Package ‘sFFLHD’

October 14, 2022

Type Package
Title Sequential Full Factorial-Based Latin Hypercube Design
Version 0.1.2
Author Collin Erickson
Maintainer Collin Erickson <collinberickson@gmail.com>
Description Gives design points from a sequential full factorial-based Latin hypercube design, as described in Duan, Ankenman, Sanchez, and Sanchez (2015, Technometrics, <doi:10.1080/00401706.2015.1108233>).
License GPL-3
LazyData TRUE
RoxygenNote 6.0.1
Imports methods, stats, conf.design, R6
Depends DoE.base
Suggests testthat

**sFFLHD-class**

*sFFLHD object that gives a batch of points at a time.*

**Description**

sFFLHD object that gives a batch of points at a time.

**Value**

A sFFLHD object

**Fields**

- **D** numeric. The number of dimensions for the design. Must be set.
- **L** numeric. The number of points in each batch, also the number of levels of each dimension. Must be set.
- **maximin** logical. Should maximin distance be used to space out points? TRUE by default. Only used while lb <= 100, not worth it once the boxes are very small.
- **a** numeric. A root of L that determines the intermediate stages. Is automatically set to smallest possible value, which is recommended.
- **b** integer. The batch number.
- **nb** integer. The number of points selected so far.
- **lb** numeric. Current levels of the small grid.
- **Lb** numeric. Current levels of the intermediate grid.
- **Xb** matrix. Current design matrix, continuous from 0 to 1.
- **Vb** matrix. Small grid design.
- **Mb** matrix. Intermediate grid design.
- **Wb** matrix. Big grid design.
- **A1** matrix. The first OA slice.
- **r** integer. Used to keep track of loop index.
- **p** integer. Used to keep track of loop index.
- **Ar** matrix. Current Ar.
- **stage** integer. Current stage.
- **vii** integer. Used to keep track of location in stage 2.
- **Fslices** list. A list of slices.
- **FF1.1** matrix. Temporary matrix used to generate slices.
- **Mb.store** matrix. Temporary storage of Mb.
- **v.shuffle** integer. A storage value for storing order. Requires extra optimization.
sFFLHDmm

Examples

s <- sFFLHD$new(D=2, L=3)
s$get.batch()
s <- sFFLHD$new(D=2, L=4)
s$get.batch()

sFFLHDmm sFFLHD maximin

Description

sFFLHD R6 object that gives a batch of points at a time using maximin. To do this it takes all
batches for stage at beginning of stage and then reorders them. Not that great in practice. Requires
extra optimization and storage.

Usage

sFFLHDmm

Format

An object of class R6ClassGenerator of length 24.

Value

A sFFLHDmm object

Fields

D numeric. The number of dimensions for the design. Must be set.
L numeric. The number of points in each batch, also the number of levels of each dimension. Must
be set.
b integer. The batch number.
s sFFLHD. The design it takes the points and then reorders them.
X matrix. The points given in the design.
Xchoices list. Batches taken from s and have been reordered, but which have not been returned to
the user yet.

Examples

s <- sFFLHDmm$new(D=2, L=3)
s$get.batch()
s <- sFFLHDmm$new(D=2, L=4)
s$get.batch()
**sFFLHD_Lflex**

**sFFLHD with flexible L**

**Description**

R6 object that gives uses a sFFLHD with L near the requested one, but gives them back in the requested L.

**Usage**

`sFFLHD_Lflex`

**Format**

An object of class `R6ClassGenerator` of length 24.

**Value**

A `sFFLHD_Lflex` object

**Fields**

- **D** numeric. The number of dimensions for the design. Must be set.
- **L** numeric. The number of points in each batch, also the number of levels of each dimension. Must be set.
- **b** integer. The batch number.
- **s** `sFFLHD`. The design it takes the points and then reorders them.
- **X** matrix. The points given in the design.
- **X_choices** matrix. Points taken from s and have been reordered, but which have not been returned to the user yet.

**Examples**

```r
s <- sFFLHD_Lflex$new(D=8, L=4)
s$get.batch()
# sFFLHD(D=7, L=10)$get.batch() doesn't work, needs L=7, 8, 9, 11
s <- sFFLHD_Lflex$new(D=7, L=10) # Uses L=9
s$get.batch()
s <- sFFLHD_Lflex$new(D=7, L=10, prefer_L="up") # Should use 11
```
split_matrix

Split a matrix by rows, based on either the number of rows per group or number of splits.

Usage

\[ \text{split_matrix}(\text{mat}, \text{rowspergroup} = \text{NULL}, \text{nsplits} = \text{NULL}, \text{shuffle} = \text{TRUE}) \]

Arguments

- **mat**: A matrix to be split.
- **rowspergroup**: Number of rows in a group.
- **nsplits**: Number of splits to make.
- **shuffle**: Should the splits be shuffled before returning?

Value

A list of the splits of the matrix.

Examples

```r
mat <- matrix(1:12, ncol=2)
split_matrix(mat, 4, shuffle=FALSE)
split_matrix(mat, 4, shuffle=TRUE)
split_matrix(mat, nsplits=3, shuffle=FALSE) # same as 4 rowspergroup
```
