Description Fit (exponential or diffusion) response-time extended multinomial processing tree (RT-MPT) models
          by Klauer and
          The RT-MPT class not only incorporate
          frequencies like traditional multinomial processing tree (MPT) models,
          but also latencies. This enables it
          to estimate process completion times and encoding plus motor execution times
          next to the process probabilities
          of traditional MPTs. 'rtmpt' is a hierarchical Bayesian framework and posterior
          samples are sampled using a Metropolis-within-Gibbs sampler (for exponential RT-MPTs) or Hamiltonian-within-Gibbs
          sampler (for diffusion RT-MPTs).

License GPL (>= 2)

Encoding UTF-8
Description

Setting multiple process thresholds (parameter a) equal. One of the process thresholds will be estimated and the other named thresholds will be set to equal the former. The equality can be removed by only using one name of a process.

Usage

```r
a2a(model, names, keep_consts = FALSE)
set_a_equal(model, names, keep_consts = FALSE)
```
Arguments

model  A list of the class drtmp_Model.

names  Character vector giving the names of the processes for which the process thresholds should be equal. If length(names) == 1 then the corresponding process threshold will be estimated (i.e., it will be set to NA).

keep_consts  Can be one of the following:

- logical value: FALSE (default) means none of the constants for names in the model will be kept; The thresholds of the reference process (i.e., first of names in alphabetical order) will be set to NA (i.e., will be estimated) and the others will be set to the name of the reference process (i.e., will be set to equal the reference process thresholds). TRUE means the constant of the reference process threshold (if specified) is used for all other processes.

- numeric value: index for names. If 1, the constant of the first process in names (in original order defined by the user) is used for all other thresholds of the processes in names. If 2, the constant of the second process is used. And so on.

Value

A list of the class drtmp_Model.

## make do = dn
new_model <- set_a_equal(model = model, names = c("do", "dn"))
new_model

---

**a2const**

*Set process threshold to constants*

**Description**

Setting process thresholds (parameter a) to constants or change it back to be estimated.

**Usage**

```r
a2const(model, names, constants = NA)
set_a_const(model, names, constants = NA)
```

**Arguments**

- `model`: An object of the class `rtmpt_model`.
- `names`: Character vector with process names.
- `constants`: Numerical vector of length one or `length(names)`. You have the following options for the elements of the numeric vector:
  - `0 < constants`: set the named threshold parameter(s) to constant value(s) larger than zero
  - `NA`: estimate the named threshold parameter(s)

**Value**

An object of the class `drtmpt_model`.

delta2delta | Set mapping between response categories and encoding plus motor execution times

**Description**

Mapping response categories with encoding and motor execution times (deltas). Unlike the processes there are no names for the different deltas and therefore a mapping from response categories to different deltas must be specified.

**Usage**

delta2delta(model, trees, categories, mappings = 0)

set_deltas_equal(model, trees, categories, mappings = 0)
Arguments

- **model**: A list of the class `ertmpt_model` or `drtmpt_model`.
- **trees**: Character or numerical vector giving the trees.
- **categories**: Character or numerical vector identifying category/ies within the specified trees for which the deltas should be changed.
- **mappings**: Numerical vector of length `length(categories)` providing the mappings. Default is 0.

Value

A list of the class `ertmpt_model`.

new_model

fit_drtmpt  

### Fit Diffusion-RT-MPT Models

**Description**

Given model and data, this function a Hamiltonian MCMC sampler and stores the samples in an mcmc.list called samples. Posterior predictive checks developed by Klauer (2010), deviance information criterion (DIC; Spiegelhalter et al., 2002), 99% and 95% highest density intervals (HDI) together with the median will be provided for the main parameters in a list called diags. Optionally, the indices widely applicable information criterion (WAIC; Watanabe, 2010; Vehtari et al., 2017) and leave-one-out cross-validation (LOO; Vehtari et al., 2017) can be saved. Additionally the log-likelihood (LogLik) can also be stored. Some specifications of the function call are also saved in specs.

**Usage**

```r
fit_drtmpt(
  model,  
data,
n.chains = 4,
n.iter = 1000,
n.phase1 = 1000,
n.phase2 = 2000,
n.thin = 1,
Rhat_max = 1.1,
Irep = 1000,
prior_params = NULL,
flags = NULL,
control = NULL
)
```

**Arguments**

- `model` A list of the class drtmpt_model.
data

Optimally, a list of class `drtmpt_data`. Also possible is a `data.frame` or a path to the text file. Both, `data.frame` and the text file must contain the column names "subj", "group", "tree", "cat", and "rt" preferably but not necessarily in this order. The values of the latter must be in milliseconds. It is always advised to use `to_drtmpt_data` first, which gives back a `drtmpt_data` list with information about the changes in the data, that were needed.

n.chains

Number of chains to use. Default is 4. Must be larger than 1 and smaller or equal to 16.

n.iter

Number of samples per chain. Default is 1000.

n.phase1

Number of samples for phase 1 (adaptation phase). Default is 1000.

n.phase2

Number of samples for phase 2. Default is 2000.

n.thin

Thinning factor. Default is 1.

Rhat_max

Maximal Potential scale reduction factor: A lower threshold that needs to be reached before the actual sampling starts. Default is 1.05

Irep

Every `Irep` samples an interim state with the current maximal potential scale reduction factor is shown. Default is 1000. The following statements must hold true for `Irep`:

- `n.phase1` is a multiple of `Irep`
- `n.phase2` is a multiple of `Irep`
- `n.phase1` is smaller than or equal to `n.phase2`,  
- `Irep` is a multiple of `n.thin` and
- `n.iter` is a multiple of `Irep / n.thin`.

prior_params

Named list with prior parameters. All parameters have default values, that lead to uninformative priors. Vectors are not allowed. Allowed parameters are:

- `prec_epsilon`: prior precision for population means of process-related parameters. Default is 1.0.
- `delta_df`: degrees of freedom of t-distribution for motor times. Default is 10.
- `delta_mu`: mean of t-distribution for motor times. Default is 0.5.
- `delta_scale`: scale of t-distribution for motor times. Default is 1.0.
- `SIGMA_Corr_eta`: shape parameter for LKJ distribution for process-related parameters. Default is 4.0.
- `SIGMA_SD_rho`: scale parameter of half-Cauchy distribution for process-related parameters. Default is 2.5.
- `GAMMA_Corr_eta`: shape parameter for LKJ distribution for motor-related parameters. Default is 4.0.
- `GAMMA_SD_rho`: scale parameter of half-Cauchy distribution for motor-related parameters. Default is 0.5.
- `Omega2_alpha`: shape parameter of gamma distribution for residual variance. Default is 0.0025.
- `Omega2_beta`: rate parameter of gamma distribution for residual variance. Default is 0.5.

flags

Either NULL or a list of
old_label
If set to TRUE the old labels of "subj" and "group" of the data will be used in the elements of the output list. Default is FALSE.

indices
Model selection indices. If set to TRUE the log-likelihood for each iteration and trial will be stored temporarily and with that the WAIC and LOO will be calculated via the loo package. If you want to have this log-likelihood matrix stored in the output of this function, you can set loglik to TRUE. Default for indices is FALSE.

loglik
If set to TRUE and indices = TRUE the log-likelihood matrix for each iteration and trial will be saved in the output as a matrix. Default is FALSE.

random_init
If set to TRUE the initial values are randomly drawn. If FALSE maximum likelihood is used for initial values.

control
Either NULL or a list of

maxthreads
for the ML estimation of the initial values and the calculation of the DIC values one can use more than n.chains threads for parallelization. Default is 4 like n.chains. maxthreads must be larger or equal to n.chains.

maxtree1_3
maxtree-depth of the no-U-turn algorithm in Phases 1 to 3

maxtree4
maxtree-depth of the no-U-turn algorithm in Phases 4

Value
A list of the class drtmpt_fit containing

samples: the posterior samples as an mcmc.list object,

diags: some diagnostics like deviance information criterion, posterior predictive checks for the frequencies and latencies, potential scale reduction factors, and also the 99% and 95% HDIs and medians for the group-level parameters,

specs: some model specifications like the model, arguments of the model call, and information about the data transformation,

indices (optional): if enabled, WAIC and LOO,

LogLik (optional): if enabled, the log-likelihood matrix used for WAIC and LOO.

summary includes posterior mean and median of the main parameters.

data_file <- system.file("extdata/data.txt", package="rtmpt")
data <- read.table(file = data_file, header = TRUE)
data_list <- to_drtmpt_data(raw_data = data, model = model)

# This might take some time
drtmpt_out <- fit_drtmpt(model = model, data = data_list, Rhat_max = 1.1)
drtmpt_out
```

### fit_ertmpt

#### Fit Exponential-RT-MPT Models

**Description**

Given model and data, this function calls an altered version of the C++ program by Klauer and Kellen (2018) to sample from the posterior distribution via a Metropolis-Gibbs sampler and storing it in an mcmc.list called samples. Posterior predictive checks developed by Klauer (2010), deviance information criterion (DIC; Spiegelhalter et al., 2002), 99% and 95% highest density intervals (HDI) together with the median will be provided for the main parameters in a list called diags. Optionally, the indices widely applicable information criterion (WAIC; Watanabe, 2010; Vehtari et al., 2017) and leave-one-out cross-validation (LOO; Vehtari et al., 2017) can be saved. Additionally, the log-likelihood (LogLik) can also be stored. Some specifications of the function call are also saved in specs.
**Usage**

```r
fit_ertmpt(
    model,
    data,
    n.chains = 4,
    n.iter = 5000,
    n.burnin = 200,
    n.thin = 1,
    Rhat_max = 1.05,
    Irep = 1000,
    prior_params = NULL,
    indices = FALSE,
    save_log_lik = FALSE,
    old_label = FALSE
)
```

**Arguments**

- **model**: A list of the class `ertmpt_model`.
- **data**: Optimally, a list of class `ertmpt_data`. Also possible is a data.frame or a path to the text file. Both, data.frame and the text file must contain the column names "subj", "group", "tree", "cat", and "rt" preferably but not necessarily in this order. The values of the latter must be in milliseconds. It is always advised to use `to_ertmpt_data` first, which gives back an `ertmpt_data` list with informations about the changes in the data, that were needed.
- **n.chains**: Number of chains to use. Default is 4. Must be larger than 1 and smaller or equal to 16.
- **n.iter**: Number of samples per chain. Default is 5000.
- **n.burnin**: Number of warm-up samples. Default is 200.
- **n.thin**: Thinning factor. Default is 1.
- **Rhat_max**: Maximal Potential scale reduction factor: A lower threshold that needs to be reached before the actual sampling starts. Default is 1.05
- **Irep**: Every `Irep` samples an interim state with the current maximal potential scale reduction factor is shown. Default is 1000. The following statements must hold true for `Irep`:
  - `n.burnin` is smaller than or equal to `Irep`,
  - `Irep` is a multiple of `n.thin` and
  - `n.iter` is a multiple of `Irep / n.thin`.
- **prior_params**: Named list with prior parameters. All parameters have default values, that lead to uninformative priors. Vectors are not allowed. Allowed parameters are:
  - **mean_of_exp_mu_beta**: This is the a priori expected exponential rate \( E(\exp(\beta)) = E(\lambda) \) and \( 1/\text{mean_of_exp_mu_beta} \) is the a priori expected process time \( 1/E(\exp(\beta)) = E(\tau) \). The default mean is set to 10, such that the expected a priori process time is 0.1 seconds.
• var_of_exp_mu_beta: The a priori group-specific variance of the exponential rates. Since \( \exp(\mu_{\beta}) \) is Gamma distributed, the rate of the distribution is just mean divided by variance and the shape is the mean times the rate. The default is set to 100.

• mean_of_mu_gamma: This is the a priori expected mean parameter of the encoding and response execution times, which follow a normal distribution truncated from below at zero, so \( \mathbb{E}(\mu_{\gamma}) < \mathbb{E}(\gamma) \). The default is 0.

• var_of_mu_gamma: The a priori group-specific variance of the mean parameter. Its default is 10.

• mean_of_omega_sqr: This is the a priori expected residual variance \( (\mathbb{E}(\omega^2)) \). Its distribution differs from the one used in the paper. Here it is a Gamma distribution instead of an improper one. The default is 0.005.

• var_of_omega_sqr: The a priori variance of the residual variance \( (\text{Var}(\omega^2)) \). The default is 0.01. The default of the mean and variance is equivalent to a shape and rate of 0.0025 and 0.5, respectively.

• df_of_sigma_sqr: A priori degrees of freedom for the individual variance of the response executions. The individual variance has a scaled inverse chi-squared prior with \( \text{df}_of\_sigma\_sqr \) degrees of freedom and \( \omega^2 \) as scale. 2 is the default and it should be an integer.

• sf_of_scale_matrix_SIGMA: The original scaling matrix \( S \) of the (scaled) inverse Wishart distribution for the process related parameters is an identity matrix \( S=I \). \( \text{sf}_of\_scale\_matrix\_SIGMA \) is a scaling factor, that scales this matrix \( (S=\text{sf}_of\_scale\_matrix\_SIGMA*I) \). Its default is 1.

• sf_of_scale_matrix_GAMMA: The original scaling matrix \( S \) of the (scaled) inverse Wishart distribution for the encoding and motor execution parameters is an identity matrix \( S=I \). \( \text{sf}_of\_scale\_matrix\_GAMMA \) is a scaling factor, that scales this matrix \( (S=\text{sf}_of\_scale\_matrix\_GAMMA*I) \). Its default is 1.

• prec_epsilon: This is epsilon in the paper. It is the precision of \( \mu_{\alpha} \) and all xi (scaling parameter in the scaled inverse Wishart distribution). Its default is also 1.

• add_df_to_invWish: If \( P \) is the number of parameters or rather the size of the scale matrix used in the (scaled) inverse Wishart distribution then \( \text{add}_df\_to\_invWish \) is the number of degrees of freedom that can be added to it. So \( \text{DF} = P + \text{add}_df\_to\_invWish \). The default for \( \text{add}_df\_to\_invWish \) is 1, such that the correlations are uniformly distributed within \([-1, 1]\).

### indices
Model selection indices. If set to TRUE the log-likelihood for each iteration and trial will be stored temporarily and with that the WAIC and LOO will be calculated via the loo package. If you want to have this log-likelihood matrix stored in the output of this function, you can set save_log_lik to TRUE. The default for indices is FALSE.

### save_log_lik
If set to TRUE and indices = TRUE the log-likelihood matrix for each iteration and trial will be saved in the output as a matrix. Its default is FALSE.

### old_label
If set to TRUE the old labels of "subj" and "group" of the data will be used in the elements of the output list. Default is FALSE.
Value

A list of the class `ertmpt_fit` containing

- **samples**: the posterior samples as an `mcmc.list` object,
- **diags**: some diagnostics like deviance information criterion, posterior predictive checks for the frequencies and latencies, potential scale reduction factors, and also the 99% and 95% HDIs and medians for the group-level parameters,
- **specs**: some model specifications like the model, arguments of the model call, and information about the data transformation,
- **indices** (optional): if enabled, WAIC and LOO,
- **LogLik** (optional): if enabled, the log-likelihood matrix used for WAIC and LOO.
- **summary** includes posterior mean and median of the main parameters.

fit_ertmpt_SBC

Simulation-based calibration for RT-MPT models

Description

Simulate data from RT-MPT models using ertmpt_model objects. The difference to sim_ertmpt_data is that here only scalars are allowed. This makes it usable for simulation-based calibration (SBC; Talts et al., 2018). You can specify the random seed, number of subjects, number of trials, and some parameters (same as prior_params from fit_ertmpt).

Usage

fit_ertmpt_SBC(
  model,
  seed,
  n.eff_samples = 99,
  n.chains = 4,
  n.iter = 5000,
  n.burnin = 200,
  n.thin = 1,
  Rhat_max = 1.05,
  Irep = 1000,
  n.subj = 40,
  n.trials = 30,
  prior_params = NULL,
  sim_list = NULL
)
Arguments

model
A list of the class ertmpt_model.

seed
Random seed number.

n.eff_samples
Number of effective samples. Default is 99, leading to 100 possible ranks (from 0 to 99).

n.chains
Number of chains to use. Default is 4. Must be larger than 1 and smaller or equal to 16.

n.iter
Number of samples per chain. Default is 5000. Must be larger or equal to n.eff_samples.

n.burnin
Number of warm-up samples. Default is 200.

n.thin
Thinning factor. Default is 1.

Rhat_max
Maximal Potential scale reduction factor: A lower threshold that needs to be reached before the actual sampling starts. Default is 1.05

Irep
Every Irep samples an interim state with the current maximal potential scale reduction factor is shown. Default is 1000. The following statements must hold true for Irep:

• n.burnin is smaller than or equal to Irep,
• Irep is a multiple of n.thin and
• n.iter is a multiple of Irep / n.thin.

n.subj
Number of subjects. Default is 40.

n.trials
Number of trials per tree. Default is 30.

prior_params
Named list of parameters from which the data will be generated. This must be the same named list as prior_params from fit_ertmpt and has the same defaults. It is not recommended to use the defaults since they lead to many probabilities close or equal to 0 and/or 1 and to RTs close or equal to 0. Allowed parameters are:

• mean_of_exp_mu_beta: This is the expected exponential rate (E(exp(beta)) = E(lambda)) and 1/mean_of_exp_mu_beta is the expected process time (1/E(exp(beta)) = E(tau)). The default mean is set to 10, such that the expected process time is 0.1 seconds.
• var_of_exp_mu_beta: The group-specific variance of the exponential rates. Since exp(mu_beta) is Gamma distributed, the rate of the distribution is just mean divided by variance and the shape is the mean times the rate. The default is set to 100.
• mean_of_mu_gamma: This is the expected mean parameter of the encoding and response execution times, which follow a normal distribution truncated from below at zero, so E(mu_gamma) < E(gamma). The default is 0.
• var_of_mu_gamma: The group-specific variance of the mean parameter. Its default is 10.
• mean_of_omega_sqr: This is the expected residual variance (E(omega^2)). The default is 0.005.
• var_of_omega_sqr: The variance of the residual variance (Var(omega^2)). The default is 0.01. The default of the mean and variance is equivalent to a shape and rate of 0.0025 and 0.5, respectively.
• df_of_sigma_sqr: degrees of freedom for the individual variance of the response executions. The individual variance follows a scaled inverse chi-squared distribution with df_of_sigma_sqr degrees of freedom and omega^2 as scale. 2 is the default and it should be an integer.
• sf_of_scale_matrix_SIGMA: The original scaling matrix (S) of the (scaled) inverse Wishart distribution for the process related parameters is an identity matrix S=I. sf_of_scale_matrix_SIGMA is a scaling factor, that scales this matrix (S=sf_of_scale_matrix_SIGMA*I). Its default is 1.
• sf_of_scale_matrix_GAMMA: The original scaling matrix (S) of the (scaled) inverse Wishart distribution for the encoding and motor execution parameters is an identity matrix S=I. sf_of_scale_matrix_GAMMA is a scaling factor that scales this matrix (S=sf_of_scale_matrix_GAMMA*I). Its default is 1.
• prec_epsilon: This is epsilon in the paper. It is the precision of mu_alpha and all xi (scaling parameter in the scaled inverse Wishart distribution). Its default is also 1.
• add_df_to_invWish: If P is the number of parameters or rather the size of the scale matrix used in the (scaled) inverse Wishart distribution then add_df_to_invWish is the number of degrees of freedom that can be added to it. So DF = P + add_df_to_invWish. The default for add_df_to_invWish is 1, such that the correlations are uniformly distributed within [-1, 1].

Value
A list of the class ertmpt_sbc containing
• ranks: the rank statistic for all parameters,
• sim_list: an object of the class ertmpt_sim,
• fit_list: an object of the class ertmpt_fit,
• specs: some specifications like the model, seed number, etc.,

```

---

**nu2const**

**Set process drift rate to constants**

**Description**

Setting process drift rate (parameter nu) to constants or change it back to be estimated.

**Usage**

```r
nu2const(model, names, constants = NA)
```
set_nu_const(model, names, constants = NA)

Arguments

- **model**: An object of the class `rtmpt_model`.
- **names**: Character vector with process names.
- **constants**: Numerical vector of length one or `length(names)`. You have the following options for the elements of the numeric vector:
  - `-Inf < constants < Inf`: set the named drift rate parameter(s) to constant value(s)
  - `NA`: estimate the named drift rate parameter(s)

Value

An object of the class `drtmpt_model`.

Author(s)

Raphael Hartmann

delta2delta, a2const, a2a, nu2nu, omega2const and omega2omega

Examples

```r
# Detect-Guess variant of the Two-High Threshold model.
# The encoding and motor execution times are assumed to be equal for each category.
# The process drift rate for guessing (g) will be set to 1.0.

mdl_2HTM <- "
# targets
do+(1-do)*g
(1-do)*(1-g)

# lures
(1-dn)*g
dn+(1-dn)*(1-g)

# do: detect old; dn: detect new; g: guess
"

model <- to_drtmpt_model(mdl_file = mdl_2HTM)

## setting drift rate for g to a constant (1.0):
new_model <- nu2const(model = model, names = c("g"), constants = c(1.0))
new_model
```
## setting drift rate of g to a constant (1.0):
```
new_model <- set_nu_const(model = model, names = c("g"), constants = c(1.0))
new_model
```

---

### Description

Setting multiple process drift rates (nu) equal. One of the process drift rates will be estimated and the other named drift rates will be set to equal the former. The equality can be removed by only using one name of a process.

### Usage

```
nu2nu(model, names, keep_consts = FALSE)
```

```
set_nu_equal(model, names, keep_consts = FALSE)
```

### Arguments

- **model**
  A list of the class `drtmpt_model`.

- **names**
  Character vector giving the names of the processes for which the process drift rates should be equal. If `length(names) = 1` then the corresponding process drift rates will be estimated (i.e., it will be set to NA)

- **keep_consts**
  Can be one of the following

  - logical value: FALSE (default) means none of the constants for names in the model will be kept; The drift rates of the reference process (i.e., first of names in alphabetical order) will be set to NA (i.e., will be estimated) and the others will be set to the name of the reference process (i.e., will be set to equal the reference process drift rate). TRUE means the constant of the reference process drift rate (if specified) is used for all other processes.

  - numeric value: index for names. If 1, the constant of the first process in names (in original order defined by the user) is used for all other drift rates of the processes in names. If 2, the constant of the second process is used. And so on.

### Value

A list of the class `drtmpt_model`.

omega2const

Set process relative starting-point to constants

Description

Setting process relative starting-point (parameter omega) to constants or change it back to be estimated.

Usage

omega2const(model, names, constants = NA)

set_omega_const(model, names, constants = NA)
Arguments

model: An object of the class rtmp_t_model.
names: Character vector with process names.
constants: Numerical vector of length one or length(names). You have the following options for the elements of the numeric vector:
- $0 < \text{constants} < 0$: set the named relative starting-point parameter(s) to constant value(s) larger than zero and smaller than 1
- NA: estimate the named relative starting-point parameter(s)

Value

An object of the class drtmp_t_model.

```
omega2omega

Set process relative starting-point equal

Description

Setting multiple process relative starting-points (omegas) equal. One of the process relative starting-points will be estimated and the other named relative starting-points will be set to equal the former. The equality can be removed by only using one name of a process.

Usage

omega2omega(model, names, keep_consts = FALSE)

set_omegas_equal(model, names, keep_consts = FALSE)

Arguments

model A list of the class drtmp_model.
names Character vector giving the names of the processes for which the process relative starting-points should be equal. If length(names) = 1 then the corresponding process relative starting-point will be estimated (i.e., it will be set to NA).

keep_consts Can be one of the following:

• logical value: FALSE (default) means none of the constants for names in the model will be kept; The relative starting-points of the reference process (i.e., first of names in alphabetical order) will be set to NA (i.e., will be estimated) and the others will be set to the name of the reference process (i.e., will be set to equal the reference process relative starting-point). TRUE means the constant of the reference process relative starting-point (if specified) is used for all other processes.

• numeric value: index for names. If 1, the constant of the first process in names (in original order defined by the user) is used for all other relative starting-points of the processes in names. If 2, the constant of the second process is used. And so on.

set_resps  Set responses in an ertmpt_model or a drtmpt_model

Description

Change the responses for a tree and the categories within that tree.

Usage

set_resps(model, tree, categories, values = 0)

Arguments

model  A list of the class ertmpt_model or drtmpt_model.
tree  Character or numerical value of the tree for which the responses should be changed.
categories  Character or numerical vector identifying category/ies within the specified tree for which the responses should be changed.
values  Numerical vector of length length(categories) providing the responses. Default is 0.

Value

A list of the class ertmpt_model or drtmpt_model.

Author(s)

Raphael Hartmann

**SimData**  

*Data simulated from the restricted 2HTM*

**Description**

Data set generated from a restricted Two-High Threshold model.

**Usage**

SimData

**Format**

A data frame with five variables:

- subj  subjects number
- group  group label of the subjects
- tree  condition of the current trial
- cat  observed response category
- rt  observed response time in ms

**Details**

Forty subjects with thirty trials per condition (Studied items, new Items) were simulated.

**Examples**

```r
# Detect-Guess variant of the restricted Two-High Threshold model.

head(SimData)

mdl_2HTM <- "
# targets
d+(1-d)*g ; 0
(1-d)*(1-g) ; 1

# lures
(1-d)*g ; 0
d+(1-d)*(1-g) ; 1

# d: detect; g: guess"

model <- to_ertmpt_model(mdl_file = mdl_2HTM)

data <- to_ertmpt_data(raw_data = SimData, model = model)
```
# this might take some time to run
ermtpt_out <- fit_ertmpt(model = model, data = data)

# convergence
## traceplot and summary of the first six parameters
coda::traceplot(ertmpt_out$samples[,1:6])
summary(ertmpt_out)

## sim_ertmpt_data
Simulate data from RT-MPT models

Description
Simulate data from RT-MPT models using ertmpt_model objects. You can specify the random seed, number of subjects, number of trials per tree, and some parameters (mainly the same as prior_params from fit_ertmpt).

Usage
sim_ertmpt_data(model, seed, n.subj, n.trials, params = NULL)

Arguments
- model: A list of the class ertmpt_model.
- seed: Random seed number.
- n.subj: Number of subjects.
- n.trials: Number of trials per tree.
- params: Named list of parameters from which the data will be generated. This must be the same named list as prior_params from fit_ertmpt, except for "mean_of_mu_alpha" and "var_of_mu_alpha", and has the same defaults. The difference to prior_params is, that vectors are allowed, but must match the length of the parameters in the model. It is not recommended to use the defaults since they lead to many probabilities close or equal to 0 and/or 1 and to RTs close or equal to 0. Allowed parameters are:
  - mean_of_mu_alpha: Probit transformed mean probability. If you want to have a group-level mean probability of 0.6, use mean_of_mu_alpha = qnorm(0.6) in the params list. Default is 0 or qnorm(.5).
  - var_of_mu_alpha: Variance of the probit transformed group-level mean probability. If specified, mu_alpha will be sampled from N(mean_of_mu_alpha, var_of_mu_alpha). If not, mu_alpha = mean_of_mu_alpha.
  - mean_of_exp_mu_beta: This is the expected exponential rate (E(exp(beta)) = E(lambda)) and 1/mean_of_exp_mu_beta is the expected process time (1/E(exp(beta)) = E(tau)). The default mean is set to 10, such that the expected process time is 0.1 seconds. For a mean process time of 200 ms, wirte mean_of_exp_mu_beta = 1000/200.
• **var_of_exp_mu_beta**: The group-specific variance of the exponential rates. Since \( \exp(\mu_{beta}) \) is Gamma distributed, the rate of the distribution is just mean divided by variance and the shape is the mean times the rate. If specified, \( \exp(\mu_{beta}) \) is sampled from Gamma \( \text{shape} = \text{mean_of_exp_mu_beta}^2 / \text{var_of_exp_mu_beta}, \text{rate} = \text{mean_of_exp_mu_beta} / \text{var_of_exp_mu_beta} \). If not, \( \mu_{alpha} = \text{mean_of_exp_mu_beta} \).

• **mean_of_mu_gamma**: This is the expected mean parameter of the encoding and response execution times, which follow a normal distribution truncated from below at zero, so \( E(\mu_{gamma}) < E(\gamma) \). The default is 0. For a mean motor time of 550 ms write \( \text{mean_of_mu_gamma} = 550 / 1000 \).

• **var_of_mu_gamma**: The group-specific variance of the mean parameter. If specified, \( \mu_{gamma} \) is sampled from N(\( \text{mean_of_mu_gamma}, \text{var_of_mu_gamma} \)). If not, \( \mu_{gamma} = \text{mean_of_mu_gamma} \).

• **mean_of_omega_sqr**: This is the expected residual variance (\( E(\omega^2) \)). The default is 0.005.

• **var_of_omega_sqr**: The variance of the residual variance (\( \text{Var}(\omega^2) \)). If specified, \( \omega^2 \) is sampled from GAMMA(\( \text{shape} = \text{mean_of_omega_sqr}^2 / \text{var_of_omega_sqr}, \text{rate} = \text{mean_of_omega_sqr} / \text{var_of_omega_sqr} \)). If not, \( \omega^2 = \text{mean_of_omega_sqr} \).

• **df_of_sigma_sqr**: Degrees of freedom for the individual variance of the response executions. The individual variance follows a scaled inverse chi-squared distribution with \( \text{df_of_sigma_sqr} \) degrees of freedom and \( \omega^2 \) as scale. 2 is the default and it should be an integer.

• **sf_of_scale_matrix_SIGMA**: The original scaling matrix (S) of the (scaled) inverse Wishart distribution for the process-related parameters is an identity matrix \( S = I \). \( \text{sf_of_scale_matrix_SIGMA} \) is a scaling factor, that scales this matrix \( S = \text{sf_of_scale_matrix_SIGMA} \times I \). Its default is 1.

• **sf_of_scale_matrix_GAMMA**: The original scaling matrix (S) of the (scaled) inverse Wishart distribution for the encoding and motor execution parameters is an identity matrix \( S = I \). \( \text{sf_of_scale_matrix_GAMMA} \) is a scaling factor that scales this matrix \( S = \text{sf_of_scale_matrix_GAMMA} \times I \). Its default is 1.

• **prec_epsilon**: This is epsilon in the paper. It is the precision of \( \xi \) (scaling parameter in the scaled inverse Wishart distribution). Its default is also 1.

• **add_df_to_invWish**: If \( P \) is the number of parameters or rather the size of the scale matrix used in the (scaled) inverse Wishart distribution then \( \text{add_df_to_invWish} \) is the number of degrees of freedom that can be added to it. So \( DF = P + \text{add_df_to_invWish} \). The default for \( \text{add_df_to_invWish} \) is 1, such that the correlations are uniformly distributed within \([-1, 1]\).

• **SIGMA**: Variance-covariance matrix of the process-related parameters. It must match the number of process-related parameters to be estimated. If scalars or vectors are given, they will be transformed into diagonal matrices using diag(SIGMA). If not specified it will be randomly generated using diag(\( \xi \))%*%invwishart(nu, S)*%diag(\( \xi \)), where nu is the number of process-related group-level parameters to be estimated plus \( \text{add_df_to_invWish} \), S is the identity matrix multiplied by \( \text{sf_of_scale_matrix_SIGMA} \), and \( \xi \)
(randomly generated from N(1, 1/prec_epsilon)) are the scaling factors for the scaled inverse Wishart distribution. If SIGMA is used, sf_of_scale_matrix_SIGMA and add_df_to_invWish will be ignored for the process-related parameters.

- GAMMA: Variance-covariance matrix of the motor time parameters. It must match the number of motor time parameters to be estimated. If scalars or vectors are given, they will be transformed into diagonal matrices using diag(SIGMA). If not specified it will be randomly generated using diag(xi)%*%rinvwishart(nu, S)%*%diag(xi), where nu is the number of motor time group-level parameters to be estimated plus add_df_to_invWish, S is the identity matrix multiplied by sf_of_scale_matrix_GAMMA, and xi (randomly generated from N(1, 1/prec_epsilon)) are the scaling factors for the scaled inverse Wishart distribution. If GAMMA is used, sf_of_scale_matrix_GAMMA and add_df_to_invWish will be ignored for the motor time parameters.

**Value**

A list of the class ertmpt_sim containing

- **data**: the data.frame with the simulated data,
- **gen_list**: a list containing lists of the group-level and subject-specific parameters for the process-related parameters and the motor-related parameters, and the trial-specific probabilities, process-times, and motor-times,
- **specs**: some specifications like the model, seed number, etc.,

**Author(s)**

Raphael Hartmann

**sim_ertmpt_data_SBC** *Simulate data from an RT-MPT model*

**Description**

Simulate data from RT-MPT models using ertmpt_model objects. The difference to sim_ertmpt_data is that here only scalars are allowed. This makes it usable for simulation-based calibration (SBC; Talts et al., 2018). You can specify the random seed, number of subjects, number of trials, and some parameters (same as prior_params from fit_ertmpt).

**Usage**

```
sim_ertmpt_data_SBC(model, seed, n.subj, n.trials, params = NULL)
```
**Arguments**

- **model**: A list of the class `ermtpt_model`.
- **seed**: Random seed number.
- **n.subj**: Number of subjects.
- **n.trials**: Number of trials per tree.
- **params**: Named list of parameters from which the data will be generated. This must be the same named list as `prior_params` from `fit_ermtpt` and has the same defaults. It is not recommended to use the defaults since they lead to many probabilities close or equal to 0 and/or 1 and to RTs close or equal to 0. Allowed parameters are:
  - **mean_of_exp_mu_beta**: This is the expected exponential rate \( E(\exp(\beta)) = E(\lambda) \) and \( 1/\text{mean_of_exp_mu_beta} \) is the expected process time \( 1/E(\exp(\beta)) = E(\tau) \). The default mean is set to 10, such that the expected process time is 0.1 seconds.
  - **var_of_exp_mu_beta**: The group-specific variance of the exponential rates. Since \( \exp(\mu_{\beta}) \) is Gamma distributed, the rate of the distribution is just mean divided by variance and the shape is the mean times the rate. The default is set to 100.
  - **mean_of_mu_gamma**: This is the expected mean parameter of the encoding and response execution times, which follow a normal distribution truncated from below at zero, so \( E(\mu_{\gamma}) < E(\gamma) \). The default is 0.
  - **var_of_mu_gamma**: The group-specific variance of the mean parameter. Its default is 10.
  - **mean_of_omega_sqr**: This is the expected residual variance \( E(\omega^2) \). The default is 0.005.
  - **var_of_omega_sqr**: The variance of the residual variance \( \text{Var}(\omega^2) \). The default is 0.01. The default of the mean and variance is equivalent to a shape and rate of 0.0025 and 0.5, respectively.
  - **df_of_sigma_sqr**: degrees of freedom for the individual variance of the response executions. The individual variance follows a scaled inverse chi-squared distribution with \( \text{df_of_sigma_sqr} \) degrees of freedom and \( \omega^2 \) as scale. 2 is the default and it should be an integer.
  - **sf_of_scale_matrix_SIGMA**: The original scaling matrix (S) of the (scaled) inverse Wishart distribution for the process related parameters is an identity matrix \( S=I \). \( \text{sf_of_scale_matrix_SIGMA} \) is a scaling factor, that scales this matrix \( S=\text{sf_of_scale_matrix_SIGMA}*I \). Its default is 1.
  - **sf_of_scale_matrix_GAMMA**: The original scaling matrix (S) of the (scaled) inverse Wishart distribution for the encoding and motor execution parameters is an identity matrix \( S=I \). \( \text{sf_of_scale_matrix_GAMMA} \) is a scaling factor that scales this matrix \( S=\text{sf_of_scale_matrix_GAMMA}*I \). Its default is 1.
  - **prec_epsilon**: This is epsilon in the paper. It is the precision of mu_alpha and all xi (scaling parameter in the scaled inverse Wishart distribution). Its default is also 1.
• add_df_to_invWish: If \( P \) is the number of parameters or rather the size of the scale matrix used in the (scaled) inverse Wishart distribution then add_df_to_invWish is the number of degrees of freedom that can be added to it. So \( DF = P + \text{add_df_to_invWish} \). The default for add_df_to_invWish is 1, such that the correlations are uniformly distributed within \([-1, 1]\).

Value

A list of the class ertmpt_sim containing

• data: the data.frame with the simulated data,
• gen_list: a list containing lists of the group-level and subject-specific parameters for the process-related parameters and the motor-related parameters, and the trial-specific probabilities, process-times, and motor-times,
• specs: some specifications like the model, seed number, etc.,

               var_of_mu_gamma = 0.0025,
               mean_of_omega_sqr = 0.005,
               }
Description

Setting multiple process completion times (taus) equal. This means all process times of negative outcomes will be set equal and all process times of positive outcomes will be set equal. Only two process times (one for the negative and one for the positive outcome) of the named processes will be estimated. The equality can be removed by just naming only one process name.

Usage

```r
tau2tau(model, names, outcome, keep_zeros = FALSE)
```

```r
set_taus_equal(model, names, outcome, keep_zeros = FALSE)
```

Arguments

- **model**: A list of the class `ertmpt_model`.
- **names**: Character vector giving the names of the processes for which the process completion times should be equal. If `length(names) = 1` then the corresponding process completion times (for negative and positive outcomes) will be estimated (i.e., they will be set to NA).
- **outcome**: Character (no vector) indicating for which process outcome the process completion times should be set equal. Allowed characters are:
  - "minus": the negative outcome of the processes.
  - "plus": the positive outcome of the processes.
  - "both": the negative and positive outcome of the processes. This will set all process completion times for the "minus" outcome equal and all process completion times for the "plus" outcome equal.
- **keep_zeros**: Can be one of the following:
  - logical value: FALSE (default) means none of the zeros for names in the model will be kept; The times of the reference process (i.e., first of names in alphabetical order) will be set to NA (i.e., will be estimated) and the others will be set to the name of the reference process (i.e., will be set to equal the reference process times). TRUE means the zero(s) of the reference process times (if specified) is used for the same outcome of all other processes.
• numeric value: index for names. If 1, the zero(s) of the first process in names (in original order defined by the user) is used for the same outcome of all other processes in names. If 2, the zero(s) of the second process is used. And so on.

Value
A list of the class ertmpt_model.

Note
If you use theta2theta() and tau2tau() with the same process names you might just change the EQN or MDL file accordingly by using the same process name for all processes which should have equal process times and probabilities.

Examples

```r
# Detect-Guess variant of the Two-High Threshold model.
# The encoding and motor execution times are assumed to be equal for each category.
# The process completion times for both detection processes ("do" and "dn") will be
# set equal.
mdl_2HTM <- "
# targets
do+(1-do)*g
(1-do)*(1-g)

# lures
(1-dn)*g
dn+(1-dn)*(1-g)

# do: detect old; dn: detect new; g: guess
"

model <- to_ertmpt_model(mdl_file = mdl_2HTM)

## make do = dn
new_model <- tau2tau(model = model, names = c("do", "dn"), outcome = "both")
new_model

## make do = dn
```
new_model <- set_taus_equal(model = model, names = c("do", "dn"), outcome = "both")
new_model

---

**tau2zero**

*Set process completion times to zero*

**Description**

Setting process completion times (taus) to zero or change it back to be estimated.

**Usage**

```r
tau2zero(model, names, outcomes, values = 0)
```

```r
set_tau_zero(model, names, outcomes, values = 0)
```

**Arguments**

- `model` A list of the class `ermtpt_model`.
- `names` Character vector with process names.
- `outcomes` Character vector of length `length(names)` indicating for which process outcome the process completion time should be zero or changed back to be estimated. Allowed characters are:
  - "minus": the negative outcome of the process.
  - "plus": the positive outcome of the process.
- `values` Numerical vector of length one or `length(names)`. You have the following options for the elements of the numeric vector:
  - 0: suppress the process time/rate, i.e., set the process completion time (tau) with the specified output to zero.
  - NA: estimate the process time (tau)

**Value**

A list of the class `ermtpt_model`.

**Author(s)**

Raphael Hartmann

**See Also**

Examples

```r
# Detect-Guess variant of the Two-High Threshold model.
# The encoding and motor execution times are assumed to be equal for each category.
# The process completion times for both failed detections will be suppressed.

mdl_2HTM <- 
"# targets
  do+(1-do)*g
  (1-do)*(1-g)

# lures
  (1-dn)*g
  dn+(1-dn)*(1-g)

# do: detect old; dn: detect new; g: guess"

model <- to_ertmpt_model(mdl_file = mdl_2HTM)

## removing the process times (tau) for the failed ("minus") detection ("do" and "dn")
new_model <- tau2zero(model = model, names = c("dn", "do"),
                      outcomes = c("minus", "minus"), values = 0)
new_model

## removing the process times (tau) for the failed ("minus") detection ("do" and "dn")
new_model <- set_tau_zero(model = model, names = c("dn", "do"),
                           outcomes = c("minus", "minus"), values = 0)
new_model
```

---

**theta2const**  
*Set process probabilities to constants*

**Description**  
Setting process probabilities (thetas) to constants or change it back to be estimated.

**Usage**  
`theta2const(model, names, constants = NA)`

`set_theta_const(model, names, constants = NA)`

**Arguments**  
- `model`  
  An object of the class `ertmpt_model`.
- `names`  
  Character vector with process names.
constants  Numerical vector of length one or length(names). You have the following options for the elements of the numeric vector:

- \( 0 < \text{constants} < 1 \): set the named probability to a constant value between zero and one
- \( \text{NA} \): estimate the named probability

Value

An object of the class \texttt{ertmpt\_model}.

new\_model
```
theta2theta - Set process probabilities equal

Description

Setting multiple process probabilities (thetas) equal. One of the process probabilities will be estimated and the other named process(es) will be set to equal the former. The equality can be removed by only using one name of a process.

Usage

theta2theta(model, names, keep_consts = FALSE)

set_thetas_equal(model, names, keep_consts = FALSE)

Arguments

- **model**: A list of the class `ertmpt_model`.
- **names**: Character vector giving the names of the processes for which the process probabilities should be equal. If `length(names) = 1` then the corresponding process probability will be estimated (i.e., it will be set to NA).
- **keep_consts**: Can be one of the following
  - Logical value: FALSE (default) means none of the constants for names in the model will be kept; The probability of the reference process (i.e., first of names in alphabetical order) will be set to NA (i.e., will be estimated) and the others will be set to the name of the reference process (i.e., will be set to equal the reference process probability). TRUE means the constant of the reference process probability (if specified) is used for all other processes.
  - Numeric value: index for names. If 1, the constant of the first process in names (in original order defined by the user) is used for all other probabilities of the processes in names. If 2, the constant of the second process is used. And so on.

Value

A list of the class `ertmpt_model`.

Note

If you use `theta2theta()` and `tau2tau()` with the same process names you might just change the EQN or MDL file accordingly by using the same process name for all processes which should have equal process times and probabilities.

----------
to_drtmpt_data  Transform data to be used in Diffusion RT-MPT model fitting

Description

Transform data, such that it can be used in fit_drtmpt. This implies changing each value/label in "subj", "group", "tree", and "cat" to numbers such that it starts from zero (e.g. data$tree = c(1,1,3,2,2,...) will be changed to data$tree = c(0,0,2,2,1,1,...)) and the columns will be ordered in the right way. "rt" must be provided in milliseconds. If it has decimal places it will be rounded to a whole number. fit_drtmpt will automatically call this function if its input is not already a drtmpt_data list, but it is advised to use it anyway because it provides information about the transformations of the data.
to_drtmpt_data

Usage

to_drtmpt_data(raw_data, model)

Arguments

raw_data    data.frame or path to data containing columns "subj", "group", "tree", "cat", and "rt". If not provided in this order it will be reordered and unused variables will be moved to the end of the new data frame.

model       A list of the class drtmpt_model.

Value

A list of the class drtmpt_data containing transformed data and information about the transformation that has been done.

  lure ; c_r ; dn
  lure ; c_r ; (1-dn)*(1-g)
"

model <- to_drtmpt_model(eqn_file = eqn_2HTM)

data_file <- system.file("extdata/labeled_data.txt", package="rtmpt")
data <- read.table(file = data_file, header = TRUE)

data_list <- to_drtmpt_data(raw_data = data, model = model)
data_list
to_drtmpt_model

Create a model list to fit a Diffusion-RT-MPT

Description

Create a model list of the class drtmpt_model by providing either eqn_file or mdl_file. If both are provided mdl_file will be used.

Usage

to_drtmpt_model(eqn_file = NULL, mdl_file = NULL)

Arguments

eqn_file Character string as shown in example 2 or path to the text file that specifies the Diffusion (RT-)MPT model with standard .eqn syntax (Heck et al., 2018; Hu, 1999). E.g. studied ; hit ; (1-do)*g for a correct guess in the detect-guess 2HT model.

mdl_file Character string as shown in example 1 or path to the text file that specifies the Diffusion (RT-)MPT model and gives on each line the equation of one category using + to separate branches and * to separate processes (Singmann and Kellen, 2013). E.g. do+(1-do)*g for the category "hit" in the detect-guess 2HT model.

Value

A list of the class drtmpt_model.

Note

Within a branch of a (RT-)MPT model it is not allowed to have the same process two or more times.

**to_ertmpt_model**

Create a model list to fit an RT-MPT

**Description**

Create a model list of the class ertmpt_model by providing either eqn_file or mdl_file. If both are provided mdl_file will be used.

**Usage**

to_ertmpt_model(eqn_file = NULL, mdl_file = NULL)
to_rtmpt_model(eqn_file = NULL, mdl_file = NULL)

**Arguments**

eqn_file Character string as shown in example 2 or path to the text file that specifies the (RT-)MPT model with standard .eqn syntax (Heck et al., 2018; Hu, 1999). E.g. studied ; hit ; (1-do)*g for a correct guess in the detect-guess 2HT model.
mdl_file  Character string as shown in example 1 or path to the text file that specifies the (RT-)MPT model and gives on each line the equation of one category using + to separate branches and * to separate processes (Singmann and Kellen, 2013). E.g. do+(1-do)*g for the category "hit" in the detect-guess 2HT model.

Value
A list of the class ertmpt_model.

Note
Within a branch of a (RT-)MPT model it is not allowed to have the same process two or more times.
