boot_samples Draw bootstrap samples

Description

Draw bootstrap samples to be used for (fast and robust) bootstrap tests for mediation analysis. Note that this function is intended for use in simulation studies, it is not expected to be called by the user.

Usage

```r
boot_samples(n, R)
```

Arguments

- `n` an integer giving the number of observations in the original data set.
- `R` an integer giving the number of bootstrap samples to be generated.

Value

An object of class "boot_samples" with the following components:

- `indices` an integer matrix in which each column contains the indices of the corresponding bootstrap sample.
- `seed` the state of the random number generator before the bootstrap samples were drawn

Examples

```r
# control parameters
n <- 100
a <- b <- c <- 0.2

# generate data
set.seed(20150326)
x <- rnorm(n)
m <- a * x + rnorm(n)
y <- b * m + c * x + rnorm(n)
simulated_data <- data.frame(x, y, m)

# perform bootstrap tests
indices <- boot_samples(n, R = 5000)
standard_boot <- test_mediation(simulated_data,
x = "x", y = "y", m = "m",
robust = FALSE,
indices = indices)
summary(standard_boot)
robust_boot <- test_mediation(simulated_data,
x = "x", y = "y", m = "m",
robust = TRUE,
indices = indices)
summary(robust_boot)
```

Description

The data were collected from 354 senior business administration students during a business simulation game at a Western European University.

The game was played for a total of 12 rounds (i.e., two separate games of 6 rounds) as part of the capstone strategy class. Students were randomly assigned to teams of four, and surveyed in three waves: prior to, during, and after the simulation game (with different variables being surveyed in the different waves).

The 354 students formed 92 teams, and the responses of individual students were aggregated to the team level. Leaving out teams with less than 50 percent response rate yields \( n = 89 \) teams. Only a small subset of the collected variables are included here.
Usage

data("BSG2014")

Format

A data frame with 89 observations on the following 7 variables.

ProcessConflict Process conflict was measured with the three item scale of Jehn (1995) and responses were aggregated.

SharedExperience Teams were randomly formed, no prior shared group experience is expected and shared group experience and training is developed during the first game for the second game. Team performance in the first game, which was determined by objective performance measures, is a good proxy for the level of shared group experience and training.

TaskConflict Task conflict was operationalized with the intra-group conflict scale of Jehn (1995). Five items on the presence of conflict were rated on a 5-point Likert scale (1 = none, 5 = a lot) and aggregated.

TeamCommitment Team commitment was measured by four items based on Mowday, Steers & Porter (1979) and responses were aggregated.

TeamPerformance Team performance in the second game was measured subjectively by the team members’ perceptions of the team’s functioning. Hackman’s (1986) Likert scale items were thereby used to operationalize team performance.

TMS Transactive memory systems (TMS) are defined as shared systems that people in relationships develop for encoding, storing, and retrieving information about different substantive domains. TMS was operationalized with Lewis’ (2003) 15-item scale that measures the three sub-dimensions of TMS (credibility, specialization and coordination). Team members responded on a 5-point scale (1 = strongly disagree, 5 = strongly agree). Following Lewis (2003), the three sub dimensions were aggregated to form the TMS construct.

ValueDiversity Value diversity was operationalized with the short version of Schwartz’s Value Survey (SVS) to measure team members’ individual values (Lindeman & Verkasalo, 2005). The responses were aggregated with the average of the coefficient of variations of each value dimension among team members.

dotplot with confidence intervals

Description

Produce a dot plot with confidence intervals of selected effects from (robust) mediation analysis.

Usage

ci_plot(object, ...)

## Default S3 method:
.ci_plot(object, parm = NULL, ...)

## S3 method for class 'boot_test_mediation'
.ci_plot(object, parm = NULL,
         type = c("boot", "data"), ...)

## S3 method for class 'sobel_test_mediation'
.ci_plot(object, parm = NULL,
         level = 0.95, ...)

## S3 method for class 'list'
.ci_plot(object, parm = NULL, type = c("boot", "data"),...
ci_plot

level = 0.95, ...)

## S3 method for class 'setup_ci_plot'
ci_plot(object, ...)

Arguments

object
  an object inheriting from class "test_mediation" containing results from (robust) mediation analysis, or a list of such objects.

... additional arguments to be passed down.

parm
  a character string specifying the effects to be included in the plot. The default is to include the direct and the indirect effect(s).

type
  a character string specifying which point estimates and confidence intervals to plot: those based on the bootstrap distribution ("boot"; the default), or those based on the original data ("data"). If "boot", the confidence intervals of effects other than the indirect effect(s) are computed using a normal approximation (i.e., assuming a normal distribution of the corresponding effect with the standard deviation computed from the bootstrap replicates). If "data", the confidence intervals of effects other than the indirect effect(s) are computed via statistical theory based on the original data (e.g., based on a t-distribution the coefficients are estimated via regression). Note that this is only relevant for mediation analysis via a bootstrap test, where the confidence interval of the indirect effect is always computed via a percentile-based method due to the asymmetry of its distribution.

level numeric; the confidence level of the confidence intervals from Sobel’s test. The default is to include 95% confidence intervals. Note that this is not used for bootstrap tests, as those require to specify the confidence level already in test_mediation().

Details

Methods first call setup_ci_plot() to extract all necessary information to produce the plot, then the "setup_ci_plot" method is called to produce the plot.

Value

An object of class "ggplot".

coef.test_mediation  Coefficients in (robust) mediation analysis

Description

Extract coefficients from models computed in (robust) mediation analysis.

Usage

## S3 method for class 'test_mediation'
coef(object, parm = NULL, ...)

## S3 method for class 'boot_test_mediation'
coef(object, parm = NULL,
   type = c("boot", "data"), ...)

## S3 method for class 'fit_mediation'
coef(object, parm = NULL, ...)
Arguments

object an object inheriting from class "test_mediation" containing results from (robust) mediation analysis, or an object inheriting from class "fit_mediation" containing a (robust) mediation model fit.

parm an integer, character or logical vector specifying the coefficients to be extracted, or NULL to extract all coefficients.

... additional arguments are currently ignored.

type a character string specifying whether to extract the means of the bootstrap distribution ("boot"; the default), or the coefficient estimates based on the full data set ("data").

Value

A numeric vector containing the requested coefficients.

Author(s)

Andreas Alfons

See Also

test_mediation(), fit_mediation(), confint()

Examples

data("BSG2014")

# fit robust mediation model and extract coefficients
fit <- fit_mediation(BSG2014,
                     x = "ValueDiversity",
                     y = "TeamCommitment",
                     m = "TaskConflict")

coef(fit)

# run fast and robust bootstrap test and extract coefficients
test <- test_mediation(fit)

coef(test, type = "data")  # from original sample
coef(test, type = "boot")  # means of bootstrap replicates

confint.test_mediation

Confidence intervals for (robust) mediation analysis

Description

Extract or compute confidence intervals for coefficients from (robust) mediation analysis.
Usage

```r
## S3 method for class 'boot_test_mediation'
confint(object, parm = NULL,
        level = NULL, type = c("boot", "data"), ...)

## S3 method for class 'sobel_test_mediation'
confint(object, parm = NULL,
        level = 0.95, ...)
```

Arguments

- `object`: an object inheriting from class "test_mediation" containing results from (robust) mediation analysis.
- `parm`: an integer, character or logical vector specifying the coefficients for which to extract or compute confidence intervals, or NULL to extract or compute confidence intervals for all coefficients.
- `level`: for the "boot_test_mediation" method, this is ignored and the confidence level of the bootstrap confidence interval for the indirect effect is used. For the other methods, the confidence level of the confidence intervals to be computed. The default is to compute 95% confidence intervals.
- `type`: a character string specifying how to compute the confidence interval of the effects other than the indirect effect(s). Possible values are "boot" (the default) to compute bootstrap confidence intervals using the normal approximation (i.e., to assume a normal distribution of the corresponding effect with the standard deviation computed from the bootstrap replicates), or "data" to compute confidence intervals via statistical theory based on the original data (e.g., based on a t-distribution the coefficients are estimated via regression). Note that this is only relevant for mediation analysis via a bootstrap test, where the confidence interval of the indirect effect is always computed via a percentile-based method due to the asymmetry of its distribution.
- `...`: additional arguments are currently ignored.

Value

A numeric matrix containing the requested confidence intervals.

```

---

cov_control

Tuning parameters for Huber M-estimation of location and scatter

**Description**

Obtain a list with tuning parameters for `cov_Huber()`.

**Usage**

```r
cov_control(prob = 0.95, max_iterations = 200, tol = 1e-07)
```

**Arguments**

- `prob` numeric; probability for the quantile of the $\chi^2$ distribution to be used as cutoff point in the Huber weight function (defaults to 0.95).
- `max_iterations` an integer giving the maximum number of iterations in the iteratively reweighted algorithm.
- `tol` a small positive numeric value to be used to determine convergence of the iteratively reweighted algorithm.

**Value**

A list with components corresponding to the arguments.

**Author(s)**

Andreas Alfons

y = "TeamCommitment",
m = "TaskConflict",
method = "covariance",
control = ctrl)

summary(test)

cov_HuberHuber M-estimator of location and scatter

Description
Compute a Huber M-estimator of location and scatter, which is reasonably robust for a small number of variables.

Usage
cov_Huber(x, control = cov_control(...), ...)

Arguments
x a numeric matrix or data frame.
control a list of tuning parameters as generated by cov_control().
... additional arguments can be used to specify tuning parameters directly instead of via control.

Details
An iterative reweighting algorithm is used to compute the Huber M-estimator. The Huber weight function thereby corresponds to a convex optimization problem, resulting in a unique solution.
Value

An object of class "cov_Huber" with the following components:

- **center**: a numeric vector containing the location vector estimate.
- **cov**: a numeric matrix containing the scatter matrix estimate.
- **prob**: numeric; probability for the quantile of the $\chi^2$ distribution used as cutoff point in the Huber weight function.
- **weights**: a numeric vector containing the relative robustness weights for the observations.
- **tau**: numeric; correction for Fisher consistency under multivariate normal distributions.
- **converged**: a logical indicating whether the iterative reweighting algorithm converged.
- **iterations**: an integer giving the number of iterations required to obtain the solution.

# define variables
x <- "ValueDiversity"
y <- "TeamCommitment"
m <- "TaskConflict"

# compute Huber M-estimator
cov_Huber(BSG2014[, c(x, y, m)])
cov_ML

Maximum likelihood estimator of mean vector and covariance matrix

Description

Compute the maximum likelihood estimator of the mean vector and the covariance matrix.

Usage

cov_ML(x, ...)

Arguments

x a numeric matrix or data frame.
... additional arguments are currently ignored.

Value

An object of class "cov_ML" with the following components:

center a numeric vector containing the mean vector estimate.
cov a numeric matrix containing the covariance matrix estimate.
n an integer giving the number of observations.

# compute Huber M-estimator
cov_ML(BSG2014[, c(x, y, m)])
**density_plot**

*Density plot of the indirect effect(s)*

**Description**

Produce a density plot of the indirect effect(s) from (robust) mediation analysis. In addition to the density, a vertical line representing the point estimate and a shaded area representing the confidence interval are drawn.

**Usage**

```r
density_plot(object, ...)```

## Default S3 method:
density_plot(object, ...)

```r
## S3 method for class 'sobel_test_mediation'
density_plot(object, grid = NULL,
              level = 0.95, ...)
```

```r
## S3 method for class 'list'
density_plot(object, grid = NULL, level = 0.95, ...)
```

```r
## S3 method for class 'setup_density_plot'
density_plot(object, ...)
```

**Arguments**

- `object` an object inheriting from class "test_mediation" containing results from (robust) mediation analysis, or a list of such objects.
- `...` additional arguments to be passed down.
- `grid` an optional numeric vector containing the values at which to evaluate the assumed normal density from Sobel’s test. The default is to take 512 equally spaced points between the estimated indirect effect ± three times the standard error according to Sobel’s formula.
- `level` numeric; the confidence level of the confidence intervals from Sobel’s test. The default is to include 95% confidence intervals. Note that this is not used for bootstrap tests, as those require to specify the confidence level already in `test_mediation()`.

**Details**

Methods first call `setup_density_plot()` to extract all necessary information to produce the plot, then the "setup_density_plot" method is called to produce the plot.
**Value**

An object of class "ggplot".

**Examples**

data("BSG2014")

# run fast and robust bootstrap test
robust_boot <- test_mediation(BSG2014,
   x = "ValueDiversity",
   y = "TeamCommitment",
   m = "TaskConflict",
   robust = TRUE)

# create plot for robust bootstrap test
density_plot(robust_boot)
density_plot(robust_boot, color = "#00BFC4", fill = "#00BFC4")

# run standard bootstrap test
standard_boot <- test_mediation(BSG2014,
   x = "ValueDiversity",
   y = "TeamCommitment",
   m = "TaskConflict",
   robust = FALSE)

# compare robust and standard tests
tests <- list(Standard = standard_boot, Robust = robust_boot)
density_plot(tests)

# the plot can be customized in the usual way
density_plot(tests) + theme_bw() +
   labs(title = "Standard vs robust bootstrap test")
Description

Produce a scatter plot of two variables used in (robust) mediation analysis together with a tolerance ellipse. Exploiting the relationship between the regression coefficients and the covariance matrix, that tolerance ellipse illustrates how well the regression results represent the data. In addition, a line that visualizes the estimated regression coefficient is added when relevant.

Usage

ellipse_plot(object, ...)

## Default S3 method:
ellipse_plot(object, horizontal = NULL,
vertical = NULL, partial = FALSE, level = 0.975, npoints = 100,
...)

## S3 method for class 'setup_ellipse_plot'
ellipse_plot(object, ...)

Arguments

- **object**: an object inheriting from class "fit_mediation" or "test_mediation" containing results from (robust) mediation analysis, or a list of such objects.
- **...**: additional arguments to be passed down.
- **horizontal**: a character string specifying the variable to be plotted on the horizontal axis. If the dependent variable is chosen for the vertical axis, a hypothesized mediator or the independent variable must be selected for the horizontal axis. If a hypothesized mediator is chosen for the vertical axis, the independent variable must be selected for the horizontal axis. The default is to plot the independent variable on the horizontal axis.
- **vertical**: a character string specifying the variable to be plotted on the vertical axis: the dependent variable or a hypothesized mediator. The default is to plot the first hypothesized mediator on the vertical axis.
- **partial**: a logical indicating whether the vertical axis should display the observed values of the selected variable (FALSE), or the partial residuals with respect to the variable on the horizontal axis (TRUE). The latter allows to display the corresponding regression coefficient by a line.
- **level**: numeric; the confidence level of the tolerance ellipse. It gives the percentage of observations that are expected to lie within the ellipse under the assumption of a normal distribution, and therefore it controls the size of the ellipse. The default is such that the ellipse is expected to contain 97.5% of the observations.
- **npoints**: The number of grid points used to evaluate and draw the ellipse. The default is to use 100 grid points.

Details

A line to visualize the corresponding regression coefficient is added if partial = TRUE, or in case of a simple mediation model (without control variables) when the hypothesized mediator is plotted on the vertical axis and the independent variable is plotted on the horizontal axis.
For robust estimation methods that return outlyingness weights for each data point, those weights are visualized by coloring the points on a grey scale. If a list of objects has been supplied and there are multiple objects from such robust methods, each method is placed in a separate panel.

Methods first call `setup_ellipse_plot()` to extract all necessary information to produce the plot, then the "setup_ellipse_plot" method is called to produce the plot.

Value

An object of class "ggplot".

ellipse_plot(tests)

# the plot can be customized in the usual way
fit_mediation

(Robustly) fit a mediation model

Description

(Robustly) estimate the effects in a mediation model.

Usage

fit_mediation(object, ...)

## S3 method for class 'formula'
fit_mediation(formula, data, ...)

## Default S3 method:
fit_mediation(object, x, y, m, covariates = NULL,
   method = c("regression", "covariance"), robust = TRUE,
   median = FALSE, control = NULL, ...)

Arguments

object

the first argument will determine the method of the generic function to be dis-
patched. For the default method, this should be a data frame containing the
variables.

... additional arguments to be passed down. For the default method, this can be
used to specify tuning parameters directly instead of via control.

formula

an object of class "formula" (or one that can be coerced to that class): a symbolic
description of the model to be fitted. Hypothesized mediator variables should
be wrapped in a call to m() (see examples), and any optional control variables
should be wrapped in a call to covariates().

data

for the formula method, a data frame containing the variables.

x a character string, an integer or a logical vector specifying the column of object
   containing the independent variable.

y a character string, an integer or a logical vector specifying the column of object
   containing the dependent variable.

m a character, integer or logical vector specifying the columns of object contain-
ing the hypothesized mediator variables.

covariates optional; a character, integer or logical vector specifying the columns of object
   containing additional covariates to be used as control variables.
method

A character string specifying the method of estimation. Possible values are
"regression" (the default) to estimate the effects via regressions, or "covariance"
to estimate the effects via the covariance matrix. Note that the effects are always
estimated via regressions if more than one hypothesized mediator is specified or
if control variables are supplied.

robust

A logical indicating whether to robustly estimate the effects (defaults to TRUE).
For estimation via regressions (method = "regression"), this can also be a
character string, with "MM" specifying the MM-estimator of regression, and
"median" specifying median regression.

median

deprecated. This argument will be removed in future versions. Use robust =
"median" for median regression.

control

A list of tuning parameters for the corresponding robust method. For robust
regression (method = "regression", and robust = TRUE or robust = "MM"), a
list of tuning parameters for lmrob() as generated by reg_control(). For Hu-
berized covariance matrix estimation (method = "covariance" and robust =
TRUE), a list of tuning parameters for cov_Huber() as generated by cov_control().
No tuning parameters are necessary for median regression (method = "regression"
and robust = "median").

details

With method = "regression", and robust = TRUE or robust = "MM", the effects are computed via
the robust MM-estimator of regression from lmrob(). This is the default behavior.
With method = "regression" and robust = "median", the effects are estimated via median re-
gressions with rq(). Unlike the robust MM-regressions above, median regressions are not robust
against outliers in the explanatory variables.
With method = "covariance" and robust = TRUE, the effects are estimated based on a Huber M-
estimator of location and scatter. Note that this covariance-based approach is less robust than the
approach based on robust MM-regressions described above.

Value

An object inheriting from class "fit_mediation" (class "reg_fit_mediation" if method = "regression"
or "cov_fit_mediation" if method = "covariance") with the following components:

a

A numeric vector containing the point estimates of the effect of the independent
variable on the proposed mediator variables.

b

A numeric vector containing the point estimates of the direct effect of the pro-
posed mediator variables on the dependent variable.

direct

Numeric; the point estimate of the direct effect of the independent variable on
the dependent variable.

total

Numeric; the point estimate of the total effect of the independent variable on the
dependent variable.

fit_mx

An object of class "lmrob" or "lm" containing the estimation results from the
regression of the proposed mediator variable on the independent variable, or
a list of such objects in case of more than one hypothesized mediator (only
"reg_fit_mediation").
fit_mediation

fit_ymx  
an object of class "lmrob" or "lm" containing the estimation results from the regression of the dependent variable on the proposed mediator and independent variables (only "reg_fit_mediation").

fit_yx  
an object of class "lm" containing the estimation results from the regression of the dependent variable on the independent variable (only "reg_fit_mediation" and if robust is FALSE).

cov  
an object of class "cov_Huber" or "cov_ML" containing the covariance matrix estimates (only "cov_fit_mediation").

x, y, m, covariates  
character vectors specifying the respective variables used.

data  
a data frame containing the independent, dependent and proposed mediator variables, as well as covariates.

robust  
either a logical indicating whether the effects were estimated robustly, or one of the character strings "MM" and "median" specifying the type of robust regressions.

control  
a list of tuning parameters used (if applicable).

Note
The formula interface is still experimental and may change in future versions.

---

**m**

Create an object of hypothesized mediators or control variables

**Description**

`m()` creates an object of hypothesized mediators, while `covariates()` creates an object of control variables. Usually, these are used in a formula specifying a mediation model.

**Usage**

```
m(...)  
covariates(...)  
```

**Arguments**

... variables are supplied as arguments, as usual separated by a comma.

**Details**

These are essentially wrappers for `cbind()` with a specific class prepended to the class(es) of the resulting object.

**Value**

`m()` returns an object of class "parallel_mediators" and `covariates()` returns an object of class "covariates". Typically, these inherit from class "matrix".

**Note**

The formula interface is still experimental and may change in future versions.

# inside formula
fit_mediation(TeamCommitment ~ m(TaskConflict) + ValueDiversity,
             data = BSG2014)

# outside formula
mediator <- with(BSG2014, m(TaskConflict))
fit_mediation(TeamCommitment ~ mediator + ValueDiversity,
              data = BSG2014)

plot-methods

Plot (robust) mediation analysis results

Description

Visualize results from (robust) mediation analysis.

Usage

## S3 method for class 'fit_mediation'
autoplot(object, ...)

## S3 method for class 'test_mediation'
autoplot(object, which = c("ci", "density", "ellipse"), ...)

## S3 method for class 'fit_mediation'
plot(x, ...)

## S3 method for class 'test_mediation'
plot(x, which = c("ci", "density", "ellipse"), ...)

Arguments

object, x  
an object inheriting from class "fit_mediation" or "test_mediation" containing results from (robust) mediation analysis.

...  
additional arguments to be passed down.

which  
a character string specifying which plot to produce. Possible values are "ci" for a dot plot of selected effects together with confidence intervals (see ci_plot()), "density" for a density plot of the indirect effect(s) (see density_plot()), or "ellipse" for a diagnostic plot of the data together with a tolerance ellipse (see ellipse_plot()).

Details

The "fit_mediation" method is a wrapper for ellipse_plot().

The "test_mediation" method calls ci_plot(), density_plot(), or ellipse_plot(), depending on the argument which.

Value

An object of class "ggplot".

Examples

data("BSG2014")

# run fast and robust bootstrap test
robust_boot <- test_mediation(BSG2014,
   x = "ValueDiversity",
   y = "TeamCommitment",
   m = "TaskConflict",
   robust = TRUE)

# create plots for robust bootstrap test
plot(robust_boot, which = "ci")
plot(robust_boot, which = "density")
plot(robust_boot, which = "ellipse")
p_value

p-Values for (robust) mediation analysis

Description

Estimate or extract the p-values for indirect effects in (robust) mediation analysis.

Usage

p_value(object, ...)

## S3 method for class 'boot_test_mediation'
p_value(object, digits = 4L, ...)

## S3 method for class 'sobel_test_mediation'
p_value(object, ...)

Arguments

object  
an object inheriting from class "test_mediation" containing results from (robust) mediation analysis.

...  
additional arguments are currently ignored.

digits  
an integer determining the number of digits of the p-values to be computed. The default is to compute 4 digits after the comma.

Details

For bootstrap tests, the p-value is estimated as the smallest significance level \( \alpha \) for which the \( (1 - \alpha) \times 100\% \) confidence interval obtained from the bootstrapped distribution of the indirect effect does not contain 0.

This is a simple implementation, where each digit after the comma is determined via a grid search. Hence computation time can be long if confidence intervals are computed via the bias-corrected and accelerated method ("bca").

For Sobel tests, the p-value is already stored in the object returned by test_mediation() and simply extracted.

Value

A numeric vector containing the p-values for the indirect effect(s).

Examples

```r
data("BSG2014")

# BCa intervals are recommended, but take a while to run
test_bca <- test_mediation(BSG2014,
  x = "ValueDiversity",
  y = "TeamCommitment",
  m = "TaskConflict",
  type = "bca")
p_value(test_bca)
```

---

**reg_control**

*Tuning parameters for MM-regression*

**Description**

Obtain a list with tuning parameters for `lmrob()`.

**Usage**

```r
reg_control(efficiency = 0.85, max_iterations = 200, tol = 1e-07,
  seed = NULL)
```

**Arguments**

- `efficiency` a numeric value giving the desired efficiency (defaults to 0.85 for 85% efficiency).
- `max_iterations` an integer giving the maximum number of iterations in various parts of the algorithm.
- `tol` a small positive numeric value to be used to determine convergence in various parts of the algorithm.
- `seed` optional initial seed for the random number generator (see `.Random.seed`).

**Value**

A list of tuning parameters as returned by `lmrob.control()`.

**Note**

This is a simplified wrapper function for `lmrob.control()`, as the latter requires detailed knowledge of the MM-type regression algorithm. Currently only 95%, 90%, 85% (the default) and 80% efficiency are supported. For other values, please specify the corresponding tuning parameters in `lmrob.control()` directly.

**Examples**

data("BSG2014")

# run fast and robust bootstrap test
ctrl <- reg_control(efficiency = 0.95)
test <- test_mediation(BSG2014, 
                        x = "ValueDiversity", 
                        y = "TeamCommitment", 
                        m = "TaskConflict", 
                        control = ctrl)

summary(test)

---

**Description**

Reperform a (fast and robust) bootstrap test or Sobel’s test for the indirect effect(s) based on results from (robust) mediation analysis.

**Usage**

retest(object, ...)

## S3 method for class 'boot_test_mediation'
retest(object, alternative = c("twosided", 
                             "less", "greater"), level = 0.95, type = c("bca", "perc"), ...)

## S3 method for class 'sobel_test_mediation'
retest(object, alternative = c("twosided", 
                             "less", "greater"), ...)
Arguments

object

an object inheriting from class "test_mediation" containing results from (robust) mediation analysis.

... additional arguments to be passed down to methods.

alternative a character string specifying the alternative hypothesis in the test for the indirect effect. Possible values are "twosided" (the default), "less" or "greater".

level numeric; the confidence level of the confidence interval in the bootstrap test. The default is to compute a 95% confidence interval.

type a character string specifying the type of confidence interval to be computed in the bootstrap test. Possible values are "bca" (the default) for the bias-corrected and accelerated bootstrap, or "perc" for the percentile bootstrap.

Value

An object of the same class as object with updated test results (see test_mediation()).

test_mediation()

Examples

data("BSG2014")

# run fast and robust bootstrap test
test <- test_mediation(BSG2014,
  x = "ValueDiversity",
  y = "TeamCommitment",
  m = "TaskConflict")

summary(test)

# now compute 97.5% confidence interval
retest(test, level = 0.975)

Description

These functions are provided for compatibility with older versions only, and may be defunct as soon as the next release.

Deprecated functions in package robmed
Usage

```r
## S3 method for class 'boot_test_mediation'
fortify(model, data, method = c("dot", "density"), parm = NULL, ...)

## S3 method for class 'sobel_test_mediation'
fortify(model, data, method = c("dot", "density"), parm = NULL, level = 0.95, ...)

## S3 method for class 'list'
fortify(model, data, ...)

plot_mediation(object, ...)
```

```r
## S3 method for class 'boot_test_mediation'
plot_mediation(object, method = c("dot", "density"), parm = NULL, ...)

## S3 method for class 'sobel_test_mediation'
plot_mediation(object, data, method = c("dot", "density"), parm = c("Direct", "ab"), level = 0.95, ...)

## S3 method for class 'list'
plot_mediation(object, data, method = c("dot", "density"), parm = NULL, level = 0.95, ...)

## Default S3 method:
plot_mediation(object, mapping = attr(object, "mapping"), facets = attr(object, "facets"), ...)
```

Arguments

- `model, object` an object inheriting from class "test_mediation" containing results from (robust) mediation analysis, or a list of such objects.
- `data` for the "boot_test_mediation" method, this is currently ignored. For the "sobel_test_mediation" method, this is an optional numeric vector containing the x-values at which to evaluate the assumed normal density from Sobel’s test (only used in case of a density plot). The default is to take 100 equally spaced points between the estimated indirect effect ± three times the standard error according to Sobel’s formula.
- `method` a character string specifying for which plot to construct the data frame. Possible values are "dot" for a dot plot of selected effects, or "density" for a density plot of the indirect effect(s).
- `parm` a character string specifying the effects to be included in a dot plot. The default is to include the direct and the indirect effect(s).
- `...` additional arguments to be passed to and from methods.
level numeric: the confidence level of the confidence intervals from Sobel's test to be included in a dot plot. The default is to include 95% confidence intervals.

mapping an aesthetic mapping to override the default behavior (see \texttt{aes()} or \texttt{aes_()}).

facets a faceting formula to override the default behavior (only used in case of a dot plot). If supplied, \texttt{facet_wrap()} or \texttt{facet_grid()} is called depending on whether the formula is one-sided or two-sided.

Details

\texttt{fortify()} supplements the estimated coefficients with other useful information for informative visualization of the (robust) mediation analysis results. It is thereby possible to construct data frames for dot plots of selected effects, as well as density plots of the indirect effect. From version 0.6.0 onwards, it is recommended to use \texttt{setup_ci()}), \texttt{setup_density()} or \texttt{setup_ellipse()} instead.

\texttt{plot_mediation()} produces a dot plot of selected effects in the mediation model, or a density plot of the indirect effect. From version 0.6.0 onwards, it is recommended to use \texttt{ci()}), \texttt{density()} or \texttt{ellipse()} instead.

Value

\texttt{fortify()} returns a data frame containing the necessary data for the selected plot, as well as additional information stored in attributes.

\texttt{plot_mediation()} returns an object of class "\texttt{ggplot}".

plot_mediation(tests, method = "density")

---

**run_shiny_app**

**Shiny app: simulation for mediation analysis with outliers**

**Description**

Compare various bootstrap methods for mediation analysis on simulated data.

**Usage**

run_shiny_app()

**Details**

The default settings follow the simulation design of Zu & Yuan (2010). You can adjust the total number of observations, the values of the coefficients in the mediation model, the number of outliers, as well as the expected distance of the outliers from the main point cloud.

As this simulation is just for illustration, the bootstrap procedures use only 1000 replicates. For each selected methods, the bootstrap distribution of the indirect effect is shown together with a shaded area representing the 95% confidence interval.

### setup_ci_plot

**Set up information for a dot plot with confidence intervals**

### Description

Extract the relevant information for a dot plot with confidence intervals of selected effects from (robust) mediation analysis.

### Usage

```r
setup_ci_plot(object, ...)  
```

**S3 method for class 'boot_test_mediation'**

```r
setup_ci_plot(object, parm = NULL,
              type = c("boot", "data"), ...)
```

**S3 method for class 'sobel_test_mediation'**

```r
setup_ci_plot(object, parm = NULL,
              level = 0.95, ...)
```

**S3 method for class 'list'**

```r
setup_ci_plot(object, ...)
```

### Arguments

- `object` an object inheriting from class "test_mediation" containing results from (robust) mediation analysis, or a list of such objects.
- `...` additional arguments to be passed down.
- `parm` a character string specifying the effects to be included in the plot. The default is to include the direct and the indirect effect(s).
- `type` a character string specifying which point estimates and confidence intervals to plot: those based on the bootstrap distribution ("boot"; the default), or those based on the original data ("data"). If "boot", the confidence intervals of effects other than the indirect effect(s) are computed using a normal approximation (i.e., assuming a normal distribution of the corresponding effect with the standard deviation computed from the bootstrap replicates). If "data", the confidence intervals of effects other than the indirect effect(s) are computed via statistical theory based on the original data (e.g., based on a t-distribution the
coefficients are estimated via regression). Note that this is only relevant for mediation analysis via a bootstrap test, where the confidence interval of the indirect effect is always computed via a percentile-based method due to the asymmetry of its distribution.

**level** numeric; the confidence level of the confidence intervals from Sobel’s test. The default is to include 95% confidence intervals. Note that this is not used for bootstrap tests, as those require to specify the confidence level already in `test_mediation()`.

**Details**

This function is used internally by `ci_plot()`. It may also be useful for users who want to produce a similar plot, but who want more control over what information to display or how to display that information.

**Value**

An object of class "setup_ci_plot" with the following components:

- **ci** a data frame consisting of column `Effect` indicating the different effects, column `Estimate` containing the point estimates, column `Lower` for the lower confidence limit, and column `Upper` for the upper confidence limit. If a list of "test_mediation" objects has been supplied, there is also a column `Method`, which takes the names or indices of the list elements to indicate the different methods.

- **level** numeric; the confidence level used for the confidence intervals of the indirect effect(s).

- **have_methods** a logical indicating whether a list of "test_mediation" objects has been supplied. If TRUE, the data frame in the `ci` component contains a column `Method`.

Andreas Alfons

**See Also**

`test_mediation()`, `ci_plot()`

**Examples**

data("BSG2014")

# run fast and robust bootstrap test
robust_boot <- test_mediation(BSG2014,
  x = "ValueDiversity",
  y = "TeamCommitment",
  m = "TaskConflict",
  robust = TRUE)

# set up information for plot
setup <- setup_ci_plot(robust_boot, parm = "ab")

# plot only density and confidence interval
ggplot() +
  geom_hline(yintercept = 0, color = "darkgrey") +
  geom_pointrange(aes(x = "Robust bootstrap", y = Estimate,
                      ymin = Lower, ymax = Upper),
                      data = setup$ci) +
  labs(x = NULL, y = "Indirect effect")

setup_density_plot

Set up information for a density plot of the indirect effect(s)

Description

Extract the relevant information for a density plot of the indirect effect(s) from results of (robust) mediation analysis.

Usage

setup_density_plot(object, ...)

## S3 method for class 'boot_test_mediation'
setup_density_plot(object, ...)

## S3 method for class 'sobel_test_mediation'
setup_density_plot(object, grid = NULL,
                    level = 0.95, ...)

## S3 method for class 'list'
setup_density_plot(object, ...)

Arguments

object       an object inheriting from class "test_mediation" containing results from (robust) mediation analysis, or a list of such objects.
...
grid        an optional numeric vector containing the values at which to evaluate the assumed normal density from Sobel’s test. The default is to take 512 equally spaced points between the estimated indirect effect ± three times the standard error according to Sobel’s formula.
level        numeric; the confidence level of the confidence intervals from Sobel’s test. The default is to include 95% confidence intervals. Note that this is not used for bootstrap tests, as those require to specify the confidence level already in test_mediation().
setup_density_plot

Details

This function is used internally by density_plot(). It may also be useful for users who want to produce a similar plot, but who want more control over what information to display or how to display that information.

Value

An object of class "setup_density_plot" with the following components:

density a data frame containing the values of the indirect effect where the density is estimated (column ab), and the estimated density values (column Density). In case of a multiple mediator model, there is a column Effect that indicates the different indirect effects. If a list of "test_mediation" objects has been supplied, there is also a column Method, which takes the names or indices of the list elements to indicate the different methods.

ci a data frame consisting of column Estimate containing the point estimates, column Lower for the lower confidence limit, and column Upper for the upper confidence limit. In case of a multiple mediator model, there is a column Effect that indicates the different indirect effects. If a list of "test_mediation" objects has been supplied, there is also a column Method, which takes the names or indices of the list elements to indicate the different methods.

test a character string indicating whether the object contains results from a bootstrap test ("boot") or a Sobel test ("sobel"), or a vector of such character strings if a list of "test_mediation" objects has been supplied.

level numeric; the confidence level used for the confidence intervals of the indirect effect(s).

have_effects a logical indicating whether the mediation model contains multiple mediators. If TRUE, the data frames in the density and ci components contain a column Effect.

have_methods a logical indicating whether a list of "test_mediation" objects has been supplied. If TRUE, the data frames in the density and ci components contain a column Method.

  labs(x = "Indirect effect", y = "Bootstrap density")

setup_ellipse_plot

Set up a diagnostic plot with a tolerance ellipse

Description

Extract the relevant information for a diagnostic plot with a tolerance ellipse from results of (robust) mediation analysis.

Usage

setup_ellipse_plot(object, ...)

## S3 method for class 'test_mediation'
setup_ellipse_plot(object, ...)

## S3 method for class 'reg_fit_mediation'
setup_ellipse_plot(object, horizontal = NULL,
                    vertical = NULL, partial = FALSE, level = 0.975, npoints = 100,
                    ...)  

## S3 method for class 'cov_fit_mediation'
setup_ellipse_plot(object, horizontal = NULL,
                    vertical = NULL, partial = FALSE, level = 0.975, npoints = 100,
                    ...)  

## S3 method for class 'list'
setup_ellipse_plot(object, ...)

Arguments

object an object inheriting from class "fit_mediation" or "test_mediation" containing results from (robust) mediation analysis, or a list of such objects.
additional arguments to be passed down.

horizontal a character string specifying the variable to be plotted on the horizontal axis. If the dependent variable is chosen for the vertical axis, a hypothesized mediator or the independent variable must be selected for the horizontal axis. If a hypothesized mediator is chosen for the vertical axis, the independent variable must be selected for the horizontal axis. The default is to plot the independent variable on the horizontal axis.

vertical a character string specifying the variable to be plotted on the vertical axis: the dependent variable or a hypothesized mediator. The default is to plot the first hypothesized mediator on the vertical axis.

partial a logical indicating whether to extract the observed values of the selected variable for the vertical axis (FALSE), or the partial residuals with respect to the variable on the horizontal axis (TRUE). The latter allows to display the corresponding regression coefficient by a line.

level numeric; the confidence level of the tolerance ellipse. It gives the percentage of observations that are expected to lie within the ellipse under the assumption of a normal distribution, and therefore it controls the size of the ellipse. The default is such that the ellipse is expected to contain 97.5% of the observations.

npoints The number of grid points used to evaluate the ellipse. The default is to use 100 grid points.

Details

This function is used internally by `ellipse_plot()`. It may also be useful for users who want to produce a similar plot, but who want more control over what information to display or how to display that information.

Value

An object of class "setup_ellipse_plot" with the following components:

data a data frame containing the coordinates of the data points to be plotted on the horizontal axis (column x) and the coordinates on the vertical axis (column y). For robust methods that assign outlyingness weights to each data point, those weights are given in column Weight. If a list of objects has been supplied and there are multiple objects from such robust methods, or if partial residuals are to be plotted on the vertical axis, there is also a column Method, which takes the names or indices of the list elements to indicate the different methods.

ellipse a data frame containing the coordinates of the tolerance ellipse on the horizontal axis (column x) and on the vertical axis (column y). If a list of objects has been supplied, there is also a column Method, which takes the names or indices of the list elements to indicate the different methods.

line a data frame with columns intercept and slope containing the intercept and slope, respectively, of the regression line to be plotted. If a list of objects has been supplied, there is also a column Method, which takes the names or indices of the list elements to indicate the different methods. This is only returned if
partial = TRUE, or in case of a simple mediation model (without control variables) when the hypothesized mediator is plotted on the vertical axis and the independent variable is plotted on the horizontal axis.

horizontal a character string giving the variable to be plotted on the horizontal axis.

vertical a character string giving the variable to be plotted on the vertical axis

partial a logical indicating whether the values to be plotted on the vertical axis correspond to the observed values of the selected variable (FALSE), or the partial residuals with respect to the variable on the horizontal axis (TRUE).

robust a logical indicating whether the object contains results from a robust method, or a vector of such logicals if a list of objects has been supplied.

have_methods a logical indicating whether a list of objects has been supplied.

**summary.test_mediation**

*Summary of results from (robust) mediation analysis*

**Description**

Summarize results from (robust) mediation analysis for proper interpretation.

**Usage**

```r
## S3 method for class 'boot_test_mediation'
summary(object, type = c("boot", "data"),
      ...)

## S3 method for class 'sobel_test_mediation'
summary(object, ...)
```

**Arguments**

- `object`: an object inheriting from class "test_mediation" containing results from (robust) mediation analysis.
- `type`: a character string specifying how to summarize the effects other than the indirect effect(s). Possible values are "boot" (the default) to compute significance tests using the normal approximation of the bootstrap distribution (i.e., to assume a normal distribution of the corresponding effect with the standard deviation computed from the bootstrap replicates), or "theory" to compute significance tests via statistical theory based on the original data (e.g., t-tests if the coefficients are estimated via regression). Note that this is only relevant for mediation analysis via a bootstrap test, where significance of the indirect effect is always assessed via a percentile-based confidence interval due to the asymmetry of its distribution.
- `...`: additional arguments are currently ignored.

**Value**

An object of class "summary_test_mediation" with the following components:

- `object`: the object passed to the summary method, which contains the results from testing the indirect effect.
- `summary`: an object containing all necessary information to summarize the effects other than the indirect effect.

**test_mediation**  
(Robust) mediation analysis

Description

Perform (robust) mediation analysis via a (fast and robust) bootstrap test or Sobel’s test.

Usage

test_mediation(object, ...)

## S3 method for class 'formula'
test_mediation(formula, data, test = c("boot", "sobel"),
  alternative = c("twosided", "less", "greater"), R = 5000,
  level = 0.95, type = c("bca", "perc"), method = c("regression", "covariance"),
  robust = TRUE, median = FALSE, control = NULL, ...)

## Default S3 method:
test_mediation(object, x, y, m, covariates = NULL,
  test = c("boot", "sobel"), alternative = c("twosided", "less", "greater"),
  R = 5000, level = 0.95, type = c("bca", "perc"),
  method = c("regression", "covariance"), robust = TRUE,
  median = FALSE, control = NULL, ...)

## S3 method for class 'fit_mediation'
test_mediation(object, test = c("boot", "sobel"),
  alternative = c("twosided", "less", "greater"), R = 5000,
  level = 0.95, type = c("bca", "perc"), ...

robmed(..., test = "boot", method = "regression", robust = TRUE,
  median = FALSE)
Arguments

object
the first argument will determine the method of the generic function to be dispatched. For the default method, this should be a data frame containing the variables. There is also a method for a mediation model fit as returned by `fit_mediation()`.

... additional arguments to be passed down. For the bootstrap tests, those can be used to specify arguments of `boot()`, for example for parallel computing.

formula
an object of class "formula" (or one that can be coerced to that class): a symbolic description of the model to be fitted. Hypothesized mediator variables should be wrapped in a call to `m()` (see examples), and any optional control variables should be wrapped in a call to `covariates()`.

data
for the formula method, a data frame containing the variables.

test
a character string specifying the test to be performed for the indirect effect. Possible values are "boot" (the default) for the bootstrap, or "sobel" for Sobel’s test. Currently, Sobel’s test is not implemented for more than one hypothesized mediator variable.

alternative
a character string specifying the alternative hypothesis in the test for the indirect effects. Possible values are "twosided" (the default), "less" or "greater".

R
an integer giving the number of bootstrap replicates. The default is to use 5000 bootstrap replicates.

level
numeric; the confidence level of the confidence interval in the bootstrap test. The default is to compute a 95% confidence interval.

type
a character string specifying the type of confidence interval to be computed in the bootstrap test. Possible values are "bca" (the default) for the bias-corrected and accelerated bootstrap, or "perc" for the percentile bootstrap.

method
a character string specifying the method of estimation for the mediation model. Possible values are "regression" (the default) to estimate the effects via regressions, or "covariance" to estimate the effects via the covariance matrix. Note that the effects are always estimated via regressions if more than one hypothesized mediator is specified or if control variables are supplied.

robust
a logical indicating whether to perform a robust test (defaults to TRUE). For estimation via regressions (method = "regression"), this can also be a character string, with "MM" specifying the MM-estimator of regression, and "median" specifying median regression.

median
deprecated. This argument will be removed in future versions. Use robust = "median" for median regression.

control
a list of tuning parameters for the corresponding robust method. For robust regression (method = "regression", and robust = TRUE or robust = "MM"), a list of tuning parameters for `lmrob()` as generated by `reg_control()`. For Huberized covariance matrix estimation (method = "covariance" and robust = TRUE), a list of tuning parameters for `cov_Huber()` as generated by `cov_control()`.

No tuning parameters are necessary for median regression (method = "regression" and robust = "median").

x
a character string, an integer or a logical vector specifying the column of object containing the independent variable.
y  a character string, an integer or a logical vector specifying the column of object containing the dependent variable.

m  a character, integer or logical vector specifying the columns of object containing the hypothesized mediator variables.

covariates  optional; a character, integer or logical vector specifying the columns of object containing additional covariates to be used as control variables.

Details

With `method = "regression"`, and `robust = TRUE` or `robust = "MM"`, the tests are based on robust regressions with the MM-estimator from `lmrob()`. The bootstrap test is thereby performed via the fast and robust bootstrap. This is the default behavior.

Note that the MM-estimator of regression implemented in `lmrob()` can be seen as weighted least squares estimator, where the weights are dependent on how much an observation is deviating from the rest. The trick for the fast and robust bootstrap is that on each bootstrap sample, first a weighted least squares estimator is computed (using those robustness weights from the original sample) followed by a linear correction of the coefficients. The purpose of this correction is to account for the additional uncertainty of obtaining the robustness weights.

With `method = "regression"` and `robust = "median"`, the tests are based on median regressions with `rq()`. Note that the bootstrap test is performed via the standard bootstrap, as the fast and robust bootstrap is not applicable. Unlike the robust regressions described above, median regressions are not robust against outliers in the explanatory variables, and the standard bootstrap can suffer from oversampling of outliers in the bootstrap samples.

With `method = "covariance"` and `robust = TRUE`, the tests are based on a Huber M-estimator of location and scatter. For the bootstrap test, the M-estimates are used to first clean the data via a transformation. Then the standard bootstrap is performed with the cleaned data. Note that this covariance-based approach is less robust than the approach based on robust regressions described above. Furthermore, the bootstrap does not account for the variability from cleaning the data.

`robmed()` is a wrapper function for performing robust mediation analysis via regressions and the fast and robust bootstrap.

Value

An object inheriting from class "test_mediation" (class "boot_test_mediation" if `test = "boot"` or "sobel_test_mediation" if `test = "sobel"`) with the following components:

- **ab**: a numeric vector containing the point estimates of the indirect effects.
- **ci**: a numeric vector of length two or a matrix of two columns containing the bootstrap confidence intervals for the indirect effects (only "boot_test_mediation").
- **reps**: an object of class "boot" containing the bootstrap replicates of the effects (only "boot_test_mediation").
- **se**: numeric; the standard error of the indirect effect according to Sobel's formula (only "sobel_test_mediation").
- **statistic**: numeric; the test statistic for Sobel's test (only "sobel_test_mediation").
- **p_value**: numeric; the p-value from Sobel's test (only "sobel_test_mediation").
alternative a character string specifying the alternative hypothesis in the test for the indirect effects.

R an integer giving the number of bootstrap replicates (only "boot_test_mediation").

level numeric; the confidence level of the bootstrap confidence interval (only "boot_test_mediation").

type a character string specifying the type of bootstrap confidence interval (only "boot_test_mediation").

fit an object inheriting from class "fit_mediation" containing the estimation results for the direct effect and the total effect in the mediation model.

Note

For the fast and robust bootstrap, the simpler correction of Salibian-Barrera & Van Aelst (2008) is used rather than the originally proposed correction of Salibian-Barrera & Zamar (2002).

The formula interface is still experimental and may change in future versions.

Robustness weights of Huber M-estimation of location and scatter

Description

Extract (relative) robustness weights of a Huber M-estimate of location and scatter.

Usage

```r
## S3 method for class 'cov_Huber'
weights(object, type = c("consistent", "relative"),
         ...)"n```

Arguments

- **object**: an object inheriting from class "cov_Huber" containing Huber M-estimates of location and scatter.
- **type**: a character string specifying the type of robustness weights to be extracted. Possible values are "consistent" and "relative". The former can be used for a robust transformation of the data such that the covariance matrix of the transformed data is Fisher consistent. Observations that are not downweighted in general receive a weight larger than 1. The latter are useful for interpretation, as observations that are not downweighted receive a relative weight of 1.
- **...**: additional arguments are currently ignored.

Examples

data("BSG2014")

# to reproduce results in paper
RNGversion("3.5.3")
seed <- 20150601

# formula interface
set.seed(seed)
test1 <- test_mediation(TeamCommitment ~ m(TaskConflict) + ValueDiversity,
                        data = BSG2014)
summary(test1)

# default method
set.seed(seed)
test2 <- test_mediation(BSG2014,
                        x = "ValueDiversity",
                        y = "TeamCommitment",
                        m = "TaskConflict")
summary(test2)
Value
A numeric vector containing the requested robustness weights.
