Package ‘sarima’

May 13, 2019

Type Package
Title Simulation and Prediction with Seasonal ARIMA Models
Version 0.8.1
Date 2019-04-15

Description Functions, classes and methods for time series modelling with ARIMA and related models. The aim of the package is to provide consistent interface for the user. For example, a single function autocorrelations() computes various kinds of theoretical and sample autocorrelations. This is work in progress, see the documentation and vignettes for the current functionality. Function sarima() fits extended multiplicative seasonal ARIMA models with trends, exogenous variables and arbitrary roots on the unit circle, which can be fixed or estimated.

Depends R (>= 2.10), FitAR, stats4

Built: R 3.7.0; x86_64-w64-mingw32; 2019-05-12 19:51:46 UTC; windows

There is a large number of packages for time series modelling. They provide a huge number of functions, often with similar or overlapping functionality and different argument conventions. One of the aims of package sarima is to provide consistent interface to some frequently used functionality.

In package sarima a consistent naming scheme is used as much as possible. Names of functions start with a lowercase letter and consist of whole words, acronyms or commonly used abbreviations. In multiword names, the second and subsequent words start with capital letters (camelCase). Only the first letter in acronyms is capitalised, e.g. Arma stands for ARMA. Formal (S4) classes follow the same rules but the first letter of the first word is capitalised, as well.

For example, the functions that compute autocorrelations, autocovariances, partial autocorrelations are called autocorrelations, autocovariances, and partialAutocorrelations, respectively. Moreover, they recognise from their argument(s) what exactly is needed. If they are given times series, they compute sample autocorrelations, etc; if they are given model specifications, they compute the corresponding theoretical properties.

This is work in progress, see also the vignette(s).

Examples

```r
## simulate a white noise ts (model from Francq & Zakoian)
n <- 5000
x <- sarima:::rgarch1pl(n, alpha = 0.3, beta = 0.55, omega = 1, n.skip = 100)

## acf and pacf
(x.acf <- autocorrelations(x))
(x.pacf <- partialAutocorrelations(x))

## portmanteau test for iid, by default gives also ci’s for the acf under H0
x.iid <- whiteNoiseTest(x.acf, h0 = "iid", nlags = c(5,10,20), x = x, method = "LiMcLeod")
x.iid

x.iid2 <- whiteNoiseTest(x.acf, h0 = "iid", nlags = c(5,10,20), x = x, method = "LjungBox")
x.iid2

## portmanteau test for garch H0
x.garch <- whiteNoiseTest(x.acf, h0 = "garch", nlags = c(5,10,20), x = x)
x.garch

## plot methods give the CI’s under H0
plot(x.acf)

## if the data are given, the CI’s under garch H0 are also given.
plot(x.acf, data = x)

## Tests based on partial autocorrelations are also available:
plot(x.pacf)
plot(x.pacf, data = x)

## Models
## AR
(ar2a1 <- ArModel(ar = c(-0.3, -0.7), sigma2 = 1))
autocorrelations(ar2a1, maxlag = 6)
```
acfGarchTest

partialAutocorrelations(\text{ar2a1}, \text{maxlag} = 6)

**acfGarchTest**  
*Test for GARCH white noise*

**Description**

Carry out a test for GARCH white noise

**Usage**

```
acfGarchTest(acr, x, nlags, interval = 0.95)
acfWnTest(acr, x, nlags, interval = 0.95, ...)
```

**Arguments**

- `acr`: autocorrelations.
- `x`: time series.
- `nlags`: how many lags to use.
- `interval`: If not NULL, compute also confidence intervals with the specified coverage probability.
- `...`: ~~ TODO: describe this argument. ~~

**Details**

Unlike the autocorrelation IID test, the time series is needed here to estimate the covariance matrix of the autocorrelations under the null hypothesis.

`acfGarchTest` performs a test for uncorrelatedness of a time series. The null hypothesis is that the time series is GARCH, see Francq C, Zakoian J (2010). *GARCH models: structure, statistical inference and financial applications*. John Wiley & Sons. ISBN 978-0-470-68391-0.

`acfWnTest` performs a test for uncorrelatedness of a time series under a weaker null hypothesis. The null hypothesis is that the time series is GARCH-type or from a stochastic volatily model, see (Kokoszka and Politis 2011).

See the references for details and precise specification of the hypotheses.

The format of the return value is the same as for `acfIidTest`.

**Value**

a list with components "test" and "ci"

Examples

```r
# see also the examples for \code{\link{whiteNoiseTest}}

n <- 5000
x <- sarima::rgarchpl(n, alpha = 0.3, beta = 0.55, omega = 1, n.skip = 100)
x.acf <- autocorrelations(x)
x.pacf <- partialAutocorrelations(x)

acfGarchTest(x.acf, x = x, nlags = c(5,10,20))
acfGarchTest(x.pacf, x = x, nlags = c(5,10,20))

# do not compute CI's:
acfGarchTest(x.pacf, x = x, nlags = c(5,10,20), interval = NULL)

# plot methods call acfGarchTest() suitably if 'x' is given:
plot(x.acf, data = x)
plot(x.pacf, data = x)

# use 90% limits:
plot(x.acf, data = x, interval = 0.90)

acfWntest(x.acf, x = x, nlags = c(5,10,20))
nvarOfAcfkP(x, maxlag = 20)
whiteNoiseTest(x.acf, h0 = "arch-type", x = x, nlags = c(5,10,20))
```

```
acfIidTest

Carry out IID tests using sample autocorrelations

Description

Carry out tests for IID from sample autocorrelations.

Usage

```r
acfIidTest(acf, n, npar = 0, nlags = npar + 1,
    method = c("LiMcLeod", "LjungBox", "BoxPierce"),
    interval = 0.95, expandCI = TRUE, ...)
```
Arguments

- `acf`: autocorrelations.
- `n`: length of the corresponding time series.
- `npar`: number of df to subtract.
- `nlags`: number of autocorrelations to use for the portmanteau statistic, can be a vector to request several such statistics.
- `method`: a character string, one of "LiMcLeod", "LjungBox" or "BoxPierce".
- `interval`: a number or NULL.
- `expandCI`: logical flag, if TRUE return a CI for each lag up to max(nlags). Used only if CI's are requested.
- `...`: additional arguments passed on to methods. In particular, some methods have argument `x` for the time series.

Details

Performs one of several tests for IID based on sample autocorrelations. A correction of the degrees of freedom for residuals from fitted models can be specified with argument `npar`. `nlags` specifies the number of autocorrelations to use in the test, it can be a vector to request several tests.

The results of the test are gathered in a matrix with one row for each element of `nlags`. The test statistic is in column "ChiSQ", degrees of freedom in "DF" and the p-value in "pvalue". The method is in attribute "method".

If `interval` is not NULL confidence intervals for the autocorrelations are computed, under the null hypothesis of independence. The coverage probability (or probabilities) is specified by `interval`.

If argument `expandCI` is TRUE, there is one row for each lag, up to max(nlags). It is best to use this feature with a single coverage probability.

If `expandCI` to FALSE the confidence intervals are put in a matrix with one row for each coverage probability.

Value

a list with components "test" and (if requested) "ci", as described in Details

Methods

signature(acf = "ANY") In this method `acf` contains the autocorrelations.

signature(acf = "missing") The autocorrelations are computed from argument `x` (the time series).

signature(acf = "SampleAutocorrelations") This is a convenience method in which argument `n` is taken from `acf` and thus does not need to be specified by the user.

Examples

tsl <- rnorm(100)

a1 <- drop(acf(tsl)$acf)
acfIidTest(a1, n = 100, nlags = c(5, 10, 20))
acfIidTest(a1, n = 100, nlags = c(5, 10, 20), method = "LjungBox")
acfIidTest(a1, n = 100, nlags = c(5, 10, 20), interval = NULL)
acfIidTest(a1, n = 100, method = "LjungBox", interval = c(0.95, 0.90), expandCI = FALSE)

## acfIidTest() is called behind the scenes by methods for autocorrelation objects
tsl_acrf <- autocorrelations(tsl)
class(tsl_acrf) # "SampleAutocorrelations"
whiteNoiseTest(tsl_acrf, h0 = "iid", nlags = c(5,10,20), method = "LiMcLeod")
plot(tsl_acrf)

## use 10% level of significance in the plot:
plot(tsl_acrf, interval = 0.9)

-----

acfMaTest  

*Autocorrelation test for MA(q)*

Description

Carry out autocorrelation test for MA(q).

Usage

acfMaTest(acf, ma, n, nlags, interval = 0.95)

Arguments

acf  

autocorrelations.

ma  

a positive integer, the moving average order.

n  

length of the corresponding time series.

nlags  

number of autocorrelations to use for the portmonteau statistic, can be a vector to request several such statistics.

interval  

a number or NULL.
armaccf_xe

Details

acfMaTest performs a test that the time series is MA(ma), under the classical assumptions of Bartlett’s formulas.

When intervals are requested, they are confidence intervals for lags from 1 to ma. For lags greater than the moving average order, ma, autocorrelations outside them suggest to reject the null hypothesis that the process is MA(ma).

Value

a list with components "test" and (if requested) "ci"

Author(s)

Georgi N. Boshnakov

See Also

whiteNoiseTest, acfIidTest acfGarchTest

armaccf_xe

Crosscovariances between an ARMA process and its innovations

Description

Compute autocovariances of ARMA models and crosscovariances between an ARMA process and its innovations.

Usage

armaccf_xe(model, lag.max = 1)
armaacf(model, lag.max, compare)

Arguments

model the model, a list with components ar, ma and sigma2 (for the time being, sigmasq is also accepted, if model$sigma2 is NULL).
lag.max maximal lag for the result.
compare if TRUE compute the autocovariances also using tacvARMA() and return both results for comparison.
Details

Given a causal ARMA model, armacf_xe computes theoretical crosscovariances $R_{xe}(0), R_{xe}(1), R_{xe}(\text{lag.max})$, where $R_{xe}(k) = E(X_t e_{t-k})$, between an ARMA process and its innovations. Negative lags are not considered since $R_{xe}(k) = 0$ for $k < 0$. The moving average polynomial may have roots on the unit circle.

This is a simple illustration of the equations I give in my time series courses.

armaacf computes ARMA autocovariances. The default method computes the zero lag autocovariance using armacf_xe() and multiplies the autocorrelations obtained from ARMAacf (which computes autocorrelations, not autocovariances). If compare = TRUE it also uses tacvfARMA from package ltsa and returns both results in a matrix for comparison. The matrix has columns "native", "tacvfARMA" and "difference", where the last column contains the (zapped) differences between the autocorrelations obtained by the two methods.

The ARMA parameters in argument model follow the Brockwell-Davis convention for the signs. Since tacvfARMA() uses the Box-Jenkins convention for the signs, the moving average parameters are negated for calls to tacvfARMA().

Value

for armacf_xe, the crosscovariances for lags 0, ..., maxlag.

for armaacf, the autocovariances, see Details.

Note

armaacf is useful for exploratory computations but autocovariances is more convenient and eliminates the need to know function names for particular cases.

autocovariances(ar2a1, maxlag = 6)
partialVariances(ar2a1, maxlag = 6)

## ARMA
( arma2a1 <- ArmaModel(ar = 0.5, ma = c(0.3, 0.7), sigma2 = 1) )
autocorrelations(arma2a1, maxlag = 6)
partialAutocorrelations(arma2a1, maxlag = 6)

## modelCoeff() returns a list with components 'ar' and 'ma'
modelCoeff(arma2a1)
modelCoeff(ma2a1)
modelCoeff(ar2a1)

## modelOrder() returns a list with components 'ar' and 'ma'
modelOrder(arma2a1)
modelOrder(ma2a1)
modelOrder(ar2a1)

as(ma2a1, "ArmaModel") # success, as expected
as(ar2a1, "ArModel") # success, as expected
as(ArmaModel(ar = c(-0.3, -0.7)), "ArModel")
# But these fail:
## as(ma2a1, "ArModel") # fails
## as(ar2a1, "ArModel") # fails
## as(arma2a1, "MaModel") # fails
```
Classes ArmaModel, Ar and Ma in package sarima.

Objects from the Class

Classes "Ar" and "Ma" are subclasses of "Arma" with the corresponding order always zero.

The recommended way to create objects from these classes is with the functions ArmaModel, Ar and Ma. Objects can also be created by calls of the form new("Arma", ..., ar, ma, mean, check). See also coerce-methods for further ways to create objects from these classes.

Slots

center: Object of class "numeric" ~
intercept: Object of class "numeric" ~
sigma2: Object of class "numeric" ~
ar: Object of class "BJfilter" ~
ma: Object of class "SPFilter" ~

new("ArModel", ar = 0.5, center = 1.23)
new("MaModel", ma = 0.9, center = 1.23)

# argument 'mean' is an alias for 'center':
new("ArmaModel", ar = 0.5, ma = 0.9, mean = 1.23)

## both center and intercept may be given
## (the mean is not equal to the intercept in this case)
new("ArmaModel", ar = 0.5, ma = 0.9, center = 1.23, intercept = 2)

## Don't use 'mean' together with 'center' and/or 'intercept'.
## new("ArmaModel", ar = 0.5, ma = 0.9, center = 1.23, mean = 4)
## new("ArmaModel", ar = 0.5, ma = 0.9, intercept = 2, mean = 4)
## Both give error message:
## Use argument 'mean' only when 'center' and 'intercept' are missing or zero

arma_Q0Gardner

Computing the initial state covariance matrix of ARMA

Description

Wrappers for the internals 'stats' functions used by arima() to compute the initial state covariance matrix of ARMA models.

Usage

arma_Q0naive(phi, theta, tol = .Machine$double.eps)
arma_Q0gnbR(phi, theta, tol = .Machine$double.eps)
Arguments

phi        autoregressive coefficients.
theta      moving average coefficients.
tol        tolerance.

Details

arima() uses one of two methods to compute the initial state covariance matrix of a stationary ARMA model. Both methods are implemented by internal non-exported C functions. arma_q0Gardner() and arma_q0bis are simple R wrappers for those functions. They are defined in the tests (TODO: put in the examples?) but are not defined in the namespace of the package since they use unexported functions.

arma_q0Gardner() implements the original method from Gardner et al (1980). arma_q0bis() is a more recent method that deals better with roots very close to the unit circle.

These functions can be useful for comparative testing. They cannot be put in package 'sarima' since they use `:::` operator and are hence inadmissible to CRAN.

Value

a matrix

References

Examples

```r
## arma_q0Gardner(phi, theta, tol = .Machine$double.eps)
## arma_q0bis(phi, theta, tol = .Machine$double.eps)
```

arma_q0gnb  Compute the initial state covariance of ARMA model

Description

Compute the initial state covariance of ARMA model

Usage

arma_q0gnb(phi, theta, tol = 2.220446e-16)
Arguments

phi autoregression parameters.
theta moving average parameters.
tol tolerance. (TODO: explain)

Details

Experimental computation of the initial state covariance matrix of ARMA models.
The numerical results are comparable to SSinit = "Rossignol2011" method in arima and related functions. The method seems about twice faster than "Rossignol2011" on the models I tried but I haven’t done systematic tests.

See section ‘examples’ below and, for more tests based on the tests from stats, the tests in test/testthat/test-arma-q0.R.

Value

a matrix

Q0b

autocorrelations  Compute autocorrelations and related quantities

Description

Generic functions for computation of autocorrelations, autocovariances and related quantities. The idea is to free the user from the need to look for specific functions that compute the desired property for their object.

Usage

autocovariances(x, maxlag, ...)
autocorrelations(x, maxlag, lag_0, ...)
partialAutocorrelations(x, maxlag, lag_0 = TRUE, ...)
partialAutocovariances(x, maxlag, ...)
partialVariances(x, ...)

Arguments

x an object for which the requested property makes sense.
maxlag the maximal lag to include in the result.
lag_0 if TRUE include lag zero.
... further arguments for methods.

Details

autocorrelations is a generic function for computation of autocorrelations. It deduces the appropriate type of autocorrelation from the class of the object. For example, for models it computes theoretical autocorrelations, while for time series it computes sample autocorrelations.

The other functions described are similar for other second order properties of x.

These functions return objects from suitable classes, all inheriting from "Lagged". The latter means that indexing starts from zero, so the value for lag zero is accessed by r[0]. Subscripting always returns the underlying data unclassed (i.e. ordinary vectors or arrays). In particular, "[]" extracts the underlying data.
Functions computing autocorrelations and partial autocorrelations have argument `lag_0` — if it is set to `FALSE`, the value for lag zero is dropped from the result and the returned object is an ordinary vector or array, as appropriate.

See the individual methods for the format of the result and further details.

**Value**

an object from a class suitable for the requested property and `x`

**Author(s)**

Georgi N. Boshnakov

**See Also**

`armacccf_xe`, `armaacf`

**Examples**

```r
v1 <- rnorm(100)
autocorrelations(v1)
v1.acf <- autocorrelations(v1, maxlag = 10)

v1.acf[1:10] # drop lag zero value (and the class)
autocorrelations(v1, maxlag = 10, lag_0 = FALSE) # same

partialAutocorrelations(v1)
partialAutocorrelations(v1, maxlag = 10)

## compute 2nd order properties from raw data
autocovariances(v1)
autocovariances(v1, maxlag = 10)
partialAutocovariances(v1, maxlag = 6)
partialAutocovariances(v1)
partialVariances(v1, maxlag = 6)
pv1 <- partialVariances(v1)

## compute 2nd order properties from raw data
autocovariances(AirPassengers, maxlag = 6)
autocorrelations(AirPassengers, maxlag = 6)
partialAutocorrelations(AirPassengers, maxlag = 6)
partialAutocovariances(AirPassengers, maxlag = 6)
partialVariances(AirPassengers, maxlag = 6)

acv <- autocovariances(AirPassengers, maxlag = 6)
autocovariances(acv) # no-op
autocovariances(acv, maxlag = 4) # trim the available lags

## compute 2nd order properties from sample autocovariances
acr <- autocorrelations(acv)
acr
partialAutocorrelations(acv)
```

signature(from = "VirtualArmaFilter", to = "list")
signature(from = "VirtualSarimaModel", to = "ArmaModel")
```
Author(s)

Georgi N. Boshnakov

Examples

```r
## the default for ARMA model is BJ for ar and SP for ma:
mo <- new("ArmaModel", ar = 0.9, ma = 0.4, sigma2 = 1)
modelPoly(mo)

## here we declare explicitly that 0.4 uses the SP convention
## (not necessary, the result is the same, but the intention is clear).
mo1 <- new("ArmaModel", ar = 0.9, ma = as(0.4, "SPFilter"), sigma2 = 1)
modelPoly(mo1)
identical(mo, mo1) ## TRUE

## if the sign of theta follows the BJ convention, this can be stated unambiguously.
## This creates the same model:
mo2 <- new("ArmaModel", ar = 0.9, ma = as(-0.4, "BJFilter"), sigma2 = 1)
modelPoly(mo2)
identical(mo, mo2) ## TRUE

## And this gives the intended model whatever the default conventions:
ar3 <- as(0.9, "BJFilter")
ma3 <- as(-0.4, "BJFilter")
mo3 <- new("ArmaModel", ar = ar3, ma = ma3, sigma2 = 1)
modelPoly(mo3)
identical(mo, mo3) ## TRUE

## The coefficients can be extracted in any particular form,
## e.g. to pass them to functions with specific requirements:
modelCoef(mo3) # coefficients of the model with the default (BD) sign convention
modelCoef(mo3, convention = "BD") # same result
modelCoef(mo3, convention = "SP") # signal processing convention

## for ltsa::tacvFARMA() the convention is BJ, so:
co <- modelCoef(mo3, convention = "BJ") # Box-Jenkins convention
ltsa::tacvFARMA(co$ar, co$ma, maxLag = 6, sigma2 = 1)
autocovariances(mo3, maxlag = 6) ## same
```

filterCoef

Description

Coefficients and other basic properties of filters.
Usage

filterCoef(object, convention, ...)
filterOrder(object, ...)
filterPoly(object, ...)
filterPolyCoef(object, lag_0 = TRUE, ...)

Arguments

object object.
convention convention for the sign.
lag_0 if FALSE, drop the coefficient of order zero.
... further arguments for methods.

Details

Generic functions to extract basic properties of filters: filterCoef returns coefficients, filterOrder returns the order, filterPoly, returns the characteristic polynomial, filterPolyCoef gives the coefficients of the characteristic polynomial.

For further details on argument convention see filterCoef-methods.

What exactly is returned depends on the specific filter classes, see the description of the corresponding methods. For the core filters, the values are as can be expected. For "ArmaFilter", the value is a list with components "ar" and "ma" giving the requested property for the corresponding part of the filter. Similarly, for "SarimaFilter" the values are lists, maybe with additional quantities.

Value

the requested property as described in Details.

Note

The filterXXX() functions are somewhat low level and technical. They should be rarely needed in routine work. The corresponding modelXXX are more flexible.

Georgi N. Boshnakov

See Also

modelOrder, modelCoef, modelPoly, modelPolyCoef, for the recommended higher level alternatives for models.
filterOrder-methods, filterCoef-methods, filterPoly-methods, filterPolyCoef-methods, for more information on the methods and the arguments.
Examples

filterPoly(as(c(0.3, 0.5), "BJfilter"))  # 1 - 0.3*x - 0.5*x^2
filterPoly(as(c(0.3, 0.5), "SPFilter"))  # 1 + 0.3*x + 0.5*x^2

## now two representations of the same filter:
fi1 <- as(c(0.3, 0.5), "BJfilter")
fi2 <- as(c(-0.3, -0.5), "SPFilter")
identical(fi2, fi1)  # FALSE, but
## fi1 and fi2 represent the same filter, eg. same ch. polynomials:
filterPoly(fi1)
filterPoly(fi2)
identical(filterPolyCoef(fi1), filterPolyCoef(fi2))

# same as above, using new()
fi1a <- new("BJFilter", coef = c(0.3, 0.5))
identical(fi1a, fi1)  # TRUE

fi2a <- new("SPFilter", coef = c(-0.3, -0.5))
identical(fi2a, fi2)  # TRUE

## conversion by as() changes the internal representation
## but represents the same filter:
identical(as(fi1, "SPFilter"), fi2)  # TRUE

c(filterOrder(fi1), filterOrder(fi2))

## these give the internally stored coefficients:
filterCoef(fi1)
filterCoef(fi2)

## with argument 'convention' the result doesn't depend
## on the internal representation:
co1 <- filterCoef(fi1, convention = "SP")
co2 <- filterCoef(fi2, convention = "SP")
identical(co1, co2)  # TRUE

Methods for filterCoef

Method for filterCoef in package sarima.

filterCoef() returns the coefficients of object. The format of the result depends on the type of
filter, see the descriptions of the individual methods below.

If argument convention is omitted, the sign convention for the coefficients is the one used in the
object. convention can be set to "BJ" or "SP" to request, respectively, the Box-Jenkins or the signal
processing convention. Also, "-" is equivalent to "BJ" and "+" to "SP".
For ARMA filters, "BJ" and "SP" request the corresponding convention for both parts (AR and MA). A widely used convention, e.g., by base R and (Brockwell and Davis 1991), is "BJ" for the AR part and "SP" for the MA part. It can be requested with `convention = "BD"`. For convenience, "-" is equivalent to "BJ", "++" to "SP", "+-" to "BD". For completeness, "+-" can be used to request "SP" for the AR part and "BJ" for the MA part.

Invalid values of `convention` throw error. In particular, low level filters, such as "BJFilter" don't know if they are AR or MA, so they throw error if `convention` is "BD" or "+-" (but "++" and "+-" are ok, since they are unambiguous). Similarly and to avoid subtle errors, the ARMA filters do not accept "+" or "-".

signature(object = "VirtualMonicFilterSpec", convention = "missing") returns `object@coef`.

signature(object = "VirtualBJFilter", convention = "character") returns the filter coefficients in the requested convention.

signature(object = "VirtualSPFilter", convention = "character") returns the filter coefficients in the requested convention.

signature(object = "BJFilter", convention = "character") returns the filter coefficients in the requested convention.

signature(object = "SPFilter", convention = "character") returns the filter coefficients in the requested convention.

signature(object = "VirtualArmaFilter", convention = "missing")

signature(object = "VirtualArmaFilter", convention = "character") Conceptually, calls `filterCoef()`, with one argument, on the AR and MA parts of the model. If `convention` is present, converts the result to the specified convention. Returns a list with the following components:

- `ar` AR coefficients.
- `ma` MA coefficients.

signature(object = "SarimaFilter", convention = "missing")

signature(object = "SarimaFilter", convention = "character") If `convention` is present, converts the coefficients to the specified convention. AR-like coefficients get the convention for the AR part, MA-like coefficients get the convention for the MA part. Returns a list with the following components:

- `nseasons` number of seasons.
- `iorder` integration order, number of (non-seasonal) differences.
- `siorder` seasonal integration order, number of seasonal differences.
- `ar` AR coefficients.
- `ma` MA coefficients.
- `sar` seasonal AR coefficients.
- `sma` seasonal MA coefficients.

**Methods**

Methods for function `filterOrder` in package `sarima`.

The following methods ensure that all filters in package `sarima` have a method for `filterOrder`.

- **signature(object = "VirtualMonicFilterSpec")** Returns `object@order`.
- **signature(object = "SarimaFilter")** Returns a list with the following components:
  - `nseasons` number of seasons.
  - `iorder` integration order, number of (non-seasonal) differences.
  - `siorder` seasonal integration order, number of seasonal differences.
  - `ar` autoregression order
  - `ma` moving average order
  - `sar` seasonal autoregression order
  - `sma` seasonal moving average order
- **signature(object = "VirtualArmaFilter")** Returns a list with the following components:
  - `ar` autoregression order.
  - `ma` moving average order.

```
Methods for filterPoly in package sarima

Methods

The methods for filterPoly take care implicitly for the sign convention used to store the coefficients in the object.

signature(object = "BJFilter") A polynomial whose coefficients are the negated filter coefficients.

signature(object = "SPFilter") A polynomial whose coefficients are as stored in the object.

signature(object = "SarimaFilter") Returns a list with the following components:

- nseasons number of seasons.
- iorder integration order, number of (non-seasonal) differences.
- siorder seasonal integration order, number of seasonal differences.
- arpoly autoregression polynomial
- mapoly moving average polynomial
- sarpoly seasonal autoregression polynomial
- smapoly seasonal moving average polynomial
- fullarpoly the polynomial obtained by multiplying out all AR-like terms, including differences.
- fullmapoly the polynomial obtained by multiplying out all MA terms
- core_sarpoly core seasonal autoregression polynomial. It is such that sarpoly(z) = core_sarpoly(z^{nseasons})
- core_smapoly core seasonal moving average polynomial. It is such that smapoly(z) = core_smapoly(z^{nseasons})

signature(object = "VirtualArmaFilter") Returns a list with the following components:

- ar autoregression polynomial.
- ma moving average polynomial.

signature(object = "VirtualMonicFilterSpec") Calls filterPolyCoef(object) and converts the result to a polynomial. Thus, it is sufficient to have a method for filterPolyCoef().

Examples

## see the examples for ?filterCoef
Methods for *filterPolyCoef* in package *sarima*.

**Methods**

The *filterPolyCoef* methods return results with the same structure as the corresponding methods for *filterPoly* but with polynomials replaced by their coefficients. If \( \text{lag}_0 \) is FALSE the order 0 coefficients are dropped.

- **signature(object = "VirtualBJFilter")** Calls *filterCoef(object)*, negates the result and prepends 1 if \( \text{lag}_0 \) is TRUE.
- **signature(object = "VirtualSPFilter")** Calls *filterCoef(object)* and prepends 1 to the result if \( \text{lag}_0 \) is TRUE.
- **signature(object = "VirtualArmaFilter")** Returns a list with the following components:
  - **ar** coefficients of the autoregression polynomial.
  - **ma** coefficients of the moving average polynomial.
- **signature(object = "BJFilter")** The coefficients of a polynomial whose coefficients are the negated filter coefficients. This is equivalent to the method for "VirtualBJFilter" but somewhat more efficient.
- **signature(object = "SPFilter")** The coefficients of a polynomial whose coefficients are as stored in the object. This is equivalent to the method for "VirtualSPFilter" but somewhat more efficient.
- **signature(object = "SarimaFilter")** Returns a list with the same components as the "SarimaFilter" method for *filterPoly*, where the polynomials are replaced by their coefficients.

fun.forecast

Forecasting functions for seasonal ARIMA models

Description
Forecasting functions for seasonal ARIMA models.

Usage
fun.forecast(past, n = max(2 * length(past), 12), eps = numeric(n), pasteps, ...)

Arguments
- past: past values of the time series, by default zeroes.
- n: number of forecasts to compute.
- eps: values of the white noise sequence (for simulation of future). Currently not used!
- pasteps: past values of the white noise sequence for models with MA terms, 0 by default.
- ...: specification of the model, passed to new() to create a "SarimaModel" object, see Details.

Details
fun.forecast computes predictions from a SARIMA model. The model is specified using the "..." arguments which are passed to new("SarimaModel", ...), see the description of class "SarimaModel" for details.

Argument past, if provided, should contain at least as many values as needed for the prediction equation. It is harmless to provide more values than necessary, even a whole time series.

fun.forecast can be used to illustrate, for example, the inherent difference for prediction of integrated and seasonally integrated models to corresponding models with roots close to the unit circle.

Value
the forecasts as an object of class "ts"

Author(s)
Georgi N. Boshnakov

Examples
f1 <- fun.forecast(past = 1, n = 100, ar = c(0.85), center = 5)
plot(f1)

f2 <- fun.forecast(past = 8, n = 100, ar = c(0.85), center = 5)
plot(f2)
f3 <- fun.forecast(past = 10, n = 100, ar = c(-0.85), center = 5)
plot(f3)

frw1 <- fun.forecast(past = 1, n = 100, iorder = 1)
plot(frw1)

frw2 <- fun.forecast(past = 3, n = 100, iorder = 1)
plot(frw2)

frw1 <- fun.forecast(past = c(1, 2), n = 100, ar = c(0.85), iorder = 1)
plot(frw1)

f12a <- fun.forecast(past = c(3, 1), n = 100, iorder = 2)
plot(f12a)

### InterceptSpec-class

#### Class InterceptSpec

**Description**

A helper class from which a number of models inherit intercept, centering and innovations variance.

**Objects from the Class**

Objects can be created by calls of the form `new("InterceptSpec", ...)`.  

**Slots**

- `center`: Object of class "numeric", centering parameter, defaults to zero.
- `intercept`: Object of class "numeric", intercept parameter, defaults to zero.
- `sigma2`: Object of class "numeric", innovations variance, defaults to NA.

**Methods**

- `sigmaSq` signature(object = "InterceptSpec"): ...

**modelCoef**

*Get the coefficients of models*

**Description**

Get the coefficients of an object, optionally specifying the expected format.

**Usage**

`modelCoef(object, convention, component, ...)`

**Arguments**

object: an object.

convention: the convention to use for the return value, a character string or any object from a supported class, see Details.

component: if not missing, specifies a component to extract, see Details.

...: not used, further arguments for methods.
**modelCoef**

Details

modelCoef is a generic function for extraction of coefficients of model objects. What 'coefficients' means depends on the class of object but it can be changed with the optional argument convention. In effect, modelCoef provides a very flexible and descriptive way of extracting coefficients from models in various forms.

The one-argument form, modelCoef(object), gives the coefficients of object. In effect it defines, for the purposes of modelCoef, the meaning of 'coefficients' for class class(modelCoef).

Argument convention can be used to specify what kind of value to return.

If convention is not a character string, only its class is used. Conceptually, the value will have the format and meaning of the value that would be returned by a call to modelCoef(obj) with obj from class class(convention).

If convention is a character string, it is typically the name of a class. In this case modelCoef(object, "someclass") is equivalent to modelCoef(object, new("someclass")). Note that this is conceptual - argument convention can be the name of a virtual class, for example. Also, for some classes of object character values other than names of classes may be supported.

For example, if obj is from class "ArmaModel", modelCoef(obj) returns a list with components "ar" and "ma", which follow the "BD" convention. So, to get such a list of coefficients from an object from any class capable of representing ARMA models, set convention = "ArmaModel" in the call to modelCoef().

modelCoef() will signal an error if object is not compatible with target (e.g. if it contains unit roots). (see filterCoef if you need to expand any multiplicative filters). **TODO: rethink this, it does not reflect current behaviour!**

If there is no class which returns exactly what is needed some additional computation may be necessary. In the above "ArmaModel" example we might need the coefficients in the "BJ" convention, so we would need to change the signs of the MA coefficients to achieve this. Since this is a very common operation, a convenience feature is available. Setting convention = "BJ" requests ARMA coefficients with "BJ" convention. For completeness, the the settings "SP" (signal processing) and "BD" (Brockwell-Davis) are also available.

The methods for modelCoef() in package "sarima" return a list with components depending on argument "convention", as outlined above.

Value

a list, with components depending on the target class, as described in Details

modelOrder, modelPoly, modelPolyCoef
Examples

```r
## define a seasonal ARIMA model, it has a number of components
m1 <- new("SarimaModel", iorder = 1, siorder = 1, ma = -0.3, sma = -0.1, nseasons = 12)
m1
## Get the coefficients corresponding to a 'flat' ARMA model,
## obtained by multiplying out AR-like and MA-like terms.
## A simple way is to use modelCoef() with a suitable convention:
modelCoef(m1, "ArmaModel")
modelCoef(m1, "ArmaFilter") ## same

## Here is another model
m1a <- new("SarimaModel", iorder = 1, siorder = 1, ar = 0.6, nseasons = 12)
modelCoef(m1a, "ArmaModel")
modelCoef(m1a, "ArmaFilter") ## same

## if only AR-like terms are allowed in a computation,
## use convention = "ArModel" to state it explicitly.
##
## this works, since m1a contains only AR-like terms:
modelCoef(m1a, "ArModel")
modelCoef(m1a, "ArFilter") ## same
## ... but these would throw errors if evaluated,
## since model m1a contains both AR-like and MA-like terms,
## Not run:
modelCoef(m1, "ArModel")
modelCoef(m1, "ArFilter")
modelCoef(m1, "MaModel")
modelCoef(m1, "MaFilter")

## End(Not run)
```

---

**modelIntercept**  
*Give the intercept parameter of a model*

---

**Description**

Give the intercept parameter of a model.

**Usage**

`modelIntercept(object)`

**Arguments**

- `object` an object from a class for which intercept is defined.

**Methods**

signature(object = "InterceptSpec")

**Author(s)**

Georgi N. Boshnakov
**modelOrder**

*Get the model order and other properties of models*

**Description**

Get the model order and other properties of models.

**Usage**

```r
modelOrder(object, convention, ...)
modelPoly(object, convention, ...)
modelPolyCoef(object, convention, lag_0 = TRUE, ...)
```

**Arguments**

- `object`: a model object.
- `convention`: convention.
- `lag_0`: if TRUE include lag_0 coef, otherwise drop it.
- `...`: further arguments for methods.

**Details**

These functions return the requested quantity, optionally requesting the returned value to follow a specific convention, see also `modelCoef`.

When called with one argument, these functions return corresponding property in the native format for the object’s class.

Argument `convention` requests the result in some other format. The mental model is that the returned value is as if the object was first converted to the class specified by `convention` and then the property extracted or computed. Normally, the object is not actually converted to that class. One obvious reason is efficiency but it may also not be possible, for example if argument `convention` is the name of a virtual class.

For example, the order of a seasonal SARIMA model is specified by several numbers. The call `modelOrder(object)` returns it as a list with components `ar`, `ma`, `sar`, `sma`, `iorder`, `siorder` and `nseasons`. For some computations all that is needed are the overall AR and MA orders obtained by multiplying out the AR-like and MA-like terms in the model. The result would be an ARMA filter and could be requested by `modelOrder(object, "ArmaFilter")`.

The above operation is valid for any ARIMA model, so will always succeed. On the other hand, if further computation would work only if there are no moving average terms in the model one could use `modelOrder(object, "ArFilter")`. Here, if `object` contains MA terms an error will be raised.

The concept is powerful and helps in writing expressive code. In this example a simple check on the returned value would do but even so, such a check may require additional care.

nvarOfAcfKP | Compute variances of autocorrelations under ARCH-type hypothesis

Description

Compute variances of autocorrelations under ARCH-type hypothesis.

Usage

nvarOfAcfKP(x, maxlag, center = FALSE, acfscale = c("one", "mom"))

Arguments

- **x**: time series.
- **maxlag**: a positive integer, the maximal lag.
- **center**: logical flag, if FALSE, the default, don’t center the time series before squaring, see Details.
- **acfscale**: character string, specifying what factor to use for the autocovariances. "one" stands for $1/n$, "mom" for $1/(n - k)$, where $n$ is the length of $x$ and $k$ is lag.

Details

nvarOfAcfKP computes estimates of $n$ times the variances of sample autocorrelations of white noise time series. It implements the result of (Kokoszka and Politis 2011) which holds under weak assumptions. In particular, it can be used to test if the true autocorrelations of a time series are equal to zero in GARCH modelling.

Value

a numeric vector
nvcovOfAcf

nvcovOfAcf # Covariances of sample autocorrelations

Description

Compute covariances of autocorrelations.

Usage

nvcovOfAcf(model, maxlag)

nvcovOfAcfBD(acf, ma, maxlag)

acf0fSquaredArmaModel(model, maxlag)

Arguments

model # a model, see Details.

maxlag # a positive integer number, the maximal lag.

acf # autocorrelations.

ma # a positive integer number, the order of the MA(q) model. The default is the maximal lag available in acf.
Details

nvcovOfAcf computes the unscaled asymptotic autocovariances of sample autocorrelations of ARMA models, under the classical assumptions when the Bartlett’s formulas are valid. It works directly with the parameters of the model and uses Boshnakov (1996). Argument model can be any specification of ARMA models for which autocorrelations() will work, e.g. a list with components "ar", "ma", and "sigma2".

nvcovOfAcfBD computes the same quantities but uses the formula given by Brockwell & Davis (1991) (eq. (7.2.6.), p. 222), which is based on the autocorrelations of the model. Argument acf contains the autocorrelations.

For nvcovOfAcfBD, argument ma asks to treat the provided acf as that of MA(ma). Only the values for lags up to ma are used and the rest are set to zero, since the autocorrelations of MA(ma) models are zero for lags greater than ma. To force the use of all autocorrelations provided in acf, set ma to the maximal lag available in acf or omit ma, since this is its default.

acfOfSquaredArmaModel(model, maxlag) is a convenience function which computes the autocovariances of the "squared" model, see Boshnakov (1996).

Value

an (maxlag,maxlag)-matrix

Note

The name of nvcovOfAcf stands for “n times the variance-covariance matrix”, so it needs to be divided by n to get the asymptotic variances and covariances.

### periodogram

Obtain the most important period lags of a time series according to a periodogram.

#### Description

Obtain the most important period lags of a time series according to a periodogram.

#### Usage

`periodogram(x, ..., no.results = 20)`

#### Arguments

- `x` A vector containing the time series values
- `...` Arguments to be passed to `spectrum`
- `no.results` The number of results to be printed at the end. Defaults to the 20 most important frequencies.
Details

Using the `spectral` function, obtain spectral density estimates at a number of frequencies and rather than plotting, obtain the rank and period of the values. Return a given number of results based on the level of interest of the user.

Value

A data.frame containing the following columns:

- `rank`: numeric vector containing the ranked importance of the frequency.
- `spectrum`: estimates of the spectral density at frequencies corresponding to `freq`.
- `frequency`: vector at which the spectral density is estimated.
- `period`: vector of corresponding periods.

---

Description

Plot methods in package `sarima`.

Methods

- `signature(x = "SampleAutocorrelations", y = "matrix")`
- `signature(x = "SampleAutocorrelations", y = "missing")`
- `signature(x = "SamplePartialAutocorrelations", y = "missing")`

x <- sarima::rgarch1pl(n, alpha = 0.3, beta = 0.55, omega = 1, n.skip = 100)
x.acf <- autocorrelations(x)
x.acf
x.pacf <- partialAutocorrelations(x)
x.pacf
plot(x.acf)
plot(x.acf, data = x)
plot(x.pacf)
plot(x.pacf, data = x)
plot(x.acf, data = x, main = "Autocorrelation test")
```
prepareSimSarima

Prepare SARIMA simulations.

Usage

prepareSimSarima(model, x = NULL, eps = NULL, n, n.start = NA, xintercept = NULL, rand.gen = rnorm)

## S3 method for class 'simSarimaFun'
print(x, ...)

Arguments

- **model**: an object from a suitable class or a list, see Details.
- **x**: initial/before values of the time series, a list, a numeric vector or time series, see Details.
- **eps**: initial/before values of the innovations, a list or a numeric vector, see Details.
- **n**: number of observations to generate, if missing an attempt is made to infer it from x and eps.
- **n.start**: number of burn-in observations.
- **xintercept**: non-constant intercept which may represent trend or covariate effects.
- **rand.gen**: random number generator, defaults to $N(0,1)$.
- **...**: ignored.

Details

prepareSimSarima does the preparatory work for simulation from a Sarima model, given the specifications and returns a function, which can be called as many times as needed.

The variance of the innovations is specified by the model and the simulated innovations are multiplied by the corresponding standard deviation. So, it is expected that the random number generator simulates from a standardised distribution.

Argument model can be from any class representing models in the SARIMA family, such as "SarimaModel", or a list with components suitable to be passed to =new()= for such models.
The canonical form of argument \( x \) is a list with components "before", "init" and "main". If any of these components is missing or NULL, it is filled suitably. Any other components are ignored. If \( x \) is not a list, it is put in component "main". Conceptually, the three components are concatenated in the given order, the simulated values are put in "main" ("before" and "init" are not changed), the "before" part is dropped and rest is returned. In effect, "before" and "init" can be viewed as initial values but "init" is considered part of the generated series.

The format for \( \text{eps} \) is the same as that of \( x \). The lengths of missing components in \( x \) are inferred from the corresponding components of \( \text{eps} \), and vice versa.

printSimSarimaFun is a print method for the objects generated by prepareSimSarima.

**Value**

for prepareSimSarima, a function to simulate time series

**Author(s)**

Georgi N. Boshnakov

**Examples**

```r
mo1 <- list(ar=0.9, iorder = 1, siorder = 1, nseasons = 4, sigma2 = 2)
fs1 <- prepareSimSarima(mo1, x = list(before = rep(0,6)), n = 100)
tmpl <- fs1()
plot(ts(tmpl))

fs2 <- prepareSimSarima(mo1, x = list(before = rep(1,6)), n = 100)
tmp2 <- fs2()
plot(ts(tmp2))

mo3 <- mo1
mo3["ar"] <- 0.5
fs3 <- prepareSimSarima(mo3, x = list(before = rep(0,6)), n = 100)
tmp3 <- fs3()
plot(ts(tmp3))
```

**sarima**  
*Fit extended SARIMA models*

**Description**

Fit extended SARIMA models, which can include lagged exogeneous variables, general unit root non-stationary factors, multiple periodicities, and multiplicative terms in the SARIMA specification. The models are specified with a flexible formula syntax and contain as special cases many models with specialised names, such as ARMAX and reg-ARIMA.

**Usage**

```
sarima(model, data = NULL, ss.method = "sarima", use.symmetry = FALSE, SSInit = "Rossignol2011")
```
Arguments

model a model formula specifying the model.
data a list or data frame, usually can be omitted.
ss.method state space engine to use, defaults to "sarima". (Note: this argument will probably be renamed.)
use.symmetry a logical argument indicating whether symmetry should be used to estimate the unit polynomial.
SSinit method to use for computation of the stationary part of the initial covariance matrix, one of "Rossignol2011", "gnb", "Gardner1980".

Details

sarima fits extended SARIMA models, which can include exogeneous variables, general unit root non-stationary factors and multiplicative terms in the SARIMA specification.

Let \{Y_t\} be a time series and \(f(t)\) and \(g(t)\) be functions of time and/or (possibly lagged) exogeneous variables.

An extended pure SARIMA model for \(Y_t\) can be written with the help of the backward shift operator as

\[ U(B)\Phi(B)Y_t = \Theta(B)\epsilon_t, \]

where \(\{\epsilon_t\}\) is white noise, and \(U(z), \Phi(z),\) and \(\Theta(z)\) are polynomials, such that all roots of \(U(z)\) are on the unit circle, while the roots of \(\Phi(z)\) and \(\Theta(z)\) are outside the unit circle. If unit roots are missing, ie \(U(z) \equiv 1\), the model is stationary with mean zero.

A reg-SARIMA or X-SARIMA model can be defined as a regression with SARIMA residuals:

\[ Y_t = f(t) + Y^c_t \]
\[ U(B)\Phi(B)Y^c_t = \Theta(B)\epsilon_t, \]

where \(Y^c_t = Y_t - f(t)\) is the centred \(Y_t\). This can be written equivalently as a single equation:

\[ U(B)\Phi(B)(Y_t - f(t)) = \Theta(B)\epsilon_t. \]

The regression function \(f(t)\) can depend on time and/or (possibly lagged) exogeneous variables. We call it centering function. If \(Y^c_t\) is stationary with mean zero, \(f(t)\) is the mean of \(Y_t\). If \(f(t)\) is constant, say \(\mu\), \(Y_t\) is stationary with mean \(\mu\). Note that the two-equation form above shows that in that case \(\mu\) is the intercept in the first equation, so it is perfectly reasonable to refer to it also as intercept but to avoid confusion we reserve the term intercept for \(g(t)\) below.

If the SARIMA part is stationary, then \(EY_t = f(t)\), so \(f(t)\) can be interpreted as trend. In this case the above specification is often referred to as mean corrected form of the model.

An alternative way to specify the regression part is to add the regression function, say \(\{g(t)\}\), to the right-hand side of the SARIMA equation:

\[ U(B)\Phi(B)Y_t = g(t) + \Theta(B)\epsilon_t. \]

In the stationary case this is the classical ARMAX specification. This can be written in two-stage form in various ways, eg

\[ U(B)\Phi(B)Y_t = (1 - \Theta(B))\epsilon_t + u_t, \]
\[ u_t = g(t) + \varepsilon_t. \]

So, in a sense, \( g(t) \) is a trend associated with the residuals from the SARIMA modelling. We refer to this form as intercept form of the model (as opposed to the mean-corrected form discussed previously).

In general, if there are no exogeneous variables the mean-corrected model is equivalent to some intercept model, which gives some justification of the terminology, as well. If there are exogeneous variables equivalence may be achievable but at the expense of introducing more lags in the model, whish is not desirable in general.

Some examples of equivalence. Let \( Y \) be a stationary SARIMA process \( (U(z) = 1) \) with mean \( \mu \). Then the mean-corrected form of the SARIMA model is

\[
\Phi(B)(Y_t - \mu) = \Theta(B)\varepsilon_t,
\]

while the intercept form is

\[
\Phi(B)Y_t = c + \Theta(B)\varepsilon_t,
\]

where \( c = \Phi(B)\mu \). So, in this case the mean-corrected model X-SARIMA model with \( f(t) = \mu \) is equivalent to the intercept model with \( g(t) = \Phi(B)\mu \).

As another example, with \( f(t) = bt \), the mean-corrected model is \((1-B)(Y_t - bt) = \varepsilon_t \). Expanding the left-hand side we obtain the intercept form \((1-B)Y_t = b + \varepsilon_t \), which demonstrates that \( Y_t \) is a random walk with drift \( g(t) = b \).

**Model specification**

Argument `model` specifies the model with a syntax similar to other model fitting functions in R. A formula can be given for each of the components discussed above as \( y \sim f \mid \text{SARIMA} \mid g \), where \( f \), \( \text{SARIMA} \) and \( g \) are model formulas giving the specifications for the centering function \( f \), the \( \text{SARIMA} \) specification, and the intercept function \( g \). In normal use only one of \( f \) or \( g \) will be different from zero. \( f \) should always be given (use \( 0 \) to specify that it is identical to zero), but \( g \) can be omitted altogether. Sometimes we refer to the terms specified by \( f \) and \( g \) by \( xreg \) and \( regx \), respectively.

**Model formulas for trends and exogeneous regressions**

The formulas for the centering and intercept (ie \( f \) and \( g \)) use the same syntax as in linear models with some additional functions for trigonometric trends, polynomial trends and lagged variables.

Here are the available specialised terms:

- \( .p(d) \) Orthogonal polynomials over \( 1:1\text{length}(y) \) of degree \( d \) (starting from degree 1, no constant).
- \( .t \) Stands for \( 1:1\text{length}(y) \). Note that powers need to be protected by \( I() \), e.g. \( y \sim 1 + .t + I(.t^2) \).
- \( .cs(s, k) \) cos/sin pair for the \( k \)-th harmonic of \( 2\pi/s \). Use vector \( k \) to specify several harmonics.
- \( .B(x, lags) \) Include lagged terms of \( x \), \( B^{lags}(x[t]) = x[t - lags] \). \( lags \) can be a vector. If \( x \) is a matrix, the specified lags are taken from each column.

**Model formulas for SARIMA models**

A flexible syntax is provided for the specification of the SARIMA part of the model. It is formed using a number of primitives for stationary and unit root components, which have non-seasonal and seasonal variants. Arbitrary number of multiplicative factors and multiple seasonalties can be specified.

The SARIMA part of the model can contain any of the following terms. They can be repeated as needed. The first argument for all seasonal operators is the number of seasons.
ar(p)  autoregression term of order p
ma(q)  moving average term of order q
sar(s,p)  seasonal autoregression term (s seasons, order p)
sma(s,q)  seasonal moving average term (s seasons, order q)
i(d)  \((1 - B)^d\)
s(seas)  summation operator, \((1 + B + \cdots + B^{\text{seas}-1})\)
u(x)  quadratic unit root term, corresponding to a complex pair on the unit circle. If \(x\) is real, it specifies the argument of one of the roots as a fraction of \(2\pi\). If \(z\) is complex, it is the root itself.

The real roots of modulus one (1 and −1) should be specified using \(i(1)\) and \(s(2)\), which correspond to \(1 - B\) and \(1 + B\), respectively.

su(s, h)  quadratic unit root terms corresponding to seasonal differencing factors. \(h\) specifies the desired harmonic which should be one of 1,2,...,[s/2]. Several harmonics can be specified by setting \(h\) to a vector.

ss(s, p)  seasonal summation operator, \((1 + B + \cdots + B^{(s-1)p})\)

Terms with parameters can contain additional arguments specifying initial values, fixed parameters, and transforms. For ar, ma, sar, sma, values of the coefficients can be specified by an unnamed argument after the parameters given in the descriptions above. In estimation these values will be taken as initial values for optimisation. By default, all coefficients are taken to be non-fixed.

Argument fixed can be used to fix some of them. If it is a logical vector it should be of length one or have the same length as the coefficients. If fixed is of length one and TRUE, all coefficients are fixed. If FALSE, all are non-fixed. Otherwise, the TRUE/FALSE values in fixed determine the fixedness of the corresponding coefficients.

fixed can also be a vector of positive integer numbers specifying the indices of fixed coefficients, the rest are non-fixed.

Sometimes it may be easier to declare more (e.g. all) coefficients as fixed and then ‘unfix’ selectively. Argument nonfixed can be used to mark some coefficients as non-fixed after they have been declared fixed. Its syntax is the same as for fixed.

TODO: streamline "atanh.tr"
TODO: describe SSinit

Value

an object from S3 class Sarima

(\textbf{Note}: the format of the object is still under development and may change; use accessor functions, such as coef(), where provided.)

Note

Currently the implementation of the intercept form (ie the third part of the model formula) is incomplete.

tmp.su
Class SarimaModel in package sarima.

Objects from the Class

Objects can be created by calls of the form `new("SarimaModel", ..., ar, ma, sar, sma)`.

Class SarimaModel represents standard SARIMA models. It has provision for centering and/or intercept (in normal use at most one of these is needed). Their default values are zeroes.

Note however that the default for the variance of the innovations (slot "sigma2") is NA. The rationale for this choice is that for some calculations the innovations’ variance is not needed and, more importantly, it is far too easy to forget to include it in the model (at least for the author), which may lead silently to wrong results if the "natural" default value of one is used.

Slots

- `center`: Object of class "numeric", a number, if not zero the ARIMA equation is for X(t) - center.
- `intercept`: Object of class "numeric", a number, the intercept in the ARIMA equation.
- `sigma2`: Object of class "numeric", a positive number, the innovations variance.
- `nseasons`: Object of class "numeric", a positive integer, the number of seasons. For non-seasonal models this is NA.
- `iorder`: Object of class "numeric", non-negative integer, the integration order.
- `siorder`: Object of class "numeric", non-negative integer, the seasonal integration order.
- `ar`: Object of class "BJFilter", the non-seasonal AR part of the model.
- `ma`: Object of class "SPFilter", the non-seasonal MA part of the model.
- `sar`: Object of class "BJFilter", the seasonal AR part of the model.
- `sma`: Object of class "SPFilter", the seasonal MA part of the model.

Extends

Methods

SARIMA models contain as special cases a number of models. The one-argument method of modelCoef is essentially a definition of model coefficients for SARIMA models. The two-argument methods request the model coefficients according to the convention of the class of the second argument. The second argument may also be a character string naming the target class.

Essentially, the methods for modelCoef are a generalisation of =as()= methods and can be interpreted as such (to an extent, the result is not necessarily from the target class, not least because the target class may be virtual).

modelCoef signature(object = "SarimaModel", convention = "missing"): Converts object to "SarimaFilter".

modelCoef signature(object = "SarimaModel", convention = "SarimaFilter"): Converts object to "SarimaFilter", equivalent to the one-argument call modelCoef(object).

modelCoef signature(object = "SarimaModel", convention = "ArFilter"): Convert object to "ArFilter". An error is raised if object has non-trivial moving average part.

modelCoef signature(object = "SarimaModel", convention = "MaFilter"): Convert object to "MaFilter". An error is raised if object has non-trivial autoregressive part.

modelCoef signature(object = "SarimaModel", convention = "ArmaFilter"): Convert object to "ArmaFilter". This operation always succeededs.

modelCoef signature(object = "SarimaModel", convention = "character"): The second argument gives the name of the target class. This is conceptually equivalent to modelCoef(object, new(convention))

modelOrder gives the order of the model according to the conventions of the target class. An error is raised if object is not compatible with the target class.

modelOrder signature(object = "SarimaModel", convention = "ArFilter"): ...

modelOrder signature(object = "SarimaModel", convention = "ArmaFilter"): ...

modelOrder signature(object = "SarimaModel", convention = "ArModel"): ...

modelOrder signature(object = "SarimaModel", convention = "MaModel"): ...

modelOrder signature(object = "SarimaModel", convention = "missing"): ...

The polynomials associated with object can be obtained with the following methods. Note that target "ArmaFilter" gives the fully expanded products of the AR and MA polynomials, as needed, e.g., for filtering.

modelPoly signature(object = "SarimaModel", convention = "ArmaFilter"): "Gives the fully expanded polynomials as a list

modelPoly signature(object = "SarimaModel", convention = "missing"): "Gives the polynomials associated with the model as a list.

modelPolyCoef signature(object = "SarimaModel", convention = "ArmaFilter"): "Give the coefficients of the fully expanded polynomials as a list.

modelPolyCoef signature(object = "SarimaModel", convention = "missing"): "Gives the coefficients of the polynomials associated with the model as a list."

*Get the innovation variance of models*

**Description**

Get the innovation variance of models.

**Usage**

`sigmaSq(object)`

**Arguments**

- `object` an object from a suitable class.
**Details**

simSq() gives the innovation variance of objects from classes for which it makes sense, such as ARMA models.

The value depends on the class of the object, e.g. for ARMA models it is a scalar in the univariate case and a matrix in the multivariate one.

**Methods**

signature(object = "InterceptSpec")

**Author(s)**

Georgi N. Boshnakov

---

**sim_sarima**

*Simulate trajectories of seasonal arima models*

**Description**

Simulate trajectories of seasonal arima models.

**Usage**

```r
sim_sarima(model, n = NA, rand.gen = rnorm, n.start = NA, x, eps, xcenter = NULL, xintercept = NULL, ...)
```

**Arguments**

- `model` specification of the model, a list, see ‘Details’.
- `rand.gen` random number generator for the innovations.
- `n` length of the time series.
- `n.start` number of burn-in observations.
- `x` initial/before values of the time series, a list, a numeric vector or time series, see Details.
- `eps` initial/before values of the innovations, a list or a numeric vector, see Details.
- `xintercept` non-constant intercept which may represent trend or covariate effects.
- `xcenter` currently ignored.
- `...` additional arguments for arima.sim and rand.gen, see ‘Details’.
Details

The model is specified by the argument "model" which is a list with elements suitable to be passed to `new("SarimaModel", ...), see the description of class "SarimaModel". Here are some of the possible components:

- **nseasons** number of seasons in a year (or whatever is the larger time unit)
- **iorder** order of differencing, specifies the factor \((1 - B)^d\) for the model.
- **siorder** order of seasonal differencing, specifies the factor \((1 - B^{period})^ds\) for the model.
- **ar** ar parameters (non-seasonal)
- **ma** ma parameters (non-seasonal)
- **sar** seasonal ar parameters
- **sma** seasonal ma parameters

Additional arguments for `rand.gen` may be specified via the "..." argument. In particular, the length of the generated series is specified with argument `n`. Arguments for `rand.gen` can also be passed via the "..." argument.

`sim_sarima` calls internally `arima.sim` to simulate the ARMA part of the model. Then undifferences the result to obtain the end result.

The function returns the simulated time series from the requested model.

Information about the model is printed on the screen if `info="print"`. To suppress this, set `info` to any other value.

Value

an object of class "ts"

Author(s)

Georgi N. Boshnakov

Examples

```r
require("PolynomF") # package "sarima" imports it, so should not be absent here.

x <- sim_sarima(n=144, model = list(ma=0.8)) # MA(1)
x <- sim_sarima(n=144, model = list(ar=0.8)) # AR(1)

x <- sim_sarima(n=144, model = list(ar=c(rep(0,11),0.8))) # SAR(1), 12 seasons
x <- sim_sarima(n=144, model = list(ma=c(rep(0,11),0.8))) # SMA(1)

# more enlightened SAR(1) and SMA(1)
x <- sim_sarima(n=144,model=list(sar=0.8, nseasons=12, sigma2 = 1)) # SAR(1), 12 seasons
x <- sim_sarima(n=144,model=list(sma=0.8, nseasons=12, sigma2 = 1)) # SMA(1)

x <- sim_sarima(n=144, model = list(iorder=1, sigma2 = 1)) # (1-B)X_t = e_t (random walk)
acf(x)
acf(diff(x))
```
Methods for summary in package sarima.

Description

Methods for summary in package sarima.
whiteNoiseTest

Usage

```r
## S3 method for class 'SarimaModel'
summary(object, ...)
## S3 method for class 'SarimaFilter'
summary(object, ...)
## S3 method for class 'SarimaSpec'
summary(object, ...)
```

Arguments

- `object` an object from the corresponding class.
- `...` further arguments for methods.

Author(s)

Georgi N. Boshnakov

Description

White noise tests.

Usage

```r
whiteNoiseTest(object, h0, ...)
```

Arguments

- `object` an object, such as sample autocorrelations or partial autocorrelations.
- `h0` the null hypothesis, currently "iid" or "garch".
- `...` additional arguments passed on to methods.

Details

`whiteNoiseTest` carries out tests for white noise. The null hypothesis is identified by argument `h0`, based on which `whiteNoiseTest` chooses a suitable function to call. The functions implementing the tests are also available to be called directly and their documentation should be consulted for further arguments that are available.

If `h0 = "iid"`, the test statistics and rejection regions can be use to test if the underlying time series is iid. Argument `method` specifies the method for portmanteau tests: one of "LiMcLeod" (default), "LjungBox", "BoxPierce".

If `h0 = "garch"`, the null hypothesis is that the time series is GARCH, see Francq \& Zakoian (2010). The tests in this case are based on a non-parametric estimate of the asymptotic covariance matrix.
Portmonteau statistics and p-values are computed for the lags specified by argument `nlags`. If it is missing, suitable lags are chosen automatically.

If argument `interval` is TRUE, confidence intervals for the individual autocorrelations or partial autocorrelations are computed.

**Value**

a list with component `test` and, if `ci=TRUE`, component `ci`.

**Note**

Further methods will be added in the future.

**Author(s)**

Georgi N. Boshnakov

**References**

**See Also**

`acfGarchTest` (`h0 = "garch"`), `acfIidTest` (`h0 = "iid"`);

`acfMaTest`

**Examples**

```r
n <- 5000
x <- sarima:::rgarch1p1(n, alpha = 0.3, beta = 0.55, omega = 1, n.skip = 100)
x.acf <- autocorrelations(x)
x.pacf <- partialAutoCorrelations(x)

x.iid <- whiteNoiseTest(x.acf, h0 = "iid", nlags = c(5,10,20), x = x, method = "LiMcLeod")
x.iid

x.iid2 <- whiteNoiseTest(x.acf, h0 = "iid", nlags = c(5,10,20), x = x, method = "LjungBox")
x.iid2

x.garch <- whiteNoiseTest(x.acf, h0 = "garch", nlags = c(5,10,20), x = x)
x.garch
```
xarmaFilter

Applies an extended ARMA filter to a time series

Description

Filter time series with an extended arma filter. If whiten is FALSE (default) the function applies the given ARMA filter to eps (eps is often white noise). If whiten is TRUE the function applies the "inverse filter" to x, effectively computing residuals.

Usage

xarmaFilter(model, x = NULL, eps = NULL, from = NULL, whiten = FALSE, xcenter = NULL, xintercept = NULL)

Arguments

x  the time series to be filtered, a vector.
eps  residuals, a vector or NULL.
model  the model parameters, a list with components "ar", "ma", "center" and "intercept", see Details.
from  the index from which to start filtering.
whiten  if TRUE use x as input and apply the inverse filter to produce eps ("whiten" x), if FALSE use eps as input and generate x ("colour" eps).
xcenter  a vector of means of the same length as the time series, see Details.
xintercept  a vector of intercepts having the length of the series, see Details.

Details

The model is specified by argument model, which is a list with the following components:

ar  the autoregression parameters,
ma  the moving average parameters,
center  center by this value,
intercept  intercept.

model$center and model$intercept are scalars and usually at most one of them is nonzero. They can be considered part of the model specification. In contrast, arguments xcenter and xintercept are vectors of the same length as x. They can represent contributions from covariate variables. Usually at most one of xcenter and xintercept is used.

The description below uses $\mu_t$ and $c_t$ for the contributions by model$center plus xcenter and model$intercept plus xintercept, respectively. The time series $\{x_t\}$ and $\{\varepsilon_t\}$ are represented by x and eps in the R code. Let

$$y_t = x_t - \mu_t$$
be the centered series. where the centering term $\mu_t$ is essentially the sum of center and $x_{center}$ and is not necessarily the mean. The equation relating the centered series, $y_t = x_t - \mu_t$, and $\epsilon_t$ is the following:

$$y_t = c_t + \sum_{i=1}^{p} \phi(i)y_{t-i} + \sum_{i=1}^{q} \theta(i)\epsilon_{t-i} + \epsilon_t$$

where $c_t$ is the intercept (basically the sum of intercept with $x_{intercept}$).

If $\text{whiten} = \text{FALSE}$, $y_t$ is computed for $t$ from $\ldots, n$ using the above formula, i.e. the filter is applied to get $y$ from $\epsilon$ (and some initial values). If $\epsilon_t$ is white noise, it can be said that $y_t$ is obtained by “colouring” the white noise $\epsilon_t$. This can be used, for example, to simulate ARIMA time series. Finally, the centering term is added back, $x_t = y_t + \mu_t$ for $t$ from $\ldots, n$, and the modified $x$ is returned. The first from $\ldots, n - 1$ elements of $x$ are left unchanged.

The inverse filter is obtained by rewriting the above equation as an equation expressing $\epsilon_t$ in terms of the remaining quantities:

$$\epsilon_t = -c_t - \sum_{i=1}^{q} \theta(i)\epsilon_{t-i} - \sum_{i=1}^{p} \phi(i)y_{t-i} + y_t$$

If $\text{whiten} = \text{TRUE}$, $\text{xarmaFilter}$ uses this formula for $t$ from $\ldots, n$ to compute $\epsilon_t$ from $y$ (and some initial values). If $\epsilon_t$ is white noise, then it can be said that the time series $y_t$ has been whitened.

In both cases the first few values in $x$ and/or $\epsilon$ are used as initial values.

The centering is formed from model$\text{center}$ and argument $x_{center}$. If model$\text{center}$ is supplied it is recycled to the length of the series, $x$, and subtracted from $x$. If argument $x_{center}$ is supplied, it is subtracted from $x$. If both model$\text{center}$ and $x_{center}$ are supplied their sum is subtracted from $x$.

$x\text{armaFilter}$ can be used to simulate ARMA series with the default value of $\text{whiten} = \text{FALSE}$. In this case $\epsilon_t$ is the input series and $y_t$ the output. Then model$\text{center}$ and/or $x_{center}$ are added to $y_t$ to form the output vector $y$.

Residuals corresponding to a series $x$ can be obtained by setting $\text{whiten} = \text{TRUE}$. In this case $x$ is the input series. The elements of the output vector $\epsilon_t$ are calculated by the formula for $\epsilon_t$ given above. There is no need in this case to restore $x$ since $\epsilon_t$ is returned.

In both cases any necessary initial values are assumed to be already in the vectors and provide the first from $\ldots, n - 1$ values in the returned vectors. Argument from should not be smaller than the default value max($p, q$)+1.

$x\text{armaFilter}$ calls the lower level function coreXarmaFilter to do the computation.

**Value**

the result of applying the filter or its inverse, as described in Details: if $\text{whiten} = \text{FALSE}$, the modified $x$; if $\text{whiten} = \text{TRUE}$, the modified $\epsilon$.
