
  alpha = 0.05,
  seed = 123,
  StdExp = 0,
  MAMethod,
  returnES = FALSE,
  AlwaysTwoSidedTests = FALSE
)
```

**Arguments**

- `mean`: the value used for the mean of control group in the simulated data. It can be any real number including zero.
- `sd`: the value used for the spread of the control group and the spread of the treatment group in the simulated data. The value must be a real value greater than 0.
- `diff`: mean+diff is the value used for the mean of the treatment group. It can be zero.
- `GroupSize`: is the size of each of the 2 groups comprising one experiment. Groupsize should be an integer of 4 or more.
- `Exp`: is the number of experiments being simulated. Exp should be an integer of 2 or more. It defaults to 5.
- `type`: specifies the distribution being simulated. The permitted values are 'n' for the normal distribution, 'l' for the lognormal distribution, 'g' for the gamma distribution and 'lap' for the Laplace distribution. The parameter defaults to 'n'.
- `StdAdj`: specifies a level used to adjust the treatment variance. It allows heterogeneity to be modelled. It defaults to zero meaning no variance heterogeneity is introduced.
- `alpha`: the Type 1 error rate level use for statistical tests (default 0.05).
- `seed`: specifies the seed to be used to initiate the simulation, so the simulation is repeatable. It defaults to 123.
- `StdExp`: if non-zero it simulates a random effect between experiments in the same family (default 0).
- `MAMethod`: the meta-analysis method needed for the call to the metafor package rma algorithm.
\textbf{returnES} \hspace{1cm} \text{Determines the format of the output. It defaults to FALSE which causes the function to output the meta-analysis results for the family of experiments. If set to TRUE it returns the effect sizes for each experiment.}

\textbf{AlwaysTwoSidedTests} \hspace{1cm} \text{If FALSE the function performs one-sided tests if diff! = 0, and two-sided tests if diff = 0. If set to TRUE the function always does two-sided tests (default: \texttt{AlwaysTwoSidedTests}=FALSE).}

\textbf{Value} \hspace{1cm} \text{Depending on the value of the \texttt{returnES} parameter, the function either returns the effect sizes for each experiment or the aggregated results for the family}

\text{NP4GMetaAnalysisSimulation}

\textit{NP4GMetaAnalysisSimulation}

\textbf{Description} \hspace{1cm} \text{This function simulates data from a family of experiments, where the number of experiments in a family is defined by the parameter \texttt{Exp}. It simulates data from one of four distributions and uses the data to construct four of groups of equal size (\texttt{GroupSize}). Two groups are assigned as control groups and their distribution is based on the parameter, mean, and the parameter, spread. However, the mean and spread for the control group in Block 2 can be adjusted using the parameters}
BlockEffect and BlockStdAdj respectively. The other two groups are treatment groups and their
distribution is based on the mean+diff and the spread parameter, but the distributions can be adjusted
using the StdAdj, BlockEffect and BlockStdAdj parameters. The data from each experiment is
analysed separately to estimate the non-parametric statistics P-hat, Cliff’s d and their variances.
In addition, the estimates of the standardized mean difference and the small sample size adjusted
standardized mean difference are calculated. The effect size statistics are then meta-analysed using
the method specified by the MAMethod parameter. We output both the average non-parametric
effect statistics across the Exp experiment analysed as if they arose from a single large experiment and
also the results of meta-analysing each non-parametric effect size. We use the standard parametric
effect sizes and their meta-analysis as baselines. Tests of significance are one-sided if the mean
difference is non-zero. If the mean difference is zero, two-sided tests are used. In addition, the
user can force the use of two-sided tests using the parameter AlwaysTwoSidedTests. This should
only be used for comparison with results reported in other simulation studies. The alpha parameter
determines the significance level used in the tests.

Usage

NP4GMetaAnalysisSimulation(
  mean,
  sd,
  diff,
  GroupSize,
  Exp = 5,
  type = "n",
  alpha = 0.05,
  seed = 123,
  StdAdj = 0,
  BlockEffect = 0,
  BlockStdAdj = 0,
  StdExp = 0,
  MAMethod,
  returnES = FALSE,
  AlwaysTwoSidedTests = FALSE
)

Arguments

mean
  The default value used for the group means in the simulated data. It can be any
  real number including zero.

sd
  The default value used for the spread of the control group and the spread of the
treatment group in the simulated data. The value must be a real value greater
  than 0.

diff
  mean+diff is the value used for the mean of the treatment group. It can be zero.

GroupSize
  is the size of each of the 4 groups comprising one experiment. Groupsize should
  be an integer of 4 or more

Exp
  is the number of experiments being simulated. Exp should be an integer of 2 or
  more. It defaults to 5.
type specifies the distribution being simulated. The permitted values are 'n' for the
normal distribution, 'l' for the lognormal distribution, 'g' for the gamma distribu-
tion and 'lap' for the Laplace distribution. The parameter defaults to 'n'.

alpha The Type 1 error rate level use for statistical tests (default 0.05).

seed specifies the seed to be used to initiate the simulation, so the simulation is re-
peatable. It defaults to 123.

StdAdj The value used to introduce heterogeneity into the treatment groups variance if
required.

BlockEffect is the effect of having two different blocks

BlockStdAdj is the variance associated with the Block. If BlockStdAdj is zero it means we
are treating the block effect as a fixed effect. If BlockStdAdj>0, we treat the
block effect as a random effect and increase the variance of Block 2 data.

StdExp if non-zero it simulates a random effect between experiments in the same family
(default 0).

MA Method defines the method used for meta-analysis

returnES This determines the format of the output. If returnES=FALSE it returns the
summary meta-analysis statistics otherwise it returns the effect sizes and their
variances for each experiment in the family

AlwaysTwoSidedTests
If this parameter is TRUE, the function always does two-sided tests. IF the
parameter is FALSE (i.e., default), the function does two-sided statistical tests
if the difference between treatment groups is 0, if the difference is not 0, it does
one-sided tests

Value
If returnES is FALSE, the function returns the summary meta-analysis summary statistics otherwise
the function returns the effect sizes for each experiment

percentageInaccuracyOfLargeSampleVarianceApproximation

Description

Plot the extent of inaccuracy using the large sample approximate effect size variance on 4 related graphs corresponding to the four different correlation values. Plot visualizes the relationship between sample size and effect size and the percentage inaccuracy of the large sample variance approximation. Function is used in a paper 'Effect Sizes and their Variance for AB/BA Crossover Design Studies' by Lech Madeyski and Barbara Kitchenham.

Usage

percentageInaccuracyOfLargeSampleVarianceApproximation(data)

Arguments

data - data behind the plot returned by getSimulatedCrossoverDataSets() or stored in reproducer::KitchenhamMadeyski.SimulatedCrossoverDataSets

Value

plot described in description

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

data <- KitchenhamMadeyski.SimulatedCrossoverDataSets
myPlot <- percentageInaccuracyOfLargeSampleVarianceApproximation(data)
**Description**

This function provides single-sided and two-sided tests of the probability of superiority (phat).

**Usage**

`PHat.test(x, y, alpha = 0.05, alternative = "two.sided", sigfig = -1)`

**Arguments**

- `x`: The data from one group
- `y`: The data from the alternative group
- `alpha`: The significance level of tests which also controls the values of the confidence interval (default 0.05)
- `alternative`: This defines whether a one-sided test or a two-sided (default) test is required. For a one-sided test use parameter values greater’ or ‘less’ to define whether the d-value should be greater or less than zero.
- `sigfig`: is the number of significant digits in the data.

**Value**

The values of phat and its standard error, the t-value, its pvalue and the upper and lower confidence interval.

**Author(s)**

Barbara Kitchenham and Lech Madeyski

**Examples**

```r
data <- set.seed(456)
x <- rnorm(10, 0, 1)
y <- rnorm(10, 0.8, 1)
PHat.test(x, y, alpha = .05, alternative = "greater", sigfig = -1)
# A tibble: 1 x 8
#  phat sqse.phat phat.df phat.tvalue phat.pvalue phat.ci.lower phat.ci.upper phat.sig
#1 0.79 0.0118 13.6 2.67 0.00924 0.599 1 TRUE

PHat.test(x, y, alpha = .05, alternative = "two.sided", sigfig = -1)
# A tibble: 1 x 8
#  phat sqse.phat phat.df phat.tvalue phat.pvalue phat.ci.lower phat.ci.upper phat.sig
#1 0.79 0.0118 13.6 2.67 0.0185 0.557 1 TRUE
```
Description

Function to plot a figure on the outcomes for individuals in each sequence group used in a paper 'Effect Sizes and their Variance for AB/BA Crossover Design Studies' by Lech Madeyski and Barbara Kitchenham

Usage

plotOutcomesForIndividualsInEachSequenceGroup(
  var,
  covar,
  meanA1,

Examples

myPlot <- plotOutcomesForIndividualsInEachSequenceGroup(25, 18.75, 50, 10, 5, 15)
Description

This function calculates the standardized effect sizes and their confidence intervals, the equivalence point biserial effect size and the $Z_r$ and $\text{var}(Z_r)$ needed for input into the metafor rma function (meta analysis). In this function the point bi-serial effect size is based on the adjusted Hedges g value. The function uses the Hedges g to r transformation to prepare for meta-analysing the data where the mean values, the standard deviations, and the number of observations are available.

Usage

```r
PrepareForMetaAnalysisGtoR(Mc, Mt, SDc, SDt, Nc, Nt)
```

Arguments

- `Mc` is a vector containing the mean value of the control group for each experiment.
- `Mt` is a vector containing the mean value of the treatment group for each experiment.
- `SDc` is a vector of the standard deviations of the control group for each experiment.
- `SDt` is a vector of the standard deviations of the the treatment group for each experiment.
- `Nc` is a vector containing the the number of observations (participants) in the control group for each experiment.
- `Nt` is a vector of the number of observations (participants) in the treatment group for each experiment.

Value

data frame incl. calculated effect sizes (Hedges’ g, Hedges’ g adjusted), upper and lower confidence bounds on Hedges’ g, $Z_r$, $\text{var}(Z_r)$, r and pvalue

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

```r
PrepareForMetaAnalysisGtoR(c(10, 10), c(12, 14), c(4, 4), c(4, 4), c(20, 20), c(40, 40))
```

```
printXTable

Description

print data table using xtable R package

Usage

printXTable(
  data,
  selectedColumns,
  tableType = "latex",
  alignCells,
  digits,
  caption,
  label,
  fontSize,
  captionPlacement = "bottom",
  alignHeader
)

Arguments

data             Data structure including columns to be printed.
selectedColumns  Columns selected to be printed.
tableType        Type of table to produce. Possible values are 'latex' or 'html'. Default value is 'latex'.
alignCells       Defines how to align data cells.
digits           Defines the number of decimal points in each column.
caption          Caption of the table.
label            Label of the table.
fontSize         Size of the font used to produce a table.
captionPlacement The caption will be have placed at the bottom of the table if captionPlacement is 'bottom' and at the top of the table if it equals 'top'. Default value is 'bottom'.
alignHeader       Defines how to align column headers of a table.

Value

A table generated on the fly on a basis of passed data (data, selectedColumns etc.).

Author(s)

Lech Madeyski
**Examples**

```r
d <- reproduc:::MadeyskiKitchenham.MetaAnalysis.PBRvsCBRorAR
printXTable(d, "Study", "latex", "cc", 0, "C", "L", "tiny", "top", "l")
```

**Description**

Plots visualize the relationship between sample size, effect size and the proportion of significant t-values using the correct analysis. Function is used in a paper 'Effect Sizes and their Variance for AB/BA Crossover Design Studies' by Lech Madeyski and Barbara Kitchenham.

**Usage**

```r
proportionOfSignificantTValuesUsingCorrectAnalysis(data)
```

**Arguments**

- `data` - data behind the plot returned by `getSimulatedCrossoverDataSets()` or stored in `reproducer::KitchenhamMadeyski.SimulatedCrossoverDataSets`

**Value**

plot described in description

**Author(s)**

Barbara Kitchenham and Lech Madeyski

**Examples**

```r
data <- KitchenhamMadeyski.SimulatedCrossoverDataSets
myPlot <- proportionOfSignificantTValuesUsingCorrectAnalysis(data)
```
proportionOfSignificantTValuesUsingIncorrectAnalysis

Description

Plots visualize the relationship between sample size, effect size and the proportion of significant t-values using the incorrect analysis. Function is used in a paper 'Effect Sizes and their Variance for AB/BA Crossover Design Studies' by Lech Madeyski and Barbara Kitchenham.

Usage

proportionOfSignificantTValuesUsingIncorrectAnalysis(data)

Arguments

data - data behind the plot returned by getSimulatedCrossoverDataSets() or stored in reproducer::KitchenhamMadeyski.SimulatedCrossoverDataSets

Value

plot described in description

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

data <- KitchenhamMadeyski.SimulatedCrossoverDataSets
myPlot <- proportionOfSignificantTValuesUsingIncorrectAnalysis(data)

Description

This function performs multiple simulations of two-group balanced experiments for one of four distributions and a specific group size. It identifies the average value of phat, Cliff’ d and their variances. It either returns the effect sizes for each non-parametric effect size or it reports the number of times the each non-parametric effect size is assessed to be significantly different from zero. We also present the values for the t-test as a comparison. For log-normal data the results of analysing the transformed data are also reported.
Usage

RandomExperimentSimulations(
    mean,
    sd,
    diff,
    N,
    reps,
    type = "n",
    seed = 123,
    StdAdj = 0,
    alpha = 0.05,
    returnData = FALSE,
    AlwaysTwoSidedTests = FALSE
)

Arguments

mean  The default mean used for both groups (one treatment group and one control group). It can be changed for the treatment group using the parameter diff
sd    This is the default spread for both groups. It must be a real value greater than 0. It can be adjusted for the treatment group using the parameter StdAdj
diff  This is added to the treatment group mean. It can be a real value and can take the value zero.
N     this is the number of observations in each group. It must be an integer greater than 3.
reps  this identifies the number of times each experiment simulation is replicated.
type  this specifies the underlying distribution used to generate the data. It takes the values ‘n’ for a normal distribution, ‘l’ for lognormal distribution, ‘g’ for a gamma distribution, ‘lap’ for a Laplace distribution.
seed  This specifies the initial seed for the set of replications (default 123).
StdAdj this specifies the extent of variance instability introduced by the treatment and it must be non-negative but can be 0.
alpha This specifies the level of significance used for statistical tests (default 0.05).
returnData If TRUE, the function returns the individual effect sizes and their variances, otherwise it returns summary statistics (default FALSE).
AlwaysTwoSidedTests If set to FALSE (default) the algorithms uses one-sided tests if diff!=0 and two-sided tests if diff=0. If set to TRUE the algorithm always uses two-sided tests.

Description

This function finds the theoretical effect sizes for a four-group randomized block experiments assuming one of four different underlying distributions specified by the type parameter. The design assumes two blocks each comprising a control and treatment group. If required a fixed Blocking effect is added to the mean for Block 2.

Usage

RandomizedBlockDesignEffectSizes(
m1, std1, m2, std2, m3, std3, m4, std4, BE = 0, type = "n"
)

Arguments

m1 The theoretical mean for the control group in Block 1
std1 The theoretical variance for the control group in Block 1
m2 The theoretical mean for the treatment group in Block 1
std2 The theoretical variance for the treatment group in Block 1
m3 The theoretical mean for the control group in Block 2
std3 The theoretical variance for the control group in Block 2
m4 The theoretical mean for the treatment group in Block 2
std4 The theoretical variance for the treatment group in Block 2
BE A fixed block effect to be added to the Block 2 mean values.
type String identifying the distribution, 'n' for normal, 'ln' for lognormal, 'lap' for Laplace, 'g' for Gamma
Value
dataframe holing the expected unstandardized mean difference effect size, the pooled within group variance, the standardized effect size and the point bi-serial correlation.

Author(s)
Barbara Kitchenham and Lech Madeyski

Examples

```r
RandomizedBlockDesignEffectSizes(m1=0,std1=1,m2=1,std2=1,m3=0,std3=1,m4=1, 
  std4=1,BE = 1,type = 'n')
# ES Var StdES rPBS
#1 1 1 0.4472136
RandomizedBlockDesignEffectSizes(m1=0,std1=1,m2=1,std2=1,m3=0,std3=1,m4=1, 
  std4=1,BE = 1,type = 'l')
# ES Var StdES rPBS

RandomizedBlockDesignEffectSizes( 
  m1=0,std1=1,m2=0.266,std2=1,m3=0,std3=1,m4=0.266,std4=1,BE = 0,type = 'l')
# ES Var StdES rPBS
#1 0.5024232 6.310995 0.1999957 0.09950162
```

Description
The function performs a heteroscedastic test of a two treatment by J blocks randomized blocks effect size. The data are assumed to be stored in $x$ in list mode. All groups are assumed to be independent. Missing values are not permitted.

Usage

```r
RandomizedBlocksAnalysis( 
  x, 
  con = c(-0.5, 0.5, -0.5, 0.5), 
  alpha = 0.05, 
  alternative = "two.sided"
)
```

Arguments

- `x` the structure holding the data. In list format, for a 2 treatment by J block randomized blocks experiments, there are 2J list elements each one specifying the outcome for a specific block and a specific treatment.
**RandomizedBlocksAnalysis**

- `con` is a 2J list containing the contrast coefficients that are used to calculate the mean effect size.
- `alpha` is the Type 1 error level used for the test of significance (default 0.05)
- `alternative` is the type of statistical test. Valid values are one of c('two.sided', 'greater', 'less')

**Value**

The t-test and its associated metrics (i.e., critical value standard error and degrees of freedom) and the estimate of the contrast with its upper and lower confidence interval bounds and p-value.

**Author(s)**

Barbara Kitchenham and Lech Madeyski

**Examples**

**RandomizedBlocksExperimentSimulations**

**title** RandomizedBlocksExperimentSimulations
**description** This function performs multiple simulations of 4 group balanced randomised Block experiments with two control groups and two treatment groups where one control group and one treatment group are assigned to block 1 and the other control group and treatment group are assigned to block 2. The simulations are based on one of four distributions and a specific group size. The function identifies the average value of the non-parametric effect sizes $\hat{P}$, Cliff’s $d$ and their variances and whether or not the statistics were significant at the 0.05 level. We also present the values of the $t$-test as a comparison.

---

**Description**

Title RandomizedBlocksExperimentSimulations description This function performs multiple simulations of 4 group balanced randomised Block experiments with two control groups and two treatment groups where one control group and one treatment group are assigned to block 1 and the other control group and treatment group are assigned to block 2. The simulations are based on one of four distributions and a specific group size. The function identifies the average value of the non-parametric effect sizes $P$-hat, Cliff’s $d$ and their variances and whether or not the statistics were significant at the 0.05 level. We also present the values of the $t$-test as a comparison.

**Usage**

```r
RandomizedBlocksExperimentSimulations(
  mean,
  sd,
  diff,
```
N,
reps,
type = "n",
alpha = 0.05,
Blockmean = 0,
BlockStdAdj = 0,
StdAdj = 0,
seed = 123,
returnData = FALSE,
AlwaysTwoSidedTests = FALSE
)

Arguments

mean
The default mean for all 4 groups. The default for the two treatment groups can be altered using the parameter diff and the block mean for block 2 can be altered using the parameter Blockmean.

diff
The is is added to the parameter mean, to define the mean of the other treatment group. It can be a real value ad can take the value zero.

N
this is the number of observations in each group. It must be an integer greater than 3.

reps
this identifies the number of times the simulation is replicated.

type
this specifies the underlying distribution used to generate the data. it takes the values 'n' for a normal distribution, 'l' for lognormal distribution,'g' for a gamma distribution, 'lap' for a Laplace distribution.

alpha
is the Type 1 error level used for constructing confidence intervals and statistical tests (default 0.05)

Blockmean
is the effect of having two different blocks

BlockStdAdj
is the variance associated with the Block mean. If Blockvar is zero it means we are treat the block effect as a fixed effect. If BlockStdAdj>0, we treat the block effect as a random effect.

StdAdj
The value used to introduce heterogeneity into the treatment groups variance if required.

seed
this specifies the seed value for the simulations and allows the experiment to be repeated.

returnData
if TRUE the function returns the generated data otherwise it returns summary statistics.

AlwaysTwoSidedTests
A boolean variable. If TRUE the simulations always used two-sided tests otherwise the simulations use one-sided tests. return depending on the parameter returnData it returns the generated nonparametric and parametric values and their statistical significance (1 for significant, 0 for not significant) or the summary statistics (averages of effect sizes and their variances and the proportion significant effect sizes)
Examples

RandomizedDesignEffectSizes

Description

This function creates the theoretical effect sizes for data from one of four different distributions for specified parameter values for the distribution specified by the type parameter. It assumes there are two samples, one corresponding to a control group and the other to the treatment group. It returns the theoretical effect sizes for a fully randomized experiment.

Usage

RandomizedDesignEffectSizes(m1, std1, m2, std2, type = "n")

Arguments

m1
The theoretical mean for the control group
std1
The theoretical variance for the control group
m2
The theoretical mean for the treatment group
std2
The theoretical variance for the treatment group
type
String identifying the distribution, 'n' for normal, 'ln' for lognormal, 'lap' for Laplace, 'g' for Gamma

Value

dataframe containing the expected values of the unstandardized mean difference effect size, the pooled within group variance, the standardized mean difference effect size and the point bi-serial correlation.

Author(s)
Barbara Kitchenham and Lech Madeyski

Examples

RandomizedDesignEffectSizes(m1=0, std1=1, m2=1, std2=3, type = 'n')
# ES Var StdES rPBS
# 1 5.4472136 0.2182179

readExcelSheet

Description
Function reads data from an Excel file from a specified sheet

Usage
readExcelSheet(path, sheet, colNames)

Arguments
- **path**: Path to an Excel file, e.g. /User/lma/datasets/MyDataSet.xls
- **sheet**: Name of a sheet within an Excel file we want to read
- **colNames**: If TRUE, first row of data will be used as column names.

Author(s)
Lech Madeyski

Examples
myPath <- system.file("extdata", "DataSet.xlsx", package = "reproducer")
Madeyski15SQJ.NDC <- readExcelSheet(path = myPath, sheet = "Madeyski15SQJ.NDC", colNames = TRUE)

reproduceForestPlotRandomEffects

Description
Function reproduces Forest Plot of a Random-Effects Meta-analysis of Mean Differences.

Usage
reproduceForestPlotRandomEffects()

Author(s)
Lech Madeyski

Examples
reproduceForestPlotRandomEffects()
Description

Function reproduces Mixed-Effects Analysis using Subject Specific Estimated Variance with Experimental Design as a Moderator.

Usage

```
reproduceMixedEffectsAnalysisWithEstimatedVarianceAndExperimentalDesignModerator()
```

Author(s)

Lech Madeyski

Examples

```
reproduceMixedEffectsAnalysisWithEstimatedVarianceAndExperimentalDesignModerator()
```
**reproduceMixedEffectsForestPlotWithExperimentalDesignModerator()**

**Description**
Function reproduces Forest Plot of a Mixed Effects Meta-analysis of Mean Differences with Experimental Design as a Moderator Variable.

**Usage**
```r
reproduceMixedEffectsForestPlotWithExperimentalDesignModerator()
```

**Author(s)**
Lech Madeyski

**Examples**
```r
reproduceMixedEffectsForestPlotWithExperimentalDesignModerator()
```

---

**reproduceSimulationResultsBasedOn500Reps1000Obs()**

**Description**
Function to calculate simulation results based on 500 repetitions of 1000 observation samples. Function is used in a paper 'Effect Sizes and their Variance for AB/BA Crossover Design Studies' by Lech Madeyski and Barbara Kitchenham.

**Usage**
```r
reproduceSimulationResultsBasedOn500Reps1000Obs()
```

**Value**
data frame including the following simulation results: 
- `# treatmentEffect.Ave` - Average Technique Effect
- `# dRM.Ave` - Average dRM
- `# dRM.Var` - Variance of dRM
- `# dRM.Var.Ave` - Average of var(dRM)
- `# dRM.Var.ModerateSampleSizeApprox` -
- `# dIG.Ave` - Average dIG
- `# dIG.Var` - Variance of dIG
- `# dIG.Var.Ave` - Average of var(dIG)
- `# dIG.Var.ModerateSampleSizeApprox` -

**Author(s)**
Lech Madeyski and Barbara Kitchenham
Examples

# return simulation results based on 500 repetitions of 1000 observation samples
simulationResultsTable500x1000 <- reproduceSimulationResultsBasedOn500Reps1000Obs()

Description

This function reproduces five of the output tables used in the systematic review paper 'Meta-analysis for Families of Experiments: A Systematic Review and Reproducibility Assessment'. It extracts the reported values for effect sizes, meta-analysis and descriptive statistics in the primary studies. It uses the descriptive statistics to re-calculate effect sizes and then performs a meta-analyses using the constructed effect sizes and compares the calculated values with the reported values.

Usage

reproduceTablesOfPaperMetaAnalysisForFamiliesOfExperiments()

Value

list incl. the data presented in five of the tables presented in the paper.

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

rrData <- reproduceTablesOfPaperMetaAnalysisForFamiliesOfExperiments()
# Reproduce Table 'Overall Mean Values of Effect Sizes Reported and Calculated':
xtab::xtable(rrData$MAStats)
# Reproduce Table 'Calculated and Reported Effect Sizes':
xtab::xtable(rrData$ESdata)
# Report values for 3 papers that reported per document
rrData$MAStatsTP1 <- data.frame(rrData$MAStatsTP1, row.names = NULL)
rrData$ESTP1res <- data.frame(rrData$ESTP1res, row.names = NULL)
xtab::xtable(rrData$MAStatsTP1)
xtab::xtable(rrData$ESTP1res)
# Report extra results for Study 8
# Reproduce Table 'Calculating r_PB Effect Size from Probabilities'
xtab::xtable(rrData$GH2015extra)
Description

Function reproduces Table, which shows the effect sizes based on mean differences.

Usage

reproduceTableWithEffectSizesBasedOnMeanDifferences()

Author(s)

Lech Madeyski

Examples

reproduceTableWithEffectSizesBasedOnMeanDifferences()

Description

Function reproduces Table with possible moderating factors.

Usage

reproduceTableWithPossibleModeratingFactors()

Author(s)

Lech Madeyski

Examples

reproduceTableWithPossibleModeratingFactors()
reproduceTableWithSourceDataByCiolkowski

Description

Function reproduces Table, which shows the effect sizes reported by Ciolkowski identifying the type of design used in each study.

Usage

reproduceTableWithSourceDataByCiolkowski()

Author(s)

Lech Madeyski

Examples

reproduceTableWithSourceDataByCiolkowski()

rSimulations

Description

This function simulates many dataset from the same bivariate distribution to investigate the distribution of correlations for specific sample sizes.

Usage

rSimulations(
    mean,  
    var,   
    diff,  
    r,     
    N,     
    reps, 
    VarAdj = 0,  
    seed = 123, 
    returnSignificant = F, 
    returndata = F, 
    plotHist = F
)
Arguments

mean The mean used for one of bivariate distributions - assumed to be the control condition in an experiment.

var The variance used for both treatment groups. It must be a real value greater than 0.

diff This value is added to the parameter mean to specify the mean for the other bivariate distribution - assumed to be the treatment condition in an experiment.

r This specifies the correlation coefficient to be used for the bivariate normal distribution it must be a value in the range [-1,1].

N The number of observations in each simulated bivariate normal data set.

reps The number of bivariate data sets that will be simulated.

VarAdj This value will be added to the variance of the treatment condition.

seed This specifies the seed value for the simulations and allows the experiment to be repeated.

returntSignificant If set to true the percentage of times the t-test delivered a value significant at the 0.05 level is reported (default returntSignificant=F).

returndata If set to FALSE, the function returns the summary information across all the replications (default returndata=F). If set to TRUE the function outputs the r and variance ratio, and variance accuracy values generated in each replication.

plothist If set to T, the function outputs a histogram of the r-values, the varprop values and the accuracy values (default plothist=F).

Value

output If returndata=F, the output returns summary information about the average of r and the variance properties across the replicated data sets. If returndata=T, the function returns the r-values obtained for each of the simulated data sets to gather with the variance ratio, the variance accuracy measure and a dummy variable indicating whether a test of significance between the mean values was significant (which is indicated by the dummy variable being set to 1) or not (which is indicated by the dummy variable being set to 0)

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

# output=rSimulations(mean=0,var=1,diff=0,r=0.25,N=4,reps=10000)
# reduced reps to pass CRAN time limits
output <- rSimulations(mean = 0, var = 1, diff = 0, r = 0.25, N = 4, reps = 1000)
output <- signif(output, 4)
output

searchForIndustryRelevantGitHubProjects

Description

Function searches for industry relevant software projects available from GitHub. The function was used to deliver a data set of software projects in an NCBI project. More details are described in a report: Lech Madeyski, "Training data preparation method," tech. rep., code quest (research project NCBI PoIR.01.01.00-0792/16), 2019, as well as a paper: Tomasz Lewowski and Lech Madeyski, "Creating evolving project data sets in software engineering", 2019. If you use this function or the returned data set than please cite: Tomasz Lewowski and Lech Madeyski, "Creating evolving project data sets in software engineering", 2019

Usage

searchForIndustryRelevantGitHubProjects(
  myToken,
  earliestPushDate,
  latestCreationDate
)

Arguments

myToken A private token used to access GitHub
earliestPushDate
Only repositories which were pushed after this date will be included in the results (i.e., repositories for which the latest push was before this date will not be included in the results)

latestCreationDate
Only repositories which were created before this date will be included in the results (i.e., repositories created after this date will not be included in the results)

Value
selected GitHub projects

Author(s)
Lech Madeyski and Tomasz Lewowski

Examples
# to run this function you need to use your own token as a parameter of the function
# use your own token as the first parameter of the function
# searchForIndustryRelevantGitHubProjects("...", "2019-03-01", "2018-08-01")

simulate2GExperimentData

Description
The function returns a two group data set based on one of four different distributions.

Usage

simulate2GExperimentData(
    mean,
    sd,
    diff,
    GroupSize,
    type = "n",
    ExpAdj = 0,
    StdAdj = 0,
    BlockEffect = 0,
    BlockStdAdj = 0
)
**Arguments**

- **mean**: The mean (or rate for gamma data) of the baseline distribution.
- **sd**: The standard deviation (or shape for gamma data) of the baseline distribution.
- **diff**: The adjustment to the baseline mean for the alternative distribution.
- **GroupSize**: An integer defining the number of data items in each group.
- **type**: A string identifying the distribution used to simulate the data: ’n’ for normal, ’ln’ for log-normal, ’g’ for gamma, ’lap’ for Laplace.
- **ExpAdj**: An additional adjustment factor that is added to both the mean value. Defaults to zero.
- **StdAdj**: An additional adjustment factor that is added to both group variance (or rate for gamma data). Defaults to zero.
- **BlockEffect**: An additional factor that is added to the mean of the both groups (shape for the gamma distribution). Defaults to zero.
- **BlockStdAdj**: An additional factor that is added to the variance of both groups (shape for the gamma distribution). Defaults to zero.

**Value**

A table with two columns (BaselineData and AlternativeData) holding the data for each group. For lognormal data an additional two columns are added which return the log transformed data.

**Author(s)**

Barbara Kitchenham and Lech Madeyski

**Examples**

```r
set.seed(236)
simulate2GExperimentData(mean = 0, sd = 1, diff = 0.5, GroupSize = 10,
  type = "n", ExpAdj = 0, StdAdj = 0, BlockEffect = 0, BlockStdAdj = 0)
# A tibble: 10 x 2
#  BaselineData AlternativeData
#  <dbl>     <dbl>
#1   -0.285   -0.255
#2   -0.972    0.112
#3   -0.549    1.36
#4    1.05     1.47
#5   -0.267    0.107
#6   -0.137    0.395
#7    1.30     1.27
#8   -0.722    1.70
#9   -0.525    0.264
#10  -0.0222   0.787
set.seed(345)
simulate2GExperimentData(mean = 0, sd = 1, diff = 0.5, GroupSize = 10,
  type = "l", ExpAdj = 0, StdAdj = 0, BlockEffect = 0, BlockStdAdj = 0)
# A tibble: 10 x 4
```
The function returns a four group data set based on one of four different distributions.

Usage

simulate4GExperimentData(
  mean,
  sd,
  diff,
  GroupSize,
  type = "n",
  ExpAdj = 0,
  StdAdj = 0,
  BlockEffect = 0,
  BlockStdAdj = 0
)

Arguments

mean
  The mean (or rate for gamma data) of the baseline distribution
sd
  The standard deviation (or shape for gamma data) of the baseline distribution
diff
  The adjustment to the baseline mean for the alternative distribution.
GroupSize
  An integer defining the number of data items in each group.
type
  A string identifying the distribution used to simulate the data: "n" for normal, "l" for log-normal, "g" for gamma, "lap" for Laplace.
ExpAdj
  An additional adjustment factor that is added to both the mean values. Defaults to zero.
simulate4GExperimentData

StdAdj An additional adjustment factor that is added to the second group variance (or rate for gamma data). Defaults to zero.

BlockEffect An additional factor that is added to the mean of the second group groups (shape for the gamma distribution). Defaults to zero.

BlockStdAdj An additional factor that is added to the variance of the second group (shape for the gamma distribution). Defaults to zero.

Value

A table with four columns (BaselineData.B1, AlternativeData.B1, BaselineData.B2, AlternativeData.B2,) holding the data for each group and block. For lognormal data an additional four columns are added which return the log transformed data for each group.

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

```r
set.seed(246)
simulate4GExperimentData(mean = 0, sd = 1, diff = 0.5, GroupSize = 5,
 type = "n", ExpAdj = 0, StdAdj = 0, BlockEffect = 0.5, BlockStdAdj = 0)
# A tibble: 5 x 4

```
**simulateRandomizedBlockDesignEffectSizes**

**Description**

This simulates a two-block and two-treatment design based on one of four distributions, and finds the values of $k_{tau}$ and Cliff's $d$ and their variances. It simulates a randomised blocks experiment with two treatment groups and two control groups each of which being divided into two blocks. It assumes equal group sizes but group spread (standard deviation can be changed, see StAdj). It returns values of both parametric and non-parametric effect sizes and their variance and significance. For the logarithmic distribution it calculates effect sizes based on the log transformed data as well as the raw data.

**Usage**

```r
simulateRandomizedBlockDesignEffectSizes(
  mean,
  sd,
  diff,
  N,
  type = "n",
  alpha = 0.05,
  Blockmean = 0,
  BlockStdAdj = 0,
  StdAdj = 0,
  AlwaysTwoSidedTests = FALSE,
  ReturnData = FALSE
)
```

**Arguments**

- **mean**: The default value for all groups which can be changed for the two treatment groups using the parameter diff and for the two block 2 groups using the parameter Blockmean.
- **sd**: The default spread used for all four groups unless adjusted by the StdAdj. It must be a real value greater than 0.
- **diff**: This is added to the parameter mean to obtain the required mean for treatment groups. It can be a real value and can take the value zero.
- **N**: this is the number of observations in each group. It must be an integer greater than 3.
- **type**: this specifies the underlying distribution used to generate the data. it takes the values 'n' for a normal distribution, 'l' for lognormal distribution,'g' for a gamma distribution, 'lap' for a Laplace distribution.
- **alpha**: The level used for statistical tests (default 0.05).
**simulateRandomizedBlockDesignEffectSizes**

- **Blockmean** if >0 an adjustment made to both group means in Block 2
- **BlockStdAdj** if >0, an adjustment that can be made to the sd of each group in block 2
- **StdAdj** this specifies the extent of variance instability introduced by the treatment and if >0 will be used to amend the sd parameter for both treatment groups. This value must be positive and less than 0.5
- **AlwaysTwoSidedTests** Logical varable (default FALSE) if TRUE the function always performs two-sided tests. Otherwise if the parameter diff is not equal to zero, the function performs one-sided tests.
- **ReturnData** Logical variable. If TRUE, the function simply returns the generated data. If false (which is default value) the function returns various effect sizes and whether the effect sizes are statistically significant.

**Value**

data frame incl. either the non-parametric and parametric effect sizes and whether the effect sizes are significant at the 0.05 level or the generated data depending on the value of the ReturnData parameter.

**Author(s)**

Barbara Kitchenham and Lech Madeyski

**Examples**

```r

```
```r
simulateRandomizedBlockDesignEffectSizes(
  mean = 0, sd = 1, diff = .5, N = 10, type = "l", alpha = 0.05,
  Blockmean = 0.5, BlockStdAdj = 0, StdAdj = 0, ReturnData = TRUE)
```

### Description

This simulates one of four data distributions (normal, log-normal, gamma and Laplace), and finds the values of \( \hat{p} \) and Cliffs \( d \) and their variances. It assumes equal group sizes. It returns values of the effect sizes and their variance for a simulated randomized experiment with two treatments. It returns whether or not each non-parametric effect size was significant. It also returns the parametric (standardized and unstandardized) Effect Size and the whether the t-test was significant.

### Usage

```r
simulateRandomizedDesignEffectSizes(
  mean, sd, diff,
  N, type = "n",
  StdAdj = 0,
  alpha = 0.05,
  AlwaysTwoSidedTests = FALSE,
)```
simulateRandomizedDesignEffectSizes(Return.Data = FALSE)
)

Arguments

mean
The mean used for one of the treatment groups (this is the rate for the gamma data)

sd
The spread used for both treatment groups. It must be a real value greater than 0 (this is the shape for the gamma data).

diff
This is added to the parameter mean, to define the mean of the other treatment group. It can be a real value and can take the value zero.

N
this is the number of observations in each group. It must be an integer greater than 3.

type
this specifies the underlying distribution used to generate the data. It takes the values 'n' for a normal distribution, 'l' for lognormal distribution, 'g' for a gamma distribution, 'lap' for a Laplace distribution.

StdAdj
this specifies the extent of variance instability to be introduced.

alpha
the level for all statistical tests (default 0.05)

AlwaysTwoSidedTests
if set to FALSE (i.e. default) the algorithms uses one-sided tests if diff!=0 and two-sided tests otherwise. If set to TRUE the algorithm always uses two-sided tests.

Return.Data if set to true the algorithm returns the data not the effect sizes (default FALSE).

Value
data frame incl. the non-parametric and parametric effect sizes and whether the effect sizes are significant at the specified alpha level. For log-normal data the function returns the effect sizes for the transformed data.

testfunctionParameterChecks

description
This is a helper function that ensures parameter values used for performing special statistical tests are valid.

usage

testfunctionParameterChecks(alternative, alpha, stderr)
**Arguments**

- alternative: The type of statistical test. Valid values are one of c('two.sided', 'greater', 'less')
- alpha: The test level. Valid values are between 0.0001 and 0.2
- stderr: The standard error of a parameter whose confidence intervals is to be calculated

**Value**

'Success' or an error message.

**Author(s)**

Barbara Kitchenham and Lech Madeyski

**Examples**

```r
#reproducer:::testfunctionParameterChecks(alternative='larger', alpha=0.1, stderr=0.002)
#Error in testfunctionParameterChecks(alternative = 'larger', alpha = 0.1) :
#  invalid alternative parameter, choose one of two.sided, greater or less
#reproducer:::testfunctionParameterChecks(alternative='greater', alpha=0.1, stderr=0.002)
#[1] 'Success'
#reproducer:::testfunctionParameterChecks(alternative='greater', alpha=0.1, stderr=0.000)
#Error in testfunctionParameterChecks(alternative = 'greater', alpha = 0.1, :
#  Improbably small variance, data are essentially constant
```

---

**transformHgtoR**

The functions transforms a vector of Hedges g values to their equivalent point bi-serial values.

**Usage**

`transformHgtoR(g, Nc, Nt)`

**Arguments**

- g: A vector of Hegdes g values.
- Nc: A vector of numbers identifying the number of control condition participants in each group
- Nt: A vector of numbers identifying the number of treatment condition participants in each group

**Value**

value of point biserial r
Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

transformHgtoR(0.4, 20, 20)
# [1] 0.1961161

transformHgtoR(0.5, 20, 20)
# [1] 0.2474665

Description

The functions transforms a vector of Hedges g values to their normal approximation of point biserial values.

Usage

transformHgtoR(g, Nc, Nt)

Arguments

g    value of Hedges’ g
Nc   the number of observations (participants) in the first (control) group
Nt   the number of observations (participants) in the second (treatment) group

Value

value of normal approximation of point biserial r

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

transformHgtoR(0.5, 20, 20)
# [1] 0.2474665
Description

This function converts a vector of point bi-serial r values with associated sample size information back to the mean difference effect size Hedges g.

Usage

transformRtoHg(r, Nc, Nt)

Arguments

- **r**: A vector of point bi-serial correlation values.
- **Nc**: A vector of the number of observations in the control condition for the related experiments.
- **Nt**: A vector of the number of observations in the treatment condition for the related experiments.

Value

value of Hedges' g

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

transformRtoHg(c(0.4, 0.2), c(20, 20), c(20, 20))
# [1] 0.8728716 0.4082483

Description

The function transforms a vector of point biserial r values to their normal approximation. It also works for the correlation r.

Usage

transformRtoZr(r)
Arguments

\( r \)  
A vector of r-values

Value

value of normal approximation of point biserial r

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

```r
reproducer::transformRtoZr(0.4)
# [1] 0.4236489
Zr <- reproducer::transformRtoZr(c(0.4, 0.2))
Zr
# [1] 0.4236489 0.2027326
```

**transformZrtoHg**

Description

Transforms Zr to Hedge’s g.

Usage

```r
transformZrtoHg(Zr, Nc, Nt)
```

Arguments

\( Zr \)  
the normal variate

\( Nc \)  
the number of observations (participants) in the first (control) group

\( Nt \)  
the number of observations (participants) in the second (treatment) group

Value

value of Hedges’ g

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

```r
transformZrtoHg(0.5, 20, 20)
# [1] 1.042191
```
Description

This function provides an approximate transformation from Zr to Hedges’ g when the number of observations in the treatment and control group are unknown. It is also used to allow the forest plots to display Hedges’ g when they are based on r. It is necessary because the transformation function in the forest plot function does not allow any parameters other than effect size used. The function assumes that Nc=Nt and gives the same results as transformZrtoHg when Nc=Nt.

Usage

transformZrtoHgapprox(Zr)

Arguments

Zr

A vector of normalised point bi-serial values

Value

approx. value of Hedges’ g

Author(s)

Barbara Kitchenham and Lech Madeyski

Examples

transformZrtoHgapprox(c(0.4, 0.2))
# [1] 0.8215047 0.4026720

describe
transformZrtoR

Description

The function transforms a vector of standardized normal variates to their equivalent r-values.

Usage

transformZrtoR(zr)

Arguments

zr

A vector of standard normal variates.
**Value**

value of point biserial r

**Author(s)**

Barbara Kitchenham and Lech Madeyski

**Examples**

```r
transformZrtoR(0.4236489)
# [1] 0.4
transformZrtoR(c(0.4236489, 0.2027326))
# [1] 0.4 0.2
```

**Description**

Function calculates the exact variance of a standardized effect size based on the relationship between t and the standardized effect size, see Morris and DeShon, Combining Effect Size Estimates in Meta-Analysis With Repeated Measures and Independent-Groups Designs, Psychological Methods, 7 (1), pp 105-125.

**Usage**

```r
varStandardizedEffectSize(d, A, f, returnVarg = TRUE)
```

**Arguments**

- `d` An unadjusted standardized effect size
- `A` The squared constant linking t and d i.e. t*sqrt(A)=d
- `f` The degrees of freedom of the t value
- `returnVarg` if set to TRUE return the variance of the small sample size adjusted standardized effect size (g), otherwise returns var(d) where d is the input parameter

**Value**

if returnVarg if set to TRUE, return var(g) otherwise var(d)

**Author(s)**

Barbara Kitchenham and Lech Madeyski
Examples

d <- 0.5
varStandardizedEffectSize(d, 2 / 20, 38, returnVarg = FALSE)
# [1] 0.1047567
varStandardizedEffectSize(d, 2 / 20, 38, returnVarg = TRUE)
# [1] 0.1090516
