Package ‘scan’

February 22, 2021

Type Package

Title Single-Case Data Analyses for Single and Multiple Baseline Designs

Version 0.51

Date 2021-2-11

Author Juergen Wilbert [aut, cre], Timo Lueke [aut]

Maintainer Juergen Wilbert <jwilbert@uni-potsdam.de>

Imports stats, nlme, utils, methods, graphics, car, MASS, knitr, kableExtra, readxl, mblm

Suggests

Depends R (>= 3.5.0)

Description A collection of procedures for analysing, visualising, and managing single-case data. These include piecewise linear regression models, multilevel models, overlap indices (PND, PEM, PAND, PET, tauU, baseline corrected tau), and randomization tests. Data preparation functions support outlier detection, handling missing values, scaling, truncating, rank transformation, and smoothing. An exporting function helps to generate html and latex tables in a publication friendly style. More details can be found at <https://jazznbass.github.io/scan-Book/>.

Description

A collection of procedures for analysing, visualising, and managing single-case data.

Author(s)

Juergen Wilbert [aut, cre]

.inheritParams

Dummy function to inherit global descriptions of parameters

Description

Dummy function to inherit global descriptions of parameters

Usage

.inheritParams(
  data, scdf, dvar, mvar, pvar, decreasing, phases, model, trend, level, slope, ...
)

)
Arguments

- **data**
  A single-case data frame. See `scdf` to learn about this format.

- **scdf**
  A single-case data frame. See `scdf` to learn about this format.

- **dvar**
  Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.

- **mvar**
  Character string with the name of the measurement time variable. Defaults to the attributes in the scdf file.

- **pvar**
  Character string with the name of the phase variable. Defaults to the attributes in the scdf file.

- **decreasing**
  If you expect data to be lower in the B phase, set `decreasing = TRUE`. Default is `decreasing = FALSE`.

- **phases**
  A vector of two characters or numbers indicating the two phases that should be compared. E.g., `phases = c("A","C")` or `phases = c(2,4)` for comparing the second to the fourth phase. Phases could be combined by providing a list with two elements. E.g., `phases = list(A = c(1,3), B = c(2,4))` will compare phases 1 and 3 (as A) against 2 and 4 (as B). Default is `phases = c("A","B")`.

- **model**
  Model used for calculating the slope parameter (see Huitema & McKean, 2000). Default is `model = "B&L-B"`. Possible values are: "B&L-B", "H-M", "Mohr#1", "Mohr#2", "JW", "JW2", and "Manly".

- **trend**
  A logical indicating if a trend parameters is included in the model.

- **level**
  A logical indicating if a level parameters is included in the model.

- **slope**
  A logical indicating if a slope parameters is included in the model.

- **...**
  Further arguments passed to the function.

---

**as_scdf**

*as_scdf Converts a data frame to an scdf object*

---

**Description**

*as_scdf Converts a data frame to an scdf object*

**Usage**

`as_scdf(object)`

**Arguments**

- **object**
  A scdf object
**autocorr**

**Autocorrelation for single-case data**

**Description**

The autocorr function calculates autocorrelations within each phase and across all phases.

**Usage**

```r
autocorr(data, dvar, pvar, mvar, lag.max = 3, ...)
autocorrSC(...)
```

**Arguments**

- `data` A single-case data frame. See `scdf` to learn about this format.
- `dvar` Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
- `pvar` Character string with the name of the phase variable. Defaults to the attributes in the scdf file.
- `mvar` Character string with the name of the measurement time variable. Defaults to the attributes in the scdf file.
- `lag.max` The lag up to which autocorrelations will be computed. Default is `lag.max = 3`.
- `...` Further arguments passed to the `acf` function

**Value**

A data frame containing separate autocorrelations for each phase and for all phases (for each single-case). If `lag.max` exceeds the length of a phase minus one, NA is returned for this cell.

**Author(s)**

Juergen Wilbert

**See Also**

trend, plm, acf

**Examples**

```r
## Compute autocorrelations for a list of four single-cases up to lag 2.
autocorr(Huber2014, lag.max = 2)
```
Beretvas2008  
**Single-case example data**

**Description**

The scan package comes with a set of fictitious and authentic single-case study data, by courtesy of the particular authors.

**Usage**

Beretvas2008

**Format**

An object of class `scdf` (inherits from `list`) of length 1.

**Value**

combine

Combine single-case data frames into a multiple case study

Description

Combine single-case data frames into a multiple case study

Usage

combine(...)

## S3 method for class 'scdf'
c(...)

Arguments

... scdf objects

Value

A scdf
corrected_tau

Baseline corrected tau

**Description**

Kendalls tau correlation for the dependent variable and the phase variable is calculated after correcting for a baseline trend.

**Usage**

```r
corrected_tau(
  data, dvar, pvar, mvar,
  phases = c(1, 2),
  alpha = 0.05,
  continuity = TRUE,
  repeated = TRUE
)
```

corrected_tauSC(...)

**Arguments**

- `data` A single-case data frame. See `scdf` to learn about this format.
- `dvar` Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
- `pvar` Character string with the name of the phase variable. Defaults to the attributes in the scdf file.
- `mvar` Character string with the name of the measurement time variable. Defaults to the attributes in the scdf file.
- `phases` A vector of two characters or numbers indicating the two phases that should be compared. E.g., `phases = c("A","C")` or `phases = c(2, 4)` for comparing the second to the fourth phase. Phases could be combined by providing a list with two elements. E.g., `phases = list(A = c(1, 3), B = c(2, 4))` will compare phases 1 and 3 (as A) against 2 and 4 (as B). Default is `phases = c("A","B")`.
- `alpha` Sets the p-value at and below which a baseline correction is applied.
- `continuity` If TRUE applies a continuity correction for calculating p
- `repeated` If TRUE applies the repeated median method for calculating slope and intercept (`mblm`)
- `...` Further arguments passed to the function.
Details

This method has been proposed by Tarlow (2016). The baseline data are checked for a significant autocorrelation (based on Kendalls Tau). If so, a non-parametric Theil-Sen regression is applied for the baseline data where the dependent values are regressed on the measurement time. The resulting slope information is then used to predict data of the B-phase. The dependent variable is now corrected for this baseline trend and the residuals of the Theil-Sen regression are taken for further calculations. Finally, a tau is calculated for the dependent variable and the dichotomous phase variable. The function here provides two extensions to this procedure: The more accurate Siegel repeated median regression is applied when repeated = TRUE and a continuity correction is applied when continuity = TRUE (both are the default settings).

Other overlap functions: `nap()`, `overlap()`, `pand()`, `pem()`, `pet()`, `pnd()`, `tau_u()`

Examples

```r
dat <- scdf(c(A = 33,25,17,25,14,13,15, B = 15,16,16,5,7,9,6,5,3,3,8,11,7))
corrected_tau(dat)
```

describeSC  

Descriptive statistics for single-case data

Description

The `describeSC` function provides common descriptive statistics for single-case data.

Usage

describeSC(data, dvar, pvar, mvar)

Arguments

- `data`  A single-case data frame. See `scdf` to learn about this format.
- `dvar`  Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
- `pvar`  Character string with the name of the phase variable. Defaults to the attributes in the scdf file.
- `mvar`  Character string with the name of the measurement time variable. Defaults to the attributes in the scdf file.
Value

A data frame of descriptive statistics (for each single-case), i.e.: number of observations, number of missing values, measures of central tendency, variation, and trend.

Author(s)

Juergen Wilbert

See Also

overlapSC, plotSC

Examples

```r
## Descriptive statistics for a study of three single-cases
describeSC(Grosche2011)

## Descriptives of a three phase design
describeSC(exampleABC)

## Not run:
## Write descriptive statistics to .csv-file
study <- describeSC(Waddell2011)
write.csv(study$descriptives, file = "descriptives.csv")

## End(Not run)
```

estimateSC

*(Deprecated function) Estimate single-case design*

Description

This function takes an scdf an extracts design parameters. The resulting in object can be used to randomly create new scdf files with the same underlying parameters. This might be useful for monte-carlo studies and bootstrapping procedures.

Usage

```r
estimateSC(data, dvar, pvar, mvar, s = NULL, rtt = NULL, model = "JW", ...)
```

Arguments

data A single-case data frame. See scdf to learn about this format.
dvar Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
estimate_design

Description

This function takes an scdf and extracts design parameters. The resulting object can be used to randomly create new scdf files with the same underlying parameters. This is useful for monte-carlo studies and bootstrapping procedures.

Usage

```r
estimate_design(
  data,
  dvar,
  pvar,
  mvar,
  m = NULL,
  s = NULL,
  rtt = NULL,
  between = TRUE,
  model = "JW",
  ...
)
```

Value

A list of parameters for each single-case. Parameters include name, length, and starting measurement time of each phase, trend level, and slope effects for each phase, mean, standard deviation, and reliability for each case.

Examples

```r
estimateSC(exampleABC)
```
Arguments

- **data**: A single-case data frame. See `scdf` to learn about this format.
- **dvar**: Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
- **pvar**: Character string with the name of the phase variable. Defaults to the attributes in the scdf file.
- **mvar**: Character string with the name of the measurement time variable. Defaults to the attributes in the scdf file.
- **m**: The mean depicting the overall distribution of which all cases are a random sample of. m is estimated when m = NULL.
- **s**: The standard deviation depicting the between case variance of the overall performance. If more than two single-cases are included in the scdf, the variance is estimated if s is set to NULL.
- **rtt**: The reliability of the measurements. The reliability is estimated when rtt = NULL.
- **between**: If FALSE trend, level, and slope effect estimations will be identical for each case. If TRUE effects are estimated for each case separately.
- **model**: Model used for calculating the slope parameter (see Huitema & McKean, 2000). Default is model = "B&L-B". Possible values are: "B&L-B", "H-M", "Mohr#1", "Mohr#2", "JW", "JW2", and "Manly".
- **...**: Further arguments passed to the lm function used for parameter estimation.

Value

A list of parameters for each single-case. Parameters include name, length, and starting measurementtime of each phase, trend level, and slope effects for each phase, mean, standarddeviation, and reliability for each case.

---

**export**

*Export scan objects to html or latex*

Description

This function is in an experimental status. Export creates html files of tables or displayes them directly in the viewer pane of rstudio. When applied in rmarkdown, tables can also be created for pdf/latex output.

Usage

```r
export(
  object,
  filename = NULL,
  kable_styling_options = list(),
  kable_options = list(),
)```
the fillmissingSC function replaces missing measurements in single-case data.

Usage

fill_missing(data, dvar, mvar, interpolation = "linear", na.rm = TRUE)
fillmissingSC(...)
Arguments

data A single-case data frame. See scdf to learn about this format.
dvar Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
mvar Character string with the name of the measurement time variable. Defaults to the attributes in the scdf file.
interpolation Alternative options not yet included. Default is interpolation = "linear".
na.rm If set TRUE, NA values are also interpolated. Default is na.rm = TRUE.
... Further arguments passed to the function.

Details

This procedure is recommended if there are gaps between measurement times (e.g. MT: 1, 2, 3, 4, 5, ... 8, 9) or explicitly missing values in your single-case data and you want to calculate overlap indices (overlapSC) or a randomization test (randSC).

Value

A single-case data frame (SCDF) with missing data points interpolated. See scdf to learn about the SCDF Format.

Author(s)

Juergen Wilbert

See Also

Other data manipulation functions: longSCDF(), outlier(), ranks(), shift(), smooth_cases(), standardize(), truncate_phase()
study <- c(Maggie, Maggie_n, Maggie_f)
names(study) <- c("original", "missing", "interpolated")
plot(study, marks = list(positions = replace.positions), style = "grid2")

hplm

Hierarchical piecewise linear model / piecewise regression

Description

The hplm function computes a hierarchical piecewise regression model.

Usage

hplm(
  data,  # A single-case data frame. See scdf to learn about this format.
  dvar,  # Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
  pvar,  # Character string with the name of the phase variable. Defaults to the attributes in the scdf file.
  mvar,  # Character string with the name of the measurement time variable. Defaults to the attributes in the scdf file.
  model = "B&L-B",  # Model used for calculating the slope parameter (see Huitema & McKean, 2000). Default is model = "B&L-B". Possible values are: "B&L-B", "H-M", "Mohr#1", "Mohr#2", "JW", "JW2", and "Manly".
  method = "ML",  # Possible values are: "B&L-B", "H-M", "Mohr#1", "Mohr#2", "JW", "JW2", and "Manly".
  control = list(opt = "optim"),  # Possible values are: "B&L-B", "H-M", "Mohr#1", "Mohr#2", "JW", "JW2", and "Manly".
  random.slopes = FALSE,
  lr.test = FALSE,
  ICC = TRUE,
  trend = TRUE,
  level = TRUE,
  slope = TRUE,
  fixed = NULL,
  random = NULL,
  update.fixed = NULL,
  data.l2 = NULL,
  ...
)

Arguments

data  Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
dvar  Character string with the name of the phase variable. Defaults to the attributes in the scdf file.
pvar  Character string with the name of the measurement time variable. Defaults to the attributes in the scdf file.
mvar  Model used for calculating the slope parameter (see Huitema & McKean, 2000). Default is model = "B&L-B". Possible values are: "B&L-B", "H-M", "Mohr#1", "Mohr#2", "JW", "JW2", and "Manly".
Method used to fit your model. Pass "REML" to maximize the restricted log-likelihood or "ML" for maximized log-likelihood. Default is "ML".

control  A list of settings for the estimation algorithm, replacing the default values passed to the function `lmeControl` of the `nlme` package.

random.slopes  If `random.slopes = TRUE` random slope effects of the level, trend, and treatment parameter are estimated.

lr.test  If set TRUE likelihood ratio tests are calculated comparing model with vs. without random slope parameters.

ICC  If ICC = TRUE an intraclass-correlation is estimated.

trend  A logical indicating if a trend parameters is included in the model.

level  A logical indicating if a level parameters is included in the model.

slope  A logical indicating if a slope parameters is included in the model.

fixed  Defaults to the fixed part of the standard piecewise regression model. The parameter phase followed by the phase name (e.g., phaseB) indicates the level effect of the corresponding phase. The parameter 'inter' followed by the phase name (e.g., interB) addresses the slope effect based on the method provide in the model argument (e.g., "B&L-B"). The formula can be changed for example to include further L1 or L2 variables into the regression model.

random  The random part of the model.

update.fixed  An easier way to change the fixed model part (e.g., . ~ . + newvariable).

data.l2  A dataframe providing additional variables at Level 2. The scdf File has to have names for all cases and the Level 2 dataframe has to have a column named 'cases' with the names of the cases the Level 2 variables belong to.

...  Further arguments passed to the lme function.

Value

- **model**  List containing information about the applied model
- **N**  Number of single-cases.
- **formula**  A list containing the fixed and the random formulas of the hplm model.
- **hplm**  Object of class lme containing the multilevel model
- **model.0**  Object of class glm containing the Zero Model.
- **ICC**  List containing intraclass correlation and test parameters.
- **model.without**  Object of class gls containing the fixed effect model.

Other regression functions: `corrected_tau()`, `mplm()`, `plm()`
Examples

```r
## Compute hplm model on a MBD over fifty cases (restricted log-likelihood)
hplm(exampleAB_50, method = "REML", random.slopes = FALSE)

## Analyzing with additional L2 variables
hplm(Leidig2018, data.l2 = Leidig2018_l2,
       update.fixed = ~ . + gender + migration + ITRF_TOTAL*phaseB,
       slope = FALSE, random.slopes = FALSE, lr.test = FALSE)
```

---

longSCDF  

Creating a long format data frame from several single-case data frames (scdf).

Description

The longSCDF function transposes a scdf into one long data frame. Additionally, a data frame can be merged that includes data of the subjects. This might be helpful to prepare data to be used with other packages than scan.

Usage

```r
longSCDF(data, l2 = NULL, id = "case")
```

Arguments

- **data**: A single-case data frame. See `scdf` to learn about this format.
- **l2**: A data frame providing additional variables at Level 2. The scdf has to have names for all cases and the Level 2 data frame has to have a column with corresponding case names.
- **id**: Variable name of the Level 2 data frame that contains the case names.

Value

Returns one data frame with data of all single-cases structured by the case variable.

Author(s)

Juergen Wilbert

See Also

Other data manipulation functions: `fill_missing()`, `outlier()`, `ranks()`, `shift()`, `smooth_cases()`, `standardize()`, `truncate_phase()`
Examples

```r
## Convert the list of three single-case data frames from Grosche (2011) into one long data frame
Grosche2011
Grosche2011_long <- longSCDF(Grosche2011)
Grosche2011_long

## Combine an scdf with data for l2
Leidig2018_long <- longSCDF(Leidig2018, l2 = Leidig2018_l2)
names(Leidig2018_long)
summary(Leidig2018_long)
```

---

makeSCDF

**Single case data frame**

Description

The class `scdf` stores single-case study data with one or more single-cases.

Usage

```r
makeSCDF(data, B.start = NULL, MT = NULL)
```

```r
cddf(
  values,
  B.start,
  mt,
  phase,
  phase.design,
  name,
  dvar = "values",
  pvar = "phase",
  mvar = "mt",
  ...
)
```

Arguments

- **data**
  A single-case data frame. See `scdf` to learn about this format.
- **B.start**
  The first measurement of phase B (simple coding if design is strictly AB).
- **MT**
  Deprecated: Measurement times
- **values**
  A vector containing measurement values of the dependent variable.
- **mt**
  A vector defining measurement times. Default is `mt = (1,2,3,\ldots,n)`.
- **phase**
  A vector defining phase assignments.
**phase.design**  
A vector defining the length and label of each phase. E.g., `phase.length = c(A1 = 10, B1 = 10, A2 = 10, B2 = 10)`.  

**name**  
A name for the case.  

**dvar**  
Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.  

**pvar**  
Character string with the name of the phase variable. Defaults to the attributes in the scdf file.  

**mvar**  
Character string with the name of the measurement time variable. Defaults to the attributes in the scdf file.  

...  
Additional variables. E.g., `teacher = c(0,1,0,1,0,0,1), lesson = c(1,3,4,5,2,3)`.  

**Details**  
The `scdf` class is a wrapper for a list containing a dataframe for each case.  
If the dependent variable is a named vector then the names are extracted to create a phase design (e.g., `values = c(A = 2,3,5,4,3, B = 6,5,4,3)` will create an AB phase design with five and four measurements). An `scdf` contains several attributes:  
- **dvar** The name of the dependent variable.  
- **phase** The name of the phase variable.  
- **mt** The name of the measurement time variable.  
- **author** Information on the author of the data.  
- **info** Further information on the data. E.g., a publication.  
- **dvar**, **phase**, and **mt** are the defaults most of the scan function use. You can change the values of the attributes with the `scdf_attr` function (e.g., `scdf_attr(exampleAB_add,"dvar") <-"depression"` defines depression as the dependent variable. Please notice that all scan functions have arguments to define **dvar**, **phase**, and **mt** for a given analysis.  

**Value**  
Returns a single-case data frame `scdf` suitable for all functions of the scan package. Multiple data sets (e.g. from Multiple Baseline Designs) can be listed.  

**Author(s)**  
Juergen Wilbert  

**Examples**

```r
## Scores on a letter naming task were collected on eleven days in a row. The intervention
## started after the fifth measurement, so the first B phase measurement was 6 (B.start = 6).
klaas <- scdf(
  c(5, 7, 8, 5, 7, 12, 16, 18, 15, 14, 19),
  B.start = 6, name = "Klaas"
)
plot(klaas)
# Alternative coding 1:
klaas <- scdf(
  c(A = 5, 7, 8, 5, 7, B = 12, 16, 18, 15, 14, 19),
  name = "Klaas"
)```
# Alternative coding 2:
klaas <- scdf(
  c(5, 7, 8, 5, 7, 12, 16, 18, 15, 14, 19),
  phase.design = c(A = 5, B = 6), name = "Klaas"
)

## Unfortunately in a similar SCDR there were no data collected on days 3 and 9. Use NA to
## pass them to the package.
emmi <- scdf(c(5, 7, NA, 5, 7, 12, 16, 18, NA, 14, 19),
  phase.design = c(A = 5, B = 6), name = "Emmi")
describeSC(emmi)

## In a MBD over three persons, data were again collected eleven days in a row. Intervention
## starting points differ between subjects as they were randomly assigned. The three SCDFs
## are then combined in a list for further conjoined analyses.
charlotte <- scdf(c(A = 5, 7, 10, 5, 12, B = 7, 10, 18, 15, 14, 19))
theresa <- scdf(c(A = 3, 4, 3, 5, B = 7, 4, 7, 8, 10, 12))
antonia <- scdf(c(A = 9, 8, 8, 7, 5, 7, B = 6, 14, 15, 12, 16))
mbd <- c(charlotte, theresa, antonia)
names(mbd) <- c("Charlotte", "Theresa", "Antonia")
overlapSC(mbd)

## In a classroom-based intervention it was not possible to measure outcomes every day, but
## only on schooldays. The sequence of measurements is passed to the package by using a
## vector of measurement times.
frida <- scdf(
  c(A = 3, 2, 4, 2, 2, 3, 5, 6, B = 8, 10, 8, 12, 14, 13, 12),
  mt = c(1, 2, 3, 4, 5, 8, 9, 10, 11, 12, 14, 15, 16, 17, 18)
)
summary(frida)
plot(frida)
describeSC(frida)

## example with two independent variables and four phases
jim <- scdf(
  zvt = c(47, 58, 76, 63, 59, 64, 69, 72, 77, 76, 73),
  d2 = c(131, 134, 141, 141, 140, 140, 138, 140, 141, 140, 138, 140),
  phase.design = c(A1 = 3, B1 = 3, A2 = 3, B2 = 3), dvar = "zvt"
)
overlapSC(jim, phases = list(c("A1", "A2"), c("B1", "B2")))

makesingleSC

## Deprecated function
Aggregate multiple single-cases into one case

Description

The makesingleSC function combines multiple single-case data frames into one single-case data
frame.
Usage

makescalereg(data, scale = FALSE, type = "add")

Arguments

data A vector with measurements, a data frame or a list of data frames.
scale Unused
type By default values with the same measurement are added. If type is set to "mean" or "median", values of the same measurement are replaced with their mean or median. Default is "add".

Details

The algorithm works the following way:

1. All values of each single-case are centred with respect to each case’s phase A mean.
2. The phase A values of all single-cases are combined in ascending order of their measurement times.
3. The phase B values of all single-cases are combined in ascending order of their measurement times.
4. Phase B values are appended to phase A values. The measurement times of phase B are shifted to start with the next MT after the end of phase A.

mplm Multivariate Piecewise linear model / piecewise regression

Description

This function is in an experimental status. The mplm function computes a multivariate piecewise regression model.
mplm

Usage

mplm(
  data,
  dvar,
  mvar,
  pvar,
  model = "B&L-B",
  trend = TRUE,
  level = TRUE,
  slope = TRUE,
  formula = NULL,
  update = NULL,
  na.action = na.omit,
  ...
)

Arguments

data A single-case data frame. See scdf to learn about this format.
dvar Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
mvar Character string with the name of the measurement time variable. Defaults to the attributes in the scdf file.
pvar Character string with the name of the phase variable. Defaults to the attributes in the scdf file.
model Model used for calculating the slope parameter (see Huitema & McKean, 2000). Default is model = "B&L-B". Possible values are: "B&L-B", "H-M", "Mohr#1", "Mohr#2", "JW", "JW2", and "Manly".
trend A logical indicating if a trend parameters is included in the model.
level A logical indicating if a level parameters is included in the model.
slope A logical indicating if a slope parameters is included in the model.
formula Defaults to the standard piecewise regression model. The parameter phase followed by the phase name (e.g., phaseB) indicates the level effect of the corresponding phase. The parameter 'inter' followed by the phase name (e.g., interB) adresses the slope effect based on the method provide in the model argument (e.g., "B&L-B"). The formula can be changed for example to include further variables into the regression model.
update An easier way to change the regression formula (e.g., . ~ . + newvariable).
na.action Defines how to deal with missing values
...
Further arguments passed to the lm function.

Value

model Character string from function call (see Arguments above).
full.model Full regression model list
The `nap` function calculates the nonoverlap of all pairs (NAP; Parker & Vannest, 2009). NAP summarizes the overlap between all pairs of phase A and phase B data points. If an increase of phase B scores is expected, a non-overlapping pair has a higher phase B data point. The NAP equals $\frac{\text{number of pairs showing no overlap}}{\text{number of pairs}}$. Because NAP can only take values between 50 and 100 percent, a rescaled and therefore more intuitive NAP (0-100%) is also displayed.

Usage

```r
nap(data, dvar, pvar, decreasing = FALSE, phases = c("A", "B"))
```

Arguments

- `data` A single-case data frame. See `scdf` to learn about this format.
- `dvar` Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
- `pvar` Character string with the name of the phase variable. Defaults to the attributes in the scdf file.
- `decreasing` If you expect data to be lower in the B phase, set `decreasing = TRUE`. Default is `decreasing = FALSE`.
- `phases` A vector of two characters or numbers indicating the two phases that should be compared. E.g., `phases = c("A", "C")` or `phases = c(2, 4)` for comparing the second to the fourth phase. Phases could be combined by providing a list with two elements. E.g., `phases = list(A = c(1, 3), B = c(2, 4))` will compare phases 1 and 3 (as A) against 2 and 4 (as B). Default is `phases = c("A", "B")`.

Value

- `nap` A data frame with NAP and additional values for each case.
- `N` Number of cases.
outlier

Description

Identifies and drops outliers within a single-case data frame (scdf).

Usage

outlier(data, dvar, pvar, mvar, criteria = c("MAD", "3.5"))

outlierSC(...)

Arguments

data A single-case data frame. See scdf to learn about this format.
dvar Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
pvar Character string with the name of the phase variable. Defaults to the attributes in the scdf file.
mvar Character string with the name of the measurement time variable. Defaults to the attributes in the scdf file.

Examples

## Calculate NAP for a study with lower expected phase B scores (e.g. aggressive behavior)
gretchen <- scdf(c(A = 12, 14, 9, 10, B = 10, 6, 4, 5, 3, 4))
nap(gretchen, decreasing = TRUE)

## Request NAP for all cases from the Grosche2011 data
nap(Grosche2011)
### criteria
Specifies the criteria for outlier identification. Set `criteria = c("SD", 2)` to define two standard deviations as limit. This is also the default setting. To use the 99% Confidence Interval use `criteria = c("CI", 0.99)`. Set `criteria = c("Cook", "4/n")` to define any data point with a Cook’s Distance greater than $4/n$ as an outlier, based on the Piecewise Linear Regression Model.

... Further arguments passed to the function.

### Value
- **data**: A single-case data frame with substituted outliers.
- **dropped.n**: A list with the number of dropped data points for each single-case.
- **dropped.mt**: A list with the measurement-times of dropped data points for each single-case (values are based on the `mt` variable of each single-case data frame).
- **sd.matrix**: A list with a matrix for each case with values for the upper and lower boundaries based on the standard deviation.
- **ci.matrix**: A list with a matrix for each single-case with values for the upper and lower boundaries based on the confidence interval.
- **cook**: A list of Cook’s Distances for each measurement of each single-case.
- **criteria**: Criteria used for outlier analysis.
- **N**: Number of single-cases.
- **case.names**: Case identifier.

### Examples
```r
## Identify outliers using 1.5 standard deviations as criterion
susanne <- rSC(level = 1.0)
res_outlier <- outlier(susanne, criteria = c("SD", 1.5))
plot(susanne, marks = res_outlier)

## Identify outliers in the original data from Grosche (2011) using Cook’s Distance greater than 4/n as criterion
res_outlier <- outlier(Grosche2011, criteria = c("Cook", "4/n"))
plot(Grosche2011, marks = res_outlier)
```
Description

The overlap function provides the most common overlap indices for single-case data and some additional statistics.

Usage

overlap(data, dvar, pvar, mvar, decreasing = FALSE, phases = c(1, 2))

overlapSC(...)

Arguments

data A single-case data frame. See scdf to learn about this format.
dvar Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
pvar Character string with the name of the phase variable. Defaults to the attributes in the scdf file.
mvar Character string with the name of the measurement time variable. Defaults to the attributes in the scdf file.
decreasing If you expect data to be lower in the B phase, set decreasing = TRUE. Default is decreasing = FALSE.
phases A vector of two characters or numbers indicating the two phases that should be compared. E.g., phases = c("A","C") or phases = c(2,4) for comparing the second to the fourth phase. Phases could be combined by providing a list with two elements. E.g., phases = list(A = c(1,3),B = c(2,4)) will compare phases 1 and 3 (as A) against 2 and 4 (as B). Default is phases = c("A","B").
... Further arguments passed to the function.

Value

overlap A data frame consisting of the following indices for each single-case for all cases: PND, PEM, PET, NAP, PAND, Tau-U (A vs. B - Trend A), Diff_mean, Diff_trend, SMD.
phases.A Selection for A phase.
phases.B Selection for B phase.
design Phase design.

Author(s)

Juergen Wilbert
See Also

Other overlap functions: `corrected_tau()`, `nap()`, `pand()`, `pem()`, `pet()`, `pnd()`., `tau_u()`

Examples

```r
## Display overlap indices for one single-case
overlap(Huitema2000, decreasing = TRUE)

## Display overlap indices for six single-cases
overlap(GruenkeWilbert2014)

## Combining phases for analysing designs with more than two phases
overlap(exampleA1B1A2B2, phases = list(c("A1","A2"), c("B1","B2")))
```

pand  Percentage of all non-overlapping data

Description

The `pand` function calculates the percentage of all non-overlapping data (PAND; Parker, Hagan-Burke, & Vannest, 2007), an index to quantify a level increase (or decrease) in performance after the onset of an intervention.

Usage

```r
pand(data, dvar, pvar, decreasing = FALSE, correction = TRUE, phases = c(1, 2))
```

Arguments

- **data**: A single-case data frame. See `scdf` to learn about this format.
- **dvar**: Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
- **pvar**: Character string with the name of the phase variable. Defaults to the attributes in the scdf file.
- **decreasing**: If you expect data to be lower in the B phase, set `decreasing = TRUE`. Default is `decreasing = FALSE`.
- **correction**: The default `correction = TRUE` makes `pand` use a frequency matrix, which is corrected for ties. A tie is counted as the half of a measurement in both phases. Set `correction = FALSE` to use the uncorrected matrix, which is not recommended.
- **phases**: A vector of two characters or numbers indicating the two phases that should be compared. E.g., `phases = c("A", "C")` or `phases = c(2, 4)` for comparing the second to the fourth phase. Phases could be combined by providing a list with two elements. E.g., `phases = list(A = c(1,3), B = c(2,4))` will compare phases 1 and 3 (as A) against 2 and 4 (as B). Default is `phases = c("A", "B")`.  

Details

The PAND indicates nonoverlap between phase A and B data (like PND), but uses all data and is therefore not based on one single (probably unrepresentative) datapoint. Furthermore, PAND allows the comparison of real and expected associations (Chi-square test) and estimation of the effect size Phi, which equals Pearson’s r for dichotomous data. Thus, phi-Square is the amount of explained variance. The original procedure for computing the PAND (Parker, Hagan-Burke, & Vannest, 2007) does not account for ambivalent datapoints (ties). The newer NAP overcomes this problem and has better precision-power (Parker, Vannest, & Davis, 2014).

Value

<table>
<thead>

Examples

```r
## Calculate the PAND for a MMBD over three cases
gunnar <- scdf(c(2,3,1,5,3,4,2,6,4,7), B.start = 5)
birgit <- scdf(c(3,3,2,4,7,4,2,1,4,7), B.start = 4)
bodo <- scdf(c(2,3,4,5,3,4,7,6,8,7), B.start = 6)
mbd <- c(gunnar, birgit, bodo)
pand(mbd)
pand(bodo)

## Calculate the PAND with an expected decrease of phase B scores
cubs <- scdf(c(20,22,24,17,21,13,10,9,20,9,18), B.start = 5)
pand(cubs, decreasing = TRUE)
```

### pem

**Percent exceeding the median**

**Description**

The `pem` function returns the percentage of phase B data exceeding the phase A median. Additionally, a chi square test against a 50/50 distribution is computed. Different measures of central tendency can be addressed for alternative analyses.

**Usage**

```r
pem(
  data,  # A single-case data frame. See scdf to learn about this format.
  dvar,  # Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
  pvar,  # Character string with the name of the phase variable. Defaults to the attributes in the scdf file.
  decreasing = FALSE,  # If you expect data to be lower in the B phase, set decreasing = TRUE. Default is decreasing = FALSE.
  binom.test = TRUE,  # Additional measures of central tendency can be addressed for alternative analyses.
  chi.test = FALSE,
  FUN = median,
  phases = c(1, 2),
  ...
)
```

**Arguments**

- `data`  
- `dvar`  
- `pvar`  
- `decreasing`  
- `binom.test`  
- `chi.test`  
- `FUN`  
- `phases`  
- `...`
binom.test  Computes a binomial test for a 50/50 distribution. Default is binom.test = TRUE.

chi.test  Computes a Chi-square test. The default setting chi.test = FALSE skips the Chi-square test.

FUN  Data points are compared with the phase A median. Use this argument to implement alternative measures of central tendency. Default is FUN = median

phases  A vector of two characters or numbers indicating the two phases that should be compared. E.g., phases = c("A", "C") or phases = c(2,4) for comparing the second to the fourth phase. Phases could be combined by providing a list with two elements. E.g., phases = list(A = c(1,3),B = c(2,4)) will compare phases 1 and 3 (as A) against 2 and 4 (as B). Default is phases = c("A","B").

...  Additional arguments for the FUN parameter (e.g. FUN = mean, trim = 0.1 will use the 10 percent trimmed arithmetic mean instead of the median for comparisons). The function must take a vector of numeric values and the na.rm argument and return a numeric value.

Author(s)
Juergen Wilbert

Other overlap functions: corrected_tau(), nap(), overlap(), pand(), pet(), pnd(), tau_u()

Examples

```r
## Calculate the PEM including the Binomial and Chi-square tests for a single-case
dat <- rSC(5, level = 0.5)
pem(dat, chi.test = TRUE)
```

Description
The pet function provides the percentage of phase B data points exceeding the prediction based on the phase A trend. A binomial test against a 50/50 distribution is computed. Furthermore, the percentage of phase B data points exceeding the upper (or lower) 95 percent confidence interval of the predicted progress is computed.

Usage

```r
pet(data, dvar, pvar, mvar, ci = 0.95, decreasing = FALSE, phases = c(1, 2))
```
Arguments

- `data`: A single-case data frame. See `scdf` to learn about this format.
- `dvar`: Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
- `pvar`: Character string with the name of the phase variable. Defaults to the attributes in the scdf file.
- `mvar`: Character string with the name of the measurement time variable. Defaults to the attributes in the scdf file.
- `ci`: Width of the confidence interval. Default is `ci = 0.95`.
- `decreasing`: If you expect data to be lower in the B phase, set `decreasing = TRUE`. Default is `decreasing = FALSE`.
- `phases`: A vector of two characters or numbers indicating the two phases that should be compared. E.g., `phases = c("A", "C")` or `phases = c(2, 4)` for comparing the second to the fourth phase. Phases could be combined by providing a list with two elements. E.g., `phases = list(A = c(1, 3), B = c(2, 4))` will compare phases 1 and 3 (as A) against 2 and 4 (as B). Default is `phases = c("A", "B")`.

Value

- `PET`: Percent exceeding the trend.
- `PET.ci`: Percent exceeding the upper / lower 95%-CI boundary.
- `p`: P value of Binomial Test.
- `ci.percent`: Width of confidence interval in percent.
- `se.factors`: Standard error.
- `N`: Number of cases.
- `decreasing`: Logical argument from function call (see Arguments above).
- `case.names`: Assigned name of single-case.
- `phases`: -

Examples

```r
## Calculate the PET and use a 99%-CI for the additional calculation
# create random example data
design <- design_rSC(n = 5, slope = 0.2)
dat <- rSC(design, seed = 23)
pet(dat, ci = .99)
```
plm

Piecewise linear model / piecewise regression

Description

The plm function computes a piecewise regression model (see Huitema & McKean, 2000).

Usage

plm(
  data,  
dvar,    
pvar,    
mvar,    
AR = 0,  
model = "B&L-B",  
family = "gaussian",  
trend = TRUE,  
level = TRUE,  
slope = TRUE,  
formula = NULL,  
update = NULL,  
na.action = na.omit,  
...  
)

Arguments

data A single-case data frame. See scdf to learn about this format.
dvar Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
pvar Character string with the name of the phase variable. Defaults to the attributes in the scdf file.
mvar Character string with the name of the measurement time variable. Defaults to the attributes in the scdf file.
AR Maximal lag of autoregression. Modeled based on the Autoregressive-Moving Average (ARMA) function. When AR is set, the family argument must be set to family = "gaussian".
model Model used for calculating the slope parameter (see Huitema & McKean, 2000). Default is model = "B&L-B". Possible values are: "B&L-B", "H-M", "Mohr#1", "Mohr#2", "JW", "JW2", and "Manly".
family Set the distribution family. Defaults to a gaussian distribution. See the family function for more details.
trend A logical indicating if a trend parameters is included in the model.
level A logical indicating if a level parameters is included in the model.
A logical indicating if a slope parameters is included in the model.

Defaults to the standard piecewise regression model. The parameter phase followed by the phase name (e.g., phaseB) indicates the level effect of the corresponding phase. The parameter 'inter' followed by the phase name (e.g., interB) addresses the slope effect based on the method provide in the model argument (e.g., "B&L-B"). The formula can be changed for example to include further variables into the regression model.

An easier way to change the regression formula (e.g., . ~ . + newvariable).

Defines how to deal with missing values

Further arguments passed to the glm function.

plm formula. Useful if you want to use the update or formula argument and you don’t know the names of the parameters.

Character string from function call (see Arguments above).

F-test values of modelfit.

Explained variance R squared for each model parameter.

Autoregression lag from function call (see Arguments above).

Distribution family from function call (see Arguments above).

Full regression model list from the gls or glm function.

Examples

## Compute a piecewise regression model for a random single-case
set.seed(123)
AB <- design_rSC(
  phase.design = list(A = 10, B = 20),
  level = list(A = 0, B = 1), slope = list(A = 0, B = 0.05),
  trend = list(0.05)
## Another example with a more complex design

```r
A1B1A2B2 <- design_rSC(
  phase.design = list(A1 = 15, B1 = 20, A2 = 15, B2 = 20),
  level = list(A1 = 0, B1 = 1, A2 = -1, B2 = 1),
  slope = list(A1 = 0, B1 = 0.0, A1 = 0, B2 = 0.0),
  trend = list(0.0))

dat <- rSC(design = A1B1A2B2, seed = 123)
plm(dat, model = "JW")
```

## no slope effects were found. Therefore you might want to drop slope estimation:

```r
plm(dat, slope = FALSE, model = "JW")
```

## and now drop the trend estimation as well

```r
plm(dat, slope = FALSE, trend = FALSE, model = "JW")
```

---

**plot.scdf**  
*Plot single-case data*

### Description

This function provides a plot of a single-case or multiple single-cases.

### Usage

```r
## S3 method for class 'scdf'
plot(....)
```

```r
plotSC(
  data,
  dvar,
  pvar,
  mvar,
  ylim = NULL,
  xlim = NULL,
  xinc = 1,
  lines = NULL,
  marks = NULL,
  phase.names = NULL,
  xlab = NULL,
  ylab = NULL,
  main = "",
  case.names = NULL,
  style = getOption("scan.plot.style"),
...)
)```

Arguments

... Further arguments passed to the plot command.

data A single-case data frame. See scdf to learn about this format.
dvar Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
pvar Character string with the name of the phase variable. Defaults to the attributes in the scdf file.
mvar Character string with the name of the measurement time variable. Defaults to the attributes in the scdf file.
ylim Lower and upper limits of the y-axis (e.g., ylim = c(0,20) sets the y-axis to a scale from 0 to 20). With multiple single-cases you can use ylim = c(0,NA) to scale the y-axis from 0 to the maximum of each case. ylim is not set by default, which makes scan set a proper scale based on the given data.
xlim Lower and upper limits of the x-axis (e.g., xlim = c(0,20) sets the x-axis to a scale from 0 to 20). With multiple single-cases you can use xlim = c(0,NA) to scale the x-axis from 0 to the maximum of each case. xlim is not set by default, which makes scan set a proper scale based on the given data.
xinc An integer. Increment of the x-axis. 1 : each mt value will be printed, 2 : every other value, 3 : every third values etc.
lines A character or list defining one or more lines or curves to be plotted. The argument is either passed as a character string (e.g., lines = "median") or as a list (e.g., list("median","trend")). Some of the procedures can be refined with an additional argument (e.g., lines = list(mean = 0.2) draws a 20%-trimmed mean line. By default no additional lines are plotted. Possible lines are:

- "median" Separate lines for phase A and B medians.
- "mean" Separate lines for phase A and B means. By default it is 10%-trimmed. Other trims can be set, using a second parameter (e.g., lines = list(mean = 0.2) draws a 20%-trimmed mean line).
- "trend" Separate lines for phase A and B trends.
- "trendA" Trend line for phase A, extrapolated throughout phase B.
- "maxA/minA" Line at the level of the highest or lowest phase A score.
- "medianA" Line at the phase A median score.
- "meanA" Line at the phase A 10%-trimmed mean score. Apply a different trim, by using the additional argument (e.g., lines = list(meanA = 0.2)).
- "plm" Regression lines for piecewise linear regression model.
- "plm.ar" Regression lines for piecewise autoregression model. The lag is specified like this: lines = list(plm.ar = 2). Default lag is set to 2.
- "movingMean" Draws a moving mean curve, with a specified lag: lines = list(movingMean = 2). Default is a lag 1 curve.
- "movingMedian" Draws a moving median curve, with a specified lag: lines = list(movingMedian = 3). Default is a lag 1 curve.
- "loreg" Draws a non-parametric local regression line. The proportion of data influencing each data point can be specified using lines = list("loreg" = 0.66). The default is 0.5.
• "lty" Use this argument to define the line type. Examples are: "solid", "dashed", "dotted".
• "lwd" Use this argument to define the line’s thickness, e.g., lwd = 4.
• "col" Use this argument to define the line’s color, e.g., col = "red".

marks A list of parameters defining markings of certain data points.
• "positions" A vector or a list of vectors indicating measurement-times to be highlighted. In case of a vector, the marked measurement-times are the same for all plotted cases. In case of a list of vectors, marks are set differently for each case. The list must have the same length as there are cases in the data file.
• "col" Color of the marks.
• "cex" Size of the marks.

Use for example marks = list(positions = c(1,8,15),col = "red",cex = 3) to make the MTs one, eight and 18 appear big and red.

phase.names By default phases are labeled based on the levels of the phase variable. Use this argument to specify different labels: phase.names = c("Baseline","Intervention").
xlab The label of the x-axis. Default is xlab = "Measurement time".

ylab The labels of the y-axis. Default is ylab = "Score".

main Main title of the plot.

case.names Case names. If not provided, names are taken from the scdf. Set case.names = "" if you don’t like to include case names.

style Either a character with the name of a pre-implemented style or a style object. See style_plot to learn about this format.

Value

Returns a plot of one or multiple single-cases.

Author(s)

Juergen Wilbert

style_plot, describeSC, overlapSC

Examples

## Request the default plot of the data from Borckhardt (2014)
plot(Borckhardt2014)

## Plot the three cases from Grosche (2011) and visualize the phase A trend
plot(Grosche2011, style = "grid", lines = "trendA")

## Request the local regression line for Georg from that data set and customize the plot
plot(Grosche2011$Georg, style = "sienna", ylim = c(0,NA),
xlab = "Training session", ylab = "Words per minute",
phase.names = c("Baseline", "Intervention"),
lines = list("loreg", lty = "solid", col = "black", lwd = 3))

## Plot a random MBD over three cases and mark interesting MTs
dat <- rSC(design = design_rSC(3))
plot(dat, marks = list(positions = list(c(2,4,5),c(1,2,3),c(7,8,9)), col = "blue",
cex = 1.4), style = c("grid", "annotate", "tiny"))

### pnd

This function returns the percentage of non-overlapping data. Due to its error-proneness the PND should not be used, but nap or pand instead (see Parker & Vannest, 2009).

#### Usage

```r
pnd(data, dvar, pvar, decreasing = FALSE, phases = c("A", "B"))
```

#### Arguments

- **data**: A single-case data frame. See scdf to learn about this format.
- **dvar**: Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
- **pvar**: Character string with the name of the phase variable. Defaults to the attributes in the scdf file.
- **decreasing**: If you expect data to be lower in the B phase, set decreasing = TRUE. Default is decreasing = FALSE.
- **phases**: A vector of two characters or numbers indicating the two phases that should be compared. E.g., phases = c("A","C") or phases = c(2, 4) for comparing the second to the fourth phase. Phases could be combined by providing a list with two elements. E.g., phases = list(A = c(1,3),B = c(2,4)) will compare phases 1 and 3 (as A) against 2 and 4 (as B). Default is phases = c("A", "B").

#### Value

- **PND**: Percentage of non-overlapping data.

Examples

```r
## Calculate the PND for multiple single-case data
pnd(GruenkeWilbert2014)
```

---

**Description**

!! This function is deprecated. Please use the power_testSC function !! The power.testSC command conducts a Monte-Carlo study on the test-power and alpha-error of a randomization-test and a piecewise-regression model. The distribution values of the Monte-Carlo sample are either specified by the user or estimated based on actual data.

**Usage**

```r
codesample
power.testSC(
  data = NULL,
  dvar,
  pvar,
  mvar,
  parameters = NULL,
  stat = c("rand.test", "plm"),
  test.parameter = c("level", "slope"),
  rand.test.stat = c("Mean B-A", "B"),
  cases = NULL,
  rtt = NULL,
  level = NULL,
  slope = NULL,
  MT = NULL,
  B.start = NULL,
  trend = NULL,
  n_sim = 100,
  limit = 5,
  m = NULL,
  s = NULL,
  startpoints = NA,
  extreme.p = 0,
  extreme.d = c(-4, -3),
  exclude.equal = "auto",
  alpha = 0.05,
  distribution = "normal",
  silent = TRUE
)
```
Arguments

data A single-case data frame. See scdf to learn about this format.
dvar Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
pvar Character string with the name of the phase variable. Defaults to the attributes in the scdf file.
mvar Character string with the name of the measurement time variable. Defaults to the attributes in the scdf file.
parameters -
stat Defines the tests the power analysis is computed for. The default stat = c("rand.test","plm") computes a power analysis for the randSC and the plm analyses. Further possibilities are "hplm" for a hierarchiacal linear regression model and "plm.poisson" for a generalized piecewise-regression model under the assumption of poisson distributed errors.
test.parameter Indicates whether the power and alpha error for a level effect, a slope effect, or both effects should be estimated. The default setting test.parameter = c("level","slope") requests both.
rand.test.stat Defines the statistic the randomization test is based on. The first values stipulates the statistic for the level-effect computation and the second value for the slope-effect computation. Default is rand.test.stat = c("Mean B-A","B"). Please see randSC for more information on the test statistics.
cases Number of cases per study.
rtt Reliability of the underlying simulated measurements. Default is rtt = 0.8.
level Defines the level increase (effect size \(d\)) at the beginning of phase B.
slope Defines the increase in scores - starting with phase B - expressed as effect size \(d\) per MT. slope = .1 generates an incremental increase of 0.1 standard deviations per MT for all phase B measurements.
MT Number of measurements (in each study).
B.start Phase B starting point. A single value (e.g., B.start = 6) defines B.start for all studies and cases. A vector of starting values is given with the chain command (e.g., B.start = c(6,7,8)). A value between 0 and 1 is interpreted as a proportion (e.g., B.start = c(0.3,0.5,0.8) would start phase B at 30, 50, and 80% of the MTs).
trend Defines the effect size \(d\) of a trend per MT added across the whole data-set.
n_sim Number of sample studies created for the the Monte-Carlo study. Default is n = 100
limit Minimal number of data points per phase in the sample. Default is limit = 5.
m Mean of the sample distribution the data are drawn from.
s Standard deviation of the sample distribution the data are drawn from.
startpoints Alternative to the limit parameter start points exactly defines the possible start points of phase B (e.g., startpoints = 4:9 restricts the phase B start points to measurements 4 to 9. startpoints overruns the limit parameter.
extreme.p  Probability of extreme values. extreme.p = .05 gives a five percent probability of an extreme value. Default is extreme.p = 0.

extreme.d  Range for extreme values, expressed as effect size \(d\). extreme.d = c(-7,-6) uses extreme values within a range of -7 and -6 standard deviations. Caution: the first value must be smaller than the second, otherwise the procedure will fail. Default is extreme.d = c(-4,-3).

exclude.equal  If set to exclude.equal = FALSE, random distribution values equal to the observed distribution are counted as null-hypothesis conform. That is, they decrease the probability of rejecting the null-hypothesis (increase the p-value). Default is exclude.equal = "auto", which means FALSE for multiple baseline designs and TRUE for one single-case.

alpha  Alpha level used to calculate the proportion of significant tests. Default is \(\alpha = 0.05\).

distribution  Indicates whether the random sample is based on a "normal" or a "poisson" distribution. Default is distribution = "normal".

silent  If set TRUE, the results are not printed after computation. Default is silent = FALSE.

power_test

parameters = mc_par,
stat = c("rand.test","hplm"),
test.parameter = "level",
startpoints = 5:12,
n_sim = 10
)

power_test

Empirical power analysis for single-case data

Description

The power_test command conducts a Monte-Carlo study on the test-power and alpha-error of a set of single-cases. The distribution values of the Monte-Carlo sample are either specified by the user or estimated based on actual data.

Usage

power_test(
  design,
  stat = c("plm_level", "rand", "tauU"),
  n_sim = 100,
  alpha = 0.05
)

power_testSC(...)

Arguments

  design  An object created by design_rSC
  stat    Defines the tests the power analysis is based on. The default stat = c("plm_level", "rand", "tauU") computes a power analysis based on tau_u, randSC and plm analyses. Further possibilities are: "plm_slope", "plm_poisson_level", "plm_poisson_slope", "hplm_level", "hplm_slope", "base_tau".
  n_sim   Number of sample studies created for the the Monte-Carlo study. Default is n = 100
  alpha   Alpha level used to calculate the proportion of significant tests. Default is alpha = 0.05.
  ...    Further arguments passed to the function.

---

### print.sc

**Print method for scan objects**

**Description**

Print method for scan objects

**Usage**

```r
## S3 method for class 'sc'
print(x, ...)
```

**Arguments**

- `x` Object
- `...` Further parameters passed to the print function

---

### print.scdf

**Print an scdf**

**Description**

Print an scdf
random

Usage

```r
## S3 method for class 'scdf'
print(
  x,
  cases =getOption("scan.print.cases"),
  rows =getOption("scan.print.rows"),
  cols =getOption("scan.print.cols"),
  long =getOption("scan.print.long"),
  digits =getOption("scan.print.digits"),
  ...
)
```

Arguments

- `x`: An scdf object
- `cases`: Number of cases to be printed. "fit" fits the number to the current screen width.
- `rows`: Number of rows to be printed.
- `cols`: Columns to be printed. "Main" only prints the dependent, measurement-time and phase variable.
- `long`: Logical. If TRUE cases are printed in one by a time.
- `digits`: Number of digits.
- `...`: Further arguments passed to the print function.

Details

Print options for scdf objects could be set globally: `getOption("scan.print.cases = "all")`, `getOption("scan.print.rows = 10")`, `getOption("scan.print.cols = "main")`, `getOption("scan.print.long = TRUE")`, `getOption("scan.print.digits = 0")`, `getOption("scan.print.scdf.name = FALSE")`

Description

The `rSC` function generates random single-case data frames for monte-carlo studies and demonstration purposes. `design_rSC` is used to set up a design matrix with all parameters needed for the `rSC` function.

Usage

```r
rSC(design = NULL, round = NA, random.names = FALSE, seed = NULL, ...)
```

```r
design_rSC(
  n = 1,
  phase.design = list(A = 5, B = 15),
)
trend = list(0),
level = list(0),
slope = list(0),
rtt = list(0.8),
m = list(50),
s = list(10),
extreme.p = list(0),
extreme.d = c(-4, -3),
missing.p = list(0),
distribution = "normal",
prob = 0.5,
MT = NULL,
B.start = NULL
)

Arguments

design A design matrix which is created by design_rSC and specifies all parameters.
round Rounds the scores to the defined decimal. To round to the second decimal, set round = 2.
random.names Is FALSE by default. If set random.names = TRUE cases are assigned random first names. If set "male" or "female" only male or female names are chosen. The names are drawn from the 2,000 most popular names for newborns in 2012 in the U.S. (1,000 male and 1,000 female names).
seed A seed number for the random generator.
... Parameters that are directly passed from the rSC function to the design_rSC function for a more concise coding.
n Number of cases to be created (Default is n = 1).
phase.design A vector defining the length and label of each phase. E.g., phase.length = c(A1 = 10, B1 = 10, A2 = 10, B2 = 10).
trend Defines the effect size d of a trend per MT added across the whole data-set. To assign different trends to several single-cases, use a vector of values (e.g. trend = c(.1, .3, .5)). If the number of cases exceeds the length of the vector, values are repeated. While using a binomial or poisson distribution, d.trend indicates an increase in points / counts per MT.
level Defines the level increase (effect size d) at the beginning of phase B. To assign different level effects to several single-cases, use a vector of values (e.g. level = c(.2, .4, .6)). If the number of cases exceeds the length of the vector, values are repeated. While using a binomial or poisson distribution, level indicates an increase in points / counts with the onset of the B-phase.
slope Defines the increase in scores - starting with phase B - expressed as effect size d per MT. slope = .1 generates an incremental increase of 0.1 standard deviations per MT for all phase B measurements. To assign different slope effects to several single-cases, use a vector of values (e.g. slope = c(.1, .2, .3)). If the number of cases exceeds the length of the vector, values are repeated. While using a binomial or poisson distribution, d.slope indicates an increase in points / counts per MT.
**rtt**  Reliability of the underlying simulated measurements. Set rtt = .8 by default. To assign different reliabilities to several single-cases, use a vector of values (e.g. \( rtt = c(0.6, 0.7, 0.8) \)). If the number of cases exceeds the length of the vector, values are repeated. rtt has no effect when you're using binomial or poisson distributed scores.

**m**  Mean of the sample distribution the scores are drawn from. Default is \( m = 50 \). To assign different means to several single-cases, use a vector of values (e.g. \( m = c(50, 42, 56) \)). If the number of cases exceeds the length of the vector, values are repeated.

**s**  Standard deviation of the sample distribution the scores are drawn from. Set to \( s = 10 \) by default. To assign different variances to several single-cases, use a vector of values (e.g. \( s = c(5, 10, 15) \)). If the number of cases exceeds the length of the vector, values are repeated.

**extreme.p**  Probability of extreme values. extreme.p = .05 gives a five percent probability of an extreme value. A vector of values assigns different probabilities to multiple cases. If the number of cases exceeds the length of the vector, values are repeated.

**extreme.d**  Range for extreme values, expressed as effect size \( d \). extreme.d = c(-7, -6) uses extreme values within a range of -7 and -6 standard deviations. In case of a binomial or poisson distribution, extreme.d indicates points / counts. Caution: the first value must be smaller than the second, otherwise the procedure will fail.

**missing.p**  Portion of missing values. missing.p = .1 creates 10% of all values as missing. A vector of values assigns different probabilities to multiple cases. If the number of cases exceeds the length of the vector, values are repeated.

**distribution**  Distribution of the scores. Default is distribution = "normal". Possible values are "normal", "binomial", and "poisson". If set to "normal", the sample of scores will be normally distributed with the parameters \( m \) and \( s \) as mean and standard deviation of the sample, including a measurement error defined by rtt. If set to "binomial", data are drawn from a binomial distribution with the expectation value \( m \). This setting is useful for generating criterial data like correct answers in a test. If set to "poisson", data are drawn from a poisson distribution, which is very common for count-data like behavioral observations. There's no measurement error is included. \( m \) defines the expectation value of the poisson distribution, lambda.

**prob**  If distribution (see below) is set "binomial", prob passes the probability of occurrence.

**MT**  Number of measurements (in each study). Default is \( MT = 20 \).

**B.start**  Phase B starting point. The default setting B.start = 6 would assign the first five scores (of each case) to phase A, and all following scores to phase B. To assign different starting points for a set of multiple single-cases, use a vector of starting values (e.g. B.start = c(6, 7, 8)). If the number of cases exceeds the length of the vector, values will be repeated.

**Value**

A single-case data frame. See scdf to learn about this format.
Examples

```r
## Create random single-case data and inspect it
design <- design_rSC(
  n = 3, rtt = 0.75, slope = 0.1, extreme.p = 0.1,
  missing.p = 0.1
)
dat <- rSC(design, round = 1, random.names = TRUE, seed = 123)
describeSC(dat)
plotSC(dat)

## And now have a look at poisson-distributed data
design <- design_rSC(
  n = 3, B.start = c(6, 10, 14), MT = c(12, 20, 22), m = 10,
  distribution = "poisson", level = -5, missing.p = 0.1
)
dat <- rSC(design, seed = 1234)
pand(dat, decreasing = TRUE, correction = FALSE)
```

**Description**

The `randSC` function computes a randomization test for single or multiple baseline single-case data. The function is based on an algorithm from the SCRT package (Bulte & Onghena, 2009, 2012), but rewritten and extended for the use in AB designs.

**Usage**

```r
rand_test(  
data, 
dvar, 
pvar, 
statistic = "Mean B-A", 
number = 500, 
complete = FALSE, 
limit = 5, 
startpoints = NA, 
exclude.equal = FALSE, 
graph = FALSE, 
output = "c", 
phases = c("A", "B"), 
seed = NULL
)
```
Arguments

- **data**: A single-case data frame. See `scdf` to learn about this format.
- **dvar**: Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
- **pvar**: Character string with the name of the phase variable. Defaults to the attributes in the scdf file.
- **statistic**: Defines the statistic on which the comparison of phases A and B is based on. Default setting is `statistic = "Mean B-A"`). The following comparisons are possible:
  - "Mean A-B": Uses the difference between the mean of phase A and the mean of phase B. This is appropriate if a decrease of scores was expected for phase B.
  - "Mean B-A": Uses the difference between the mean of phase B and the mean of phase A. This is appropriate if an increase of scores was expected for phase B.
  - "Mean |A-B|": Uses the absolute value of the difference between the means of phases A and B.
  - "Median A-B": The same as "Mean A-B", but based on the median.
  - "Median B-A": The same as "Mean B-A", but based on the median.
- **number**: Sample size of the randomization distribution. The exactness of the p-value can not exceed $1/\text{number}$ (i.e., `number = 100` results in p-values with an exactness of one percent). Default is `number = 500`. For faster processing use `number = 100`. For more precise p-values set `number = 1000`.
- **complete**: If `TRUE`, the distribution is based on a complete permutation of all possible starting combinations. This setting overwrites the `number` Argument. The default setting is `FALSE`.
- **limit**: Minimal number of data points per phase in the sample. The first number refers to the A-phase and the second to the B-phase (e.g., `limit = c(5, 3)`). If only one number is given, this number is applied to both phases. Default is `limit = 5`.
- **startpoints**: Alternative to the `limit`-parameter `startpoints` exactly defines the possible start points of phase B (e.g., `startpoints = 4:9` restricts the phase B start points to measurements 4 to 9. `startpoints` overruns the `limit`-parameter.
- **exclude.equal**: If set to `exclude.equal = FALSE`, which is the default, random distribution values equal to the observed distribution are counted as null-hypothesis conform. That is, they decrease the probability of rejecting the null-hypothesis (increase the p-value). `exclude.equal` should be set to `TRUE` if you analyse one single-case design (not a multiple baseline data set) to reach a sufficient power. But be aware, that it increases the chance of an alpha-error.
graph  If graph = TRUE, a histogram of the resulting distribution is plotted. It's FALSE by default.
output  If set to the default output = "C", detailed information is provided. Set output = "p", to only return the resulting p value.
phases  A vector of two characters or numbers indicating the two phases that should be compared. E.g., phases = c("A", "C") or phases = c(2, 4) for comparing the second and the fourth phase. Phases could be combined by providing a list with two elements. E.g., phases = list(A = c(1, 3), B = c(2, 4)) will compare phases 1 and 3 (as A) against 2 and 4 (as B). Default is phases = c("A", "B").
seed  A seed number for the random generator.
...  Further arguments passed to the function.

Value

statistic  Character string from function call (see Arguments above).
N  Number of single-cases.
n1  Number of data points in phase A.
n2  Number of data points in phase B.
limit  Numeric from function call (see Arguments above).
startpoints  A vector defining the start points passed from the function call (see Arguments above).
p.value  P-value of the randomization test for the given data.
number  Sample size of randomization distribution from function call (see Arguments above).
complete  Logical argument from function call (see Arguments above).
observed.statistic  Test statistic observed for the given single-case data. (see statistic in the Arguments above.)
Z  Z-value of observed test statistic.
p.z.single  Probability of z-value.
distribution  Test statistic distribution from randomized data sets.
possible.combinations  Number of possible combinations under the given restrictions.
auto.corrected.number  TRUE indicates that a corrected number of combinations was used. This happens, if the number of possible combinations (under the given restrictions) undercuts the requested number of combinations.

rand_test(byHeart2011[1], statistic = "Median B-A", graph = TRUE, seed = 123)

## Compute a randomization test on the Grosche2011 data using complete permutation
rand_test(Grosche2011, statistic = "Median B-A", complete = TRUE, limit = 4, seed = 123)
```

ranks

Rank-transformation of single-case data files

Description

Rank-transformation of single-case data files

Usage

```r
ranks(data, var, grand = TRUE, ...)

rankSC(...)
```

Arguments

- `data`: A single-case data frame. See `scdf` to learn about this format.
- `var`: A string or string vector with the names of the variables to be ranked.
- `grand`: If TRUE, ranks will be calculated across all cases. If FALSE ranks are calculated within each case.
- `...`: Additional parameters passed to the `rank` function.

Value

An `scdf` object where the values of the variable(s) are replaced with ranks.

Author(s)

Juergen Wilbert

**rci**  
*Reliable change index*

Description

**CAUTION! This function is still under development and not ready for use!** The `rciSC` function computes three indices of reliable change (Wise, 2004) and corresponding descriptive statistics.

Usage

```r
rci(data, dvar, pvar, rel, ci = 0.95, graph = FALSE, phases = c(1, 2))
rciSC(...)
rCi(...)
```

Arguments

- **data**  
  A single-case data frame. See `scdf` to learn about this format.

- **dvar**  
  Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.

- **pvar**  
  Character string with the name of the phase variable. Defaults to the attributes in the scdf file.

- **rel**  
  Reliability of the measure, used to compute the standard error.

- **ci**  
  Width of confidence interval as a decimal. Default is `ci = 0.95` applying a 95% confidence interval.

- **graph**  
  If set `TRUE`, a box plot of phase A and B scores is displayed. `graph = FALSE` by default.

- **phases**  
  A vector of two characters or numbers indicating the two phases that should be compared. E.g., `phases = c("A","C")` or `phases = c(2,4)` for comparing the second to the fourth phase. Phases could be combined by providing a list with two elements. E.g., `phases = list(A = c(1,3), B = c(2,4))` will compare phases 1 and 3 (as A) against 2 and 4 (as B). Default is `phases = c("A","B")`.

- **...**  
  Further arguments passed to the function.

**readSC**

*Read single-case data from files*

**Description**
Use the `readSC` function to import single-case data from structured .csv or the `readSC.excel` function for importing excel files.

**Usage**
```
readSC(
  filename = NULL,
  data = NULL,
  sep = ",",
  dec = ",.",
  sort.labels = FALSE,
  cvar = "case",
  pvar = "phase",
  dvar = "values",
  mvar = "mt",
  phase.names = NULL,
  type = "csv",
  ...
```

readSC.excel(...)

Arguments

filename A character string defining the file to be imported (e.g. "SC_Anita.csv"). If filename is left empty a dialog box for choosing will be opened.
data A data frame. As an alternative to filename a dataframe could be directly provided.
sep The field separator string. Values within rows have to be separated by this string. Default is sep = ",".
dec The string used for decimal points in the file. Must be a single character. Default is dec = ".".
sort.labels If set TRUE, the resulting list is sorted by label names (alphabetically increasing).
cvar Sets the variable name of the "case" variable. Defaults to "case".
pvar Sets the variable name of the "phase" variable. Defaults to "phase".
dvar Sets the variable name of the "values" variable. Defaults to "values".
mvar Sets the variable name of the "mt" variable. Defaults to "mt".
phase.names A character vector with phase names. Defaults to the phase names provided in the phase variable.
type Format of the file to be imported. Either "csv" or "excel" is possible.
... Further arguments passed to the read.table command.

Value

Returns a single-case data frame. See scdf to learn about the format of these data frames.

---

### scdf_attr

**Set and get scdf attributes**

**Description**

Set and get scdf attributes

**Usage**

scdf_attr(x, var)

scdf_attr(x, var) <- value

**Arguments**

- **x**: Variable
- **var**: Attribute
- **value**: set value

**Value**

Attribute value

---

### select_cases

**Select a subset of cases**

**Description**

Select a subset of cases

**Usage**

select_cases(scdf, ...)

**Arguments**

- **scdf**: A single-case data frame. See `scdf` to learn about this format.
- **...**: Selection criteria. Either numeric or as characters.
Value

An scdf with a subset of cases

Examples

```r
select_cases(exampleAB, "Johanna", "Karolina")
# or: select_cases(exampleAB, c("Johanna", "Karolina"))
select_cases(exampleAB, 1:2)
# or: select_cases(exampleAB, 1:2)
select_cases(exampleAB, "-Johanna")
# or: select_cases(exampleAB, c("-Johanna", "-Karolina"))
```

### Shift values in a single-case data file

Description

Shifting the values might be helpful in cases where the measurement time is given as a time variable (see example below).

Usage

```r
shift(data, value, var)
shiftSC(...)
```

Arguments

- `data`: A single-case data frame. See `scdf` to learn about this format.
- `value`: Number by which to shift the values
- `var`: Character string with the name of the target variable. Defaults to the measurement time variable.
- `...`: Further arguments passed to the function.

Value

A scdf with shifted data

See Also

Other data manipulation functions: `fill_missing()`, `longSCDF()`, `outlier()`, `ranks()`, `smooth_cases()`, `standardize()`, `truncate_phase()`

Examples

```r
### Shift the measurement time for a better estimation of the intercept
ex <- shift(example_A24, value = -1996)
plm(ex)
```
smooth_cases  

Smoothing single-case data

Description

The smooth_cases function provides procedures to smooth single-case data (i.e., to eliminate noise). A moving average function (mean- or median-based) replaces each data point by the average of the surrounding data points step-by-step. With a local regression function, each data point is regressed by its surrounding data points.

Usage

smooth_cases(data, dvar, mvar, FUN = "movingMedian", intensity = NULL)

smoothSC(...)

Arguments

data  A single-case data frame. See scdf to learn about this format.
dvar  Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
mvar  Character string with the name of the measurement time variable. Defaults to the attributes in the scdf file.
FUN  Function determining the smoothed scores. Default FUN = "movingMedian" is a moving Median function. Further possible values are: "movingMean" and a non-parametric "localRegression".
intensity  For FUN = "movingMedian" and "movingMean" it is the lag used for computing the average. Default is intensity = 1. In case of FUN = "localRegression" it is the proportion of surrounding data influencing each data point, which is intensity = 0.2 by default.
...  Further arguments passed to the function.

Value

Returns a data frame (for each single-case) with smoothed data points. See scdf to learn about the format of these data frames.

Author(s)

Juergen Wilbert

See Also

Other data manipulation functions: fill_missing(), longSCDF(), outlier(), ranks(), shift(), standardize(), truncate_phase()
### Examples

```r
## Use the three different smoothing functions and compare the results
study <- c(
  "Original" = Huber2014$Berta,
  "Moving Median" = smooth_cases(Huber2014$Berta, FUN = "movingMedian"),
  "Moving Mean" = smooth_cases(Huber2014$Berta, FUN = "movingMean"),
  "Local Regression" = smooth_cases(Huber2014$Berta, FUN = "localRegression")
)
plot(study)
```

---

**standardize**

*Standardize values of an scdf file*

#### Description

This function scales the measured values of an scdf file. It allows for mean centering and standardization based on each single-case data set or a scaling across all cases included in an scdf.

#### Usage

```r
standardize(
  data,        
  var,         
  center = TRUE, 
  scale = FALSE, 
  m = 0,       
  sd = 1,      
  grand = TRUE 
)
```

#### Arguments

- **data**: A single-case data frame. See `scdf` to learn about this format.
- **var**: A character string or a vector of character strings with variable names that should be scaled.
- **center**: If set `TRUE`, data are mean centered.
- **scale**: If set `TRUE`, the standard deviation is set.
- **m**: The target mean for centering.
- **sd**: The target standard deviation for scaling
- **grand**: If set `TRUE`, scaling is based on the mean and standard deviation of all measurements across all single-cases within the scdf.

#### Value

An scdf with the scaled values.
The `style_plot` function is used to create graphical styles for a single-case plot.

**Usage**

```r
style_plot(style = "default", ...)  
style_plotSC(...)  
style.plotSC(...)  
```

**Arguments**

- `style` Predefined styles.
- `...` Further arguments passed to the plot command.

**Details**

`style_plot("")` will return a list of predefined styles. Predefined styles can be combined with `style_plot(style = c("grid2","tiny"))` where settings of a latter style overwrite settings of the former. Additional style parameters are set following the style argument and can be combined with those: `style_plot(style = "grid2",fill = "grey50",pch = 18)`.

```r
## Standardize a multiple case scdf and compute an hplm
ex_sc <- standardize(exampleAB_50, var = "values", center = TRUE, scale = TRUE)
hplm(ex_sc)
```
Value

Returns a list to be provided or the style argument of the plot function.

- **fill** If set, the area under the line is filled with the given color (e.g., \texttt{fill = "tomato"}). Use the standard R command \texttt{colors()} to get a list of all possible colours. 
- **fill** is empty by default.
- **annotations** A list of parameters defining annotations to each data point. This adds the score of each MT to your plot.
  - "pos" Position of the annotations: 1 = below, 2 = left, 3 = above, 4 = right.
  - "col" Color of the annotations.
  - "cex" Size of the annotations.
  - "round" Rounds the values to the specified decimal.
- **annotations** = \texttt{list(pos = 3, col = "brown", round = 1)} adds scores rounded to one decimal above the data point in brown color to the plot.
- **"lwd"** Width of the plot line. Default is \texttt{lwd = 2}.
- **"pch"** Point type. Default is \texttt{pch = 17} (triangles). Other options are for example: 16 (filled circles) or "A" (uses the letter A).
- **"main"** Main title of the plot.
- **"mai"** Sets the margins of the plot.
- **"bty"** Shape of the frame surrounding the inner plot
- **"fill.bg"** Backgroundcolor of the plot.
- **"grid"** Color of a grid.
- **"text.ABlag"** Text displayed between phases.
- **"cex.axis"** Size of the axis annotations
- **"las"** Orientation of the axis annotations
- **"col.lines"** Color of the lines
- **"col.dots"** Color of the dots
- **"col.separator"** Color of the phase seperating lines
- **"col.bg"** Color of the outer plot
- **"col"** General color setting for the plot
- **"col.text"** Color of all labels of the plot.

See Also

\texttt{plot.scdf}
Examples

```r
newstyle <- style_plot(style = "default")
newstyle$text.ABlag <- c("START","END")
newstyle$col.dots <- ""
newstyle$annotations <- list(cex = 0.6, col = "grey10", offset = 0.4)
plot(exampleABC, style = newstyle)
```

subset.scdf  Subset cases, rows, and variables

Description

Subset cases, rows, and variables

Usage

```r
## S3 method for class 'scdf'
subset(x, subset, select, cases, ...)
```

Arguments

- `x`  
  An scdf object.
- `subset`  
  Logical expression indicating rows to keep: missing values are taken as false.
- `select`  
  Expression, indicating columns to select from an scdf.
- `cases`  
  Expression, indicating cases to keep from an scdf.
- `...`  
  [use not implemented yet]

Value

An scdf with cases filtered by the filter expression.

Examples

```rsubset(exampleAB, (values < 60 & phase == "A") | (values >= 60 & phase == "B"))
subset(exampleAB_add, select = c(-cigarrrets, -depression))
subset(exampleAB, cases = c(Karolina, Johanna))
subset(exampleA1B1A2B2, phase %in% c("A1", "B2"), cases = Pawel:Moritz)
```
### summary.scdf

**Summary function for a scdf**

#### Description

Summary function for a scdf

#### Usage

```r
## S3 method for class 'scdf'
summary(object, ...)
```

#### Arguments

- `object`: scdf
- `...`: not in use

### tau_u

**Tau-U for single-case data**

#### Description

This function calculates indices of the Tau-U family as proposed by Parker et al. (2011).

#### Usage

```r
tau_u(  
  data,  
  dvar,  
  pvar,  
  tau_method = "b",  
  method = "complete",  
  phases = c(1, 2),  
  fisher = TRUE,  
  continuity_correction = FALSE  
)

tauUSC(...)  
```
Arguments

data A single-case data frame. See `scdf` to learn about this format.
dvar Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
pvar Character string with the name of the phase variable. Defaults to the attributes in the scdf file.
tau_method Character with values "a" or "b" (default) indicating whether Kendall Tau A or Kendall Tau B is applied.
method "complete" (default) or "parker". The latter calculates the number of possible pairs as described in Parker et al. (2011) which might lead to tau-U values greater than 1.
phases A vector of two characters or numbers indicating the two phases that should be compared. E.g., phases = c("A", "C") or phases = c(2,4) for comparing the second to the fourth phase. Phases could be combined by providing a list with two elements. E.g., phases = list(A = c(1,3),B = c(2,4)) will compare phases 1 and 3 (as A) against 2 and 4 (as B). Default is phases = c("A", "B").
fisher If TRUE, meta analyses of Tau U is based on Fisher Z transformed correlations.
continuity_correction If TRUE, a continuity correction is applied for calculating p-values of correlations. This parameter is not yet implemented.
...
Further arguments passed to the function.

Details

Tau-U is an inconsistently operationalized construct.

Value

table A data frame containing statistics from the Tau-U family, including: Pairs, positive and negative comparisons, S, and Tau
matrix The matrix of comparisons used for calculating the statistics.
tau_u Tau-U value.

Examples

```r
## Calculate tau-U for the example from Parker et al. (2011)
bob <- scdf(c(A = 2, 3, 5, 3, B = 4, 5, 5, 7, 6), name = "Bob")
tau_u(bob)

## Calculate tau-U based on Kendall Tau A
tau_u(Grosche2011$Eva, tau_method = "a")

## Request tau-U for all single-cases from the Grosche2011 data
tau_u(Grosche2011)
```

---

**trend**

*Trend analysis for single-cases data*

Description

The `trendSC` function provides an overview of linear trends in single-case data. By default, it gives you the intercept and slope of a linear and a squared regression of measurement-time on scores. Models are computed separately for each phase and across all phases. For a more advanced application, you can add regression models using the R specific formula class.

Usage

```r
trend(data, dvar, pvar, mvar, offset = -1, model = NULL)
trendSC(...)```

Arguments

- **data**: A single-case data frame. See `scdf` to learn about this format.
- **dvar**: Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
- **pvar**: Character string with the name of the phase variable. Defaults to the attributes in the scdf file.
- **mvar**: Character string with the name of the measurement time variable. Defaults to the attributes in the scdf file.
- **offset**: An offset for the first measurement-time of each phase (MT). If set `offset = 0`, the phase measurement is handled as MT 1. Default is `offset = -1`, setting the first value of MT to 0.
- **model**: A string or a list of (named) strings each depicting one regression model. This is a formula expression of the standard R class. The parameters of the model are `values`, `mt` and `phase`.
- **...**: Further arguments passed to the function.
**truncation_phase**

**Value**
- **trend**: A matrix containing the results (Intercept, B and beta) of separate regression models for phase A, phase B, and the whole data.
- **offset**: Numeric argument from function call (see Arguments section).

**Author(s)**
Juergen Wilbert

**See Also**
descibeSC, autocorrSC, plm

**Examples**

```r
## Compute the linear and squared regression for a random single-case design <- design_rSC(slope = 0.5) matthea <- rSC(design) trendSC(matthea)

## Besides the linear and squared regression models compute two custom models: ## a) a cubic model, and b) the values predicted by the natural logarithm of the measurement time. design <- design_rSC(slope = 0.3) ben <- rSC(design) trend(ben, offset = 0, model = c("Cubic" = values ~ I(mt^3), "Log Time" = values ~ log(mt)))
```

**DESCRIPTION**

This function truncates data points at the beginning and / or end each phase.

**Usage**

```r
truncation_phase(
  data,
  dvar, 
  pvar, 
  truncate = list(A = c(0, 0), B = c(0, 0)), 
  na = TRUE 
)
```

truncationSC(...)
Arguments

data  A single-case data frame. See scdf to learn about this format.
dvar  Character string with the name of the dependent variable. Defaults to the attributes in the scdf file.
pvar  Character string with the name of the phase variable. Defaults to the attributes in the scdf file.
truncate  A list with a vector of two (beginning and end) values for each phase defining the number of data points to be deleted. For lists of single-case data frames, the truncation is adapted to the length of each phase for each single case.
na  If FALSE, the truncated measurement times are deleted. If TRUE, NAs are set for the dependent variable.
...  Further arguments passed to the function.

Value

A truncated data frame (for each single-case).

Author(s)

Juergen Wilbert

See Also

Other data manipulation functions: fill_missing(), longSCDF(), outlier(), ranks(), shift(), smooth_cases(), standardize()

Examples

# Truncate the first two data points of both phases and compare the two data sets
study <- c(
  "Original" = byHeart2011[1],
  "Selected" = truncate_phase(byHeart2011[1], truncate = list(A = c(2, 0), B = c(2, 0)))
)
plot(study)

writeSC  Export data into a .csv-file

Description

This function restructures and exports single-case data into a .csv-file.

Usage

writeSC(data, filename = NULL, sep = "", dec = ".", ...)
Arguments

data  A single-case data frame. See `scdf` to learn about this format.
filename  A character string defining the output file name (e.g. "SC_data.csv").
sep  The field separator string. Values within rows will be separated by this string. Default is `sep = ",",`.
dec  The string used for decimal points. Must be a single character. Default is `dec = "."`.
...  Further arguments passed to `write.table`.
