Package ‘rgeos’

October 31, 2017

Title Interface to Geometry Engine - Open Source ('GEOS')
Version 0.3-26
Date 2017-10-30
Depends R (>= 3.3.0)
Imports methods, sp (>= 1.1-0), utils, stats, graphics
LinkingTo sp
Suggests maptools (>= 0.8-5), testthat, XML, maps, rgdal
LazyLoad yes
Description Interface to Geometry Engine - Open Source ('GEOS') using the C 'API' for topology operations on geometries. The 'GEOS' library is external to the package, and, when installing the package from source, must be correctly installed first. Windows and Mac Intel OS X binaries are provided on 'CRAN'.
License GPL (>= 2)

URL https://r-forge.r-project.org/projects/rgeos/
    http://trac.osgeo.org/geos/
SystemRequirements GEOS (>= 3.2.0); for building from source: GEOS from http://trac.osgeo.org/geos/; GEOS OSX frameworks built by William Kyngesburye at http://www.kyngchaos.com/ may be used for source installs on OSX.
NeedsCompilation yes

Description

Calculates the area of the given geometry.

Usage

gArea(spgeom, byid=FALSE)

Arguments

spgeom sp object as defined in package sp
byid Logical determining if the function should be applied across subgeometries (TRUE) or the entire object (FALSE)

Value

Returns the area of the geometry in the units of the current projection. By definition non-[MULTI]POLYGON geometries have an area of 0. The area of a POLYGON is the area of its shell less the area of any holes. Note that this value may be different from the area slot of the Polygons class as this value does not subtract the area of any holes in the geometry.

Author(s)

Roger Bivand & Colin Rundel

p1@polygons[[1]]@area

gArea(p2)
p2@polygons[[1]]@area
gBoundary

Boundary of Geometry

Description

Function for determining the Boundary of the given geometry as defined by SFS Section 2.1.13.1

Usage

\[ \text{gBoundary}(\text{spgeom}, \text{byid}=\text{FALSE}, \text{id} = \text{NULL}) \]

Arguments

- **spgeom**: sp object as defined in package sp
- **byid**: Logical determining if the function should be applied across subgeometries (TRUE) or the entire object (FALSE)
- **id**: Character vector defining id labels for the resulting geometries, if unspecified returned geometries will be labeled based on their parent geometries’ labels.

Value

Depending of the class of the spgeom the returned results will differ.

Based on the documentation of JTS (on which GEOS is based) the following outputs are expected:

- **Point**: empty GeometryCollection
- **MultiPoint**: empty GeometryCollection
- **LineString**: if closed: empty MultiPoint if not closed: MultiPoint containing the two endpoints.
- **MultiLineString**: MultiPoint obtained by applying the Mod-2 rule to the boundaries of the element LineStrings
- **LinearRing**: empty MultiPoint
- **Polygon**: MultiLineString containing the LinearRings of the shell and holes, in that order (SFS 2.1.10)
- **MultiPolygon**: MultiLineString containing the LinearRings for the boundaries of the element polygons, in the same order as they occur in the MultiPolygon (SFS 2.1.12/JTS)
- **GeometryCollection**: The boundary of an arbitrary collection of geometries whose interiors are disjoint consist of geometries drawn from the boundaries of the element geometries by application of the Mod-2 rule (SFS Section 2.1.13.1)

The mod-2 rule states that for a multiline a point is on the boundary if and only if it on the boundary of an odd number of subgeometries of the multiline (See example below).

gBuffer

Examples

```r
x = readWKT("POLYGON((0 0,10 0,10,0 0,0 0))")
b = gBoundary(x)

plot(x,col='black')
plot(b,col='red',lwd=3,add=TRUE)

# mod-2 rule example
x1 = readWKT("MULTILINESTRING((2 2,0),(2 0 2))")
x2 = readWKT("MULTILINESTRING((2 2 0),(2 0,2),(2 2 4 2))")
x3 = readWKT("MULTILINESTRING((2 2 0),(2 0 2),(2 2 4 2),(2 2 4 2))")
x4 = readWKT("MULTILINESTRING((2 2 0),(2 0 2),(2 2 4 2),(2 2 4 2))")

b1 = gBoundary(x1)
b2 = gBoundary(x2)
b3 = gBoundary(x3)
b4 = gBoundary(x4)

par(mfrow=c(2,2))
plot(x1); plot(b1,pch=16,col='red',add=TRUE)
plot(x2); plot(b2,pch=16,col='red',add=TRUE)
plot(x3); plot(b3,pch=16,col='red',add=TRUE)
plot(x4); plot(b4,pch=16,col='red',add=TRUE)
```

---

**gBuffer**

**Buffer Geometry**

**Description**

Expands the given geometry to include the area within the specified width with specific styling options.

**Usage**

```r
gBuffer(spgeom, byid=FALSE, id=NULL, width=1.0, quadsegs=5, capStyle="ROUND", joinStyle="ROUND", mitreLimit=1.0)
```

**Arguments**

- **spgeom**
  - sp object as defined in package sp
- **byid**
  - Logical determining if the function should be applied across subgeometries (TRUE) or the entire object (FALSE)
- **id**
  - Character vector defining id labels for the resulting geometries, if unspecified returned geometries will be labeled based on their parent geometries’ labels.
width  Distance from original geometry to include in the new geometry. Negative values are allowed. Either a numeric vector of length 1 when byid is FALSE; if byid is TRUE: of length 1 replicated to the number of input geometries, or of length equal to the number of input geometries

quadsegs  Number of line segments to use to approximate a quarter circle.

capStyle  Style of cap to use at the ends of the geometry. Allowed values: ROUND, FLAT, SQUARE

joinStyle  Style to use for joints in the geometry. Allowed values: ROUND, MITRE, BEVEL

mitreLimit  Numerical value that specifies how far a joint can extend if a mitre join style is used.

Value

SpatialPolygons (or a SpatialPolygonsDataFrame if byid=TRUE and spgeom has a data.frame); if negative width(s) lead the object to disappear, NULL is returned for byid FALSE, and component Polygons objects are dropped if empty for byid TRUE; the SpatialPolygonsDataFrame is subsetted by row.names or id if given to retain non-empty geometry rows

---

gCentroid

### Centroid of Geometry

**Description**

Function calculates the centroid of the given geometry.

**Usage**

```r
?gCentroid
```

```r
gCentroid(spgeom, byid=FALSE, id = NULL)
```
Arguments

- **spgeom**: sp object as defined in package `sp`
- **byid**: Logical determining if the function should be applied across subgeometries (TRUE) or the entire object (FALSE)
- **id**: Character vector defining id labels for the resulting geometries, if unspecified returned geometries will be labeled based on their parent geometries' labels.

Details

Returns a SpatialPoints object of the centroid(s) for `spgeom`.

Author(s)

Roger Bivand & Colin Rundel

See Also

- `gBoundary`
- `gConvexHull`
- `gEnvelope`
- `gPointOnSurface`

Examples

```r
x = readWKT(paste("GEOMETRYCOLLECTION(POLYGON((0 0,10 0,10,0 10,0 0)),", "POLYGON((15 0,25 15,35 0,15 0))")

# Centroids of both the square and circle independently
c1 = gCentroid(x, byid=TRUE)
# Centroid of square and circle together
c2 = gCentroid(x)

plot(x)
plot(c1, col='red', add=TRUE)
plot(c2, col='blue', add=TRUE)
```

---

Description

Functions for testing whether one geometry contains or is contained within another geometry
gContains

Usage

\[
gContains(spgeom1, spgeom2 = \text{NULL}, byid = \text{FALSE}, \text{prepared} = \text{TRUE}, 
\text{returnDense} = \text{TRUE}, \text{STRsubset} = \text{FALSE}, \text{checkValidity} = \text{FALSE})
\]
\[
gContainsProperly(spgeom1, spgeom2 = \text{NULL}, byid = \text{FALSE}, \text{returnDense} = \text{TRUE}, 
\text{checkValidity} = \text{FALSE})
\]
\[
gCovered(spgeom1, spgeom2 = \text{NULL}, byid = \text{FALSE}, \text{returnDense} = \text{TRUE}, \text{checkValidity} = \text{FALSE})
\]
\[
gCoveredBy(spgeom1, spgeom2 = \text{NULL}, byid = \text{FALSE}, \text{returnDense} = \text{TRUE}, \text{checkValidity} = \text{FALSE})
\]
\[
gWithin(spgeom1, spgeom2 = \text{NULL}, byid = \text{FALSE}, \text{returnDense} = \text{TRUE}, \text{checkValidity} = \text{FALSE})
\]

Arguments

- **spgeom1**, **spgeom2**: sp objects as defined in package sp. If spgeom2 is NULL then spgeom1 is compared to itself.
- **byid**: Logical vector determining if the function should be applied across ids (TRUE) or the entire object (FALSE) for spgeom1 and spgeom2.
- **prepared**: Logical determining if prepared geometry (spatially indexed) version of the GEOS function should be used. In general prepared geometries should be faster than the alternative.
- **returnDense**: default TRUE, if false returns a list of the length of spgeom1 of integer vectors listing the \(1:|\text{length}(\text{spgeom2})\) indices which would be TRUE in the dense logical matrix representation; useful when the sizes of the byid=TRUE returned matrix is very large and it is sparse; essential when the returned matrix would be too large.
- **checkValidity**: default FALSE; error messages from GEOS do not say clearly which object fails if a topology exception is encountered. If this argument is TRUE, gIsValid is run on each in turn in an environment in which object names are available. If objects are invalid, this is reported and those affected are named.
- **STRsubset**: logical argument for future use.

Value

- gContains returns TRUE if none of the point of spgeom2 is outside of spgeom1 and at least one point of spgeom2 falls within spgeom1.
- gContainsProperly returns TRUE under the same conditions as gContains with the additional requirement that spgeom2 does not intersect with the boundary of spgeom1. As such any given geometry will Contain itself but will not ContainProperly itself.
- gCovers returns TRUE if no point in spgeom2 is outside of spgeom1. This is slightly different from gContains as it does not require a point within spgeom1 which can be an issue as boundaries are not considered to be "within" a geometry, see gBoundary for specifics of geometry boundaries.
- gCoveredBy is the converse of gCovers and is equivalent to swapping spgeom1 and spgeom2.
- gWithin is the converse of gContains and is equivalent to swapping spgeom1 and spgeom2.

Note

Error messages from GEOS, in particular topology exceptions, report 0-based object order, so geom 0 is spgeom1, and geom 1 is spgeom2.

title(paste("Contains: ",gContains(p1,p13),
"\nContainsProperly:",gContainsProperly(p1,p13),
"\nCovers: ",gCovers(p1,p13)))
```

**gConvexHull**

**Convex Hull of Geometry**

**Description**

Function produces the Convex Hull of the given geometry, the smallest convex polygon that contains all subgeometries.

**Usage**

```r
gConvexHull(spgeom, byid=FALSE, id = NULL)
```

**Arguments**

- `spgeom`  
  sp object as defined in package sp

- `byid`  
  Logical determining if the function should be applied across subgeometries (TRUE) or the entire object (FALSE)

- `id`  
  Character vector defining id labels for the resulting geometries, if unspecified returned geometries will be labeled based on their parent geometries’ labels.

**Details**

Returns the convex hull as a SpatialPolygons object.

**Author(s)**

Roger Bivand & Colin Rundel

**See Also**

- `gBoundary`
- `gCentroid`
- `gEnvelope`
- `gPointOnSurface`

**Examples**

```r
x = readWKT(paste("POLYGON((0 40,10 50,0 60,40 60,40 100,50 90,60 100,60", "60,100 60,90 50,100 40,60 40,60 0,50 10,40 0,40 40,0 40))
"))

ch = gConvexHull(x)

plot(x,col='blue',border='blue')
plot(ch,add=TRUE)
```
gCROSSES

Geometry Relationships - Crosses and Overlaps

Description

Functions for testing whether geometries share some but not all interior points

Usage

gCROSSES(spgeom1, spgeom2 = NULL, byid = FALSE, returnDense=TRUE, checkValidity=FALSE)
gOVERLAPS(spgeom1, spgeom2 = NULL, byid = FALSE, returnDense=TRUE, checkValidity=FALSE)

Arguments

spgeom1, spgeom2
sp objects as defined in package sp. If spgeom2 is NULL then spgeom1 is compared to itself.

byid Logical vector determining if the function should be applied across ids (TRUE) or the entire object (FALSE) for spgeom1 and spgeom2

returnDense default TRUE, if false returns a list of the length of spgeom1 of integer vectors listing the indices which would be TRUE in the dense logical matrix representation; useful when the sizes of the byid=TRUE returned matrix is very large and it is sparse; essential when the returned matrix would be too large

checkValidity default FALSE; error messages from GEOS do not say clearly which object fails if a topology exception is encountered. If this argument is TRUE, gISValid is run on each in turn in an environment in which object names are available. If objects are invalid, this is reported and those affected are named

Value

gCROSSES returns TRUE when the geometries share some but not all interior points, and the dimension of the intersection is less than that of at least one of the geometries.
gOVERLAPS returns TRUE when the geometries share some but not all interior points, and the intersection has the same dimension as the geometries themselves.

Note

Error messages from GEOS, in particular topology exceptions, report 0-based object order, so geom 0 is spgeom1, and geom 1 is spgeom2.

```

---

gDelaunayTriangulation

*Compute Delaunay triangulation between points*

Description

Function to compute the Delaunay triangulation between points; only available for GEOS >= 3.4.0.
Usage

\texttt{gDelaunayTriangulation(spgeom, tolerance=0.0, onlyEdges=FALSE)}

Arguments

- \texttt{spgeom} \hspace{1em} \text{sp points object as defined in package sp}
- \texttt{tolerance} \hspace{1em} \text{Numerical tolerance value to be used in triangulation}
- \texttt{onlyEdges} \hspace{1em} \text{Logical, default returns triangles as polygons, if TRUE, returns a SpatialLines object with a single MULTILINESTRING}

Details

When \texttt{onlyEdges} is TRUE, the SpatialLines object may be de-merged to identify the input points that are touched by each edge, making it possible to identify spatial neighbours.

Value

Either a SpatialPolygons object or a SpatialLines object containing a single Lines object of the undirected edges in the triangulation.

Author(s)

Roger Bivand

o <- order(out3[,1], out3[,2])
out4 <- out3[o,]
out5 <- data.frame(from=out4[,1], to=out4[,2], weight=1)
head(out5)
}
```
### Description

Function for determining the difference between the two given geometries.

### Usage

```r
gDifference(spgeom1, spgeom2, byid=FALSE, id=NULL, drop_lower_td=FALSE, unaryUnion_if_byid_false=TRUE, checkValidity=FALSE)
```

### Arguments

- **spgeom1, spgeom2**: sp objects as defined in package sp
- **byid**: Logical vector determining if the function should be applied across ids (TRUE) or the entire object (FALSE) for spgeom1 and spgeom2
- **id**: Character vector defining id labels for the resulting geometries, if unspecified returned geometries will be labeled based on their parent geometries’ labels.
- **drop_lower_td**: default FALSE; if TRUE, objects will be dropped from output GEOMETRYCOLLECTION objects to simplify output if their topological dimension is less than the minimum topological dimension of the input objects.
- **unaryUnion_if_byid_false**: default TRUE; if byid takes a FALSE in either position, the subgeometries are combined first to avoid possible topology exceptions (change in 0.3-13, previous behaviour did not combine subgeometries, and may be achieved by setting this argument FALSE
- **checkValidity**: default FALSE; error messages from GEOS do not say clearly which object fails if a topology exception is encountered. If this argument is TRUE, gIsValid is run on each in turn in an environment in which object names are available. If objects are invalid, this is reported and those affected are named

### Details

Returns the regions of spgeom1 that are not within spgeom2. If the geometries do not intersect then the result is just spgeom1. Note that the function is not symmetric for spgeom1 and spgeom2.
Note

Error messages from GEOS, in particular topology exceptions, report 0-based object order, so geom 0 is spgeom1, and geom 1 is spgeom2.

Examples

```r
x = readWKT("POLYGON ((0 0, 0 10, 10 10, 10 0, 0 0))")
y = readWKT("POLYGON ((3 3, 7 3, 7 7, 3 7, 3 3))")

d = gDifference(x,y)
plot(d,col='red',pbg='white')

# Empty geometry since y is completely contained with x
d2 = gDifference(y,x)
```

gDistance

Distance between geometries

Description

Calculates the distance between the given geometries

Usage

```r
gDistance(spgeom1, spgeom2=NULL, byid=FALSE, hausdorff=FALSE, densifyFrac = NULL)
gWithinDistance(spgeom1, spgeom2=NULL, dist, byid=FALSE, hausdorff=FALSE, densifyFrac=NULL)
```

Arguments

- `spgeom1, spgeom2`: sp objects as defined in package sp. If spgeom2 is NULL then spgeom1 is compared to itself.
- `byid`: Logical vector determining if the function should be applied across ids (TRUE) or the entire object (FALSE) for spgeom1 and spgeom2.
- `hausdorff`: Logical determining if the discrete Hausdorff distance should be calculated.
- `densifyFrac`: Numerical value between 0 and 1 that determines the fraction by which to densify each segment of the geometry.
- `dist`: Numerical value that determines cutoff distance.
Details

Discrete Hausdorff distance is essentially a measure of the similarity or dissimilarity of the two geometries, see references below for more detailed explanations / descriptions.

If `hausdorff` is TRUE and `densifyfrac` is specified then the geometries’ segments are densified by splitting each segment into equal length subsegments whose fraction of the total length is equal to `densifyfrac`.

Value

`gDistance` by default returns the cartesian minimum distance between the two geometries in the units of the current projection. If `hausdorff` is TRUE then the Hausdorff distance is returned for the two geometries.

`gWithinDistance` returns TRUE if returned distance is less than or equal to the specified `dist`.

gEnvelope

Envelope of Geometry

Description
Function calculates the rectangular bounding box for the given geometry.

Usage

\[
gEnvelope(\text{spgeom}, \text{byid}=\text{FALSE}, \text{id} = \text{NULL})
\]

Arguments
- \text{spgeom}: sp object as defined in package \text{sp}
- \text{byid}: Logical determining if the function should be applied across subgeometries (TRUE) or the entire object (FALSE)
- \text{id}: Character vector defining id labels for the resulting geometries, if unspecified returned geometries will be labeled based on their parent geometries' labels.

Details
Returns the rectangular bounding box as a \text{SpatialPolygons} object. If \text{spgeom} is a degenerate case (horizontal/vertical line, single point) then the function may return an object with lower dimension (\text{SpatialLines} or \text{SpatialPoints}) or an invalid polygon.

Examples

```r
x = readWKT(paste("POLYGON((0 40,10 50,0 60,40 60,40 100,50 90,60 100,60", "60,100 60,90 50,100 40,60 40,60 0,50 10,40 0,40 40,0 40))"))
env = gEnvelope(x)

plot(x,col='blue',border='blue')
plot(env,add=TRUE)

#Degenerate Cases
gEnvelope(readWKT("POINT(1 1)")) #returns SpatialPoints
```
gequals

Geometry Relationships - Equality

Description

Function for testing equivalence of the given geometries

Usage

gequals(spgeom1, spgeom2 = NULL, byid = FALSE, returnDense=TRUE, checkValidity=FALSE)
gequalsExact(spgeom1, spgeom2 = NULL, tol=0.0, byid = FALSE, returnDense=TRUE, checkValidity=FALSE)

Arguments

spgeom1, spgeom2
sp objects as defined in package sp. If spgeom2 is NULL then spgeom1 is compared to itself.

byid
Logical vector determining if the function should be applied across ids (TRUE) or the entire object (FALSE) for spgeom1 and spgeom2

tol
Numerical value of tolerance to use when assessing equivalence

returnDense
default TRUE, if false returns a list of the length of spgeom1 of integer vectors listing the 1:length(spgeom2) indices which would be TRUE in the dense logical matrix representation; useful when the sizes of the byid=TRUE returned matrix is very large and it is sparse; essential when the returned matrix would be too large

checkValidity
default FALSE; error messages from GEOS do not say clearly which object fails if a topology exception is encountered. If this argument is TRUE, isValid is run on each in turn in an environment in which object names are available. If objects are invalid, this is reported and those affected are named

Value

gequals returns TRUE if geometries are "spatially equivalent" which requires that spgeom1 is within spgeom2 and spgeom2 is within spgeom1, this ignores ordering of points within the geometries. Note that it is possible for geometries with different coordinates to be "spatially equivalent".

gequalsExact returns TRUE if geometries are "exactly equivalent" which requires that spgeom1 and spgeom1 are "spatially equivalent" and that their constituent points are in the same order.
**Note**

Error messages from GEOS, in particular topology exceptions, report 0-based object order, so geom 0 is spgeom1, and geom 1 is spgeom2.

gEquals(l1,l2)
gEqualsExact(l1,l2)
```
**gInterpolate**

Interpolate Points along Line Geometry

Description

Return points at specified distances along a line.

Usage

```r
gInterpolate(spgeom, d, normalized = FALSE)
```

Arguments

- `spgeom`: SpatialLines or SpatialLinesDataFrame object
- `d`: Numeric vector specifying the distance along the line geometry
- `normalized`: Logical determining if normalized distances should be used

Details

If `normalized=TRUE`, the distances will be interpreted as fractions of the line length.

Value

SpatialPoints object

Author(s)

Rainer Stuetz

gInterpolate

Examples

```r
gInterpolate(readWKT("LINESTRING(25 50, 100 125, 150 190)")),
d=seq(0, 1, by = 0.2), normalized = TRUE)
```
gIntersection  

Geometry Intersections

Description

Function for determining the intersection between the two given geometries.

Usage

gIntersection(spgeom1, spgeom2, byid=FALSE, id=NULL, drop_not_poly, drop_lower_td=FALSE, unaryUnion_if_byid_false=TRUE, checkValidity=FALSE)

Arguments

- spgeom1, spgeom2: sp objects as defined in package sp
- byid: Logical vector determining if the function should be applied across ids (TRUE) or the entire object (FALSE) for spgeom1 and spgeom2.
- id: Character vector defining id labels for the resulting geometries, if unspecified returned geometries will be labeled based on their parent geometries’ labels.
- drop_not_poly: deprecated argument, use drop_lower_td.
- drop_lower_td: default FALSE; if TRUE, objects will be dropped from output GEOMETRYCOLLECTION objects to simplify output if their topological dimension is less than the minimum topological dimension of the input objects.
- unaryUnion_if_byid_false: default TRUE; if byid takes a FALSE in either position, the subgeometries are combined first to avoid possible topology exceptions (change in 0.3-13, previous behaviour did not combine subgeometries, and may be achieved by setting this argument FALSE).
- checkValidity: default FALSE; error messages from GEOS do not say clearly which object fails if a topology exception is encountered. If this argument is TRUE, isValid is run on each in turn in an environment in which object names are available. If objects are invalid, this is reported and those affected are named.

Details

Returns all spatial intersections as sp objects of the appropriate class. If the geometries do not intersect then an empty geometry is returned.

Note

Error messages from GEOS, in particular topology exceptions, report 0-based object order, so geom 0 is spgeom1, and geom 1 is spgeom2.

Description

Function for testing if the geometries have at least one point in common or no points in common

Usage

```r
gIntersects(spgeom1, spgeom2 = NULL, byid = FALSE, prepared=TRUE, returnDense=TRUE, checkValidity=FALSE)  
gDisjoint(spgeom1, spgeom2 = NULL, byid = FALSE, returnDense=TRUE, checkValidity=FALSE)
```

Arguments

- `spgeom1`, `spgeom2`:
  sp objects as defined in package sp. If `spgeom2` is NULL then `spgeom1` is compared to itself.
- `byid`:
  Logical vector determining if the function should be applied across ids (TRUE) or the entire object (FALSE) for `spgeom1` and `spgeom2`.
- `prepared`:
  Logical determining if prepared geometry (spatially indexed) version of the GEOS function should be used. In general prepared geometries should be faster than the alternative.
- `returnDense`:
  default `TRUE`, if false returns a list of the length of `spgeom1` of integer vectors listing the `length(spgeom2)` indices which would be `TRUE` in the dense logical matrix representation; useful when the sizes of the `byid=TRUE` returned matrix is very large and it is sparse; essential when the returned matrix would be too large.
- `checkValidity`:
  default `FALSE`; error messages from GEOS do not say clearly which object fails if a topology exception is encountered. If this argument is `TRUE`, `gIsValid` is run on each in turn in an environment in which object names are available. If objects are invalid, this is reported and those affected are named.

Value

- `gIntersects` returns `TRUE` if `spgeom1` and `spgeom2` have at least one point in common.
- `gDisjoint` returns `TRUE` if `spgeom1` and `spgeom2` have no points in common.

Both return a conforming logical matrix if `byid = TRUE`.

Note

Error messages from GEOS, in particular topology exceptions, report 0-based object order, so geom 0 is `spgeom1`, and geom 1 is `spgeom2`.

**gIsEmpty**

**Description**

Tests if the given geometry is empty

**Usage**

```r
gIsEmpty(spgeom, byid = FALSE)
```

**Arguments**

- `spgeom`: sp object as defined in package sp
- `byid`: Logical determining if the function should be applied across subgeometries (TRUE) or the entire object (FALSE)

**Details**

Because no sp Spatial object may be empty, the function exists but cannot work, as `readWKT` is not permitted to create an empty object.

**Value**

Returns TRUE if the given geometry is empty, FALSE otherwise.

**Author(s)**

Roger Bivand & Colin Rundel

**See Also**

`gIsRing` `gIsSimple` `gIsValid`

**Examples**

```r
try(gIsEmpty(readWKT("POINT EMPTY")))
gIsEmpty(readWKT("POINT(1 1)"))
try(gIsEmpty(readWKT("LINESTRING EMPTY")))
gIsEmpty(readWKT("LINESTRING(0 0,1 1)"))
try(gIsEmpty(readWKT("POLYGON EMPTY")))
gIsEmpty(readWKT("POLYGON((0 0,1 1,0,0))"))
```
gIsRing  

Is Geometry a Ring?

Description

Tests if the given geometry is a ring

Usage

\[ \text{gIsRing(spgeom, byid = FALSE)} \]

Arguments

- `spgeom`: sp object as defined in package sp
- `byid`: Logical determining if the function should be applied across subgeometries (TRUE) or the entire object (FALSE)

Value

Returns TRUE if the geometry is a LINEARRING.

Returns TRUE if the geometry is a LINESTRING that is both Simple (\text{gIsSimple}) and Closed (end points intersect), FALSE otherwise.

Returns FALSE if the geometry is a [MULTI]POINT, MULTILINESTRING, or [MULTI]POLYGON.

Author(s)

Roger Bivand & Colin Rundel

plot(p2);title(paste("POLYGON\nRing:",gIsRing(p2)));
```
**gIsSimple**

*Is Geometry Simple?*

**Description**

Function tests if the given geometry is simple

**Usage**

`gIsSimple(spgeom, byid = FALSE)`

**Arguments**

- `spgeom`: sp object as defined in package sp
- `byid`: Logical determining if the function should be applied across subgeometries (TRUE) or the entire object (FALSE)

**Details**

Simplicity is used in reference to 0 and 1-dimensional geometries ([MULTI]POINT and [MULTI]LINESTRING) whereas Validity (`gIsValid`) is used in reference to 2-dimensional geometries ([MULTI]POLYGON).

A POINT is always simple.

A MULTIPOINT is simple if no two points are identical.

A LINESTRING is simple if it does not pass through the same point twice (self intersection) except at the end points, in which case it is a ring (`gIsRing`).

A MULTILINESTRING is simple if all of its subgeometries are simple and none of the subgeometries intersect except at end points.

A [MULTI]POLYGON is simple by definition.

Many of the functions in rgeos expect simple/valid geometries and may exhibit unpredictable behavior if given an invalid geometry. Checking of validity/simplicity can be computationally expensive for complex geometries and so is not done by default, any new geometries should be checked.

**Value**

Returns TRUE if the given geometry does not contain anomalous points, such as self intersection or self tangency.

plot(ml3);title(paste("Simple: ",gIsSimple(ml3)))
Details

Validity is used in reference to 2-dimensional geometries (LINEARRING and (MULTI)POLYGON) whereas Simplicity (gIsSimple) is used in reference to 0 and 1-dimensional geometries ((MULTI)POINT and (MULTI)LINESTRING).

A LINEARRING is valid if it does not intersect itself.

A POLYGON is valid if no two rings in the boundary (made up of an exterior ring and interior rings) cross. The boundary of a POLYGON may intersect at a POINT but only as a tangent (i.e. not on a line). A POLYGON may not have cut lines or spikes and the interior rings must be contained entirely within the exterior ring.

A MULTIPOLYGON is valid if and only if all of its elements are valid and the interiors of no two elements intersect. The boundaries of any two elements may touch, but only at a finite number of POINTs.

Many of the functions in rgeos expect simple/valid geometries and may exhibit unpredictable behavior if given an invalid geometry. Checking of validity/simplicity can be computationally expensive for complex geometries and so is not done by default, any new geometries should be checked.

Value

By default will return TRUE if the given geometry is well formed, FALSE otherwise. If reason is set to TRUE then a character string is returned describing the geometry, "Valid Geometry" if it is valid or details of the specific issue. Any given geometry may have multiple issues that make it invalid, gIsValid will only return the first, once it has been corrected additionally checking is necessary to confirm that additional issues do not remain.

---

gLength

**Description**

Calculates the length of the given geometry.

**Usage**

`gLength(spgeom, byid=FALSE)`

**Arguments**

- `spgeom`: sp object as defined in package sp
- `byid`: Logical determining if the function should be applied across subgeometries (TRUE) or the entire object (FALSE)
Value

Returns the length of the geometry in the units of the current projection. By definition [MULTI]POINTs have a length of 0. The length of POLYGONs is the sum of the length of their shell and their hole(s).

gNearestPoints | Closest Points of two Geometries

Description

Return closest points of two geometries.

Usage

gNearestPoints(spgeom1, spgeom2)

Arguments

spgeom1, spgeom2

sp objects as defined in package sp.

Value

The closest points of the two geometries or NULL on exception. The first point comes from spgeom1 geometry and the second point comes from spgeom2.

Author(s)

Rainer Stuetz
gNode

Linestring Noder

Description

Function attempts to node a linestring object, inserting coordinates at intersection points; only available for GEOS >= 3.4.0.

Usage

gNode(spgeom);

Arguments

spgeom an sp object inheriting from SpatialLines

Details

Because gPolygonize expects linestrings to be fully noded, as such they must not cross and must touch only at endpoints. gNodeee takes an object inheriting from SpatialLines and attempts to add omitted nodes. Issue reported by Nicola Farina 21 March 2014.

Value

Returns a noded linestring object.

}

Description

A class for representing polygons composed of multiple contours, some of which may be holes.
Objects from the Class

Objects can be created by calls of the form \texttt{new("gpc.poly", ...)} or by reading in from a file using \texttt{read.polyfile}.

Slots

\texttt{pts} Object of class “list”. Actually, \texttt{pts} is a list of lists with length equal to the number of contours in the "gpc.poly" object. Each element of \texttt{pts} is a list of length 3 with names \texttt{x}, \texttt{y}, and \texttt{hole}. \texttt{x} and \texttt{y} are vectors containing the \texttt{x} and \texttt{y} coordinates, respectively, while \texttt{hole} is a logical indicating whether or not the contour is a hole.

Methods

\begin{verbatim}
[ signature(x = "gpc.poly")]: ...
append.poly signature(x = "gpc.poly", y = "gpc.poly"): ...
area.poly signature(object = "gpc.poly"): ...
coerce signature(from = "matrix", to = "gpc.poly"): ...
coerce signature(from = "data.frame", to = "gpc.poly"): ...
coerce signature(from = "numeric", to = "gpc.poly"): ...
coerce signature(from = "list", to = "gpc.poly"): ...
coerce signature(from = "SpatialPolygons", to = "gpc.poly"): ...
coerce signature(from = "gpc.poly", to = "matrix"): ...
coerce signature(from = "gpc.poly", to = "numeric"): ...
coerce signature(from = "gpc.poly", to = "SpatialPolygons"): ...
get.bbox signature(x = "gpc.poly"): ...
get.pts signature(object = "gpc.poly"): ...
intersect signature(x = "gpc.poly", y = "gpc.poly"): ...
plot signature(x = "gpc.poly"): The argument poly.args can be used to pass a list of additional arguments to be passed to the underlying polygon call.
scale.poly signature(x = "gpc.poly"): ...
setdiff signature(x = "gpc.poly", y = "gpc.poly"): ...
show signature(object = "gpc.poly"): Scale \texttt{x} and \texttt{y} coordinates by amount \texttt{xscale} and \texttt{yscale}. By default \texttt{xscale} equals \texttt{yscale}.
symdiff signature(x = "gpc.poly", y = "gpc.poly"): ...
union signature(x = "gpc.poly", y = "gpc.poly"): ...
tristrip signature(x = "gpc.poly"): ...
triangulate signature(x = "gpc.poly"): ...
\end{verbatim}

Note

The class "gpc.poly.nohole" is identical to "gpc.poly" except the hole flag for each contour of a "gpc.poly.nohole" object is always FALSE.
Examples

```r
## Make some random polygons
set.seed(100)
a <- cbind(rnorm(100), rnorm(100))
a <- a[chull(a), ]

## Convert 'a' from matrix to "gpc.poly"
a <- as(a, "gpc.poly")

b <- cbind(rnorm(100), rnorm(100))
b <- as(b[chull(b), ], "gpc.poly")

## More complex polygons with an intersection
p1 <- read.polyfile(system.file("poly-ex-gpc/ex-poly1.txt", package = "rgeos"))
p2 <- read.polyfile(system.file("poly-ex-gpc/ex-poly2.txt", package = "rgeos"))

## Plot both polygons and highlight their intersection in red
plot(append.poly(p1, p2))
plot(intersect(p1, p2), poly.args = list(col = 2), add = TRUE)

## Highlight the difference p1 \ p2 in green
plot(setdiff(p1, p2), poly.args = list(col = 3), add = TRUE)

## Highlight the difference p2 \ p1 in blue
plot(setdiff(p2, p1), poly.args = list(col = 4), add = TRUE)

## Plot the union of the two polygons
plot(union(p1, p2))

## Take the non-intersect portions and create a new polygon
## combining the two contours
p.comb <- append.poly(setdiff(p1, p2), setdiff(p2, p1))
plot(p.comb, poly.args = list(col = 2, border = 0))

## Coerce from a matrix
x <-
structure(c(0.0934073560027759, 0.192713393476752, 0.410062456627342,

0.17997658040276, 0.341542002301496, 0.445109321058688,
0.610817031707196, 0.596317606444189, 0.459608745684695,
0.215189873417722), .Dim = c(7, 2))
```
x1 <- as(x, "gpc.poly")
y1 <- as(y, "gpc.poly")

plot(append.poly(x1, y1))
plot(intersect(x1, y1), poly.args = list(col = 2), add = TRUE)

## Show the triangulation
#plot(append.poly(x1, y1))
#triangles <- triangulate(append.poly(x1,y1))
#for (i in 0:(nrow(triangles)/3 - 1))
# polygon(triangles[3*i + 1:3,], col="lightblue")

gpc.poly.nohole-class  Class "gpc.poly.nohole"

Description
A class for representing polygons with multiple contours but without holes.

Objects from the Class
Objects can be created by calls of the form ‘new("gpc.poly.nohole", ...) or by calling read.polyfile’.

Slots
pts  Object of class “list”. See the help for “gpc.poly” for details.

Extends
Class “gpc.poly”, directly.

Methods
coerce signature(from = "numeric", to = "gpc.poly.nohole"): ...

Note
This class is identical to “gpc.poly” and is needed because the file formats for polygons without holes is slightly different from the file format for polygons with holes. For a “gpc.poly.nohole” object, the hole flag for each contour is always FALSE.
Also, write.polyfile will write the correct file format, depending on whether the object is of class “gpc.poly” or “gpc.poly.nohole”.

gPointOnSurface

Description

Function returns a point on the surface of the given geometry

Usage

gPointOnSurface(spgeom, byid=FALSE, id = NULL)

Arguments

spgeom sp object as defined in package sp
byid Logical determining if the function should be applied across subgeometries (TRUE) or the entire object (FALSE)
id Character vector defining id labels for the resulting geometries, if unspecified returned geometries will be labeled based on their parent geometries' labels.

Details

Returns a SpatialPoints object with a point that intersects with the geometry

---

### gPolygonize

**Linestring Polygonizer**

#### Description

Function attempts to polygonize the given list of linestrings. If the linestrings are not noded (coordinates inserted at intersection points), the function may fail. `gNode` may be tried to insert such missing points.

#### Usage

```r
library(sp)
gPolygonize( splist, getCutEdges=FALSE);
```

#### Arguments

- `splist` a list of sp `SpatialLines` objects
- `getCutEdges` Logical vector indicating if cut edges should be returned

#### Details

Polygonization is the process of forming polygons from linestrings which enclose an area. Linestrings are expected to be fully noded, as such they must not cross and must touch only at endpoints. `gPolygonize` takes a list of fully noded linestrings and forms all the polygons which are enclosed by the lines. Polygonization errors such as dangling lines or cut lines can be identified and reported.

#### Value

By default returns polygons generated by polygonizing the given linestrings. If `getCutEdges` is `TRUE` then any cut edges are returned.

```
gProject

Project Points to Line Geometry

Description

Return distances along geometry to points nearest the specified points.

Usage

\[
gProject(\text{spgeom}, \text{sppoint, normalized = FALSE})
\]

Arguments

- \text{spgeom}  
  SpatialLines or SpatialLinesDataFrame object
- \text{sppoint}  
  SpatialPoints or SpatialPointsDataFrame object
- \text{normalized}  
  Logical determining if normalized distances should be used

Details

If \text{normalized}=\text{TRUE}, distances normalized to the length of the geometry are returned, i.e., values between 0 and 1.

Value

A numeric vector containing the distances along the line to points nearest to the specified points.

Author(s)

Rainer Stuetz

gInterpolate

Examples

\[
\begin{align*}
\text{l} & \leftarrow \text{readWKT("LINESTRING(0 1, 3 4, 5 6)")} \\
\text{p1} & \leftarrow \text{readWKT("MULTIPOINT(3 2, 3 5)")} \\
\text{frac} & \leftarrow \text{gProject(l, p1)} \\
\text{p2} & \leftarrow \text{gInterpolate(l, frac)} \\
\text{plot(l, axes=TRUE)} \\
\text{plot(p1, col = "blue", add = TRUE)} \\
\text{plot(p2, col = "red", add = TRUE)}
\end{align*}
\]
Description

Determines the relationships between two geometries by comparing the intersection of Interior, Boundary and Exterior of both geometries to each other. The results are summarized by the Dimensionally Extended 9-Intersection Matrix or DE-9IM.

Usage

gRelate(spgeom1, spgeom2 = NULL, pattern = NULL, byid = FALSE, checkValidity=FALSE)

Arguments

- spgeom1, spgeom2: sp objects as defined in package sp. If spgeom2 is NULL then spgeom1 is compared to itself.
- byid: Logical vector determining if the function should be applied across ids (TRUE) or the entire object (FALSE) for spgeom1 and spgeom2
- pattern: Character string containing intersection matrix pattern to match against DE-9IM for given geometries. Wild card * or * characters allowed.
- checkValidity: default FALSE; error messages from GEOS do not say clearly which object fails if a topology exception is encountered. If this argument is TRUE, gisValid is run on each in turn in an environment in which object names are available. If objects are invalid, this is reported and those affected are named

Details

Each geometry is decomposed into an interior, a boundary, and an exterior region, all the resulting geometries are then tested by intersection against one another resulting in 9 total comparisons. These comparisons are summarized by the dimensions of the intersection region, as such intersection at point(s) is labeled P, at linestring(s) is labeled Q, at polygons(s) is labeled R, and if they do not intersect labeled F.

If a pattern is specified then limited matching with wildcards is possible, * matches any character whereas T matches any non-F character.

See references for additional details.

Value

By default returns a 9 character string that represents the DE-9IM.

If pattern returns TRUE if the pattern matches the DE-9IM.
Note

Error messages from GEOS, in particular topology exceptions, report 0-based object order, so geom 0 is spgeom1, and geom 1 is spgeom2.

defaultplot = function() {
  plot(bbox,border='grey')
}
**gSimplify**

**Simplify Geometry**

**Description**

Function simplifies the given geometry using the Douglas-Peuker algorithm

**Usage**

```r
gSimplify(spgeom, tol, topologyPreserve=FALSE)
```

**Arguments**

- `spgeom` sp object as defined in package sp
- `tol` Numerical tolerance value to be used by the Douglas-Peuker algorithm
- `topologyPreserve` Logical determining if the algorithm should attempt to preserve the topology of the original geometry
Details

When applied to lines it is possible for the resulting geometry to lose simplicity (\texttt{gIsSimple}). If topologyPreserve is not specified it is also possible that the resulting geometries may no longer be valid (\texttt{gIsValid}). Remember to check the resulting geometry as many other functions rely on simplicity and or validity when performing their calculations.

Value

Returns a simplified version of the given geometry when applied to \texttt{[MULTI]LINEs} or \texttt{[MULTI]POLYGONs}.

### gSymdifference

\textit{Geometry Symmetric Difference}

\textbf{Description}

Function for determining the symmetric difference between the two given geometries

\textbf{Usage}

```r
gSymdifference(spgeom1, spgeom2, byid=FALSE, id=NULL, drop_lower_td=FALSE, unaryUnion_if_byid_false=TRUE, checkValidity=FALSE)
```
gSymdifference

Arguments

spgeom1, spgeom2
sp objects as defined in package sp

byid
Logical vector determining if the function should be applied across ids (TRUE) or the entire object (FALSE) for spgeom1 and spgeom2

id
Character vector defining id labels for the resulting geometries, if unspecified returned geometries will be labeled based on their parent geometries’ labels.

drop_lower_td
default FALSE; if TRUE, objects will be dropped from output GEOMETRYCOLLECTION objects to simplify output if their topological dimension is less than the minimum topological dimension of the input objects.

unaryUnion_if_byid_false
default TRUE; if byid takes a FALSE in either position, the subgeometries are combined first to avoid possible topology exceptions (change in 0.3-13, previous behaviour did not combine subgeometries, and may be achieved by setting this argument FALSE

checkValidity
default FALSE; error messages from GEOS do not say clearly which object fails if a topology exception is encountered. If this argument is TRUE, gIsValid is run on each in turn in an environment in which object names are available. If objects are invalid, this is reported and those affected are named

Details

Returns the regions of spgeom1 and spgeom2 that do not intersect. If the geometries do not intersect then spgeom1 and spgeom2 will be returned as separate subgeometries.

Note

Error messages from GEOS, in particular topology exceptions, report 0-based object order, so geom 0 is spgeom1, and geom 1 is spgeom2.

y = readWKT("POLYGON ((5 5, 15 5, 15 15, 5 15, 5 5))")

d = gSymdifference(x,y)
plot(d,col='red',bg='white')
gTones

Geometry Relationships - Touches

Description
Functions for testing if the geometries have at least one boundary point in common, but no interior points.

Usage
gTones(spgeom1, spgeom2 = NULL, byid = FALSE, returnDense=TRUE, checkValidity=FALSE)

Arguments

spgeom1, spgeom2
sp objects as defined in package sp. If spgeom2 is NULL then spgeom1 is compared to itself.

byid
Logical vector determining if the function should be applied across ids (TRUE) or the entire object (FALSE) for spgeom1 and spgeom2.

returnDense
default TRUE, if false returns a list of the length of spgeom1 of integer vectors listing the indices which would be TRUE in the dense logical matrix representation; useful when the sizes of the byid=TRUE returned matrix is very large and it is sparse; essential when the returned matrix would be too large.

checkValidity
default FALSE; error messages from GEOS do not say clearly which object fails if a topology exception is encountered. If this argument is TRUE, gIsValid is run on each in turn in an environment in which object names are available. If objects are invalid, this is reported and those affected are named.

Value
Returns TRUE if the intersection of the boundaries of the two geometries is not empty.

Note
Error messages from GEOS, in particular topology exceptions, report 0-based object order, so geom 0 is spgeom1, and geom 1 is spgeom2.

**gUnion**

*Geometry Union*

**Description**

Functions for joining intersecting geometries.

**Usage**

```r
gUnion(spgeom1, spgeom2, byid=FALSE, id=NULL, drop_lower_td=FALSE, 
       unaryUnion_if_byid_false=TRUE, checkValidity=FALSE)
gUnionCascaded(spgeom, id = NULL)
gUnaryUnion(spgeom, id = NULL)
gLineMerge(spgeom, byid=FALSE, id = NULL)
```
Arguments

spgeom1, spgeom2
- sp objects as defined in package sp

byid
- Logical vector determining if the function should be applied across ids (TRUE) or the entire object (FALSE) for spgeom1 and spgeom2

id
- Character vector defining id labels for the resulting geometries, if unspecified returned geometries will be labeled based on their parent geometries’ labels; it may contain NA values for input objects not included in the union; it should define the memberships of the output Polygons objects

drop_lower_td
- default FALSE; if TRUE, objects will be dropped from output GEOMETRYCOLLECTION objects to simplify output if their topological dimension is less than the minimum topological dimension of the input objects.

spgeom
- sp Polygon(s) or Line(s) depending on the function used

unaryunion_if_byid_false
- default TRUE; if byid takes a FALSE in either position, the subgeometries are combined first to avoid possible topology exceptions (change in 0.3-13, previous behaviour did not combine subgeometries, and may be achieved by setting this argument FALSE

checkValidity
- default FALSE; error messages from GEOS do not say clearly which object fails if a topology exception is encountered. If this argument is TRUE, gIsValid is run on each in turn in an environment in which object names are available. If objects are invalid, this is reported and those affected are named

Details

Returns an sp object with intersecting geometries merged. If geometries do not intersect then both are returned as distinct subgeometries.

gUnionCascaded expects a single sp object of class SpatialPolygons with subgeometries which it unions together. gUnionCascaded can only dissolve MultiPolygon objects, so GeometryCollection objects to be dissolved, here a SpatialPolygons object, must be flattened a Polygons object; if GEOS version 3.3.0 is available, use gUnaryUnion.

gUnaryUnion expects a single sp object of class SpatialPolygons with subgeometries which it unions together; introduced in GEOS version 3.3.0, and handles GeometryCollection objects. If the id argument is used, it should be a character vector defining the memberships of the output Polygons objects, equal in length to the length of the polygons slot of spgeom.

gLineMerge is similar to gUnionCascaded but is written to work with lines, specifically it joins line segments with intersecting end points.

Note

Error messages from GEOS, in particular topology exceptions, report 0-based object order, so geom 0 is spgeom1, and geom 1 is spgeom2.

**new-generics**

*Generics/Methods for polygon objects*

**Description**

Some generic functions and methods for polygon objects

**Usage**

```r
append.poly(x, y)
area.poly(object, ...)
get pts(object)
```
get.bbox(x)
scale.poly(x, ...)
tristrip(x)
triangulate(x)

Arguments

x, object A polygon object
y A polygon object
... Other arguments passed to methods

Details

The result of `tristrip(x)` is a list of two-column matrices. Each matrix is a tristrip, i.e. the rows are vertices of triangles, with each overlapping triple of rows corresponding to a separate triangle.

The result of `triangulate(x)` is a single two-column matrix. The rows are vertices of triangles, taken in non-overlapping triples.

Methods

`append.poly` signature(x = "gpc.poly", y = "gpc.poly"): Combine all contours of two "gpc.poly" objects and return the combined polygon as a "gpc.poly" object.

`area.poly` signature(object = "gpc.poly"): Compute and return the sum of the areas of all contours in a "gpc.poly" object.

`scale.poly` signature(x = "gpc.poly"): Scale (divide) the x and y coordinates of a "gpc.poly" object by the amount xscale and yscale, respectively. Return a scaled "gpc.poly" object.

`get.pts` signature(object = "gpc.poly"): Return the list of x and y coordinates of the vertices of a "gpc.poly" object.

`get.bbox` signature(x = "gpc.poly"): Return the bounding box for a "gpc.poly" object.

`tristrip` signature(x = "gpc.poly"): Return a tristrip list for a "gpc.poly" object.

`triangulate` signature(x = "gpc.poly"): Return a matrix of vertices of a triangulation of a "gpc.poly" object.

Author(s)

Roger D. Peng; GPC Library by Alan Murta; tristrip additions by Duncan Murdoch

See Also

"gpc.poly" class documentation.

Examples

```r
holepoly <- read.polyfile(system.file("poly-ex-gpc/hole-poly.txt", package ="rgeos"), nohole = FALSE)
area.poly(holepoly)
stopifnot(area.poly(holepoly) == 8)
```
Find spatial join or intersections

Usage

overGeomGeom(x, y, returnList = FALSE, fn = NULL, ..., minDimension = -1)
overGeomGeomDF(x, y, returnList = FALSE, fn = NULL, ..., minDimension = -1)

Arguments

x, y see over
returnList see over
fn see over
...
minDimension integer; if -1, gIntersects is used to find geometry intersections; if 0, 1 or 2, gRelate is used. If gRelate is used, intersecting geometries are ordered by the dimension of the intersection (2: area overlap; 1: line in common; 0: point in common), and minDimension determines the minimum dimension of intersection required.

Value

see over

Note

gRelate (minDimension > -1) is likely to be substantially slower than gIntersects.

Author(s)

Edzer Pebesma

Examples

p1 = readWKT("POLYGON((0 0.95 0.31,0.59 -0.81,-0.59 -0.81,-0.95 0.31,0 1))")
p2 = readWKT("POLYGON((2 2,-2 2,-2,-2,2 2),(-1 1, -1 1, -1, -1, -1))")

overGeomGeom(p1,p2)
polyfile

Read/Write polygon data

Description

Read/Write polygon and contour information from/to a text file.

Usage

```r
read.polyfile(filename, nohole = TRUE)
write.polyfile(poly, filename = "GPCpoly.txt")
```

Arguments

- `filename` the name of the file (a character string) from/to which data should be read/written.
- `nohole` Is this a polygon without holes?
- `poly` an object of class "gpc.poly"

Details

The text file representation of a polygon is of the following format:

```
<number of contours>
<number of points in first contour>
x1 y1
x2 y2
...
<number of points in second contour>
x1 y1
x2 y2
...
```

For example, a data file for a polygon with 2 contours (a four-sided object and a triangle) might look like:

```
2
4
1.0 1.0
1.0 2.0
3.4 3.21
10 11.2
3
21.0 11.2
22.3 99.2
4.5 5.4
```

The vertices of the polygon can be ordered either clockwise or counter-clockwise.
If a polygon has contours which are holes, then the format is slightly different. Basically, a flag is set to indicate that a particular contour is a hole. The format is

```
<number of contours>
<number of points in first contour>
<hole flag>
x1 y1
x2 y2
...
<number of points in second contour>
<hole flag>
x1 y1
x2 y2
...
```

The hole flag is either 1 to indicate a hole, or 0 for a regular contour. For example, a four-sided polygon with a triangular hole would be written as:

```
2
3
1
4.0 4.0
6.0 5.0
5.0 6.0
4
0
2.0 1.0
8.0 2.0
7.0 9.0
1.0 7.0
```

**Value**

If `nohole` is TRUE (the default) `read.polyfile` returns an object of class "gpc.poly.nohole". This object has the hole flag set to FALSE for all contours. If `nohole` is FALSE, then an object of class "gpc.poly" is returned.

`write.polyfile` does not return anything useful.

**Examples**

```r
## None right now.
```
polygonsLabel  

*Compute optimal label positions for polygons*

**Description**

Compute optimal positions for placing labels inside polygons, and optionally plot the labels. Various algorithms for finding the 'optimal' label positions are supported.

**Usage**

```r
polygonsLabel(pols, labels = NULL, method = c("maxdist", "buffer", "centroid", "random", "inpolygon")[1], gridpoints = 60, polypart = c("all", "largest")[1], cex = 1, doPlot = TRUE, ...)
```

**Arguments**

- `pols` Object of class, or deriving from, `SpatialPolygons`.
- `labels` Character vector of labels. Will be recycled to have the same number of elements as the number of polygons in `pols`. If `labels` is `NULL` or empty, the label box is taken as a square with sides equal to the current line height (see the `cex` argument).
- `method` The method(s) to use when finding label positions. Will be recycled. Valid methods are `maxdist` (currently the default), `buffer`, `centroid`, `random` and `inpolygon`.
- `gridpoints` Number of grid points to use for the initial grid search in the `maxdist` method.
- `polypart` Should all (default) or only the `largest` polygon part of each polygon in `pols` be used for the calculations? Will be recycled. Setting this to `largest` is very useful when labelling detailed coastlines of a country, consisting of a large polygon (where the label should be placed) and very many tiny islands, as it will greatly speed up the search for an optimal label position. But do note that this also removes any holes (e.g., lakes) before calculating the label position, so the labels are no longer guaranteed not to overlap a hole.
- `cex` Magnification factor for text labels. Is used both when plotting the labels and when calculating the label positions.
- `doPlot` Plot the labels on the current graphics device. Calls the `text` function internally.

**Details**

There are no perfect definitions of 'optimal' label positions, but any such position should at least satisfy a few requirements: The label should be positioned wholly inside the polygon. It should also be far from any polygon edges. And, though more difficult to quantify, it should be positioned in the visual centre (or bulk) of the polygon. The algorithms implemented here seems to generally do a very good job of finding optimal (or at least 'good') label positions.
The maxdist method is currently the default, and tries to find the label position with a maximal distance from the polygon edges. More precisely, it finds a position where the minimal distance of any point on the (rectangular) label box to the polygon boundary is maximised. It does this by first trying a grid search, using gridpoints regular grid points on the polygon, and then doing local optimisation on the best grid point. The default grid is quite coarse, but usually gives good results in a short amount of time. But for very complicated (and narrow) polygons, it may help increasing gridpoints. Note that while this method gives good results for most natural polygons, e.g., country outlines, the theoretical optimal position is not necessarily unique, and this is sometimes seen when applying the method to regular polygons, like rectangles (see example below), where the resulting position may differ much from what one would judge to be the visual centre of the polygon.

The buffer method works by shrinking the polygon (using negative buffering) until the convex hull of the shrunken polygon can fit wholly inside the original polygon. The label position is then taken as the centroid of the shrunken polygon. This method usually gives excellent results, is surprisingly fast, and seems to capture the ‘visual centre’ idea of an optimal label position well. However, it does not guarantee that the label can fit wholly inside the polygon. (However, if it does not fit, there are usually no other better position either.)

The centroid method simply returns the centroid of each polygon. Note that although this is the geometrical/mathematical centre of the polygon, it may actually be positioned outside the polygon. For regular polygons (rectangles, hexagons), it gives perfect results. Internally, this method uses the coordinates function. There are three reasons this method is supported: To make it easy to find the centroid of the largest polygon part of a polygon (using the polypart argument), to make it easy to use the centroid algorithm along with other algorithms (using the vector nature of the method argument), and for completeness.

The random method returns a random position guaranteed to be inside the polygon. This will rarely be an optimal label position!

The inpolygon method finds an arbitrary position in the polygon. This position is usually quite similar to the centroid, but is guaranteed to be inside the polygon. Internally, the method uses the gPointOnSurface function.

**Value**

A two-column matrix is returned, with each row containing the horizontal and vertical coordinates for the corresponding polygon. If doPlot is TRUE (the default), the labels are also plotted on the current graphics device, with the given value of cex (font size scaling).

**Note**

Note that both the labels, method and polypart arguments are vectors, so it’s possible to use different options for each polygon in the pols object.

RGEOS Experimental Functions

**Experimental Functions**

### Description

Functions still under development using the GEOS STRtree structure to find intersecting object component envelopes (bounding boxes).

### Usage

- `gUnarySTRtreeQuery(obj)`
- `gBinarySTRtreeQuery(obj1, obj2)`
- `poly_findInBoxGEOS(spl, as_points=TRUE)`

### Arguments

- `obj, obj1, obj2`
  - Objects inheriting from either SpatialPolygons or SpatialLines, `obj2` may also inherit from SpatialPoints
- `spl`
  - Object that inherits from the SpatialPolygons class
- `as_points`
  - Logical value indicating if the polygon should be treated as points
Details

gUnarySTRtreeQuery and poly_findInBoxGEOS do the same thing, but poly_findInBoxGEOS uses the as_points argument to build the input envelopes from proper geometries. gUnarySTRtreeQuery and gBinarySTRtreeQuery build input envelopes by disregarding topology and reducing the coordinates to a multipoint representation. This permits the tree to be built and queried even when some geometries are invalid. gUnarySTRtreeQuery and poly_findInBoxGEOS return a list of length (n-1) of 1-based indices only for the “greater than i” indices. gBinarySTRtreeQuery returns a list of the length of obj2 with 1-based indices of obj1.

Examples

```r
if (require(maptools)) {
  xx <- readShapeSpatial(system.file("shapes/fylk-val-ll.shp",
    package="maptools")[[1]], proj4string=CRS("+proj=longlat +datum=WGS84"))
a0 <- gUnarySTRtreeQuery(xx)
a0
  bbxx <- bbox(xx)
  wdb_lines <- system.file("share/wdbBorders.c.b", package="maptools")
  xxx <- Rgshhs(wdb_lines, xlim=bbxx[1,], ylim=bbxx[2,])
a1 <- gBinarySTRtreeQuery(xxx, xxx)
a1
  ncl <- readShapePoly(system.file("shapes/sids.shp", package="maptools")[[1]],
    proj4string=CRS("+proj=longlat +datum=NAD27"))
a2 <- gUnarySTRtreeQuery(ncl)
a3 <- poly_findInBoxGEOS(ncl)
  all.equal(a2, a3)
a2
  pl <- slot(ncl, "polygons")[[4]]
a5 <- gUnarySTRtreeQuery(pl)
a5
  SG <- SobjSpatialGrid(ncl, n=400)
  obj1 <- as(as(SG, "SpatialPixels"), "SpatialPolygons")
a4 <- gBinarySTRtreeQuery(ncl, obj1)
  plot(ncl, col="orange", border="yellow")
  plot(obj1, angle=sapply(a4, is.null)*45, density=20, lwd=0.5, add=TRUE)
  set.seed(1)
  pts <- spsample(ncl, n=10, type="random")
  res <- gBinarySTRtreeQuery(ncl, pts)
}
```
**RGEOS Polygon Hole Comment Functions**

**Description**

Utility functions for assigning ownership of holes to parent polygons

**Usage**

```r
createSPComment(sppoly, which=NULL, overwrite=TRUE)
createPolygonsComment(poly)
  set_do_poly_check(value)
  get_do_poly_check()
```

**Arguments**

- `sppoly`: Object that inherits from the `SpatialPolygons` class
- `which`: Vector, which subset of geometries in `sppoly` should comment attributes be generated
- `overwrite`: Logical, if a comment attribute already exists should it be overwritten
- `poly`: Object of class `Polygons`
- `value`: logical value to set “do_poly_check” option, default TRUE

**Details**

In order for rgeos to function properly it is necessary that all holes within a given POLYGON or MULTIPOLYGON geometry must belong to a specific polygon. The `SpatialPolygons` class implementation does not currently include this information. To work around this limitation rgeos uses an additional comment attribute on the `polygons` class that indicates which hole belongs to which polygon.

Under the current implementation this comment is a text string of numbers separated by spaces where the order of the numbers corresponds to the order of the Polygon objects in the Polygons slot of the Polygons object. A 0 implies the Polygon object is a polygon, a non-zero number implies that the Polygon object is a hole with the value indicating the index of the Polygon that “owns” the hole.

`createPolygonsComment` attempts to create a valid comment for a `Polygons` object by assessing which polygons contain a given hole (using `gContains`). Ownership is assigned to the smallest polygon (by area) that contains the given hole. This is not guaranteed to generate valid polygons, always check the resulting objects for validity.

`createSPComment` attempts to create valid comments for all or a subset of polygons within a `SpatialPolygons` object.

**Warning: check polygons**

The helper functions get and set the imposition of checking of objects inheriting from `SpatialPolygons` for proper assignment of hole interior rings to exterior rings in `Polygons` objects. The internal GEOS representation defines a POLYGON object as a collection of only one exterior ring and from zero to many interior rings, so an `sp` `Polygons` object corresponds to a GEOS MULTIPOLYGON object, but without proper hole assignment. By default `do_poly_check` is TRUE; if it is set to FALSE using `set_do_poly_check(FALSE)`, and the `Polygons` object is not valid in GEOS terms, GEOS may crash R, which is why checks are imposed by default.
The details below show how hole assignment is handled in the package; here we assume that the hole status slots of all Polygon objects in a given Polygons object are set correctly. In the examples below, we use a data set from `maptools` which has the holes correctly assigned, and we see that the SpatialPolygons object is geometrically valid both initially and after removing the comment attribute on the only Polygons object in `usa` - regenerating internally within `rgeos` from the hole status slots since `do_poly_check` is TRUE.

If we modify `usa` by setting all hole status slots to FALSE, the SpatialPolygons object is geometrically invalid even though a comment attribute can be created - the function `createSPComment` is deceived by the incorrect hole status slots. To rectify this, we use `checkPolygonsHoles` from `maptools` on each Polygons object. This function calls `gContains`, `gContainsProperly`, `gEquals` and `createPolygonsComment` from `rgeos` to check whether the hole status slots are set correctly. Experience shows that many imported datasets from for example publically provided shapefiles have incorrect hole status values. Running `checkPolygonsHoles` is time-consuming when the number of member Polygon objects is large - attempts will be made to make this more efficient.

**Warning: planar geometries**

The geometries handled by GEOS are assumed to be planar, so that any `rgeos` functions making measurements will give incorrect results when used on geographical coordinates measured in decimal degrees. Topological functions may work satisfactorily, but will not understand spherical wrap-around.

Description

Utility functions for the RGEOS package

Usage

```r
getscale()
setscale(scale=100000000)
translate(spgeom)
checkP4S(p4s)

version_GEOS()
rgeos_extSoftVersion()
version_GEOS0()
set_RGEOS_polyThreshold(value)
get_RGEOS_polyThreshold()
set_RGEOS_warnSlivers(value)
get_RGEOS_warnSlivers()
set_RGEOS_dropSlivers(value)
get_RGEOS_dropSlivers()
```

Arguments

- `scale`: Numeric value determining the precision of translated geometries
- `spgeom`: sp object as defined in package sp
- `p4s`: Either a character string or an object of class CRS
- `value`: the value to be passed to an RGEOS option in its environment

Details

getScale and setScale are used to get and set the scale option in the rgeos environment. This option is used to determine the precision of coordinates when translating to and from GEOS C objects. Precision is defined as \( \frac{1}{\text{scale}} \). The final example is a use case reported by Mao-Gui Hu, who has also made the objects available, where the default scale defeats an intended line intersection operation; changing the scale temporarily resolves the issue.

In order to permit polygon slivers to be detected, reported and dropped, the user may set a numeric value for polyThreshold and logical values for warnSlivers and dropSlivers. By default, the threshold is 0.0, and warning and dropping are FALSE. To detect slivers, the threshold may be set to a small value and warnSlivers set to TRUE. To drop slivers from returned Polygons and Polygon objects, set dropSlivers to TRUE for a non-zero threshold.

translate is a testing function which translates the sp object into a GEOS C object and then back into an sp object and is used extensively in the translation unit tests. In all cases it is expected that `spgeom` and `translate(spgeom)` should be identical.

checkP4S is a validation function for proj4strings and is used in testing.

version_GEOS returns the full runtime version string, and version_GEOS0 only the GEOS version number.

RGEOS WKT Functions

Description

Functions for reading and writing Well Known Text (WKT)

Usage

readWKT(text, id = NULL, p4s = NULL)
writeWKT(spggeom, byid = FALSE)

Arguments

text character string of WKT
id character vector of unique ids to label geometries. Length must match the number of subgeometries in the WKT
p4s Either a character string or an object of class CRS
spgeom sp object as defined in package sp
byid Logical determining if the function should be applied across subgeometries (TRUE) or the entire object (FALSE)
**Details**

readWKT processes the given WKT string and returns an appropriate sp geometry object. If id is not specified then geometries will be labeled by their index position. Because no sp Spatial object may be empty, readWKT is not permitted to create an empty object.

writeWKT converts an sp geometry object to a GEOS C object which is then written out as a WKT string. If byid is TRUE then each subgeometry is individually converted to a WKT string.

**Ring-class**

**Class “Ring”**

**Description**

class for linear ring
Objects from the Class

Objects can be created by calls to the function `Ring`

Slots

- `coords`: Object of class "matrix"; coordinates of the ring; first point should equal the last point
- `ID`: Object of class "character"; unique identifier string

Methods

Methods defined with class "Ring" in the signature:

- **bbox** signature(obj = "Ring"): retrieves the bbox element
- **coordinates** signature(object = "Ring"): retrieves the coords element from Ring objects in rings slot
- **coordnames** signature(object = "Ring"): retrieves coordinate names
- **coerce** signature(from = "Ring", to = "SpatialPoints"): ...

Author(s)

Colin Rundel

See Also

- **Ring**

Examples

#none

SpatialCollections create SpatialCollections

Description

create object of class `SpatialCollections`

Usage

```
SpatialCollections(points=NULL, lines=NULL, rings=NULL, polygons=NULL, plotOrder=c(4,3,2,1), proj4string=CRS(as.character(NA)))
```
SpatialCollections-class

Arguments

- **points**: list with objects of class `SpatialPoints-class`
- **lines**: list with objects of class `SpatialLines-class`
- **rings**: list with objects of class `SpatialRings-class`
- **polygons**: list with objects of class `SpatialPolygons-class`
- **plotOrder**: numeric vector of length 4 that determines the order in which the geometries will be plotted. By default polygons will be plotted followed by rings, then lines and finally points.
- **proj4string**: Object of class "CRS" holding a valid proj4 string

Value

`SpatialCollections` returns object of class `SpatialCollections`

See Also

`SpatialCollections-class` `SpatialPoints-class` `SpatialLines-class` `SpatialRings-class` `SpatialPolygons-class`

SpatialCollections-class

Class "SpatialCollections"

Description

class to hold SpatialPoints, SpatialLines, SpatialRings, and SpatialPolygons (without attributes)

Objects from the Class

Objects can be created by calls to the function `SpatialCollections`

Slots

- **pointobj**: Object of class `SpatialPoints` or NULL
- **lineobj**: Object of class `SpatialLines` or NULL
- **ringobj**: Object of class `SpatialRings` or NULL
- **polyobj**: Object of class `SpatialPolygons` or NULL
- **plotOrder**: Numeric vector of length 4

Extends

Class "Spatial", directly.
Methods

Methods defined with class "SpatialCollections" in the signature:

- **plot** signature(x = "SpatialCollections", y = "missing"): plot objects within the SpatialCollections object in the order specified by plotOrder slot
- **row.names** signature(object = “SpatialCollections”): retrieves the ID elements from non-NULL geometry slots

SpatialRings create SpatialRings or SpatialRingsDataFrame

Description

create objects of class SpatialRings or SpatialRingsDataFrame

Usage

Ring(coords,ID=as.character(NA))
SpatialRings(RingList, proj4string=CRS(as.character(NA)))
SpatialRingsDataFrame(sr, data, match.ID = TRUE)

Arguments

- **coords** 2-column numeric matrix with coordinates; first point (row) should equal last coordinates (row); if the hole argument is not given, the status of the polygon as a hole or an island will be taken from the ring direction, with clockwise meaning island, and counter-clockwise meaning hole
- **ID** character vector of length one with identifier
- **RingList** list with objects of class Ring-class
- **proj4string** Object of class "CRS" holding a valid proj4 string
- **sr** object of class SpatialRings-class
SpatialRings-class

- **data**: object of class data.frame; the number of rows in data should equal the number of Lines elements in sl.
- **match.ID**: logical: (default TRUE): match SpatialLines member Lines ID slot values with data frame row names, and re-order the data frame rows if necessary.

**Value**

- Ring returns object of class Ring
- SpatialRings returns object of class SpatialRings
- SpatialRingsDataFrame returns object of class SpatialRingsDataFrame

**See Also**

Ring-class, SpatialRings-class, SpatialRingsDataFrame-class

**SpatialRings-class  Class "SpatialRings"**

**Description**

class to hold linear ring topology (without attributes)

**Objects from the Class**

Objects can be created by calls to the function SpatialRings

**Slots**

- **rings**: Object of class "list"; list elements are all of class Ring-class
- **bbox**: Object of class "matrix"; see Spatial-class
- **proj4string**: Object of class "CRS"; see CRS-class

**Extends**

Class "Spatial", directly.

**Methods**

Methods defined with class "SpatialRings" in the signature:

- `[` signature(obj = "SpatialRings"): select subset of (sets of) rings; NAs are not permitted in the row index
- `plot` signature(x = "SpatialRings", y = "missing"): plot rings in SpatialRings object
- `bbox` signature(obj = "SpatialRings"): retrieves the bbox element
- `coordinates` signature(object = "SpatialRings"): retrieves the coords element from Ring objects in rings slot
- `coordnames` signature(object = "SpatialRings"): retrieves coordinate names
row.names signature(object = "SpatialRings"): retrieves the ID element from Ring objects in rings slot
spChFIDs signature(obj="SpatialRings", x="character"): replaces ID element
coerce signature(from = "SpatialRings", to = "SpatialPoints"): ...

SpatialRingsDataFrame-class

Class "SpatialRingsDataFrame"

Description
class to hold linear ring topology (without attributes)

Objects from the Class
Objects can be created by calls to the function SpatialRingsDataFrame

Slots
data: Object of class "data.frame"; attribute table
rings: Object of class "list"; list elements are all of class Ring-class
bbox: Object of class "matrix"; see Spatial-class
proj4string: Object of class "CRS"; see CRS-class

Extends
Class "SpatialRings", directly. Class "Spatial", by class "SpatialRings".
Methods

Methods defined with class "SpatialRingsDataFrame" in the signature:

- `signature(obj = "SpatialRingsDataFrame")`: select subset of (sets of) rings; NAs are not permitted in the row index
- `plot signature(x = "SpatialRingsDataFrame", y = "missing")`: plot rings in SpatialRingsDataFrame object
- `bbox signature(obj = "SpatialRingsDataFrame")`: retrieves the bbox element
- `coordinates signature(object = "SpatialRingsDataFrame")`: retrieves the coords element from Ring objects in rings slot
- `coord.names signature(object = "SpatialRingsDataFrame")`: retrieves coordinate names
- `row.names signature(object = "SpatialRingsDataFrame")`: retrieves the ID element from Ring objects in rings slot
- `spChFIDs signature(obj="SpatialRingsDataFrame", x="character")`: replaces ID element
- `names signature(object = "SpatialRingsDataFrame")`: retrieves names from data element
- `dim signature(object = "SpatialRingsDataFrame")`: retrieves dimensions of data element
- `coerce signature(from = "SpatialRingsDataFrame", to = "SpatialPoints")`: ...
- `coerce signature(from = "SpatialRingsDataFrame", to = "SpatialRings")`: ...
- `coerce signature(from = "SpatialRingsDataFrame", to = "data.frame")`: ...
