`robustX-package` *eXperimental eXtraneous ... Functionality for Robust Statistics*

Description

The package **robustX** aims to be a collection of R functionality for robust statistics of methods and ideas that are considered as proposals, experimental, for experiences or just too much specialized to be part of the "Robust Basics" package **robustbase**.

Details

Package:	robustX

BACON *BACON for Regression or Multivariate Covariance Estimation*

Description

BACON, short for '**B**locked **A**daptive **C**omputationally-Efficient **O**utlier **N**ominators', is a somewhat robust algorithm (set), with an implementation for regression or multivariate covariance estimation.

`BACON()` applies the multivariate (covariance estimation) algorithm, using `mvBACON(x)` in any case, and when `y` is not `NULL` adds a regression iteration phase, using the auxiliary `.lmBACON()` function.

Usage

```
BACON(x, y = NULL, intercept = TRUE,
      m = min(collect * p, n * 0.5),
      init.sel = c("Mahalanobis", "dUniMedian", "random", "manual"),
      man.sel, init.fraction = 0, collect = 4,
      alpha = 0.95, maxsteps = 100, verbose = TRUE)

## *Auxiliary* function:
.lmBACON(x, y, intercept = TRUE,
         init.dis, init.fraction = 0, collect = 4,
         alpha = 0.95, maxsteps = 100, verbose = TRUE)
```

Arguments

x	a multivariate matrix of dimension [n x p] considered as containing no missing values.
y	the response (n vector) in the case of regression, or NULL for the multivariate case, where just mvBACON() is returned.
intercept	logical indicating if an intercept has to be used for the regression.
m	integer in 1:n specifying the size of the initial basic subset; used only when init.sel is not "manual"; see mvBACON.
init.sel	character string, specifying the initial selection mode; see mvBACON.
man.sel	only when init.sel == "manual", the indices of observations determining the initial basic subset (and m <- length(man.sel)).
init.dis	the distances of the x matrix used for the initial subset determined by mvBACON.
init.fraction	if this parameter is > 0 then the tedious steps of selecting the initial subset are skipped and an initial subset of size n * init.fraction is chosen (with smallest dis)
collect	numeric factor chosen by the user to define the size of the initial subset (p * collect)
alpha	significance level.
maxsteps	the maximal number of iteration steps (to prevent infinite loops)
verbose	logical indicating if messages are printed which trace progress of the algorithm.

Details

Notably about the initial selection mode, init.sel, see its description in the mvBACON arguments list.

Value

BACON(x,y,..) (for regression) returns a list with components

subset	the observation indices (in 1:n) denoting a subset of "good" supposedly outlier-free observations.
tis	the $t_i(y_m, X_m)$ of eq (6) in the reference; the clean "basic subset" in the algorithm is defined the observations i with the smallest $\|t_i\|$, and the t_i can be regarded as scaled predicted errors.
mv.dis	the (final) discrepancies or distances of mvBACON().
mv.subset	the "good" subset from mvBACON(), used to start the regression iterations.

Note

"BACON" was also chosen in honor of Francis Bacon:

Whoever knows the ways of Nature will more easily notice her deviations; and, on the other hand, whoever knows her deviations will more accurately describe her ways.
Francis Bacon (1620), Novum Organum II 29.

Author(s)

Ueli Oetliker, Swiss Federal Statistical Office, for S-plus 5.1; 25.05.2001; modified six times till 17.6.2001.

Port to R, testing etc, by Martin Maechler. Daniel Weeks (at pitt.edu) proposed a fix to a long standing buglet in `GiveTis()` computing the t_i, which was further improved Maechler, for **robustX** version 1.2-3 (Feb. 2019).

`mvBACON`, the multivariate version of the BACON algorithm.

Examples

```
data(starsCYG, package = "robustbase")
## Plot simple data and fitted lines
plot(starsCYG)
lmST <- lm(log.light ~ log.Te, data = starsCYG)
abline(lmST, col = "gray") # least squares line
str(B.ST <- with(starsCYG,  BACON(x = log.Te, y = log.light)))
## 'subset': A good set of of points (to determine regression):
colB <- adjustcolor(2, 1/2)
points(log.light ~ log.Te, data = starsCYG, subset = B.ST$subset,
       pch = 19, cex = 1.5, col = colB)
## A BACON-derived line:
lmB <- lm(log.light ~ log.Te, data = starsCYG, subset = B.ST$subset)
abline(lmB, col = colB, lwd = 2)

require(robustbase)
(RlmST <- lmrob(log.light ~ log.Te, data = starsCYG))
abline(RlmST, col = "blue")
```

---

covNNC *Robust Covariance Estimation via Nearest Neighbor Cleaning*

Description

`covNNC()` estimates robust covariance/dispersion matrices by the nearest neighbor variance estimation (NNVE) or (rather) "Nearest Neighbor Cleaning" (NNC) method of Wang and Raftery (2002, *JASA*).

Usage

```
covNNC(X, k = min(12, n - 1), pnoise = 0.05, emconv = 0.001,
       bound = 1.5, extension = TRUE, devsm = 0.01)
```

Arguments

X	matrix in which each row represents an observation or point and each column represents a variable.
k	desired number of nearest neighbors (default is 12)
pnoise	percent of added noise
emconv	convergence tolerance for EM
bound	value used to identify surges in variance caused by outliers wrongly included as signal points (`bound = 1.5` means a 50 percent increase)
extension	whether or not to continue after reaching the last chi-square distance. The default is to continue, which is indicated by setting `extension = TRUE`.
devsm	when `extension = TRUE`, the algorithm stops if the relative difference in variance is less than `devsm`. (default is 0.01)

Value

A list with components

cov	covariance matrix
mu	mean vector
postprob	posterior probability
classification	classification (0=noise otherwise 1) obtained by rounding `postprob`
innc	list of initial nearest neighbor cleaning results (components are the covariance, mean, posterior probability and classification)

Note

Terms of use: GPL version 2 or newer.

MM: Even though `covNNC()` is backed by a serious scientific publication, I cannot recommend its use at all.

Author(s)

Naisyin Wang <nwang@stat.tamu.edu> and Adrian Raftery <raftery@stat.washington.edu> with contributions from Chris Fraley <fraley@stat.washington.edu>.

`covNNC()`, then named `cov.nnve()`, used to be (the only function) in CRAN package **covRobust** (2003), which was archived in 2012.

Martin Maechler allowed `ncol(X) == 1`, sped up the original code, by reducing the amount of scaling; further, the accuracy was increased (using internal `q.dDk()`). The original version is available, unexported as `robustX:::covNNC1`.

hbk.x <- data.matrix(hbk[, 1:3])
covNNC(hbk.x)
```

L1median *Compute the Multivariate L1-Median aka 'Spatial Median'*

Description

Compute the multivariate L_1-median m, also called "Spatial Median", i.e., the minimizer of

$$\sum_{i=1}^{n} \|x_i - m\|,$$

where $\|u\| = \sqrt{\sum_{j=1}^{p} u_j^2}$.

As a convex problem, there's always a global minimizer, computable not by a closed formula but rather an iterative search. As the (partial) first derivatives of the objective function is undefined at the data points, the minimization is not entirely trivial.

Usage

```
L1median(X, m.init = colMedians(X), weights = NULL,
method = c("nlm", "HoCrJo", "VardiZhang", optimMethods, nlminbMethods),
pscale = apply(abs(centr(X, m.init)), 2, mean, trim = 0.40),
tol = 1e-08, maxit = 200, trace = FALSE,
zero.tol = 1e-15, ...)
```

Arguments

X	numeric matrix of dimension $n \times p$, say.
m.init	starting value for m; typically and by default the coordinatewise median.
weights	optional numeric vector of non-negative weights; currently only implemented for method "VardiZhang".
method	character string specifying the computational method, i.e., the algorithm to be used (can be abbreviated).
pscale	numeric p-vector of positive numbers, the coordinate-wise scale (typical size of δm_j), where m is the problem's solution.
tol	positive number specifying the (relative) convergence tolerance.
maxit	positive integer specifying the maximal number of iterations (before the iterations are stopped prematurely if necessary).
trace	an integer specifying the tracing level of the iterations; 0 does no tracing
zero.tol	for method "VardiZhang", a small positive number specifying the tolerance for determining that the iteration is 'exactly' at a data point (which is a singularity).
...	optional arguments to nlm() or the control (list) arguments of optim(), or nlminb(), respectively.

Details

Currently, we have to refer to the "References" below.

Value

currently the result *depends* strongly on the method used.

FIXME. This will change considerably.

Author(s)

Martin Maechler. Method "HoCrJo" is mostly based on Kristel Joossens' R function, implementing Hossjer and Croux (1995).

mvBACON *BACON: Blocked Adaptive Computationally-Efficient Outlier Nominators*

Description

This function performs an outlier identification algorithm to the data in the x array [n x p] and y vector [n] following the lines described by Hadi et al. for their BACON outlier procedure.

Usage

```
mvBACON(x, collect = 4, m = min(collect * p, n * 0.5), alpha = 0.95,
        init.sel = c("Mahalanobis", "dUniMedian", "random", "manual"),
        man.sel, maxsteps = 100, allowSingular = FALSE, verbose = TRUE)
```

Arguments

x	numeric matrix (of dimension $[nxp]$), not supposed to contain missing values.
collect	a multiplication factor c, when init.sel is not "manual", to define m, the size of the initial basic subset, as $m := c{\cdot}p$, in practice, m <- min(p * collect, n/2).
m	integer in 1:n specifying the *size* of the initial basic subset; used only when init.sel is not "manual".
alpha	significance level for the χ^2 cutoff, used to define the next iterations basic subset.
init.sel	character string, specifying the initial selection mode; implemented modes are:
	"Mahalanobis" based on Mahalanobis distances (default); the version $V1$ of the reference; affine invariant but not robust.

"dUniMedian" based on the distances from the **uni**variate medians; ; the version $V2$ of the reference; robust but not affine invariant.

"random" based on a random selection, i.e., reproducible only via `set.seed()`.

"manual" based on manual selection; in this case, a vector `man.sel` containing the indices of the selected observations must be specified.

`"Mahalanobis"`, `"dUniMedian"` where proposed by Hadi and the other authors in the reference as versions 'V_1' and 'V_2', as well as `"manual"`, while `"random"` is provided in order to study the behaviour of BACON.

`man.sel` only when `init.sel == "manual"`, the indices of observations determining the initial basic subset (and `m <- length(man.sel)`).

`maxsteps` maximal number of iteration steps.

`allowSingular` logical indicating a solution should be sought also when no matrix of rank p is found.

`verbose` logical indicating if messages are printed which trace progress of the algorithm.

Value

a list with components

`subset` logical vector of length `n` where the `i`-th entry is true iff the i-th observation is part of the final selection.

`dis` numeric vector of length `n` with the (Mahalanobis) distances.

`cov` $p \times p$ matrix, the corresponding robust estimate of covariance.

Author(s)

Ueli Oetliker, Swiss Federal Statistical Office, for S-plus 5.1. Port to R, testing etc, by Martin Maechler

See Also

`covMcd` for a high-breakdown (but more computer intensive) method; `BACON` for a "generalization", notably to *regression*.

Examples

```
 require(robustbase) # for example data and covMcd():
## simple 2D example :
 plot(starsCYG, main = "starsCYG  data  (n=47)")
 B.st <- mvBACON(starsCYG)
 points(starsCYG[ ! B.st$subset,], pch = 4, col = 2, cex = 1.5)
 stopifnot(identical(which(!B.st$subset), c(7L,9L,11L,14L,20L,30L,34L)))
```

```
## finds the clear outliers (and 3 "borderline")

## 'coleman' from pkg 'robustbase'
coleman.x <- data.matrix(coleman[, 1:6])
Cc <- covMcd (coleman.x) # truly robust
summary(Cc) # -> 6 outliers (1,3,10,12,17,18)
Cb1 <- mvBACON(coleman.x) ##-> subset is all TRUE hmm??
Cb2 <- mvBACON(coleman.x, init.sel = "dUniMedian")
stopifnot(all.equal(Cb1, Cb2))
Cb.r <- lapply(1:20, function(i) { set.seed(i)
                    mvBACON(coleman.x, init.sel="random", verbose=FALSE) })
nm <- names(Cb.r[[1]]); nm <- nm[nm != "steps"]
all(eqC <- sapply(Cb.r[-1], function(CC) all.equal(CC[nm], Cb.r[[1]][nm]))) # TRUE
## --> BACON always  breaks down, i.e., does not see the outliers here
## breaks down even when manually starting with all the non-outliers:
Cb.man <- mvBACON(coleman.x, init.sel = "manual",
                  man.sel = setdiff(1:20, c(1,3,10,12,17,18)))
which( ! Cb.man$subset) # the outliers according to mvBACON : _none_
```

`Qrot` *Rotation Matrix to Specific Direction*

Description

Construct the $p \times p$ rotation matrix that rotates the unit vector (1,0,....0), i.e., the x_1-axis, onto (1,1,1,...1)/$\sqrt{p}$, or more generally to $u/\|u\|$ ($u :=$`unit.image`).

Usage

```
Qrot(p, transpose = FALSE, unit.image = rep(1, p))
```

Arguments

`p`	integer; the dimension (of the vectors involved).
`transpose`	logical indicating if the *transposed* matrix is to returned.
`unit.image`	numeric vector of length p onto which the unit vector should be rotated; defaults to *"the diagonal"* $\propto(1, 1, 1, ..., 1)$.

Details

The `qr` decomposition is used for a Gram-Schmitt basis orthogonalization.

Value

$p \times p$ orthogonal matrix which rotates $(1, 0, ..., 0)$ onto a vector proportional to `unit.image`.

Author(s)

Martin Maechler

See Also

qr, matrix (and vector) multiplication, %*%.

Examples

```
Q <- Qrot(6)
zapsmall(crossprod(Q)) # 6 x 6 unity <==> Q'Q = I  <==> Q orthogonal

if(require("MASS")) {
  Qt <- Qrot(6, transpose = TRUE)
  stopifnot(all.equal(Qt, t(Q)))
  fractions(Qt ^2) # --> 1/6  1/30  etc, in an almost lower-triagonal matrix
}
```

---

rbwheel *Multivariate Barrow Wheel Distribution Random Vectors*

Description

Generate p-dimensional random vectors according to Stahel's Barrow Wheel Distribution.

Usage

```
rbwheel(n, p, frac = 1/p, sig1 = 0.05, sig2 = 1/10,
        rGood = rnorm,
        rOut = function(n) sqrt(rchisq(n, p - 1)) * sign(runif(n, -1, 1)),
        U1 = rep(1, p),
        scaleAfter = TRUE, scaleBefore = FALSE, spherize = FALSE,
        fullResult = FALSE)
```

Arguments

n	integer, specifying the sample size.
p	integer, specifying the dimension (aka number of variables).
frac	numeric, the proportion of outliers. The default, $1/p$, corresponds to the (asymptotic) breakdown point of M-estimators.
sig1	thickness of the "wheel", ($= \sigma$ (good[,1])), a non-negative numeric.
sig2	thickness of the "axis" (compared to 1).
rGood	function; the generator for "good" observations.
rOut	function, generating the outlier observations.
U1	p-vector to which $(1, 0, \ldots, 0)$ is rotated.
scaleAfter	logical indicating if the matrix is re-scaled *after* rotation (via scale()).. Default TRUE; note that this used to be false by default in the first public version.
scaleBefore	logical indicating if the matrix is re-scaled before rotation (via scale()).

`spherize`	logical indicating if the matrix is to be "spherized", i.e., rotated and scaled to have empirical covariance I_p. This means that the principal components are used (before rotation).
`fullResult`	logical indicating if in addition to the $n \times p$ matrix, some intermediate quantities are returned as well.

Details

....

Value

By default (when `fullResult` is `FALSE`), an $n \times p$ matrix of n sample vectors of the p dimensional barrow wheel distribution, with an attribute, `n1` specifying the exact number of "good" observations, $n1 \approx (1 - f) \cdot n$, $f =$`frac`.

If `fullResult` is `TRUE`, a list with components

`X`	the $n \times p$ matrix of above, `X = X0 %*% A`, where `A <- Qrot(p, u = U1)`, and `X0` is the corresponding matrix before rotation, see below.
`X0`	.....
`A`	the $p \times p$ rotation matrix, see above.
`n1`	the number of "good" observations, see above.
`n2`	the number of "outlying" observations, $n2 = n - n1$.

Examples

```
set.seed(17)
rX8 <- rbwheel(1000,8, fullResult = TRUE, scaleAfter=FALSE)
with(rX8, stopifnot(all.equal(X, X0 %*% A,    tol = 1e-15),
                    all.equal(X0, X %*% t(A), tol = 1e-15)))
##--> here, don't need to keep X0 (nor A, since that is Qrot(p))

## for n = 100,  you  don't see "it", but may guess .. :
n <- 100
pairs(r <- rbwheel(n,6))
n1 <- attr(r,"n1") ; pairs(r, col=1+((1:n) > n1))

## for n = 500, you *do* see it :
n <- 500
```

```
pairs(r <- rbwheel(n,6))
## show explicitly
n1 <- attr(r,"n1") ; pairs(r, col=1+((1:n) > n1))

## but increasing sig2 does help:
pairs(r <- rbwheel(n,6, sig2 = .2))

## show explicitly
n1 <- attr(r,"n1") ; pairs(r, col=1+((1:n) > n1))

set.seed(12)
pairs(X <- rbwheel(n, 7, spherize=TRUE))
colSums(X) # already centered

if(require("ICS")) {
  # ICS: Compare M-estimate [Max.Lik. of t_{df = 2}] with high-breakdown :
  stopifnot(require("MASS"))
  X.paM <- ics(X, S1 = cov, S2 = function(.) cov.trob(., nu=2)$cov, stdKurt = FALSE)
  X.paM.<- ics(X, S1 = cov, S2 = function(.) tM(., df=2)$V, stdKurt = FALSE)
  X.paR <- ics(X, S1 = cov, S2 = function(.) covMcd(.)$cov, stdKurt = FALSE)
  plot(X.paM) # not at all clear
  plot(X.paM.)# ditto
  plot(X.paR)# very clear
}
## Similar such experiments --->  demo(rbwheel_d)  and   demo(rbwheel_ics)
##                                --------------         -----------------
```

---

reclas *Recursive Robust Median-like Location and Scale*

Description

Calculate an estimate of location, asymptotically equivalent to the median, and an estimate of scale equal to the **MEAN** absolute deviation. Both done recursively.

Usage

```
reclas(y, b = 0.2, mfn = function(n) 0.1 * n^(-0.25),
     nstart = 30, m0 = median(y0),
     scon=NULL, updateScale = is.null(scon))
```

Arguments

y	numeric vector of i.i.d. data whose location and scale parameters are to be estimated.
b	numeric tuning parameter (default value equal to that used by Holst, 1987).
mfn	a function of the index of the data which must be positive and and tend to 0 as the index tends to infinity. The default function is that used by Holst, 1987.
nstart	number of starting values: Starting values for the algorithm are formed from the first nstart values of y. The default value is that used in Cameron and Turner, 1993.
m0	value for the initial approximate median; by default, the median of the first nstart observations.
scon	value for the scale parameter s, a function or NULL. When NULL, as by default, the scale is initialized to the mean of the absolute differences between the first nstart y values and m0. If scon is a function, the initial scale is set to scon(y0, m0), where y0 is the vector of the first nstart y values. Note that scon also determines the default for updateScale.
updateScale	a logical indicating if the scale, initialized from scon should be updated in each iteration. Otherwise, the the scale is held constant throughout and the algorithm becomes equivalent to the algorithm of Holst.

Value

An S3 "object" of class "reclas"; simply a list with entries

locn	the successive recursive estimates of location. The first nstart - 1 of these are NA.
scale	the successive recursive estimates of scale **if** updateScale is true; otherwise the constant value used for the scale.
updateScale	the same as the function argument.
call	the function call, i.e., match.call.

There is a plot method for "reclas", see the examples.

Author(s)

<r.turner@auckland.ac.nz> http://www.stat.auckland.ac.nz/~rolf

Extensions by Martin Maechler (scon as function; updateScale, plot()).

Examples

```
set.seed(42)
y <- rt(10000, df = 1.5) # not quite Gaussian ...
z1 <- reclas(y)
z3 <- reclas(y, scon= 1  ) # correct fixed scale
z4 <- reclas(y, scon= 100) # wrong fixed scale
z2 <- reclas(y, # a more robust initial scale:
           scon = function(y0, m0) robustbase::Qn(y0 - m0),
           updateScale = TRUE) # still updated

## Visualizing -- using the plot() method for "reclas":
M <- median(y) ; yl <- c(-1,1)* 0.5
OP <- par(mfrow=c(2,2), mar=.1+c(3,3,1,1), mgp=c(1.5, .6, 0))
 plot(z1, M=M, ylim=yl)
 plot(z2, M=M, ylim=yl)
 plot(z3, M=M, ylim=yl)
 plot(z4, M=M, ylim=yl)
par(OP)
```
