Package ‘scrutiny’

February 24, 2024

Title Error Detection in Science

Version 0.4.0

Maintainer Lukas Jung <jung-lukas@gmx.net>

Description Test published summary statistics for consistency
(Brown and Heathers, 2017, <doi:10.1177/1948550616673876>);
analytic-grimmer-possibility-standard-deviations/>;
The package also provides infrastructure for implementing new
error detection techniques.

Index 102
audit

**Summarize scrutiny objects**

**Description**

audit() summarizes the results of scrutiny functions like grim_map() that perform tests on data frames.

See below for a record of such functions. Go to the documentation of any of them to learn about its audit() method.

**Usage**

audit(data)

**Arguments**

data

A data frame that inherits one of the classes named below.

**Details**

audit() is an S3 generic. It looks up the (invisible) scrutiny class of a tibble returned by any function named below. You don’t need to deal with the classes directly. Behind the scenes, they mediate between these functions and their associated summary statistics.

**Value**

A tibble (data frame) with test summary statistics.

**Run before audit()**

<table>
<thead>
<tr>
<th>Function</th>
<th>Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>grim_map()</td>

<td>&quot;scr_audit_seq&quot;</td>
</tr>
<tr>
<td>audit_total_n()</td>
<td>&quot;scr_audit_total_n&quot;</td>
</tr>
</tbody>
</table>

**Examples**

# For basic GRIM-testing:
pigs1 %>%
grim_map() %>%
audit()

# For duplicate detection:
pigs4 %>%
duplicate_count() %>%
audit()

---

**Description**

audit_seq() and audit_total_n() summarize the results of functions that end on _seq and _total_n, respectively.

See below for a record of such functions. Go to the documentation of any of them to learn about the way its output is processed by audit_seq() or audit_total_n().

**Usage**

audit_seq(data)

audit_total_n(data)

**Arguments**

data A data frame that inherits one of the classes named below.

**Details**

All functions named below that end on _seq were made by function_map_seq(). All that end on _total_n were made by function_map_total_n().

**Value**

A tibble (data frame) with test summary statistics.

**Before audit_seq()**

<table>
<thead>
<tr>
<th>Function</th>
<th>Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>grim_map_seq()</td>
<td>&quot;scr_grim_map_seq&quot;</td>
</tr>
<tr>
<td>grimmer_map_seq()</td>
<td>&quot;scr_grimmer_map_seq&quot;</td>
</tr>
<tr>
<td>debit_map_seq()</td>
<td>&quot;scr_debit_map_seq&quot;</td>
</tr>
</tbody>
</table>
Before audit_total_n()

Function | Class
---|---
grim_map_total_n() | "scr_grim_map_total_n"
grimmer_map_total_n() | "scr_grimmer_map_total_n"
debit_map_total_n() | "scr_debit_map_total_n"

Examples

# For GRIM-testing with dispersed inputs:
out <- pigs1 %>%
grim_map_seq() %>%
audit_seq()
out

# Follow up on `audit_seq()` or
# `audit_total_n()` with `audit()`:
audit(out)

audit_cols_minimal | Compute minimal audit() summaries

Description

Call audit_cols_minimal() within your audit() methods for the output of consistency test mapper functions such as grim_map(). It will create a tibble with the three minimal, required columns:

1. incons_cases counts the inconsistent cases, i.e., the number of rows in the mapper’s output where "consistency" is FALSE.
2. all_cases is the total number of rows in the mapper’s output.
3. incons_rate is the ratio of incons_cases to all_cases.

You can still add other columns to this tibble. Either way, make sure to name your method correctly.

See examples.

Usage

audit_cols_minimal(data, name_test)

Arguments

data | Data frame returned by a mapper function, such as grim_map().
name_test | String (length 1). Short, plain-text name of the consistency test, such as "GRIM". Only needed for a potential alert.
check_audit_special

Value

A tibble (data frame) with the columns listed above.

See Also

For context, see vignette("consistency-tests-in-depth"). In case you don’t call audit_cols_minimal(), you should call check_audit_special().

Examples

# For a mapper function called `schlim_map`
# that applies a test called SCHLIM and returns
# a data frame with the `"scr_schlim_map"` class:
audit.scr_schlim_map <- function(data) {
  audit_cols_minimal(data, name_test = "SCHLIM")
}

# If you like, add other summary columns
# with `dplyr::mutate()` or similar.

check_audit_special Alert user if more specific audit_*() summaries are available

Description

(Note: Ignore this function if your audit() method calls audit_cols_minimal().)
Call check_audit_special() within an audit() method for a consistency test mapper function, such as audit.scr_grim_map(). It checks if the input data frame was the product of a function produced by function_map_seq() or function_map_total_n().
If so, the function issues a gentle alert to the user that points to audit_seq() or audit_total_n(), respectively.

Usage

check_audit_special(data, name_test)

Arguments

data The audit() method’s input data frame.
name_test String (length 1). Short, plain-text name of the consistency test, such as "GRIM".

Value

No return value. Might print an alert.

See Also

vignette("consistency-tests-in-depth"), for context.
check_mapper_input_colnames

Check that a mapper's input has correct column names

Description

When called within a consistency test mapper function, check_mapper_input_colnames() makes sure that the input data frame has correct column names:

- They include all the key columns corresponding to the test applied by the mapper.
- They don’t already include "consistency".

If either check fails, the function throws an informative error.

Usage

check_mapper_input_colnames(data, reported, name_test)

Arguments

data: Data frame. Input to the mapper function.
reported: String vector of the "key" column names that data must have, such as c("x", "n") for grim_map().
name_test: String (length 1). Short, plain-text name of the consistency test that the mapper function applies, such as "GRIM".

Value

No return value. Might throw an error.

See Also

vignette("consistency-tests-in-depth"), for context and the "key columns" terminology.
Description

- `is_map_df()` tests whether an object is the output of a scrutiny-style mapper function for consistency tests, like `grim_map()`. These mapper functions also include those produced by `function_map()`, `function_map_seq()`, and `function_map_total_n()`.
- `is_map_basic_df()` is a variant of `is_map_df()` that tests whether an object is the output of a "basic" mapper function. This includes functions like `grim_map()` and those produced by `function_map()`, but not those produced by `function_map_seq()` or `function_map_total_n()`.
- `is_map_seq_df()` tests whether an object is the output of a function that was produced by `function_map_seq()`.
- `is_map_total_n_df()` tests whether an object is the output of a function that was produced by `function_map_total_n()`.

Usage

```r
is_map_df(x)

is_map_basic_df(x)

is_map_seq_df(x)

is_map_total_n_df(x)
```

Arguments

- `x` Object to be tested.

Details

Sections 3, 6, and 7 of vignette("consistency-tests-in-depth") discuss which function factories produce which functions, and which of these new, factory-made functions return which kinds of tibbles.

These tibbles are what the `is_map_()` functions test for. As an example, `function_map_seq()` produces `grim_map_seq()`, and this new function returns a tibble. `is_map_df()` and `is_map_seq_df()` return TRUE for this tibble, but `is_map_basic_df()` and `is_map_total_n_df()` return FALSE.

For an overview, see the table at the end of vignette("consistency-tests-in-depth").

Value

Logical (length 1).

Examples

```r
# Example test output:
df1 <- grim_map(pigs1)
df2 <- grim_map_seq(pigs1)
df3 <- grim_map_total_n(tibble::tribble(
  ~x1,  ~x2,  ~n,
  "3.43", "5.28", 90,

```
The DEBIT (descriptive binary) test

Description

debit() tests summaries of binary data for consistency: If the mean and the standard deviation of binary data are given, are they consistent with the reported sample size?

The function is vectorized, but it is recommended to use debit_map() for testing multiple cases.

Usage

debit(
  x,
  sd,
  n,
  formula = "mean_n",
  rounding = "up_or_down",
  threshold = 5,
  symmetric = FALSE
)
debit_map

Arguments

x  String. Mean of a binary distribution.

sd  String. Sample standard deviation of a binary distribution.

n  Integer. Total sample size.

formula  String. Formula used to compute the SD of the binary distribution. Currently, only the default, "mean_n", is supported.

rounding  String. Rounding method or methods to be used for reconstructing the SD values to which sd will be compared. Default is "up_or_down" (from 5). See vignette("rounding-options").

threshold  Integer. If rounding is set to "up_from", "down_from", or "up_from_or_down_from", set threshold to the number from which the reconstructed values should then be rounded up or down. Otherwise irrelevant. Default is 5.

symmetric  Logical. Set symmetric to TRUE if the rounding of negative numbers with "up", "down", "up_from", or "down_from" should mirror that of positive numbers so that their absolute values are always equal. Default is FALSE.

Value

Logical. TRUE if x, sd, and n are mutually consistent, FALSE if not.

References

See Also

debit_map() applies debit() to any number of cases at once.

Examples

# Check single cases of binary
# summary data:
debit(x = "0.36", sd = "0.11", n = 20)

# debi_map() applies debit() to any number of cases at once.

Description

Call debit_map() to use DEBIT on multiple combinations of mean, standard deviation, and sample size of binary distributions. Mapping function for debit().

For summary statistics, call audit() on the results.
Usage

debit_map(
    data,
    x = NULL,
    sd = NULL,
    n = NULL,
    rounding = "up_or_down",
    threshold = 5,
    symmetric = FALSE,
    show_rec = TRUE,
    extra = Inf
)

Arguments

data               Data frame.
x, sd, n            Optionally, specify these arguments as column names in data.
rounding, threshold, symmetric
    Arguments passed on to debit(), with the same defaults.
show_rec            If set to FALSE, the resulting tibble only includes the columns x, sd, n, and consistency. Default is TRUE.
extra                Not currently used.

Value

A tibble with (at least) these columns –

- x, sd, n: the inputs.
- consistency: DEBIT consistency of x, sd, and n.

By default, the tibble also includes the rounding method, boundary values, and information about the boundary values being inclusive or not. The tibble has the scr_debit_map class, which is recognized by the audit() generic.

Summaries with audit()

There is an S3 method for the audit() generic, so you can call audit() following debit_map(). It returns a tibble with these columns —

1. incon_cases: the number of DEBIT-inconsistent cases.
2. all_cases: the total number of cases.
3. incons_rate: the rate of inconsistent cases.
4. mean_x: the mean x (mean) value.
5. mean_sd: the mean sd value.
6. distinct_n: the number of distinct n values.
References

Examples

# Call `debit_map()` on binary summary
# data such as these:
pigs3

# The `consistency` column shows
# whether the values to its left
# are DEBIT-consistent:
pigs3 %>%
  debit_map()

# Get test summaries with `audit()`:
pigs3 %>%
  debit_map() %>%
  audit()

---

deb\texttt{i}t\texttt{m}_{a\texttt{p}}\texttt{e}_{\texttt{s}} \texttt{c}_\texttt{q}_{\texttt{e}} \texttt{n}_\texttt{t} \texttt{s} \texttt{e}_\texttt{q} \texttt{u}_\texttt{n}_{\texttt{g}} \texttt{D}\texttt{E}\texttt{B}\texttt{I}\texttt{T} \texttt{w}_{\texttt{i}} \texttt{t}_{\texttt{h}} \texttt{h}_{\texttt{e}} \texttt{d} \texttt{D}_{\texttt{E}}\texttt{B}\texttt{I}\texttt{T} \texttt{w}_{\texttt{i}} \texttt{t} \texttt{d} \texttt{e} \texttt{r} \texttt{s}_{\texttt{i}} \texttt{p}_{\texttt{s}_{\texttt{e}}}{\texttt{d}} \texttt{r} \texttt{i}_{\texttt{s}_{\texttt{p}}} \texttt{e}_{\texttt{s}} {\texttt{e}}_{\texttt{n}_{\texttt{p}}} \texttt{s} \texttt{e}_{\texttt{q}} \texttt{u}_{\texttt{n}}\texttt{t} \texttt{s}_{\texttt{s}} \texttt{e}_{\texttt{q}} \texttt{u}_{\texttt{n}}\texttt{s}

Description

debit_map_seq() applies DEBIT with values surrounding the input values. This provides an easy and powerful way to assess whether small errors in computing or reporting may be responsible for DEBIT inconsistencies in published statistics.

Usage

debit_map_seq(
  data,
  x = NULL,
  sd = NULL,
  n = NULL,
  var = Inf,
  dispersion = 1:5,
  out_min = "auto",
  out_max = NULL,
  include_reported = FALSE,
  include_consistent = FALSE,
  ...
)

Arguments

- **data**: A data frame that `debit_map()` could take.
- **x, sd, n**: Optionally, specify column names in `data` as these arguments.
- **var**: String. Names of the columns that will be dispersed. Default is `c("x", "sd", "n")`.
- **dispersion**: Numeric. Sequence with steps up and down from the `var` inputs. It will be adjusted to these values’ decimal levels. For example, with a reported 8.34, the step size is 0.01. Default is `1:5`, for five steps up and down.
- **out_min, out_max**: If specified, output will be restricted so that it’s not below `out_min` or above `out_max`. Defaults are "auto" for `out_min`, i.e., a minimum of one decimal unit above zero; and NULL for `out_max`, i.e., no maximum.
- **include_reported**: Logical. Should the reported values themselves be included in the sequences originating from them? Default is `FALSE` because this might be redundant and bias the results.
- **include_consistent**: Logical. Should the function also process consistent cases (from among those reported), not just inconsistent ones? Default is `FALSE` because the focus should be on clarifying inconsistencies.
- **...**: Arguments passed down to `debit_map()`.

Value

A tibble (data frame) with detailed test results.

Summaries with `audit_seq()`

You can call `audit_seq()` following `debit_map_seq()`. It will return a data frame with these columns:

- **x**, **sd**, and **n** are the original inputs, tested for consistency here.
- **hits_total** is the total number of DEBIT-consistent value sets found within the specified dispersion range.
- **hits_x** is the number of DEBIT-consistent value sets found by varying `x`.
- **hits_sd** and **hits_n** as well as **n** and **hits_n**.
- **Note that any consistent reported cases will be counted by the hits_* columns if both include_reported and include_consistent are set to TRUE.**
- **diff_x** reports the absolute difference between `x` and the next consistent dispersed value (in dispersion steps, not the actual numeric difference). **diff_x_up** and **diff_x_down** report the difference to the next higher or lower consistent value, respectively.
- **diff_sd**, **diff_sd_up**, and **diff_sd_down** do the same for `sd`.
- **Likewise with diff_n, diff_n_up, and diff_n_down.**

Call `audit()` following `audit_seq()` to summarize results even further. It’s mostly self-explaining, but **na_count** and **na_rate** are the number and rate of times that a difference could not be computed because of a lack of corresponding hits within the dispersion range.
**Examples**

```r
# 'debit_map_seq()' can take any input
# that 'debit_map()' can take:
pigs3

# Results from testing some few rows:
out <- pigs3 %>%
dplyr::slice(3:4) %>%
debit_map_seq()

out

# Case-wise summaries with 'audit_seq()'
# can be more important than the raw results:
out %>%
audit_seq()
```

---

**debit_map_total_n**  
*Use DEBIT with hypothetical group sizes*

---

**Description**

`debit_map_total_n()` extends DEBIT to cases where only group means and standard deviations (SDs) were reported, not group sizes.

The function is analogous to `grim_map_total_n()` and `grimmer_map_total_n()`, relying on the same infrastructure.

**Usage**

```r
debit_map_total_n(
  data,
  x1 = NULL,
  x2 = NULL,
  sd1 = NULL,
  sd2 = NULL,
  dispersion = 0:5,
  n_min = 1L,
  n_max = NULL,
  constant = NULL,
  constant_index = NULL,
  ...
)
```

**Arguments**

- **data**  
  Data frame with string columns `x1`, `x2`, `sd1`, and `sd2`, as well as numeric column `n`. The first two are reported group means. `sd1` and `sd2` are reported group SDs.
debit_map_total_n

\( n \) is the reported total sample size. It is not very important whether a value is in \( x_1 \) or in \( x_2 \) because, after the first round of tests, the function switches roles between \( x_1 \) and \( x_2 \), and reports the outcomes both ways. The same applies to \( sd_1 \) and \( sd_2 \). However, do make sure the \( x^* \) and \( sd^* \) values are paired accurately, as reported.

\( x_1, x_2, sd_1, sd_2 \)

- Optionally, specify these arguments as column names in data.
- dispersion Numeric. Steps up and down from half the \( n \) values. Default is \( 0:5 \), i.e., half \( n \) itself followed by five steps up and down.
- n_min Numeric. Minimal group size. Default is 1.
- n_max Numeric. Maximal group size. Default is \( \text{NULL} \), i.e., no maximum.
- constant Optionally, add a length-2 vector or a list of length-2 vectors (such as a data frame with exactly two rows) to accompany the pairs of dispersed values. Default is \( \text{NULL} \), i.e., no constant values.
- constant_index Integer (length 1). Index of constant or the first constant column in the output tibble. If \( \text{NULL} \) (the default), constant will go to the right of \( n \_change \).
- ... Arguments passed down to debit_map().

Value

A tibble with these columns:

- \( x \) and \( sd \), the group-wise reported input statistics, are repeated in row pairs.
- \( n \) is dispersed from half the input \( n \) with \( n \_change \) tracking the differences.
- both_consistent flags scenarios where both reported \( x \) and \( sd \) values are consistent with the hypothetical \( n \) values.
- case corresponds to the row numbers of the input data frame.
- dir is "forth" in the first half of rows and "back" in the second half. "forth" means that \( x_2 \) and \( sd_2 \) from the input are paired with the larger dispersed \( n \), whereas "back" means that \( x_1 \) and \( sd_1 \) are paired with the larger dispersed \( n \).
- Other columns from debit_map() are preserved.

Summaries with audit_total_n()

You can call audit_total_n() following up on debit_map_total_n() to get a tibble with summary statistics. It will have these columns:

- \( x_1, x_2, sd_1, sd_2, \) and \( n \) are the original inputs.
- hits_total is the number of scenarios in which all of \( x_1, x_2, sd_1, \) and \( sd_2 \) are DEBIT-consistent. It is the sum of hits_forth and hits_back below.
- hits_forth is the number of both-consistent cases that result from pairing \( x_2 \) and \( sd_2 \) with the larger dispersed \( n \) value.
- hits_back is the same, except \( x_1 \) and \( sd_1 \) are paired with the larger dispersed \( n \) value.
- scenarios_total is the total number of test scenarios, whether or not both \( x_1 \) and \( sd_1 \) as well as \( x_2 \) and \( sd_2 \) are DEBIT-consistent.
- hit_rate is the ratio of hits_total to scenarios_total.

Call audit() following audit_total_n() to summarize results even further.
References

See Also

`function_map_total_n()`, which created the present function using `debit_map()`.

Examples

```r
# Run `debit_map_total_n()` on data like these:

df <- tibble::tribble(
  ~x1, ~x2, ~sd1, ~sd2, ~n,
  "0.30", "0.28", "0.17", "0.10", 70,
  "0.41", "0.39", "0.09", "0.15", 65
)

debit_map_total_n(df)
```

---

**debit_plot**  
*Visualize DEBIT results*

Description

Plot a distribution of binary data and their mutual DEBIT consistency. Call this function only on a data frame that resulted from a call to `debit_map()`.

Various parameters of the individual geoms can be controlled via arguments.

Usage

```r
debit_plot(
  data,
  show_outer_boxes = TRUE,
  show_labels = TRUE,
  show_full_scale = TRUE,
  show_theme_other = TRUE,
  color_cons = "royalblue1",
  color_incons = "red",
  line_alpha = 1,
  line_color = "black",
  line_linetype = 1,
  line_width = 0.5,
  line_size = 0.5,
  rect_alpha = 1,
)```

debit_plot

```r
tile_alpha = 0.15,
tile_height_offset = 0.025,
tile_width_offset = 0.025,
tile_height_min = 0.0375,
tile_width_min = 0.0385,
label_alpha = 0.5,
label_linetype = 3,
label_size = 3.5,
label_linesize = 0.75,
label_force = 175,
label_force_pull = 0.75,
label_padding = 0.5
)
```

**Arguments**

- **data**
  Data frame. Result of a call to `debit_map()`.

- **show_outer_boxes**
  Logical. Should outer tiles surround the actual data points, making it easier to spot them and to assess their overlap? Default is `TRUE`.

- **show_labels**
  Logical. Should the data points have labels (of the form "mean; SD")? Default is `TRUE`.

- **show_full_scale**
  Logical. Should the plot be fixed to full scale, showing the entire consistency line independently of the data? Default is `TRUE`.

- **show_theme_other**
  Logical. Should the theme be modified in a way fitting the plot structure? Default is `TRUE`.

- **color_cons, color_incons**
  Strings. Colors of the geoms representing consistent and inconsistent values, respectively.

- **line_alpha, line_color, line_linetype, line_width, line_size**
  Parameters of the curved DEBIT line.

- **rect_alpha**
  Parameter of the DEBIT rectangles. (Due to the nature of the data mapping, there can be no leeway regarding the shape or size of this particular geom.)

- **tile_alpha, tile_height_offset, tile_width_offset, tile_height_min, tile_width_min**
  Parameters of the outer tiles surrounding the DEBIT rectangles. Offset refers to the distance from the rectangles within.

- **label_alpha, label_linetype, label_size, label_linesize, label_force, label_force_pull, label_padding**
  Parameters of the labels showing mean and SD values. Passed on to `ggrepel::geom_text_repel()`. See there for more information.

**Details**

The labels are created via `ggrepel::geom_text_repel()`, so the algorithm is designed to minimize overlap with the tiles and other labels. Yet, they don’t take the DEBIT line into account, and their locations are ultimately random. You might therefore have to resize the plot or run the function a few times until the labels are localized in a satisfactory way.
An alternative to the present function would be an S3 method for `ggplot2::autoplot()`. However, a standalone function such as this allows for customizing geom parameters and might perhaps provide better accessibility overall.

**Value**

A `ggplot` object.

**References**

**Examples**

```r
# Run `debit_plot()` on the output of `debit_map()`:
pigs3 %>%
  debit_map() %>%
  debit_plot()
```

---

## decimal_places

**Count decimal places**

**Description**

decimal_places() counts the decimal places in a numeric vector, or in a string vector that can be coerced to numeric.

decimal_places_scalar() is much faster but only takes a single input. It is useful as a helper within other single-case functions.

**Usage**

```r
decimal_places(x, sep = "\".")
decimal_places_scalar(x, sep = "\".")
```

**Arguments**

- `x` Numeric (or string that can be coerced to numeric). Object with decimal places to count.
- `sep` Substring that separates the mantissa from the integer part. Default is "\." which renders a decimal point.
Details

Decimal places in numeric values can’t be counted accurately if the number has 15 or more characters in total, including the integer part and the decimal point. A possible solutions is to enter the number as a string to count all digits. (Converting to string is not sufficient – those numbers need to be entered in quotes.)

The functions ignore any whitespace at the end of a string, so they won’t mistake spaces for decimal places.

Value

Integer. Number of decimal places in x.

Trailing zeros

If trailing zeros matter, don’t convert numeric values to strings: In numeric values, any trailing zeros have already been dropped, and any information about them was lost (e.g., 3.70 returns 3.7). Enter those values as strings instead, such as "3.70" instead of 3.70. However, you can restore lost trailing zeros with restore_zeros() if the original number of decimal places is known.

If you need to enter many such values as strings, consider using tibble::tribble() and drawing quotation marks around all values in a tribble() column at once via RStudio’s multiple cursors.

See Also

decimal_places_df(), which applies decimal_places() to all numeric-like columns in a data frame.

Examples

```r
# 'decimal_places()' works on both numeric values
# and strings...
decimal_places(x = 2.851)
decimal_places(x = "2.851")

# ... but trailing zeros are only counted within
# strings:
decimal_places(x = c(7.3900, "7.3900"))

# This doesn't apply to non-trailing zeros; these
# behave just like any other digit would:
decimal_places(x = c(4.08, "4.08"))

# Whitespace at the end of a string is not counted:
decimal_places(x = "6.0   ")

# 'decimal_places_scalar()' is much faster,
# but only works with a single number or string:
decimal_places_scalar(x = 8.13)
decimal_places_scalar(x = "5.024")
```
**decimal_places_df**  
*Count decimal places in a data frame*

**Description**

For every value in a column, decimal_places_df() counts its decimal places. By default, it operates on all columns that are coercible to numeric.

**Usage**

```r
decimal_places_df(
  data,
  cols = everything(),
  check_numeric_like = TRUE,
  sep = "\\.
)
```

**Arguments**

- **data**  
  Data frame.

- **cols**  
  Select columns from data using tidyselect. Default is everything(), but restricted by check_numeric_like.

- **check Numeric_like**  
  Logical. If TRUE (the default), the function only operates on numeric columns and other columns coercible to numeric, as determined by is_numeric_like().

- **sep**  
  Substring that separates the mantissa from the integer part. Default is "\".", which renders a decimal point.

**Value**

Data frame. The values of the selected columns are replaced by the numbers of their decimal places.

**See Also**

Wrapped functions: decimal_places(), dplyr::across().

**Examples**

```r
# Coerce all columns to string:
iris <- iris %>%
  tibble::as_tibble() %>%
  dplyr::mutate(across(everything(), as.character))

# The function will operate on all numeric-like columns but not on "Species":
iris %>%
decimal_places_df()
```
# Operate on some select columns only
# (from among the numeric-like columns):
iris %>%
decimal_places_df(cols = starts_with("Sepal"))

---

**disperse**  
*Vary hypothetical group sizes*

## Description

Some published studies only report a total sample size but no group sizes. However, group sizes are crucial for consistency tests such as GRIM. Call `disperse()` to generate possible group sizes that all add up to the total sample size, if that total is even.

`disperse2()` is a variant for odd totals. It takes two consecutive numbers and generates decreasing values from the lower as well as increasing values from the upper. In this way, all combinations still add up to the total.

`disperse_total()` directly takes the total sample size, checks if it's even or odd, splits it up accordingly, and applies `disperse()` or `disperse2()`, respectively.

These functions are primarily intended as helpers. They form the backbone of `grim_map_total_n()` and all other functions created with `function_map_total_n()`.

## Usage

```r
disperse(
  n,
  dispersion = 0:5,
  n_min = 1L,
  n_max = NULL,
  constant = NULL,
  constant_index = NULL
)
```

```r
disperse2(
  n,
  dispersion = 0:5,
  n_min = 1L,
  n_max = NULL,
  constant = NULL,
  constant_index = NULL
)
```

```r
disperse_total(
  n,
  dispersion = 0:5,
  n_min = 1L,
)```
Arguments

- **n**: Numeric:
  - In `disperse()`, single number from which to go up and down. This should be half of an even total sample size.
  - In `disperse2()`, the two consecutive numbers closest to half of an odd total sample size (e.g., c(25, 26) for a total of 51).
  - In `disperse_total()`, the total sample size.

- **dispersion**: Numeric. Vector that determines the steps up and down from `n` (or, in `disperse_total()`, from half `n`). Default is `0:5`.

- **n_min**: Numeric. Minimal group size. Default is `1L`.

- **n_max**: Numeric. Maximal group size. Default is `NULL`, i.e., no maximum.

- **constant**: Optionally, add a length-2 vector or a list of length-2 vectors (such as a data frame with exactly two rows) to accompany the pairs of dispersed values. Default is `NULL`, i.e., no constant values.

- **constant_index**: Integer (length 1). Index of `constant` or the first `constant` column in the output tibble. If `NULL` (the default), `constant` will go to the right of `n_change`.

Details

If any group size is less than `n_min` or greater than `n_max`, it is removed. The complementary size of the other group is also removed.

Constant values are pairwise repeated. That is why `constant` must be a length-2 atomic vector or a list of such vectors. If `constant` is a data frame or some other named list, the resulting columns will have the same names as the list-element names. If the list is not named, the new column names will be "constant1", "constant2", etc; or just "constant", for a single pair.

Value

A tibble (data frame) with these columns:

- `n`: includes the dispersed `n` values. Every pair of consecutive rows has `n` values that each add up to the total.
- `n_change`: records how the input `n` was transformed to the output `n`. In `disperse2()`, the `n_change` strings label the lower of the input `n` values `n1` and the higher one `n2`.

References

See Also

`function_map_total_n()`, `grim_map_total_n()`, and `seq_distance_df()`.  

Examples

```r  
# For a total sample size of 40,  
# set 'n' to '20':  
disperse(n = 20)  

# Specify 'dispersion' to control  
# the steps up and down from 'n':  
# dispense(n = 20, dispersion = c(3, 6, 10))  

# In 'disperse2()', specify 'n' as two  
# consecutive numbers -- i.e., group sizes:  
# disperse2(n = c(25, 26))  

# Use the total sample size directly  
# with 'disperse_total()'. An even total  
# internally triggers 'disperse()'...  
# disperse_total(n = 40)  

# ...whereas an odd total triggers 'disperse2()':  
# disperse_total(n = 51)  

# You may add values that repeat along with the  
# dispersed ones but remain constant themselves.  
# Such values can be stored in a length-2 vector  
# for a single column...  
# disperse_total(37, constant = c("5.24", "3.80"))  

# ...or a list of length-2 vectors for multiple  
# columns. This includes data frames with 2 rows:  
# df_constant <- tibble::tibble(  
#     name = c("Paul", "Mathilda"), age = 27:28,  
#     registered = c(TRUE, FALSE)  
# )  
# disperse_total(37, constant = df_constant)  
```

duplicate_count() returns a frequency table. When searching a data frame, it includes values from all columns for each frequency count.

This function is a blunt tool designed for initial data checking. It is not too informative if many values have few characters each.

For summary statistics, call `audit()` on the results.
**duplicate_count**

**Usage**

```r
duplicate_count(
  x,
  ignore = NULL,
  locations_type = c("character", "list"),
  numeric_only = deprecated()
)
```

**Arguments**

- `x` Vector or data frame.
- `ignore` Optionally, a vector of values that should not be counted.
- `locations_type` String. One of "character" or "list". With "list", each locations value is a vector of column names, which is better for further programming. By default ("character"), the column names are pasted into a string, which is more readable.
- `numeric_only` [Deprecated] No longer used: All values are coerced to character.

**Details**

Don’t use `numeric_only`. It no longer has any effect and will be removed in the future. The only reason for this argument was the risk of errors introduced by coercing values to numeric. This is no longer an issue because all values are now coerced to character, which is more appropriate for checking reported statistics.

**Value**

If `x` is a data frame or another named vector, a tibble with four columns. If `x` isn’t named, only the first two columns appear:

- `value`: All the values from `x`.
- `frequency`: Absolute frequency of each value in `x`, in descending order.
- `locations`: Names of all columns from `x` in which value appears.
- `locations_n`: Number of columns named in `locations`.

The tibble has the `scr_dup_count` class, which is recognized by the `audit()` generic.

**Summaries with audit()**

There is an S3 method for the `audit()` generic, so you can call `audit()` following `duplicate_count()`. It returns a tibble with summary statistics for the two numeric columns, `frequency` and `locations_n` (or, if `x` isn’t named, only for `frequency`).

**See Also**

- `duplicate_count_colpair()` to check each combination of columns for duplicates.
- `duplicate_tally()` to show instances of a value next to each instance.
- `janitor::get_dupes()` to search for duplicate rows.
Examples

```
# Count duplicate values...
iris %>%
  duplicate_count()

# ...and compute summaries:
iris %>%
  duplicate_count() %>%
  audit()

# Any values can be ignored:
iris %>%
  duplicate_count( ignore = c("setosa", "versicolor", "virginica"))
```

duplicate_count_colpair

### Count duplicate values by column

duplicate_count_colpair() takes a data frame and checks each combination of columns for duplicates. Results are presented in a tibble, ordered by the number of duplicates.

**Usage**

```
duplicate_count_colpair(
  data,  # Data frame.
  ignore = NULL,  # Optionally, a vector of values that should not be checked for duplicates.
  show_rates = TRUE,  # Logical. If TRUE (the default), adds columns rate_x and rate_y. See value section. Set show_rates to FALSE for higher performance.
  na.rm = deprecated()  # [Deprecated] Missing values are never counted in any case.
)
```

**Arguments**

- **data**: Data frame.
- **ignore**: Optionally, a vector of values that should not be checked for duplicates.
- **show_rates**: Logical. If TRUE (the default), adds columns rate_x and rate_y. See value section. Set show_rates to FALSE for higher performance.
- **na.rm**: [Deprecated] Missing values are never counted in any case.

**Value**

A tibble (data frame) with these columns –

- **x** and **y**: Each line contains a unique combination of data's columns, stored in the x and y output columns.
- **count**: Number of "duplicates", i.e., values that are present in both x and y.
• total_x, total_y, rate_x, and rate_y (added by default): total_x is the number of non-missing values in the column named under x. Also, rate_x is the proportion of x values that are duplicated in y, i.e., count / total_x. Likewise with total_y and rate_y. The two rate_* columns will be equal unless NA values are present.

**Summaries with audit()**

There is an S3 method for audit(), so you can call audit() following duplicate_count_colpair(). It returns a tibble with summary statistics.

**See Also**

• duplicate_count() for a frequency table.
• duplicate_tally() to show instances of a value next to each instance.
• janitor::get_dups() to search for duplicate rows.
• corrr::colpair_map(), a versatile tool for pairwise column analysis which the present function wraps.

**Examples**

```r
# Basic usage:
mtcars %>%
  duplicate_count_colpair()

# Summaries with `audit()`:
mtcars %>%
  duplicate_count_colpair() %>%
  audit()
```

---

duplicate_detect  Detect duplicate values

**Description**

[Superseded]

duplicate_detect() is superseded because it’s less informative than duplicate_tally() and duplicate_count(). Use these functions instead.

For every value in a vector or data frame, duplicate_detect() tests whether there is at least one identical value. Test results are presented next to every value.

This function is a blunt tool designed for initial data checking. Don’t put too much weight on its results.

For summary statistics, call audit() on the results.

**Usage**

duplicate_detect(x, ignore = NULL, colname_end = "dup", numeric_only)
Arguments

x  Vector or data frame.
ignore Optionally, a vector of values that should not be checked. In the test result columns, they will be marked NA.
colname_end String. Name ending of the logical test result columns. Default is "dup".
numeric_only [Deprecated] No longer used: All values are coerced to character.

Details

This function is not very informative with many input values that only have a few characters each. Many of them may have duplicates just by chance. For example, in R’s built-in iris data set, 99% of values have duplicates.

In general, the fewer values and the more characters per value, the more significant the results.

Value

A tibble (data frame). It has all the columns from x, and to each of these columns’ right, the corresponding test result column.

The tibble has the scr_dup_detect class, which is recognized by the audit() generic.

Summaries with audit()

There is an S3 method for the audit() generic, so you can call audit() following duplicate_detect(). It returns a tibble with these columns —

• term: The original data frame’s variables.
• dup_count: Number of "duplicated" values of that term variable: those which have at least one duplicate anywhere in the data frame.
• total: Number of all non-NA values of that term variable.
• dup_rate: Rate of "duplicated" values of that term variable.

The final row, .total, summarizes across all other rows: It adds up the dup_count and total_count columns, and calculates the mean of the dup_rate column.

See Also

• duplicate_tally() to count instances of a value instead of just stating whether it is duplicated.
• duplicate_count() for a frequency table.
• duplicate_count_colpair() to check each combination of columns for duplicates.
• janitor::get_dupes() to search for duplicate rows.
Examples

# Find duplicate values in a data frame...
duplicate_detect(x = pigs4)

# ...or in a single vector:
duplicate_detect(x = pigs4$snout)

# Summary statistics with `audit()`:
pigs4 %>%
  duplicate_detect() %>%
  audit()

# Any values can be ignored:
pigs4 %>%
  duplicate_detect(ignore = c(8.131, 7.574))

duplicate_tally

## Count duplicates at each observation

### Description

For every value in a vector or data frame, duplicate_tally() counts how often it appears in total. Tallies are presented next to each value.

For summary statistics, call audit() on the results.

### Usage

duplicate_tally(x, ignore = NULL, colname_end = "n")

### Arguments

- **x** Vector or data frame.
- **ignore** Optionally, a vector of values that should not be checked. In the test result columns, they will be marked NA.
- **colname_end** String. Name ending of the logical test result columns. Default is "n".

### Details

This function is not very informative with many input values that only have a few characters each. Many of them may have duplicates just by chance. For example, in R’s built-in iris data set, 99% of values have duplicates.

In general, the fewer values and the more characters per value, the more significant the results.

### Value

A tibble (data frame). It has all the columns from x, and to each of these columns' right, the corresponding tally column.

The tibble has the scr_dup_detect class, which is recognized by the audit() generic.
Summaries with **audit()**

There is an S3 method for the `audit()` generic, so you can call `audit()` following `duplicate_tally()`. It returns a tibble with summary statistics.

See Also

- `duplicate_count()` for a frequency table.
- `duplicate_count_colpair()` to check each combination of columns for duplicates.
- `janitor::get_dupes()` to search for duplicate rows.

Examples

```r
# Tally duplicate values in a data frame...
duplicate_tally(x = pigs4)

# ...or in a single vector:
duplicate_tally(x = pigs4$snout)

# Summary statistics with `audit()`:
pigs4 %>%
  duplicate_tally() %>%
  audit()

# Any values can be ignored:
pigs4 %>%
  duplicate_tally(ignore = c(8.131, 7.574))
```

---

**fractional-rounding**

*Generalized rounding to the nearest fraction of a specified denominator*

Description

Two functions that round numbers to specific fractions, not just to the next higher decimal level. They are inspired by `janitor::round_to_fraction()` but feature all the options of `reround()`:

- `reround_to_fraction()` closely follows `janitor::round_to_fraction()` by first rounding to fractions of a whole number, then optionally rounding the result to a specific number of digits in the usual way.

- `reround_to_fraction_level()` rounds to the nearest fraction of a number at the specific decimal level (i.e., number of digits), without subsequent rounding. This is closer to conventional rounding functions.
Usage

reround_to_fraction(
  x = NULL,
  denominator = 1,
  digits = Inf,
  rounding = "up_or_down",
  threshold = 5,
  symmetric = FALSE
)

eround_to_fraction_level(
  x = NULL,
  denominator = 1,
  digits = 0L,
  rounding = "up_or_down",
  threshold = 5,
  symmetric = FALSE
)

Arguments

x Numeric. Vector of numbers to be rounded.

denominator Numeric (>= 1). x will be rounded to the nearest fraction of denominator. Default is 1.

digits Numeric (whole numbers).
  • In reround_to_fraction(): If digits is specified, the values resulting from fractional rounding will subsequently be rounded to that many decimal places. If set to "auto", it internally becomes ceiling(log10(denominator)) + 1, as in janitor::round_to_fraction(). Default is Inf, in which case there is no subsequent rounding.
  • In reround_to_fraction_level(): This function will round to a fraction of the number at the decimal level specified by digits. Default is 0.

rounding, threshold, symmetric
  More arguments passed down to reround().

Value

Numeric vector of the same length as x unless rounding is either of "up_or_down", "up_from_or_down_from", and "ceiling_or_floor". In these cases, it will always have length 2.

See Also

eround(), which the functions wrap, and janitor::round_to_fraction(), part of which they copy.
Examples

```r
e # `reround_to_fraction()` rounds `0.4`
# to `0` if `denominator` is `1`, which
# is the usual integer rounding...
e reround_to_fraction(0.4, denominator = 1, rounding = "even")

# ...but if `denominator` is `2`, it rounds to the nearest
# fraction of 2, which is `0.5`:
e reround_to_fraction(0.4, denominator = 2, rounding = "even")

# Likewise with fractions of 3:
e reround_to_fraction(0.25, denominator = 3, rounding = "even")

# The default for `rounding` is to round
# both up and down, as in `reround()`:
e reround_to_fraction(0.4, denominator = 2)

# These two rounding procedures differ
# at the tie points:
e reround_to_fraction(0.25, denominator = 2)

# `reround_to_fraction_level()``, in contrast,
# uses `digits` to determine some decimal level,
# and then rounds to the closest fraction at
# that level:
e reround_to_fraction_level(0.12345, denominator = 2, digits = 0)
e reround_to_fraction_level(0.12345, denominator = 2, digits = 1)
e reround_to_fraction_level(0.12345, denominator = 2, digits = 2)
```

---

**function_map**

*Create new *_map() functions*

**Description**

`function_map()` creates new basic mapper functions for consistency tests, such as `grim_map()` or `debit_map()`.

For context, see *Creating basic mappers with function_map()*.

**Usage**

```r
function_map(
  .fun,
  .reported,
  .name_test,
  .name_key_result = "consistency",
  .name_class = NULL,
  .args_disabled = NULL,
  .col_names = NULL,
)```
function_map

```
.col_control = NULL,
.col_filler = NULL,
...
```

**Arguments**

- `.fun` Single-case consistency testing function that will be applied to each row in a data frame. The function must return a single logical value, i.e., TRUE, FALSE, or NA.
- `.reported` String. Names of the columns to be tested.
- `.name_test` String (length 1). Plain-text name of the consistency test, such as "GRIM".
- `.name_key_result` (Experimental) Optionally, a single string that will be the name of the key result column in the output. Default is "consistency".
- `.name_class` String. Optionally, one or more classes to be added to the output data frame. Default is NULL, i.e., no extra class (but see Details).
- `.args_disabled` Optionally, a string vector with names of arguments of the *_scalar() function that don't work with the factory-made function. If the user tries to specify these arguments, an informative error will be thrown.
- `.col_names` (Experimental) Optionally, a string vector with the names of additional columns that are derived from the *_scalar() function. Requires .col_control and .col_filler specifications.
- `.col_control` (Experimental) Optionally, a single string with the name of the *_scalar() function's logical argument that controls if the columns named in .col_names will be displayed.
- `.col_filler` (Experimental) Optionally, a vector specifying the values of .col_names columns in rows where the *_scalar() function only returned the consistency value.
  - These dots must be empty.

**Details**

The output tibble returned by the factory-made function will inherit one or two classes independently of the .name_class argument:

- It will inherit a class named "scr{tolower(.name_test)}_map"; for example, the class is "scr_grim_map" if .name_test is "GRIM".
- If a rounding argument is specified via . . . , or else if .fun has a rounding argument with a default, the output tibble will inherit a class named "scr_rounding_{(rounding)}"; for example, "scr_rounding_up_or_down".

**Value**

A factory-made function with these arguments:

- data: Data frame with all the columns named in .reported. It must have columns named after the key arguments in .fun. Other columns are permitted.
function_map_seq

Create new *_map_seq() functions

Description

function_map_seq() is the engine that powers functions such as grim_map_seq(). It creates new, "factory-made" functions that apply consistency tests such as GRIM or GRIMMER to sequences of specified variables. The sequences are centered around the reported values of those variables.

By default, only inconsistent values are dispersed from and tested. This provides an easy and powerful way to assess whether small errors in computing or reporting may be responsible for inconsistencies in published statistics.

For background and more examples, see the sequence mapper section of Consistency tests in depth.

Value returned by the factory-made function

A tibble that includes "consistency": a logical column showing whether the values to its left are mutually consistent (TRUE) or not (FALSE).

Examples

# Basic test implementation for "SCHLIM",
# a mock test with no real significance:
schlim_scalar <- function(y, n) {
  (y / 3) > n
}

# Let the function factory produce
# a mapper function for SCHLIM:
schlim_map <- function_map(
  .fun = schlim_scalar,
  .reported = c("y", "n"),
  .name_test = "SCHLIM"
)

# Example data:
df1 <- tibble::tibble(y = 16:25, n = 3:12)

# Call the "factory-made" function:
schlim_map(df1)
function_map_seq

Usage

function_map_seq(
  .fun,
  .var = Inf,
  .reported,
  .name_test,
  .name_key_result = "consistency",
  .name_class = NULL,
  .args_disabled = NULL,
  .dispersion = 1:5,
  .out_min = "auto",
  .out_max = NULL,
  .include_reported = FALSE,
  .include_consistent = FALSE,
  ...
)

Arguments

.fun Function such as grim_map(), or one made by function_map(): It will be used to test columns in a data frame for consistency. Test results are logical and need to be contained in a column called "consistency" that is added to the input data frame. This modified data frame is then returned by .fun.

.var String. Variables that will be dispersed by the manufactured function. Defaults to .reported.

.reported String. All variables the manufactured function can disperse in principle.

.name_test String (length 1). The name of the consistency test, such as "GRIM", to be optionally shown in a message when using the manufactured function.

.name_key_result (Experimental) Optionally, a single string that will be the name of the key result column in the output. Default is "consistency".

.name_class String. If specified, the tibbles returned by the manufactured function will inherit this string as an S3 class. Default is NULL, i.e., no extra class.

.args_disabled String. Optionally, names of the basic *_map() function’s arguments. These arguments will throw an error if specified when calling the factory-made function.

.dispersion Numeric. Sequence with steps up and down from the reported values. It will be adjusted to these values’ decimal level. For example, with a reported 8.34, the step size is 0.01. Default is 1:5, for five steps up and down.

.out_min, .out_max If specified when calling a factory-made function, output will be restricted so that it’s not below .out_min or above .out_max. Defaults are "auto" for .out_min, i.e., a minimum of one decimal unit above zero; and NULL for .out_max, i.e., no maximum.

.include_reported Logical. Should the reported values themselves be included in the sequences originating from them? Default is FALSE because this might be redundant and bias the results.
Logical. Should the function also process consistent cases (from among those reported), not just inconsistent ones? Default is FALSE because the focus should be on clarifying inconsistencies.

These dots must be empty.

Details

All arguments of function_map_seq() set the defaults for the arguments in the manufactured function. They can still be specified differently when calling the latter.

If functions created this way are exported from other packages, they should be written as if they were created with purrr adverbs; see explanations there, and examples in the export section of Consistency tests in depth.

This function is a so-called function factory: It produces other functions, such as grim_map_seq(). More specifically, it is a function operator because it also takes functions as inputs, such as grim_map(). See Wickham (2019, ch. 10-11).

Value

A function such as those below. ("Testable statistics" are variables that can be selected via var, and are then varied. All variables except for those in parentheses are selected by default.)

<table>
<thead>
<tr>
<th>Manufactured function</th>
<th>Testable statistics</th>
<th>Test vignette</th>
</tr>
</thead>
<tbody>
<tr>
<td>grim_map_seq()</td>
<td>&quot;x&quot;, &quot;n&quot;, (&quot;items&quot;)</td>
<td>vignette(&quot;grim&quot;)</td>
</tr>
<tr>
<td>grimmer_map_seq()</td>
<td>&quot;x&quot;, &quot;sd&quot;, &quot;n&quot;, (&quot;items&quot;)</td>
<td>vignette(&quot;grimmer&quot;)</td>
</tr>
<tr>
<td>debit_map_seq()</td>
<td>&quot;x&quot;, &quot;sd&quot;, &quot;n&quot;</td>
<td>vignette(&quot;debit&quot;)</td>
</tr>
</tbody>
</table>

The factory-made function will also have dots, ..., to pass arguments down to .fun, i.e., the basic mapper function such as grim_map().

Conventions

The name of a function returned by function_map_seq() should mechanically follow from that of the input function. For example, grim_map_seq() derives from grim_map(). This pattern fits best if the input function itself is named after the test it performs on a data frame, followed by _map: grim_map() applies GRIM, grimmer_map() applies GRIMMER, etc.

Much the same is true for the classes of data frames returned by the manufactured function via the .name_class argument of function_map_seq(). It should be the function’s own name preceded by the name of the package that contains it, or by an acronym of that package’s name. Therefore, some existing classes are scr_grim_map_seq and scr_grimmer_map_seq.

References

Examples

# Function definition of `grim_map_seq()`:
grim_map_seq <- function_map_seq(
  .fun = grim_map,
  .reported = c("x", "n"),
  .name_test = "GRIM",
)

function_map_total_n  Create new *_map_total_n() functions

Description

`function_map_total_n()` is the engine that powers functions such as `grim_map_total_n()`. It creates new, "factory-made" functions for consistency tests such as GRIM or GRIMMER. The new functions take reported summary statistics (e.g., means) and apply those tests in cases where only a total sample size is known, not group sizes.

This works by making `disperse_total()` create multiple pairs of hypothetical group sizes, all of which add up to the reported total. There need to be exactly two groups.

For background and more examples, see the total-n mapper section of Consistency tests in depth.

Usage

function_map_total_n(
  .fun,  
  .reported,  
  .name_test,  
  .name_key_result = "consistency",  
  .name_class = NULL,  
  .dispersion = 0:5,  
  .n_min = 1L,  
  .n_max = NULL,  
  .constant = NULL,  
  .constant_index = NULL,  
  ...  
)

Arguments

.fun Function such as `grim_map()`, or one made by `function_map()`: It will be used to test columns in a data frame for consistency. Test results are logical and need to be contained in a column called `consistency` that is added to the input data frame. This modified data frame is then returned by `.fun`.

.reported String. Names of the columns containing group-specific statistics that were reported alongside the total sample size(s). They will be tested for consistency with the hypothetical group sizes. Examples are "x" for GRIM and c("x", "n"),
function_map_total_n

"sd") for DEBIT. In the data frame with reported group statistics that the manufactured function takes as an input, each will need to fan out like "x1", "x2", "sd1", and "sd2".

.name_test String (length 1). The name of the consistency test, such as "GRIM", to be optionally shown in a message when using the manufactured function.

.name_key_result (Experimental) Optionally, a single string that will be the name of the key result column in the output. Default is "consistency".

.name_class String. If specified, the tibbles returned by the manufactured function will inherit this string as an S3 class. Default is NULL, i.e., no extra class.

.dispersion, .n_min, .n_max, .constant, .constant_index Arguments passed down to disperse_total(), using defaults from there.
... These dots must be empty.

Details

If functions created by function_map_total_n() are exported from other packages, they should be written as if they were created with purrr adverbs; see explanations there, and examples in the export section of Consistency tests in depth.

This function is a so-called function factory: It produces other functions, such as grim_map_total_n(). More specifically, it is a function operator because it also takes functions as inputs, such as grim_map(). See Wickham (2019), ch. 10-11.

Value

A function such as these:

<table>
<thead>
<tr>
<th>Manufactured function</th>
<th>Reported statistics</th>
<th>Test vignette</th>
</tr>
</thead>
<tbody>
<tr>
<td>grim_map_total_n()</td>
<td>&quot;x&quot;</td>
<td>vignette(&quot;grim&quot;)</td>
</tr>
<tr>
<td>grimmer_map_total_n()</td>
<td>&quot;x&quot;, &quot;sd&quot;</td>
<td>vignette(&quot;grimmer&quot;)</td>
</tr>
<tr>
<td>debit_map_total_n()</td>
<td>&quot;x&quot;, &quot;sd&quot;</td>
<td>vignette(&quot;debit&quot;)</td>
</tr>
</tbody>
</table>

The factory-made function will also have dots,..., to pass arguments down to .fun, i.e., the basic mapper function.

Conventions

The name of a function returned by function_map_total_n() should mechanically follow from that of the input function. For example, grim_map_total_n() derives from grim_map(). This pattern fits best if the input function itself is named after the test it performs on a data frame, followed by _map: grim_map() applies GRIM, grimmer_map() applies GRIMMER, etc.

Much the same is true for the classes of data frames returned by the manufactured function via the .name_class argument of function_map_total_n(). It should be the function’s own name preceded by the name of the package that contains it, or by an acronym of that package’s name. Therefore, some existing classes are scr_grim_map_total_n and scr_grimmer_map_total_n.

`function_map_seq()`

Examples

```r
# Function definition of `grim_map_total_n()`:
grim_map_total_n <- function_map_total_n(
  .fun = grim_map,
  .reported = "x",
  .name_test = "GRIM"
)
```

---

**grim**

*The GRIM test (granularity-related inconsistency of means)*

**Description**

`grim()` checks if a reported mean value of integer data is mathematically consistent with the reported sample size and the number of items that compose the mean value.

Set `percent` to `TRUE` if `x` is a percentage. This will convert `x` to a decimal number and adjust the decimal count accordingly.

The function is vectorized, but it is recommended to use `grim_map()` for testing multiple cases.

**Usage**

```r
grim(
  x,
  n,
  items = 1,
  percent = FALSE,
  show_rec = FALSE,
  rounding = "up_or_down",
  threshold = 5,
  symmetric = FALSE,
  tolerance = .Machine$double.eps^0.5
)
```
Arguments

- **x**: String. The reported mean or percentage value.
- **n**: Integer. The reported sample size.
- **items**: Numeric. The number of items composing x. Default is 1, the most common case.
- **percent**: Logical. Set percent to TRUE if x is a percentage. This will convert it to a decimal number and adjust the decimal count (i.e., increase it by 2). Default is FALSE.
- **show_rec**: Logical. For internal use only. If set to TRUE, the output is a matrix that also contains intermediary values from GRIM-testing. Don’t specify this manually; instead, use show_rec in `grim_map()`. Default is FALSE.
- **rounding**: String. Rounding method or methods to be used for reconstructing the values to which x will be compared. Default is "up_or_down" (from 5).
- **threshold**: Numeric. If rounding is set to "up_from", "down_from", or "up_from_or_down_from", set threshold to the number from which the reconstructed values should then be rounded up or down. Otherwise, this argument plays no role. Default is 5.
- **symmetric**: Logical. Set symmetric to TRUE if the rounding of negative numbers with "up", "down", "up_from", or "down_from" should mirror that of positive numbers so that their absolute values are always equal. Default is FALSE.
- **tolerance**: Numeric. Tolerance of comparison between x and the possible mean or percentage values. Default is circa 0.000000015 (1.490116e-08), as in `dplyr::near()`.

Details

The x values need to be strings because only strings retain trailing zeros, which are as important for the GRIM test as any other decimal digits.

Use `restore_zeros()` on numeric values (or values that were numeric values at some point) to easily supply the trailing zeros they might once have had. See documentation there.

Browse the source code in the `grim.R` file. `grim()` is a vectorized version of the internal `grim_scalar()` function found there.

Value

Logical. TRUE if x, n, and items are mutually consistent, FALSE if not.

References

See Also

`grim_map()` applies `grim()` to any number of cases at once.
Examples

# A mean of 5.19 is not consistent with a sample size of 28:
grim(x = "5.19", n = 28)  # `x` in quotes!

# However, it is consistent with a sample size of 32:
grim(x = "5.19", n = 32)

# For a scale composed of two items:
grim(x = "2.84", n = 16, items = 2)

# With percentages instead of means -- here, 71%:
grim(x = "71", n = 43, percent = TRUE)

grim-stats Possible GRIM inconsistencies

Description

Even without GRIM-testing, means / proportions and sample sizes of granular distributions entail some key data:

- grim_total() returns the absolute number of GRIM-inconsistencies that are possible given the mean or percentage's number of decimal places (D) and the corresponding sample size.
- grim_ratio() returns a proportion that is normalized by \(10^D\), and therefore comparable across mean or percentage values reported to varying D.
- grim_ratio_upper() returns the upper bound of grim_ratio() for a given D.

For discussion, see vignette("grim"), section GRIM statistics.

Usage

grimm total(x, n, items = 1, percent = FALSE)
grim_ratio(x, n, items = 1, percent = FALSE)
grim_ratio_upper(x, percent = FALSE)

Arguments

- **x**: String or numeric (length 1). Mean or percentage value computed from data with integer units (e.g., mean scores on a Likert scale or percentage of study participants in some condition). Note: Numeric inputs don't include trailing zeros, but these are important for GRIM functions. See documentation for grim()

- **n**: Integer. Sample size corresponding to x.

- **items**: Integer. Number of items composing the mean or percentage value in question. Default is 1.

- **percent**: Logical. Set percent to TRUE if x is expressed as a proportion of 100 rather than 1. The functions will then account for this fact through increasing the decimal count by 2. Default is FALSE.
Value

Integer or double. The number or proportion of possible GRIM inconsistencies.

References

See Also

grim() for the GRIM test itself; as well as grim_map() for applying it to many cases at once.

Examples

# Many value sets are inconsistent here:
grim_total(x = "83.29", n = 21)
grim_ratio(x = "83.29", n = 21)

# No sets are inconsistent in this case...
grim_total(x = "5.14", n = 83)
grim_ratio(x = "5.14", n = 83)

# ... but most would be if `x` was a percentage:
grim_total(x = "5.14", n = 83, percent = TRUE)
grim_ratio(x = "5.14", n = 83, percent = TRUE)

Description

grimmer() checks if reported mean and SD values of integer data are mathematically consistent with the reported sample size and the number of items that compose the mean value. It works much like grim().

The function is vectorized, but it is recommended to use grimmer_map() for testing multiple cases.

Usage

grimmer(
  x,
  sd,
  n,
  items = 1,
  show_reason = FALSE,
  rounding = "up_or_down",
  threshold = 5,
Arguments

x  String. The reported mean value.

sd String. The reported standard deviation.

n Integer. The reported sample size.

items (NOTE: Don’t use the items argument. It currently contains a bug that will be fixed in the future.) Integer. The number of items composing the x and sd values. Default is 1, the most common case.

show_reason Logical. For internal use only. If set to TRUE, the output is a list of length-2 lists which also contain the reasons for inconsistencies. Don’t specify this manually; instead, use show_reason in grimmer_map(). Default is FALSE.

rounding String. Rounding method or methods to be used for reconstructing the values to which x will be compared. Default is "up_or_down" (from 5).

threshold Numeric. If rounding is set to "up_from", "down_from", or "up_from_or_down_from", set threshold to the number from which the reconstructed values should then be rounded up or down. Otherwise, this argument plays no role. Default is 5.

symmetric Logical. Set symmetric to TRUE if the rounding of negative numbers with "up", "down", "up_from", or "down_from" should mirror that of positive numbers so that their absolute values are always equal. Default is FALSE.

tolerance Numeric. Tolerance of comparison between x and the possible mean or percentage values. Default is circa 0.000000015 (1.490116e-08), as in dplyr::near().

Details

GRIMMER was originally devised by Anaya (2016). The present implementation follows Allard’s (2018) refined Analytic-GRIMMER (A-GRIMMER) algorithm. It adapts the R function aGrimmer() provided by Allard and modifies it to accord with scrutiny’s standards, as laid out in vignette("consistency-tests-in-depth"), sections 1-2. The resulting grimmer() function, then, is a vectorized version of this basic implementation. For more context and variable name translations, see the top of the R/grimmer.R, the source file.

The present implementation can differ from Allard’s in a small number of cases. In most cases, this means that the original flags a value set as inconsistent, but scrutiny’s grimmer*() functions don’t. For details, see the end of tests/testthat/test-grimmer.R, the grimmer() test file.

Value

Logical. TRUE if x, sd, n, and items are mutually consistent, FALSE if not.

References

Examples

# A mean of 5.23 is not consistent with an SD of 2.55
# and a sample size of 35:
grimmer(x = "5.23", sd = "2.55", n = 35)

# However, mean and SD are consistent with a
# sample size of 31:
grimmer(x = "5.23", sd = "2.55", n = 31)

# For a scale composed of two items:
grimmer(x = "2.74", sd = "0.96", n = 63, items = 2)

Description

Call grimmer_map() to GRIMMER-test any number of combinations of mean, standard deviation, sample size, and number of items. Mapping function for GRIMMER-testing.

For summary statistics, call audit() on the results. Visualize results using grim_plot(), as with GRIM results.

Usage

grimmer_map(
  data,
  items = 1,
  merge_items = TRUE,
  x = NULL,
  sd = NULL,
  n = NULL,
  show_reason = TRUE,
  rounding = "up_or_down",
  threshold = 5,
  symmetric = FALSE,
  tolerance = .Machine$double.eps^0.5
)

Arguments

data Data frame with columns x, sd, n, and optionally items (see documentation for grim()). Any other columns in data will be returned alongside GRIMMER test results.

items (NOTE: Don’t use the items argument. It currently contains a bug that will be fixed in the future.) Integer. If there is no items column in data, this specifies the number of items composing the x and sd values. Default is 1, the most common case.
merge_items Logical. If TRUE (the default), there will be no items column in the output. Instead, values from an items column or argument will be multiplied with values in the n column. This does not affect GRIM- or GRIMMER-testing.

x, sd, n Optionally, specify these arguments as column names in data.

show_reason Logical (length 1). Should there be a reason column that shows the reasons for inconsistencies (and NA for consistent values)? Default is FALSE.

rounding, threshold, symmetric, tolerance Further parameters of GRIMMER-testing; see documentation for grimmer().

Value

A tibble with these columns –

- x, sd, n: the inputs.
- consistency: GRIMMER consistency of x, n, and items.
- <extra>: any columns from data other than x, n, and items.

The tibble has the scr_grimmer_map class, which is recognized by the audit() generic. It also has the scr_grim_map class, so it can be visualized by grim_plot().

Summaries with audit()

There is an S3 method for audit(), so you can call audit() following grimmer_map() to get a summary of grimmer_map()’s results. It is a tibble with a single row and these columns –

1. incons_cases: number of GRIMMER-inconsistent value sets.
2. all_cases: total number of value sets.
3. incons_rate: proportion of GRIMMER-inconsistent value sets.
4. fail_grim: number of value sets that fail the GRIM test.
5. fail_test1: number of value sets that fail the first GRIMMER test (sum of squares is a whole number).
6. fail_test2: number of value sets that fail the second GRIMMER test (matching SDs).
7. fail_test3: number of value sets that fail the third GRIMMER test (equal parity).

# The `consistency` column shows whether
# the values to its left are GRIMMER-consistent.
# If they aren't, the `reason` column says why:
pigs5 %>%
grimmer_map()

# Get summaries with `audit()`:
pigs5 %>%
grimmer_map() %>%
audit()

---

### grimmer_map_seq

**GRIMMER-testing with dispersed inputs**

#### Description

`grimmer_map_seq()` performs GRIMMER-testing with values surrounding the input values. This provides an easy and powerful way to assess whether small errors in computing or reporting may be responsible for GRIMMER inconsistencies in published statistics.

Call `audit_seq()` on the results for summary statistics.

#### Usage

```r
grimmer_map_seq(
  data,
  x = NULL,
  sd = NULL,
  n = NULL,
  var = Inf,
  dispersion = 1:5,
  out_min = "auto",
  out_max = NULL,
  include_reported = FALSE,
  include_consistent = FALSE,
  ...
)
```

#### Arguments

- **data**  
  A data frame that `grimmer_map()` could take.

- **x, sd, n**  
  Optionally, specify these arguments as column names in `data`.

- **var**  
  String. Names of the columns that will be dispersed. Default is `c("x", "sd", "n")`. 
**dispersion**

Numeric. Sequence with steps up and down from the `var` inputs. It will be adjusted to these values’ decimal levels. For example, with a reported 8.34, the step size is 0.01. Default is 1:5, for five steps up and down.

**out_min, out_max**

If specified, output will be restricted so that it’s not below `out_min` or above `out_max`. Defaults are "auto" for `out_min`, i.e., a minimum of one decimal unit above zero; and NULL for `out_max`, i.e., no maximum.

**include_reported**

Logical. Should the reported values themselves be included in the sequences originating from them? Default is FALSE because this might be redundant and bias the results.

**include_consistent**

Logical. Should the function also process consistent cases (from among those reported), not just inconsistent ones? Default is FALSE because the focus should be on clarifying inconsistencies.

... Arguments passed down to `grimmer_map()`. *(NOTE: Don’t use the items argument. It currently contains a bug that will be fixed in the future.)*

**Value**

A tibble (data frame) with detailed test results.

**Summaries with `audit_seq()`**

You can call `audit_seq()` following `grimmer_map_seq()`. It will return a data frame with these columns:

- `x`, `sd`, and `n` are the original inputs, tested for consistency here.
- `hits_total` is the total number of GRIMMER-consistent value sets found within the specified dispersion range.
- `hits_x` is the number of GRIMMER-consistent value sets found by varying `x`.
- Accordingly with `sd` and `hits_sd` as well as `n` and `hits_n`.
- (Note that any consistent reported cases will be counted by the `hits_*` columns if both `include_reported` and `include_consistent` are set to TRUE.)
- `diff_x` reports the absolute difference between `x` and the next consistent dispersed value (in dispersion steps, not the actual numeric difference). `diff_x_up` and `diff_x_down` report the difference to the next higher or lower consistent value, respectively.
- `diff_sd`, `diff_sd_up`, and `diff_sd_down` do the same for `sd`.
- Likewise with `diff_n`, `diff_n_up`, and `diff_n_down`.

Call `audit()` following `audit_seq()` to summarize results even further. It’s mostly self-explaining, but `na_count` and `na_rate` are the number and rate of times that a difference could not be computed because of a lack of corresponding hits within the dispersion range.
grimmer_map_total_n

Examples

# 'grimmer_map_seq()' can take any input
# that 'grimmer_map()' can take:
pigs5

# All the results:
out <- grimmer_map_seq(pigs5, include_consistent = TRUE)
out

# Case-wise summaries with 'audit_seq()'
# can be more important than the raw results:
out %>%
  audit_seq()

grimmer_map_total_n  GRIMMER-testing with hypothetical group sizes

Description

When reporting group means, some published studies only report the total sample size but no group sizes corresponding to each mean. However, group sizes are crucial for GRIMMER-testing.

In the two-groups case, grimmer_map_total_n() helps in these ways:

- It creates hypothetical group sizes. With an even total sample size, it incrementally moves up and down from half the total sample size. For example, with a total sample size of 40, it starts at 20, goes on to 19 and 21, then to 18 and 22, etc. With odd sample sizes, it starts from the two integers around half.
- It GRIMMER-tests all of these values together with the group means.
- It reports all the scenarios in which both "dispersed" hypothetical group sizes are GRIMMER-consistent with the group means.

All of this works with one or more total sample sizes at a time. Call audit_total_n() for summary statistics.

Usage

grimmer_map_total_n(
  data,
  x1 = NULL,
  x2 = NULL,
  sd1 = NULL,
  sd2 = NULL,
  dispersion = 0:5,
  n_min = 1L,
  n_max = NULL,
  constant = NULL,
  constant_index = NULL,
  ...
)
Arguments

data
Data frame with string columns x1, x2, sd1, and sd2, as well as numeric column n. The first two are reported group means. sd1 and sd2 are reported group SDs. n is the reported total sample size. It is not very important whether a value is in x1 or in x2 because, after the first round of tests, the function switches roles between x1 and x2, and reports the outcomes both ways. The same applies to sd1 and sd2. However, do make sure the x* and sd* values are paired accurately, as reported.

x1, x2, sd1, sd2
Optionally, specify these arguments as column names in data.

dispersion
Numeric. Steps up and down from half the n values. Default is 0:5, i.e., half n itself followed by five steps up and down.

n_min
Numeric. Minimal group size. Default is 1.

n_max
Numeric. Maximal group size. Default is NULL, i.e., no maximum.

constant
Optionally, add a length-2 vector or a list of length-2 vectors (such as a data frame with exactly two rows) to accompany the pairs of dispersed values. Default is NULL, i.e., no constant values.

constant_index
Integer (length 1). Index of constant or the first constant column in the output tibble. If NULL (the default), constant will go to the right of n_change.

...
Arguments passed down to grimmer_map(). (NOTE: Don’t use the items argument. It currently contains a bug that will be fixed in the future.)

Value

A tibble with these columns:

- x, the group-wise reported input statistic, is repeated in row pairs.
- n is dispersed from half the input n, with n_change tracking the differences.
- both_consistent flags scenarios where both reported x values are consistent with the hypothetical n values.
- case corresponds to the row numbers of the input data frame.
- dir is “forth” in the first half of rows and “back” in the second half. “forth” means that x2 from the input is paired with the larger dispersed n, whereas “back” means that x1 is paired with the larger dispersed n.
- Other columns from grimmer_map() are preserved.

Summaries with audit_total_n()

You can call audit_total_n() following up on grimmer_map_total_n() to get a tibble with summary statistics. It will have these columns:

- x1, x2, sd1, sd2, and n are the original inputs.
- hits_total is the number of scenarios in which all of x1, x2, sd1, and sd2 are GRIMMER-consistent. It is the sum of hits_forth and hits_back below.
- **hits_forth** is the number of both-consistent cases that result from pairing \( x_2 \) and \( sd_2 \) with the larger dispersed \( n \) value.
- **hits_back** is the same, except \( x_1 \) and \( sd_1 \) are paired with the larger dispersed \( n \) value.
- **scenarios_total** is the total number of test scenarios, whether or not both \( x_1 \) and \( sd_1 \) as well as \( x_2 \) and \( sd_2 \) are GRIMMER-consistent.
- **hit_rate** is the ratio of **hits_total** to **scenarios_total**.

**References**

**See Also**

`function_map_total_n()`, which created the present function using `grimmer_map()`.

**Examples**

```r
# Run `grimmer_map_total_n()` on data like these:
df <- tibble::tribble(~x1, ~x2, ~sd1, ~sd2, ~n,
                     "3.43", "5.28", "1.09", "2.12", 70,
                     "2.97", "4.42", "0.43", "1.65", 65)
df

griminator_map_total_n(df)

# `audit_total_n()` summaries can be more important than the detailed results themselves.
# The `hits_total` column shows all scenarios in which both divergent `n` values are GRIMMER-consistent with the `\(x^*\)` values when paired with them both ways:
df %>%
grimeter_map_total_n() %>%
audit_total_n()

# By default (`dispersion = 0:5`), the function goes five steps up and down from `n`. If this sequence gets longer, the number of hits tends to increase:
df %>%
grimeter_map_total_n(dispersion = 0:10) %>%
audit_total_n()
```
**grim_granularity**

**Granularity of non-continuous scales**

**Description**

grim_granularity() computes the minimal difference between two means or proportions of ordinal or interval data.

grim_items() is the reverse: It converts granularity values to the number of scale items, which might then be used for consistency testing functions such as grim().

**Usage**

grim_granularity(n, items = 1)

grim_items(n, gran, tolerance = .Machine$double.eps^0.5)

**Arguments**

- **n** Numeric. Sample size.
- **items** Numeric. Number of items composing the scale. Default is 1, which will hold for most non-Likert scales.
- **gran** Numeric. Granularity.
- **tolerance** Numeric. In grim_items(), tolerance is the maximal amount by which results may differ from being whole numbers. If they exceed that amount, a warning will be shown.

**Details**

These two functions differ only in the names of their arguments — the underlying formula is the same (and it’s very simple). However, for clarity, they are presented as distinct.

The output of grim_items() should be whole numbers, because scale items have a granularity of 1. If they differ from the next whole number by more than a numeric tolerance (which is determined by the argument by that name), a warning will be shown.

It would be wrong to determine a scale’s granularity from the minimal distance between two values in a given distribution. This would only signify how those values actually do differ, not how they can differ a priori based on scale design. Also, keep in mind that continuous scales have no granularity at all.

**Value**

Numeric. Granularity or number of items.

**References**

**Examples**

# If a non-Likert scale ranges from 0 to 3
# and measures 16 cases:
grim_granularity(n = 16) # `items = 1` by default

# Same but Likert scale with 2 items:
grim_granularity(n = 16, items = 2)

# If a scale is applied to a single case
# and has a granularity of 0.5:
grim_items(n = 1, gran = 0.5)

# With more cases, a warning appears
# because items can only be whole numbers:
grim_items(n = c(10, 15, 20), gran = 0.5)

---

**grim_map**

*GRIM-test many cases at once*

---

**Description**

Call `grim_map()` to GRIM-test any number of combinations of mean/proportion, sample size, and number of items. Mapping function for GRIM-testing.

Set `percent` to `TRUE` if the `x` values are percentages. This will convert `x` values to decimals and adjust the decimal count accordingly.

Display intermediary numbers from GRIM-testing in columns by setting `show_rec` to `TRUE`.

For summary statistics, call `audit()` on the results.

**Usage**

```r
grim_map(
  data,
  items = 1,
  merge_items = TRUE,
  percent = FALSE,
  x = NULL,
  n = NULL,
  show_rec = FALSE,
  show_prob = FALSE,
  rounding = "up_or_down",
  threshold = 5,
  symmetric = FALSE,
  tolerance = .Machine$double.eps^0.5,
  testables_only = FALSE,
  extra = Inf
)
```
Arguments

data Data frame with columns x, n, and optionally items (see documentation for grim()). By default, any other columns in data will be returned alongside GRIM test results (see extra below).

items Integer. If there is no items column in data, this specifies the number of items composing the x values. Default is 1, the most common case.

merge_items Logical. If TRUE (the default), there will be no items column in the output. Instead, values from an items column or argument will be multiplied with values in the n column. This does not affect GRIM-testing.

percent Logical. Set percent to TRUE if the x values are percentages. This will convert them to decimal numbers and adjust the decimal count (i.e., increase it by 2). It also affects the ratio column. Default is FALSE.

x, n Optionally, specify these arguments as column names in data.

show_rec Logical. If set to TRUE, the reconstructed numbers from GRIM-testing are shown as columns. See section Reconstructed numbers below. Default is FALSE.

show_prob Logical. If set to TRUE, adds a prob column that contains the probability of GRIM inconsistency. This is simply the ratio column censored to range between 0 and 1. Default is FALSE.

rounding, threshold, symmetric, tolerance Further parameters of GRIM-testing; see documentation for grim().

testables_only Logical. If testables_only is set to TRUE, only GRIM-testable cases (i.e., those with a positive GRIM ratio) are included. Default is FALSE.

extra String or integer. The other column(s) from data to be returned in the output tibble alongside test results, referenced by their name(s) or number(s). Default is Inf, which returns all columns. To return none of them, set extra to 0.

Value

A tibble with these columns –

• x, n: the inputs.
• consistency: GRIM consistency of x, n, and items.
• <extra>: any columns from data other than x, n, and items.
• ratio: the GRIM ratio; see grim_ratio().

The tibble has the scr_grim_map class, which is recognized by the audit() generic.

Reconstructed numbers

If show_rec is set to TRUE, the output includes the following additional columns:

• rec_sum: the sum total from which the mean or proportion was ostensibly derived.
• rec_x_upper: the upper reconstructed x value.
• rec_x_lower: the lower reconstructed x value.
• rec_x_upper_rounded: the rounded rec_x_upper value.
• `rec_x_lower_rounded`: the rounded `rec_x_lower` value.

With the default for rounding, "up_or_down", each of the last two columns is replaced by two columns that specify the rounding procedures (i.e., "_up" and "_down").

**Summaries with `audit()`**

There is an S3 method for `audit()`, so you can call `audit()` following `grim_map()` to get a summary of `grim_map()`'s results. It is a tibble with one row and these columns –

1. `incons_cases`: number of GRIM-inconsistent value sets.
2. `all_cases`: total number of value sets.
3. `incons_rate`: proportion of GRIM-inconsistent value sets.
4. `mean_grim_ratio`: average of GRIM ratios.
5. `incons_to_ratio`: ratio of `incons_rate` to `mean_grim_ratio`.
6. `testable_cases`: number of GRIM-testable value sets (i.e., those with a positive ratio).
7. `testable_rate`: proportion of GRIM-testable value sets.

**References**

**Examples**

# Use `grim_map()` on data like these:
```r
pigs1
```

# The `consistency` column shows whether the values to its left are GRIM-consistent:
```r
pigs1 %>%
  grim_map()
```

# Display intermediary numbers from GRIM-testing with `show_rec = TRUE`:
```r
pigs1 %>%
  grim_map(show_rec = TRUE)
```

# Get summaries with `audit()`:
```r
pigs1 %>%
  grim_map() %>%
  audit()
```
grim_map_seq

GRIM-testing with dispersed inputs

Description

grim_map_seq() performs GRIM-testing with values surrounding the input values. This provides an easy and powerful way to assess whether small errors in computing or reporting may be responsible for GRIM inconsistencies in published statistics.

Call audit_seq() on the results for summary statistics.

Usage

grim_map_seq(
  data,
  x = NULL,
  n = NULL,
  var = Inf,
  dispersion = 1:5,
  out_min = "auto",
  out_max = NULL,
  include_reported = FALSE,
  include_consistent = FALSE,
  ...
)

Arguments

data A data frame that grim_map() could take.

x, n Optionally, specify these arguments as column names in data.

var String. Names of the columns that will be dispersed. Default is c("x", "n").

dispersion Numeric. Sequence with steps up and down from the var inputs. It will be adjusted to these values’ decimal levels. For example, with a reported 8.34, the step size is 0.01. Default is 1:5, for five steps up and down.

out_min, out_max If specified, output will be restricted so that it’s not below out_min or above out_max. Defaults are "auto" for out_min, i.e., a minimum of one decimal unit above zero; and NULL for out_max, i.e., no maximum.

include_reported Logical. Should the reported values themselves be included in the sequences originating from them? Default is FALSE because this might be redundant and bias the results.

include_consistent Logical. Should the function also process consistent cases (from among those reported), not just inconsistent ones? Default is FALSE because the focus should be on clarifying inconsistencies.

... Arguments passed down to grim_map().
Value
A tibble (data frame) with detailed test results.

Summaries with audit_seq()
You can call audit_seq() following grim_map_seq(). It will return a data frame with these columns:

- x and n are the original inputs, tested for consistency here.
- hits_total is the total number of GRIM-consistent value sets found within the specified dispersion range.
- hits_x is the number of GRIM-consistent value sets found by varying x.
- Accordingly with n and hits_n.

(Note that any consistent reported cases will be counted by the hits_* columns if both include_reported and include_consistent are set to TRUE.)
- diff_x reports the absolute difference between x and the next consistent dispersed value (in dispersion steps, not the actual numeric difference). diff_x_up and diff_x_down report the difference to the next higher or lower consistent value, respectively.
- diff_n, diff_n_up, and diff_n_down do the same for n.

Call audit() following audit_seq() to summarize results even further. It’s mostly self-explaining, but na_count and na_rate are the number and rate of times that a difference could not be computed because of a lack of corresponding hits within the dispersion range.

Examples

# `grim_map_seq()` can take any input
# that `grim_map()` can take:
pigs1

# All the results:
out <- grim_map_seq(pigs1, include_consistent = TRUE)
out

# Case-wise summaries with `audit_seq()`
# can be more important than the raw results:
out %>%
  audit_seq()
**grim_map_total_n**

**Description**

When reporting group means, some published studies only report the total sample size but no group sizes corresponding to each mean. However, group sizes are crucial for GRIM-testing.

In the two-groups case, `grim_map_total_n()` helps in these ways:

- It creates hypothetical group sizes. With an even total sample size, it incrementally moves up and down from half the total sample size. For example, with a total sample size of 40, it starts at 20, goes on to 19 and 21, then to 18 and 22, etc. With odd sample sizes, it starts from the two integers around half.
- It GRIM-tests all of these values together with the group means.
- It reports all the scenarios in which both "dispersed" hypothetical group sizes are GRIM-consistent with the group means.

All of this works with one or more total sample sizes at a time. Call `audit_total_n()` for summary statistics.

**Usage**

```r
grim_map_total_n(
  data,
  x1 = NULL,
  x2 = NULL,
  dispersion = 0:5,
  n_min = 1L,
  n_max = NULL,
  constant = NULL,
  constant_index = NULL,
  ...
)
```

**Arguments**

- **data** Data frame with string columns `x1` and `x2`, and numeric column `n`. The first two are group mean or percentage values with unknown group sizes, and `n` is the total sample size. It is not very important whether a value is in `x1` or in `x2` because, after the first round of tests, the function switches roles between `x1` and `x2`, and reports the outcomes both ways.
- **x1, x2** Optionally, specify these arguments as column names in `data`.
- **dispersion** Numeric. Steps up and down from half the `n` values. Default is `0:5`, i.e., half `n` itself followed by five steps up and down.
- **n_min** Numeric. Minimal group size. Default is 1.
- **n_max** Numeric. Maximal group size. Default is `NULL`, i.e., no maximum.
- **constant** Optionally, add a length-2 vector or a list of length-2 vectors (such as a data frame with exactly two rows) to accompany the pairs of dispersed values. Default is `NULL`, i.e., no constant values.
- **constant_index** Integer (length 1). Index of `constant` or the first constant column in the output tibble. If `NULL` (the default), constant will go to the right of `n_change`.
- **...** Arguments passed down to `grim_map()`.
Value

A tibble with these columns:

- \( x \), the group-wise reported input statistic, is repeated in row pairs.
- \( n \) is dispersed from half the input \( n \), with \( n_{\text{change}} \) tracking the differences.
- \texttt{both_consistent} flags scenarios where both reported \( x \) values are consistent with the hypothetical \( n \) values.
- \texttt{case} corresponds to the row numbers of the input data frame.
- \texttt{dir} is "forth" in the first half of rows and "back" in the second half. "forth" means that \( x_2 \) from the input is paired with the larger dispersed \( n \) value, whereas "back" means that \( x_1 \) is paired with the larger dispersed \( n \).
- Other columns from \texttt{grim_map()} are preserved.

Summaries with \texttt{audit_total_n()}

You can call \texttt{audit_total_n()} following up on \texttt{grim_map_total_n()} to get a tibble with summary statistics. It will have these columns:

- \( x_1 \), \( x_2 \), and \( n \) are the original inputs.
- \( \texttt{hits_total} \) is the number of scenarios in which both \( x_1 \) and \( x_2 \) are GRIM-consistent. It is the sum of \( \texttt{hits_forth} \) and \( \texttt{hits_back} \) below.
- \( \texttt{hits_forth} \) is the number of both-consistent cases that result from pairing \( x_2 \) with the larger dispersed \( n \) value.
- \( \texttt{hits_back} \) is the same, except \( x_1 \) is paired with the larger dispersed \( n \) value.
- \( \texttt{scenarios_total} \) is the total number of test scenarios, whether or not both \( x_1 \) and \( x_2 \) are GRIM-consistent.
- \( \texttt{hit_rate} \) is the ratio of \( \texttt{hits_total} \) to \( \texttt{scenarios_total} \).

Call \texttt{audit()} following \texttt{audit_total_n()} to summarize results even further.

References

See Also

\texttt{function_map_total_n()}, which created the present function using \texttt{grim_map()}.  

\texttt{grim_map_total_n}
Examples

# Run `grim_map_total_n()` on data like these:
df <- tibble::tribble(  
x1, x2, n,  
"3.43", "5.28", 90,  
"2.97", "4.42", 103
)

df

grim_map_total_n(df)

# `audit_total_n()` summaries can be more important than  
# the detailed results themselves.  
# The `hits_total` column shows all scenarios in  
# which both divergent `n` values are GRIM-consistent 
# with the `x*` values when paired with them both ways:

# By default (`dispersion = 0:5`), the function goes 
# five steps up and down from `n`. If this sequence 
# gets longer, the number of hits tends to increase:

df %>%  
grim_map_total_n(dispersion = 0:10) %>%  
audit_total_n()

grim_plot

Visualize GRIM test results

Description

grim_plot() visualizes summary data and their mutual GRIM consistency. Call this function only 
on a data frame that resulted from a call to grim_map().

Consistent and inconsistent value pairs from the input data frame are shown in distinctive colors. 
By default, consistent value pairs are blue and inconsistent ones are red. These and other parameters 
of the underlying geoms can be controlled via arguments.

The background raster follows the rounding argument from the grim_map() call (unless any of 
the plotted mean or proportion values has more than 2 decimal places, in which case a gradient is 
shown, not a raster).

Usage

grim_plot(  
data = NULL,  
show_data = TRUE,  
show_raster = TRUE,  
show_gradient = TRUE,  
)
n = NULL,
digits = NULL,
rounding = "up_or_down",
color_cons = "royalblue1",
color_incons = "red",
tile_alpha = 1,
tile_size = 1.5,
raster_alpha = 1,
raster_color = "grey75"
)

Arguments

data Data frame. Result of a call to grim_map().
show_data Logical. If set to FALSE, test results from the data are not displayed. Choose this if you only want to show the background raster. You can then control plot parameters directly via the n, digits, and rounding arguments. Default is TRUE.
show_raster Logical. If TRUE (the default), the plot has a background raster.
show_gradient Logical. If the number of decimal places is 3 or greater, should a gradient be shown to signal the overall probability of GRIM inconsistency? Default is TRUE.
n Integer. Maximal value on the x-axis. Default is NULL, in which case n becomes 10 ^ digits (e.g., 100 if digits is 2).
digits Integer. Only relevant if show_data is set to FALSE. The plot will then be constructed as it would be for data where all x values have this many decimal places. Default is 2.
rounding String. Only relevant if show_data is set to FALSE. The plot will then be constructed as it would be for data rounded in this particular way. Default is "up_or_down".
color_cons, color_incons Strings. Fill colors of the consistent and inconsistent scatter points. Defaults are "royalblue1" (consistent) and "red" (inconsistent).
tile_alpha, tile_size Numeric. Further parameters of the scatter points: opacity and, indirectly, size. Defaults are 1 and 1.5.
raster_alpha, raster_color Numeric and string, respectively. Parameters of the background raster: opacity and fill color. Defaults are 1 and "grey75".

Value

A ggplot object.

Background raster
The background raster shows the probability of GRIM-inconsistency for random means or proportions, from 0 (all inconsistent) to the greatest number on the x-axis (all consistent). If the number of
decimal places in the inputs – means or percentages – is 3 or greater, individual points would be too small to display. In these cases, there will not be a raster but a gradient, showing the overall trend.

As any raster only makes sense with respect to one specific number of decimal places, the function will throw an error if these numbers differ among input x values (and show_raster is TRUE). You can avoid the error and force plotting by specifying digits as the number of decimal places for which the raster or gradient should be displayed.

For 1 or 2 decimal places, the raster will be specific to the rounding procedure. As the raster varies by rounding procedure, it will automatically correspond to the rounding argument specified in the preceding grim_map() call. This works fast because the raster is based on data saved in the package itself, so these data don’t need to be generated anew every time the function is called. Inconsistent value sets are marked with dark boxes. All other places in the raster denote consistent value sets. The raster is independent of the data – it only follows the rounding specification in the grim_map() call and the digits argument in grim_plot().

Display an “empty” plot, one without empirical test results, by setting show_data to FALSE. You can then control key parameters of the plot with digits and rounding.

With grim_map()’s default for rounding, "up_or_down", strikingly few values are flagged as inconsistent for sample sizes 40 and 80 (or 4 and 8). This effect disappears if rounding is set to any other value (see vignette("rounding-options")).

The 4/8 leniency effect arises because accepting values rounded either up or down is more careful and conservative than any other rounding procedure. In any case, grim_plot() doesn’t cause this effect — it only reveals it.

References

Examples

```r
# Call `grim_plot()` following `grim_map()`:
pigs1 %>%
  grim_map() %>%
  grim_plot()

# If you change the rounding procedure
# in `grim_map()`, the plot will
# follow automatically if there is
# a difference:
pigs1 %>%
  grim_map(rounding = "ceiling") %>%
  grim_plot()

# For percentages, the y-axis
# label also changes automatically:
pigs2 %>%
  grim_map(percent = TRUE) %>%
  grim_plot()
```
is_numeric_like

Test whether a vector is numeric or coercible to numeric

Description

is_numeric_like() tests whether an object is "coercible to numeric" by the particular standards of scrutiny. This means:

- Integer and double vectors are TRUE.
- Logical vectors are FALSE, as are non-vector objects.
- Other vectors (most likely strings) are TRUE if all their non-NA values can be coerced to non-NA numeric values, and FALSE otherwise.
- Factors are first coerced to string, then tested.
- Lists are tested like atomic vectors unless any of their elements have length greater 1, in which case they are always FALSE.
- If all values are non-numeric, non-logical NA, the output is also NA.

See details for discussion.

Usage

is_numeric_like(x)

Arguments

x 
Object to be tested.

Details

The scrutiny package often deals with "number-strings", i.e., strings that can be coerced to numeric without introducing new NAs. This is a matter of displaying data in a certain way, as opposed to their storage mode.

is_numeric_like() returns FALSE for logical vectors simply because these are displayed as strings, not as numbers, and the usual coercion rules would be misleading in this context. Likewise, the function treats factors like strings because that is how they are displayed: the fact that factors are stored as integers is irrelevant.

Why store numbers as strings or factors? Only these data types can preserve trailing zeros, and only if the data were originally entered as strings. See vignette("wrangling"), section Trailing zeros.

Value

Logical (length 1).

See Also

The vctrs package, which provides a serious typing framework for R; in contrast to this rather ad-hoc function.
Examples

# Numeric vectors are `TRUE`:
is_numeric_like(x = 1:5)
is_numeric_like(x = 2.47)

# Logical vectors are always `FALSE`:
is_numeric_like(x = c(TRUE, FALSE))

# Strings are `TRUE` if all of their non-`NA` values can be coerced to non-`NA` numbers, # and `FALSE` otherwise:
is_numeric_like(x = c("42", "0.7", NA))
is_numeric_like(x = c("42", "xyz", NA))

# Factors are treated like their string equivalents:
is_numeric_like(x = as.factor(c("42", "0.7", NA)))
is_numeric_like(x = as.factor(c("42", "xyz", NA)))

# Lists behave like atomic vectors if all of their elements have length 1...
is_numeric_like(x = list("42", "0.7", NA))
is_numeric_like(x = list("42", "xyz", NA))

# ...but if they don't, they are `FALSE`:
is_numeric_like(x = list("42", "0.7", NA, c(1, 2, 3)))

# If all values are `NA`, so is the output...
is_numeric_like(x = as.character(c(NA, NA, NA)))

# ...unless the `NA`s are numeric or logical:
is_numeric_like(x = as.numeric(c(NA, NA, NA)))
is_numeric_like(x = c(NA, NA, NA))

---

manage_helper_col  Helper column operations

Description

If your consistency test mapper function supports helper columns, call `manage_helper_col()` internally; once for every such column. It will check whether a helper column is compatible with its eponymous argument, i.e., if the argument was not specified by the user but has its default value.

By default (`affix = TRUE`), the function will add the column to the mapper’s input data frame. It returns the input data frame, so reassign its output to that variable.

All of this only works in mapper functions that were "handwritten" using `function()`, as opposed to those produced by `function_map()`. See vignette("consistency-tests-in-depth"), section Writing mappers manually.
manage_key_colnames

Usage
manage_helper_col(data, var_arg, default, affix = TRUE)

Arguments
- data: The data frame that is the mapper function’s first argument.
- var_arg: The argument to the mapper function that has the same name as the helper column you want to manage.
- default: The default for the argument that was specified in var_arg.
- affix: Logical (length 1). If data doesn’t include the helper column already, should var_arg be added to data, bearing its proper name? Default is TRUE.

Value
data, possibly modified (see affix argument).

manage_key_colnames

Description
A handwritten mapper function for consistency tests, such as grim_map(), may include arguments named after the key columns in its input data frame. When such an argument is specified by the user as a column name of the input data frame, it identifies a differently-named column as that key column.

Create such functionality in three steps:
1. Add arguments to your mapper function named after the respective key columns. They should be NULL by default; e.g., x = NULL, n = NULL.
2. Within the mapper, capture the user input by quoting it using rlang::enexpr(). Reassign these values to the argument variables; e.g., x <- rlang::enexpr(x) and n <- rlang::enexpr(n).
3. For every such argument, call manage_key_colnames() and reassign its value to the input data frame variable, adding a short description; e.g., data <- manage_key_colnames(data, x, "mean/proportion") and data <- manage_key_colnames(data, n, "sample size").

Usage
manage_key_colnames(data, arg, description = NULL)

Arguments
- data: The mapper function’s input data frame.
- arg: Symbol. The quoted input variable, captured by rlang::enexpr().
- description: String (length 1). Short description of the column in question, to be inserted into an error message.
Value
The input data frame, `data`, possibly modified.

See Also
`vignette("consistency-tests-in-depth")`, for context.

**Description**
`before_parens()` and `inside_parens()` extract substrings from before or inside parentheses, or similar separators like brackets or curly braces.
See `split_by_parens()` to split some or all columns in a data frame into both parts.

**Usage**
```r
before_parens(string, sep = "parens")
inside_parens(string, sep = "parens")
```

**Arguments**
- `string` Vector of strings with parentheses or similar.
- `sep` String. What to split by. Either "parens", "brackets", "braces", or a length-2 vector of custom separators. See examples for `split_by_parens()`. Default is "parens".

**Value**
String vector of the same length as `string`. The part of `string` before or inside `sep`, respectively.

**Examples**
```r
x <- c(
  "3.72 (0.95)",
  "5.86 (2.75)",
  "3.06 (6.48)"
)
before_parens(string = x)
inside_parens(string = x)
```
**pigs1**

*Means and sample sizes for GRIM-testing*

**Description**

A fictional dataset with means and sample sizes of flying pigs. It can be used to demonstrate the functionality of `grim_map()` and functions building up on it.

**Usage**

`pigs1`

**Format**

A tibble (data frame) with 12 rows and 2 columns. The columns are:

- `x` String. Means.
- `n` Numeric. Sample sizes.

**Value**

A tibble (data frame).

**See Also**

- `pigs2` for GRIM-testing percentages instead of means, `pigs3` for DEBIT-testing, and `pigs4` for detecting duplicates.
- `pigs2` for GRIM-testing percentages instead of means, `pigs3` for DEBIT-testing, `pigs4` for detecting duplicates, and `pigs5` for GRIMMER-testing.

---

**pigs2**

*Percentages and sample sizes for GRIM-testing*

**Description**

A fictional dataset with percentages and sample sizes of flying pigs. It can be used to demonstrate the functionality of `grim_map()`, particularly its percent argument, and functions building up on it.

**Usage**

`pigs2`
**Format**

A tibble (data frame) with 6 rows and 2 columns. The columns are:

- x String. Percentages.
- n Numeric. Sample sizes.

**Value**

A tibble (data frame).

**See Also**

- pigs1 for GRIM-testing means instead of percentages, pigs3 for DEBIT-testing, and pigs4 for detecting duplicates.
- pigs1 for GRIM-testing means, pigs3 for DEBIT-testing, pigs4 for detecting duplicates, and pigs5 for GRIMMER-testing.

---

**Description**

A fictional dataset with means and standard deviations from a binary distribution related to flying pigs. It can be used to demonstrate the functionality of debit_map() and functions building up on it.

**Usage**

pigs3

**Format**

A tibble (data frame) with 7 rows and 3 columns. The columns are:

- x String. Means.
- n Numeric. Sample sizes.

**Value**

A tibble (data frame).

**See Also**

- pigs1 for GRIM-testing means, pigs2 for GRIM-testing percentages, and pigs4 for detecting duplicates.
- pigs1 for GRIM-testing means, pigs2 for GRIM-testing percentages instead of means, pigs4 for detecting duplicates, and pigs5 for GRIMMER-testing.
Data with duplications

Description
A fictional dataset with observations of flying pigs. It contains multiple duplicates. The dataset can be used to demonstrate the functionality of duplicate_*( ) functions such as duplicate_count().

Usage
pigs4

Format
A tibble (data frame) with 5 rows and 3 columns, describing various body measures of the fictional pigs. The columns are:

- **snout** String. Snout width.
- **tail** String. Tail length.
- **wings** String. Wingspan.

Value
A tibble (data frame).

See Also
pigs1 for GRIM-testing means, pigs2 for GRIM-testing percentages, pigs3 for using DEBIT, and pigs5 for GRIMMER-testing.

Means, SDs, and sample sizes for GRIMMER-testing

Description
A fictional dataset with means, standard deviations (SDs), and sample sizes of flying pigs. It can be used to demonstrate the functionality of grimmer_map() and functions building up on it.

Usage
pigs5
reround

Format

A tibble (data frame) with 12 rows and 3 columns. The columns are:

x String. Means.
sd String. Standard deviations.
n Numeric. Sample sizes.

Value

A tibble (data frame).

See Also

pigs1 for (only) GRIM-testing the same means as here, pigs2 for GRIM-testing percentages instead of means, pigs3 for DEBIT-testing, and pigs4 for detecting duplicates.

reround

General interface to reconstructing rounded numbers

Description

geround() takes one or more intermediate reconstructed values and rounds them in some specific way – namely, the way they are supposed to have been rounded originally, in the process that generated the reported values.

This function provides an interface to all of scrutiny’s rounding functions as well as base::round(). It is used as a helper within grim(), grimmer(), and debit(); and it might find use in other places for consistency testing or reconstruction of statistical analyses.

Usage

geround(
  x,
  digits = 0L,
  rounding = "up_or_down",
  threshold = 5,
  symmetric = FALSE
)

Arguments

x Numeric. Vector of possibly original values.
digits Integer. Number of decimal places in the reported key values (i.e., mean or percentage within grim(), or standard deviation within grimmer()).
rounding String. The rounding method that is supposed to have been used originally. See vignette("rounding-options"). Default is "up_or_down", which returns two values: x rounded up and down.
threshold  Integer. If rounding is set to "up_from", "down_from", or "up_from_or_down_from", threshold must be set to the number from which the reconstructed values should then be rounded up or down. Otherwise irrelevant. Default is 5.

symmetric  Logical. Set symmetric to TRUE if the rounding of negative numbers with "up_or_down", "up", "down", "up_from_or_down_from", "up_from", or "down_from" should mirror that of positive numbers so that their absolute values are always equal. Otherwise irrelevant. Default is FALSE.

Details

reround() internally calls the appropriate rounding function(s) determined by the rounding argument. See vignette("rounding-options") for a complete list of values that rounding can take.

For the specific rounding functions themselves, see documentation at round_up(), round_ceiling(), and base::round().

Value

Numeric vector of length 1 or 2. (It has length 1 unless rounding is "up_or_down", "up_from_or_down_from", or "ceiling_or_floor", in which case it has length 2.)

Description

restore_zeros() takes a vector with values that might have lost trailing zeros, most likely from being registered as numeric. It turns each value into a string and adds trailing zeros until the mantissa hits some limit.

The default for that limit is the number of digits in the longest mantissa of the vector’s values. The length of the integer part plays no role.

Don’t rely on the default limit without checking: The original width could have been larger because the longest extant mantissa might itself have lost trailing zeros.

restore_zeros_df() is a variant for data frames. It wraps restore_zeros() and, by default, applies it to all columns that are coercible to numeric.

Usage

restore_zeros(
  x,
  width = NULL,
  sep_in = "\",
  sep_out = sep_in,
  sep = deprecated()
)
restore_zeros_df(
  data,
  cols = everything(),
  check_numeric_like = TRUE,
  check_decimals = FALSE,
  width = NULL,
  sep_in = "\"\.",
  sep_out = NULL,
  sep = deprecated()
)

Arguments

x Numeric (or string coercible to numeric). Vector of numbers that might have lost trailing zeros.

width Integer. Number of decimal places the mantissas should have, including the restored zeros. Default is NULL, in which case the number of characters in the longest mantissa will be used instead.

sep_in Substring that separates the input’s mantissa from its integer part. Default is "\"\.", which renders a decimal point.

sep_out Substring that will be returned in the output to separate the mantissa from the integer part. By default, sep_out is the same as sep_in.

sep [Deprecated] Use sep_in, not sep. If sep is specified nonetheless, sep_in takes on sep’s value.

data Data frame or matrix. Only in restore_zeros_df(), and instead of x.

cols Only in restore_zeros_df(). Select columns from data using tidyselect. Default is everything(), which selects all columns that pass the test of check_numeric_like.

check_numeric_like Logical. Only in restore_zeros_df(). If TRUE (the default), the function will skip columns that are not numeric or coercible to numeric, as determined by is_numeric_like().

check_decimals Logical. Only in restore_zeros_df(). If set to TRUE, the function will skip columns where no values have any decimal places. Default is FALSE.

Details

These functions exploit the fact that groups of summary values such as means or percentages are often reported to the same number of decimal places. If such a number is known but values were not entered as strings, trailing zeros will be lost. In this case, restore_zeros() or restore_zeros_df() will be helpful to prepare data for consistency testing functions such as grim_map() or grimmer_map().
For \code{restore_zeros()}, a string vector. At least some of the strings will have newly restored zeros, unless (1) all input values had the same number of decimal places, and (2) width was not specified as a number greater than that single number of decimal places.

For \code{restore_zeros_df()}, a data frame.

Displaying decimal places

You might not see all decimal places of numeric values in a vector, and consequently wonder if \code{restore_zeros()}, when applied to the vector, adds too many zeros. That is because displayed numbers, unlike stored numbers, are often rounded.

For a vector \code{x}, you can count the characters of the longest mantissa from among its values like this:

\begin{alltt}
x %>% decimal_places() %>% max()
\end{alltt}

See Also

Wrapped functions: \code{sprintf()}.

Examples

\begin{alltt}
# By default, the target width is that of
# the longest mantissa:
vec <- c(212, 75.38, 4.9625)
vec %>%
    restore_zeros()

# Alternatively, supply a number via 'width':
vec %>%
    restore_zeros(width = 6)

# For better printing:
iris <- tibble::as_tibble(iris)

# Apply 'restore_zeros()' to all numeric
# columns, but not to the factor column:
iris %>%
    restore_zeros_df()

# Select columns as in 'dplyr::select()':
iris %>%
    restore_zeros_df(starts_with("Sepal"), width = 3)
\end{alltt}

---

\code{reverse_map_seq} \emph{Reverse the \_map\_seq() process}
reverse_map_total_n

Description

reverse_map_seq() takes the output of a function created by function_map_seq() and reconstructs the original data frame.

See audit_seq(), which takes reverse_map_seq() as a basis.

Usage

reverse_map_seq(data)

Arguments

data Data frame that inherits the "scr_map_seq" class.

Value

The reconstructed tibble (data frame) which a factory-made *_map_seq() function took as its data argument.

Examples

# Originally reported summary data...
pigs1

# ...GRIM-tested with varying inputs...
out <- grim_map_seq(pigs1, include_consistent = TRUE)

# ...and faithfully reconstructed:
reverse_map_seq(out)

reverse_map_total_n Reverse the *_map_total_n() process

Description

reverse_map_total_n() takes the output of a function created by function_map_total_n() and reconstructs the original data frame.

See audit_total_n(), which takes reverse_map_total_n() as a basis.

Usage

reverse_map_total_n(data)

Arguments

data Data frame that inherits the "scr_map_total_n" class.
Value
The reconstructed tibble (data frame) which a factory-made *_map_total_n() function took as its data argument.

Examples
# Originally reported summary data...
df <- tibble::tribble(
  ~x1, ~x2, ~n,
  "3.43", "5.28", 90,
  "2.97", "4.42", 103
)
df

# ...GRIM-tested with dispersed 'n' values...
out <- grim_map_total_n(df)
out

# ...and faithfully reconstructed:
reverse_map_total_n(out)

Common rounding procedures

Description
round_up() rounds up from 5, round_down() rounds down from 5. Otherwise, both functions work like base::round().
round_up() and round_down() are special cases of round_up_from() and round_down_from(), which allow users to choose custom thresholds for rounding up or down, respectively.

Usage
round_up_from(x, digits = 0L, threshold, symmetric = FALSE)
round_down_from(x, digits = 0L, threshold, symmetric = FALSE)
round_up(x, digits = 0L, symmetric = FALSE)
round_down(x, digits = 0L, symmetric = FALSE)

Arguments
x Numeric. The decimal number to round.
digits Integer. Number of digits to round x to. Default is 0.
threshold Integer. Only in round_up_from() and round_down_from(). Threshold for rounding up or down, respectively. Value is 5 in round_up()'s internal call to round_up_from() and in round_down()'s internal call to round_down_from().
symmetric: Logical. Set symmetric to TRUE if the rounding of negative numbers should mirror that of positive numbers so that their absolute values are equal. Default is FALSE.

Details

These functions differ from `base::round()` mainly insofar as the decision about rounding 5 up or down is not based on the integer portion of `x` (i.e., no "rounding to even"). Instead, in `round_up_from()`, that decision is determined by the threshold argument for rounding up, and likewise with `round_down_from()`. The threshold is constant at 5 for `round_up()` and `round_down()`.

As a result, these functions are more predictable and less prone to floating-point number quirks than `base::round()`. Compare `round_down()` and `base::round()` in the data frame for rounding 5 created in the Examples section below: `round_down()` yields a continuous sequence of final digits from 0 to 9, whereas `base::round()` behaves in a way that can only be explained by floating point issues.

However, this surprising behavior on the part of `base::round()` is not necessarily a flaw (see its documentation, or this vignette: https://rpubs.com/maechler/Rounding). In the present version of R (4.0.0 or later), `base::round()` works fine, and the functions presented here are not meant to replace it. Their main purpose as helpers within scrutiny is to reconstruct the computations of researchers who might have used different software. See vignette("rounding-options").

Value

Numeric. `x` rounded to `digits`.

See Also

`round_ceiling()` always rounds up, `round_floor()` always rounds down, `round_trunc()` always rounds toward 0, and `round_anti_trunc()` always round away from 0.

Examples

# Both `round_up()` and `round_down()` work like
# `base::round()` unless the closest digit to be
# cut off by rounding is 5:

```
rround_up(x = 9.273, digits = 1) # 7 cut off
rround_down(x = 9.273, digits = 1) # 7 cut off
base::round(x = 9.273, digits = 1) # 7 cut off
```

```
rround_up(x = 7.584, digits = 2) # 4 cut off
rround_down(x = 7.584, digits = 2) # 4 cut off
base::round(x = 7.584, digits = 2) # 4 cut off
```

# Here is the borderline case of 5 rounded by
# `round_up()`, `round_down()`, and `base::round()`:

```
original <- c( # Define example values
  0.05, 0.15, 0.25, 0.35, 0.45,
)
rounding-uncommon

Uncommon rounding procedures

Description

Always round up, down, toward zero, or away from it:

- `round_ceiling()` always rounds up.
- `round_floor()` always rounds down.
- `round_trunc()` always rounds toward zero.
- `round_anti_trunc()` always rounds away from zero. (0 itself is rounded to 1.)
- `anti_trunc()` does not round but otherwise works like `round_anti_trunc()`.

Despite not being widely used, they are featured here in case they are needed for reconstruction.

Usage

`round_ceiling(x, digits = 0L)`

`round_floor(x, digits = 0L)`

`round_trunc(x, digits = 0L)`

`anti_trunc(x)`

`round_anti_trunc(x, digits = 0L)`

Arguments

- `x` Numeric. The decimal number to round.
- `digits` Integer. Number of digits to round x to. Default is 0.
rounding_bias

Details

round_ceiling(), round_floor(), and round_trunc() generalize the base R functions ceiling(), floor(), and trunc(), and include them as special cases: With the default value for digits, 0, these round_* functions are equivalent to their respective base counterparts.

The last round_* function, round_anti_trunc(), generalizes another function presented here: anti_trunc() works like trunc() except it moves away from 0, rather than towards it. That is, whereas trunc() minimizes the absolute value of x (as compared to the other rounding functions), anti_trunc() maximizes it. anti_trunc(x) is therefore equal to trunc(x) + 1 if x is positive, and to trunc(x) - 1 if x is negative.

round_anti_trunc(), then, generalizes anti_trunc() just as round_ceiling() generalizes ceiling(), etc.

Moreover, round_trunc() is equivalent to round_floor() for positive numbers and to round_ceiling() for negative numbers. The reverse is again true for round_anti_trunc(): It is equivalent to round_ceiling() for positive numbers and to round_floor() for negative numbers.

Value

Numeric. x rounded to digits (except for anti_trunc(), which has no digits argument).

See Also

round_up() and round_down() round up or down from 5, respectively. round_up_from() and round_down_from() allow users to specify custom thresholds for rounding up or down.

Examples

# Always round up:
round_ceiling(x = 4.52, digits = 1) # 2 cut off

# Always round down:
round_floor(x = 4.67, digits = 1) # 7 cut off

# Always round toward 0:
round_trunc(8.439, digits = 2) # 9 cut off
round_trunc(-8.439, digits = 2) # 9 cut off

# Always round away from 0:
round_anti_trunc(x = 8.421, digits = 2) # 1 cut off
round_anti_trunc(x = -8.421, digits = 2) # 1 cut off

---

rounding_bias Compute rounding bias

Description

Rounding often leads to bias, such that the mean of a rounded distribution is different from the mean of the original distribution. Call rounding_bias() to compute the amount of this bias.
rounding_bias

Usage

rounding_bias(
  x,
  digits,
  rounding = "up",
  threshold = 5,
  symmetric = FALSE,
  mean = TRUE
)

Arguments

x Numeric or string coercible to numeric.
digits Integer. Number of decimal digits to which x will be rounded.
rounding String. Rounding procedure that will be applied to x. See vignette("rounding-options"). Default is "up".
threshold, symmetric Further arguments passed down to reround().
mean Logical. If TRUE (the default), the mean total of bias will be returned. Set mean to FALSE to get a vector of individual biases the length of x.

details

Bias is calculated by subtracting the original vector, x, from a vector rounded in the specified way. The function passes all arguments except for mean down to reround(). Other than there, however, rounding is "up" by default, and it can't be set to "up_or_down", "up_from_or_down_from", or "ceiling_or_floor".

Value

Numeric. By default of mean, the length is 1; otherwise, it is the same length as x.

Examples

# Define example vector:
vec <- seq_distance(0.01, string_output = FALSE)
vec

# The default rounds `x` up from 5:
rounding_bias(x = vec, digits = 1)

# Other rounding procedures are supported,
# such as rounding down from 5...
rounding_bias(x = vec, digits = 1, rounding = "down")

# ...or rounding to even with `base::round()`
rounding_bias(x = vec, digits = 1, rounding = "even")
Description

Data frames sometimes have wrong column names, while the correct column names are stored in one or more rows in the data frame itself. To remedy this issue, call `row_to_colnames()` on the data frame: It replaces the column names by the values of the specified rows (by default, only the first one). These rows are then dropped by default.

Usage

```r
row_to_colnames(data, row = 1L, collapse = " ", drop = TRUE)
```

Arguments

- `data` Data frame or matrix.
- `row` Integer. Position of the rows (one or more) that jointly contain the correct column names. Default is 1.
- `collapse` String. If the length of `row` is greater than 1, each new column name will be that many row values pasted together. `collapse`, then, is the substring between two former row values in the final column names. Default is " " (a space).
- `drop` Logical. If TRUE (the default), the rows specified with `row` are removed.

Details

If multiple rows are specified, the row values for each individual column are pasted together. Some special characters might then be missing.

This function might be useful when importing tables from PDF, e.g. with `tabulizer`. In R, these data frames (converted from matrices) do sometimes have the issue described above.

Value

A tibble (data frame).

See Also

`unheadr::mash_colnames()`, a more sophisticated solution to the same problem.
**Description**

Compute the sample SD of binary data (i.e., only 0 and 1 values) in either of four ways, each based on different inputs:

- `sd_binary_groups()` takes the cell sizes of both groups, those coded as 0 and those coded as 1.
- `sd_binary_0_n()` takes the cell size of the group coded as 0 and the total sample size.
- `sd_binary_1_n()` takes the cell size of the group coded as 1 and the total sample size.
- `sd_binary_mean_n()` takes the mean and the total sample size.

These functions are used as helpers inside `debit()`, and consequently `debit_map()`.

**Usage**

```r
sd_binary_groups(group_0, group_1)
sd_binary_0_n(group_0, n)
sd_binary_1_n(group_1, n)
sd_binary_mean_n(mean, n)
```

**Arguments**

- `group_0` Integer. Cell size of the group coded as 0.
- `group_1` Integer. Cell size of the group coded as 1.
- `n` Integer. Total sample size.
- `mean` Numeric. Mean of the binary data.

**Value**

Numeric. Sample standard deviation.

**References**

**See Also**

- `is_subset_of_vals(x, 0, 1)` checks whether `x` (a list or atomic vector) contains nothing but binary numbers.
Examples

# If 127 values are coded as 0 and 153 as 1...
sd_binary_groups(group_0 = 127, group_1 = 153)

# ...so that n = 280:
sd_binary_0_n(group_0 = 127, n = 280)
sd_binary_1_n(group_1 = 153, n = 280)

# If only the mean and total sample size are
given, or these are more convenient to use,
# they still lead to the same result as above
# if the mean is given with a sufficiently
# large number of decimal places:
sd_binary_mean_n(mean = 0.5464286, n = 280)

---

seq-decimal  
Sequence generation at decimal level

Description

Functions that provide a smooth interface to generating sequences based on the input values’ decimal depth. Each function creates a sequence with a step size of one unit on the level of the input values’ ultimate decimal digit (e.g., 2.45, 2.46, 2.47, ...):

- **seq_endpoint()** creates a sequence from one input value to another. For step size, it goes by the value with more decimal places.
- **seq_distance()** only takes the starting point and, instead of the endpoint, the desired output length. For step size, it goes by the starting point by default.

**seq_endpoint_df()** and **seq_distance_df()** are variants that create a data frame. Further columns can be added as in **tibble::tibble()**. Regular arguments are the same as in the respective non-**df** function, but with a dot before each.

Usage

```r
dseq_endpoint(from, to, offset_from = 0L, offset_to = 0L, string_output = TRUE)
sseq_distance(
  from,
  by = NULL,
  length_out = 10L,
  dir = 1,
  offset_from = 0L,
  offset_to = 0L,
  string_output = TRUE
)

dseq_endpoint_df(
  .from,
```
Arguments

from, .from Numeric (or string coercible to numeric). Starting point of the sequence.

to, .to Numeric (or string coercible to numeric). Endpoint of the sequence. Only in seq_endpoint() and seq_endpoint_df().

offset_from, .offset_from Integer. If set to a non-zero number, the starting point will be offset by that many units on the level of the last decimal digit. Default is 0.

offset_to, .offset_to Integer. If set to a non-zero number, the endpoint will be offset by that many units on the level of the last decimal digit. Default is 0. Only in seq_endpoint() and seq_endpoint_df().

string_output, .string_output Logical or string. If TRUE (the default), the output is a string vector. Decimal places are then padded with zeros to match from's (or to's) number of decimal places. "auto" works like TRUE if and only if from (.from) is a string.

by, .by Numeric. Only in seq_distance() and seq_distance_df(). Step size of the sequence. If not set, inferred automatically. Default is NULL.

length_out, .length_out Integer. Length of the output vector (i.e., the number of its values). Default is 10. Only in seq_distance() and seq_distance_df().

dir, .dir Integer. If set to -1, the sequence goes backward. Default is 1. Only in seq_distance() and seq_distance_df().

... Further columns, added as in tibble::tibble(). Only in seq_endpoint_df() and seq_distance_df().

Details

If either from or to ends on zero, be sure to enter that value as a string! This is crucial because trailing zeros get dropped from numeric values. A handy way to format numeric values or number-
strings correctly is `restore_zeros()`. The output of the present functions is like that by default (of `string_output`).

In `seq_endpoint()` and `seq_endpoint_df()`, the step size is determined by `from` and `to`, whichever has more decimal places. In `seq_distance()` and `seq_distance_df()`, it’s determined by the decimal places of `from`.

These functions are scrutiny’s take on `base::seq()`, and themselves wrappers around it.

**Value**

String by default of `string_output`, numeric otherwise.

**See Also**

`seq_disperse()` for sequences centered around the input.

**Examples**

```r
# Sequence between two points:
seq_endpoint(from = 4.7, to = 5)

# Sequence of some length; default is 10:
seq_distance(from = 0.93)
seq_distance(from = 0.93, length_out = 5)

# Both of these functions can offset the
# starting point...
seq_endpoint(from = 14.2, to = 15, offset_from = 4)
seq_distance(from = 14.2, offset_from = 4)

# ...but only `seq_endpoint()` can offset the
# endpoint, because of its `to` argument:
seq_endpoint(from = 9.5, to = 10, offset_to = 2)

# In return, `seq_distance()` can reverse its direction:
seq_distance(from = 20.03, dir = -1)

# Both functions have a `_df` variant that returns
# a data frame. Arguments are the same but with a
# `dot, and further columns can be added as in
# `tibble::tibble()`:
seq_endpoint_df(.from = 4.7, .to = 5, n = 20)
seq_distance_df(.from = 0.43, .length_out = 5, sd = 0.08)
```
Description

Predicate functions that test whether \( x \) is a numeric vector (or coercible to numeric) with some special properties:

- \texttt{is_seq_linear()} tests whether every two consecutive elements of \( x \) differ by some constant amount.
- \texttt{is_seq_ascending()} and \texttt{is_seq_descending()} test whether the difference between every two consecutive values is positive or negative, respectively. \texttt{is_seq_dispersed()} tests whether \( x \) values are grouped around a specific central value, \texttt{from}, with the same distance to both sides per value pair. By default (\texttt{test_linear = TRUE}), these functions also test for linearity, like \texttt{is_seq_linear()}.

\( NA \) elements of \( x \) are handled in a nuanced way. See \texttt{Value} section below and the examples in \texttt{vignette("devtools")}, section \texttt{NA handling}.

Usage

\begin{verbatim}
is_seq_linear(x, tolerance = .Machine$double.eps^0.5)

is_seq_ascending(x, test_linear = TRUE, tolerance = .Machine$double.eps^0.5)

is_seq_descending(x, test_linear = TRUE, tolerance = .Machine$double.eps^0.5)

is_seq_dispersed(
    x,
    from,
    test_linear = TRUE,
    tolerance = .Machine$double.eps^0.5
)
\end{verbatim}

Arguments

\begin{itemize}
  \item \texttt{x} \hspace{2cm} Numeric or coercible to numeric, as determined by \texttt{is_numeric_like()}. Vector to be tested.
  \item \texttt{tolerance} \hspace{2cm} Numeric. Tolerance of comparison between numbers when testing. Default is circa 0.000000015 (1.490116e-08), as in \texttt{dplyr::near()}. Default is \texttt{TRUE}.
  \item \texttt{test_linear} \hspace{2cm} Logical. In functions other than \texttt{is_seq_linear()}, should \( x \) also be tested for linearity? Default is \texttt{TRUE}.
  \item \texttt{from} \hspace{2cm} Numeric or coercible to numeric. Only in \texttt{is_seq_dispersed()}. It will test whether \texttt{from} is at the center of \( x \), and if every pair of other values is equidistant to it.
\end{itemize}

Value

A single logical value. If \( x \) contains at least one \texttt{NA} element, the functions return either \texttt{NA} or \texttt{FALSE}:

- If all elements of \( x \) are \texttt{NA}, the functions return \texttt{NA}. 
- If some but not all elements are NA, they check if x might be a sequence of the kind in question: Is it a linear (and / or ascending, etc.) sequence after the NAs were replaced by appropriate values? If so, they return NA; otherwise, they return FALSE.

See Also

validate::is_linear_sequence(), which is much like is_seq_linear() but more permissive with NA values. It comes with some additional features, such as support for date-times.

Examples

# These are linear sequences...
is_seq_linear(x = 3:7)
is_seq_linear(x = c(3:7, 8))

# ...but these aren't:
is_seq_linear(x = c(3:7, 9))
is_seq_linear(x = c(10, 3:7))

# All other 'is_seq_*()' functions
# also test for linearity by default:
is_seq_ascending(x = c(2, 7, 9))
is_seq_ascending(x = c(2, 7, 9), test_linear = FALSE)

is_seq_descending(x = c(9, 7, 2))
is_seq_descending(x = c(9, 7, 2), test_linear = FALSE)

is_seq_dispersed(x = c(2, 3, 5, 7, 8), from = 5)
is_seq_dispersed(x = c(2, 3, 5, 7, 8), from = 5, test_linear = FALSE)

# These fail their respective
# individual test even
# without linearity testing:
is_seq_ascending(x = c(1, 7, 4), test_linear = FALSE)
is_seq_descending(x = c(9, 15, 3), test_linear = FALSE)
is_seq_dispersed(1:10, from = 5, test_linear = FALSE)

seq_disperse

Sequence generation with dispersion at decimal level

Description

seq_disperse() creates a sequence around a given number. It goes a specified number of steps up and down from it. Step size depends on the number’s decimal places. For example, 7.93 will be surrounded by values like 7.91, 7.92, and 7.94, 7.95, etc.

seq_disperse_df() is a variant that creates a data frame. Further columns can be added as in tibble::tibble(). Regular arguments are the same as in seq_disperse(), but with a dot before each.
Usage

```r
seq_disperse(
  from,
  by = NULL,
  dispersion = 1:5,
  offset_from = 0L,
  out_min = "auto",
  out_max = NULL,
  string_output = TRUE,
  include_reported = TRUE,
  track_diff_var = FALSE,
  track_var_change = deprecated()
)
```

```r
seq_disperse_df(
  .from,
  .by = NULL,
  ...,
  .dispersion = 1:5,
  .offset_from = 0L,
  .out_min = "auto",
  .out_max = NULL,
  .string_output = TRUE,
  .include_reported = TRUE,
  .track_diff_var = FALSE,
  .track_var_change = FALSE
)
```

Arguments

- `from, .from` Numeric (or string coercible to numeric). Starting point of the sequence.
- `by, .by` Numeric. Step size of the sequence. If not set, inferred automatically. Default is `NULL`.
- `dispersion, .dispersion` Numeric. Vector that determines the steps up and down, starting at `from` (or `.from`, respectively) and proceeding on the level of its last decimal place. Default is `1:5`, i.e., five steps up and down.
- `offset_from, .offset_from` Integer. If set to a non-zero number, the starting point will be offset by that many units on the level of the last decimal digit. Default is `0`.
- `out_min, .out_min, out_max, .out_max` If specified, output will be restricted so that it’s not below `out_min` or above `out_max`. Defaults are "auto" for `out_min`, i.e., a minimum of one decimal unit above zero; and `NULL` for `out_max`, i.e., no maximum.
- `string_output, .string_output` Logical or string. If `TRUE` (the default), the output is a string vector. Decimal places are then padded with zeros to match `from`’s number of decimal places. "auto" works like `TRUE` if and only if `from(.from)` is a string.
include_reported, .include_reported
Logical. Should from (.from) itself be part of the sequence built around it?
Default is TRUE for the sake of continuity, but this can be misleading if the focus
is on the dispersed values, as opposed to the input.

track_diff_var, .track_diff_var
Logical. In seq_disperse(), ignore this argument. In seq_disperse_df(),
default is TRUE, which creates the "diff_var" output column.

track_var_change, .track_var_change
[Deprecated] Renamed to track_diff_var / .track_diff_var.

Further columns, added as in tibble::tibble(). Only in seq_disperse_df().

Details
Unlike seq_endpoint() and friends, the present functions don’t necessarily return continuous or
even regular sequences. The greater flexibility is due to the dispersion (.dispersion) argument,
which takes any numeric vector. By default, however, the output sequence is regular and continuous.
Underlying this difference is the fact that seq_disperse() and seq_disperse_df() do not wrap
around base::seq(), although they are otherwise similar to seq_endpoint() and friends.

Value
- seq_disperse() returns a string vector by default (string_output = TRUE) and a numeric
  vector otherwise.
- seq_disperse_df() returns a tibble (data frame). The sequence is stored in the x column. x
  is string by default (.string_output = TRUE), numeric otherwise. Other columns might have
  been added via the dots (...).

See Also
Conceptually, seq_disperse() is a blend of two function families: those around seq_endpoint()
and those around disperse(). The present functions were originally conceived for seq_disperse_df()
to be a helper within the function_map_seq() implementation.

Examples
# Basic usage:
seq_disperse(from = 4.02)

# If trailing zeros don’t matter,
# the output can be numeric:
seq_disperse(from = 4.02, string_output = FALSE)

# Control steps up and down with
# 'dispersion' (default is '1:5'):
seq_disperse(from = 4.02, dispersion = 1:10)

# Sequences might be discontinuous...
disp1 <- seq(from = 2, to = 10, by = 2)
seq_disperse(from = 4.02, dispersion = disp1)
# ...or even irregular:
disp2 <- c(2, 3, 7)
seq_disperse(from = 4.02, dispersion = disp2)

# The data frame variant supports further
# columns added as in `tibble::tibble()`:
seq_disperse_df(.from = 4.02, n = 45)

---

### seq_length

**Set sequence length**

#### Description

`seq_length()` seamlessly extends or shortens a linear sequence using the sequence’s own step size. Alternatively, you can directly set the length of a linear sequence in this way: `seq_length(x) <- value`.

#### Usage

```r
seq_length(x, value)
seq_length(x) <- value
```

#### Arguments

- **x**
  - Numeric or coercible to numeric. `x` must be linear, i.e., each of its elements must differ from the next by the same amount.

- **value**
  - Numeric (whole number, length 1). The new length for `x`.

#### Value

A vector of the same type as `x`, with length `value`.

- If `value > length(x)`, all original element of `x` are preserved. A number of new elements equal to the difference is appended at the end.
- If `value == length(x)`, nothing changes.
- If `value < length(x)`, a number of elements of `x` equal to the difference is removed from the end.

#### Examples

```r
x <- 3:7

# Increase the length of 'x' from 5 to 10:
seq_length(x, 10)

# Modify 'x' directly (but get
```
seq_test_ranking

# the same results otherwise):
seq_length(x) <- 10
x

# Likewise, decrease the length:
x <- 3:7
seq_length(x, 2)
seq_length(x) <- 2
x

# The functions are sensitive to decimal levels.
# They also return a string vector if (and only if)
# 'x' is a string vector:
x <- seq_endpoint(from = 0, to = 0.5)
x
seq_length(x, 10)
seq_length(x) <- 10
x

# Same with decreasing the length:
seq_length(x, 2)
seq_length(x) <- 2
x

---

seq_test_ranking   Rank sequence test results

Description

Run this function after generating a sequence with seq_endpoint_df() or seq_distance_df() and testing it with one of scrutiny’s mapping functions, such as grim_map(). It will rank the test’s consistent and inconsistent results by their positions in the sequence.

Usage

seq_test_ranking(x, explain = TRUE)

Arguments

x      Data frame.
explain If TRUE (the default), results come with an explanation.

Details

The function checks the provenance of the test results and throws a warning if it’s not correct.
Value

A tibble (data frame). The function will also print an explanation of the results. See examples.

Examples

```r
seq_distance_df(.from = "0.00", n = 50) %>%
grim_map() %>%
seq_test_ranking()
```

split_by_parens

Split columns by parentheses, brackets, braces, or similar

Description

Summary statistics are often presented like "2.65 (0.27)". When working with tables copied into R, it can be tedious to separate values before and inside parentheses. `split_by_parens()` does this automatically.

By default, it operates on all columns. Output can optionally be pivoted into a longer format by setting `transform` to `TRUE`.

Choose separators other than parentheses with the `sep` argument.

Usage

```r
split_by_parens(
  data, 
  cols = everything(), 
  check_sep = TRUE, 
  keep = FALSE, 
  transform = FALSE, 
  sep = "parens", 
  end1 = "x", 
  end2 = "sd", 
  ... 
)
```

Arguments

- `data`: Data frame.
- `cols`: Select columns from `data` using `tidyselect`. Default is `everything()`, which selects all columns that pass `check_sep`.
- `check_sep`: Logical. If `TRUE` (the default), columns are excluded if they don’t contain the `sep` elements.
- `keep`: Logical. If set to `TRUE`, the originally selected columns that were split by the function also appear in the output. Default is `FALSE`.
- `transform`: Logical. If set to `TRUE`, the output will be pivoted to be better suitable for typical follow-up tasks. Default is `FALSE`. 
split_by_parens

sep

String. What to split by. Either "parens", "brackets", or "braces"; or a length-2 vector of custom separators (see Examples). Default is "parens".

end1, end2

Strings. Endings of the two column names that result from splitting a column. Default is "x" for end1 and "sd" for end2.

... These dots must be empty.

Value

Data frame.

See Also

- `before_parens()` and `inside_parens()` take a string vector and extract values from the respective position.
- `dplyr::across()` powers the application of the two above functions within `split_by_parens()`, including the creation of new columns.
- `tidyr::separate_wider_delim()` is a more general function, but it does not recognize closing elements such as closed parentheses.

Examples

```r
# Call `split_by_parens()` on data like these:
df1 <- tibble::tribble(~drone, ~selfpilot,
                      "0.09 (0.21)", "0.19 (0.13)",
                      "0.19 (0.28)", "0.53 (0.10)",
                      "0.62 (0.16)", "0.50 (0.11)",
                      "0.15 (0.35)", "0.57 (0.16)",
)

# Basic usage:
df1 %>%
  split_by_parens()

# Name specific columns with `cols` to only split those:
df1 %>%
  split_by_parens(cols = drone)

# Pivot the data into a longer format
# by setting `transform` to `TRUE`:
df1 %>%
  split_by_parens(transform = TRUE)

# Choose different column names or
# name suffixes with `end1` and `end2`:
df1 %>%
  split_by_parens(end1 = "beta", end2 = "se")

df1 %>%
  split_by_parens(
```
subset-superset

Test for subsets, supersets, and equal sets

Description

Predicate functions that take a vector and test whether it has some particular relation to another vector. That second vector is entered in either of three ways –

Enter it directly (basic functions):

`is_subset_of()` tests if a vector is a subset of another vector; i.e., if all its elements are contained in the second one. `is_superset_of()` does the reverse: It tests if the first vector contains all elements of the second one. `is_equal_set()` tests if both vectors have exactly the same values.

Enter its values:

`is_subset_of_vals()`, `is_superset_of_vals()`, and `is_equal_set_vals()` are variants that each take a single vector plus any number of other arguments. These are treated like elements of the second vector in the basic functions above.
Enter multiple vectors that jointly contain its values:

Finally, is_subset_of_vecs(), is_superset_of_vecs(), and is_equal_set_vecs() take one vector plus any number of other vectors and treat their elements (!) like elements of a second vector in the basic functions above.

Each is_subset*() function has an is_proper_subset*() variant. These variants also test whether the sets are unequal, so that x is a subset of y but y is not a subset of x. The same applies to is_superset*() functions and their is_proper_superset*() variants.

Usage

is_subset_of(x, y)

is_superset_of(x, y)

is_equal_set(x, y)

is_proper_subset_of(x, y)

is_proper_superset_of(x, y)

is_subset_of_vals(x, ...)

is_superset_of_vals(x, ...)

is_equal_set_vals(x, ...)

is_proper_subset_of_vals(x, ...)

is_proper_superset_of_vals(x, ...)

is_subset_of_vecs(x, ...)

is_superset_of_vecs(x, ...)

is_equal_set_vecs(x, ...)

is_proper_subset_of_vecs(x, ...)

is_proper_superset_of_vecs(x, ...)

Arguments

x A vector.

y A vector. Only in the basic functions, not those with *_vals() or *_vecs().

... In the *_vals() functions, any number of values x might contain; in the *_vecs() functions, any number of vectors the elements of which x might contain.
Details

The *_vals()* variants are meant for flexible, interactive subset/superset testing. That is, in order to test whether certain values collectively fulfill the role of the second vector, you can just add them to the function call.

The *_vecs()* variants likewise offer flexibility, but also bridge the gap between vectors and values contained in them.

All functions simply check if values are present, regardless of how often a value occurs. In other words, they look for types but don’t count tokens.

Value

A single logical value. TRUE if the respective test was passed, FALSE otherwise.

Examples

```r
# Define example vectors:
ab <- c("a", "b")
abc <- c("a", "b", "c")
abcde <- c("a", "b", "c", "d", "e")

# `is_subset_of()` tests if a vector is
# completely covered by another one:
abc %>% is_subset_of(ab)
abc %>% is_subset_of(abc)
abc %>% is_subset_of(abcde)

# To the contrary, `is_superset_of()` tests if the
# first vector completely covers the second one:
abc %>% is_superset_of(ab)
abc %>% is_superset_of(abc)
abc %>% is_superset_of(abcde)

# `is_equal_set()` tests both of the above --
# i.e., if both vectors have exactly the
# same values:
abc %>% is_equal_set(ab)
abc %>% is_equal_set(abc)
abc %>% is_equal_set(abcde)

# Each of the three functions has a `*_vals()` variant
# that doesn't take a second vector like the first
# one, but any number of other arguments. These are
# jointly treated like the elements of the second
# vector in the basic functions:
abc %>% is_subset_of_vals("a", "b")
abc %>% is_subset_of_vals("a", "b", "c")
abc %>% is_subset_of_vals("a", "b", "c", "d", "e")

# (... and likewise for supersets and equal sets.)
```
unnest_consistency_cols

Unnest a test result column

Description

Within a consistency test mapper function, it may become necessary to unpack a column resulting from a basic \_scalar() testing function. That will be the case if a show\_* argument of the mapper function like show_rec in grim_map() is TRUE, and the \_scalar() function returns a list of values, not just a single value.

At the point where such a list is stored in a data frame column (most likely “consistency”), call unnest_consistency_cols() to unnest the results into multiple columns.

Usage

unnest_consistency_cols(results, col_names, index = FALSE, col = "consistency")

Arguments

results     Data frame containing a list-column by the name passed to col.

col_names   String vector of new names for the unnested columns. It should start with the same string that was given for col.

index       Logical. Should the list-column be indexed into? Default is FALSE.

col         String (length 1). Name of the list-column within results to operate on. Default is "consistency".

Details

This function is a custom workaround in place of tidyr::unnest_wider(), mirroring some of the latter’s functionality. It was created because unnest_wider() can be too slow for use as a helper function.

Value

Data frame. The column names are determined by col_names.

See Also

vignette("consistency-tests-in-depth"), for context.
unround

Reconstruct rounding bounds

Description

unround() takes a rounded number and returns the range of the original value: lower and upper bounds for the hypothetical earlier number that was later rounded to the input number. It also displays a range with inequation signs, showing whether the bounds are inclusive or not.

By default, the presumed rounding method is rounding up (or down) from 5. See the Rounding section for other methods.

Usage

unround(x, rounding = "up_or_down", threshold = 5, digits = NULL)

Arguments

x | String or numeric. Rounded number. x must be a string unless digits is specified (most likely by a function that uses unround() as a helper).
rounding | String. Rounding method presumably used to create x. Default is "up_or_down". For more, see section Rounding.
threshold | Integer. Number from which to round up or down. Other rounding methods are not affected. Default is 5.
digits | Integer. This argument is meant to make unround() more efficient to use as a helper function so that it doesn’t need to redundantly count decimal places. Don’t specify it otherwise. Default is NULL, in which case decimal places really are counted internally and x must be a string.

Details

The function is vectorized over x and rounding. This can be useful to unround multiple numbers at once, or to check how a single number is unrounded with different assumed rounding methods.

If both vectors have a length greater than 1, it must be the same length. However, this will pair numbers with rounding methods, which can be confusing. It is recommended that at least one of these input vectors has length 1.

Why does x need to be a string if digits is not specified? In that case, unround() must count decimal places by itself. If x then was numeric, it wouldn’t have any trailing zeros because these get dropped from numerics.

Trailing zeros are as important for reconstructing boundary values as any other trailing digits would be. Strings don’t drop trailing zeros, so they are used instead.

Value

A tibble with seven columns: range, rounding, lower, incl_lower, x, incl_upper, and upper. The range column is a handy representation of the information stored in the columns from lower to upper, in the same order.
Rounding

Depending on how x was rounded, the boundary values can be inclusive or exclusive. The incl_lower and incl_upper columns in the resulting tibble are TRUE in the first case and FALSE in the second. The range column reflects this with equation and inequation signs.

However, these ranges are based on assumptions about the way x was rounded. Set rounding to the rounding method that hypothetically lead to x:

<table>
<thead>
<tr>
<th>Value of rounding</th>
<th>Corresponding range</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;up_or_down&quot; (default)</td>
<td>lower &lt;= x &lt;= upper</td>
</tr>
<tr>
<td>&quot;up&quot;</td>
<td>lower &lt;= x &lt; upper</td>
</tr>
<tr>
<td>&quot;down&quot;</td>
<td>lower &lt; x &lt;= upper</td>
</tr>
<tr>
<td>&quot;even&quot;</td>
<td>(no fix range)</td>
</tr>
<tr>
<td>&quot;ceiling&quot;</td>
<td>lower &lt; x = upper</td>
</tr>
<tr>
<td>&quot;floor&quot;</td>
<td>lower = x &lt; upper</td>
</tr>
<tr>
<td>&quot;trunc&quot; (positive x)</td>
<td>lower = x &lt; upper</td>
</tr>
<tr>
<td>&quot;trunc&quot; (negative x)</td>
<td>lower &lt; x = upper</td>
</tr>
<tr>
<td>&quot;trunc&quot; (zero x)</td>
<td>lower &lt; x &lt; upper</td>
</tr>
<tr>
<td>&quot;anti_trunc&quot; (positive x)</td>
<td>lower &lt; x = upper</td>
</tr>
<tr>
<td>&quot;anti_trunc&quot; (negative x)</td>
<td>lower = x &lt; upper</td>
</tr>
<tr>
<td>&quot;anti_trunc&quot; (zero x)</td>
<td>(undefined; NA)</td>
</tr>
</tbody>
</table>

Base R’s own round() (R version >= 4.0.0), referenced by rounding = "even", is reconstructed in the same way as "up_or_down", but whether the boundary values are inclusive or not is hard to predict. Therefore, unround() checks if they are, and informs you about it.

See Also

For more about rounding "up", "down", or to "even", see round_up().

For more about the less likely rounding methods, "ceiling", "floor", "trunc", and "anti_trunc", see round_ceiling().

Examples

# By default, the function assumes that `x`
# was either rounded up or down:
unround(x = "2.7")

# If `x` was rounded up, run this:
unround(x = "2.7", rounding = "up")

# Likewise with rounding down...
unround(x = "2.7", rounding = "down")

# ...and with `base::round()` which, broadly
# speaking, rounds to the nearest even number:
unround(x = "2.7", rounding = "even")

# Multiple input number-strings return
# multiple rows in the output data frame:
unround(x = c(3.6, "5.20", 5.174))

write_doc_audit

**Documentation template for audit()**

### Description

`write_doc_audit()` creates a roxygen2 block section to be inserted into the documentation of a mapper function such as `grim_map()` or `debit_map()`: functions for which there are, or should be, `audit()` methods. The section informs users about the ways in which `audit()` summarizes the results of the respective mapper function.

Copy the output from your console and paste it into the roxygen2 block of your `_map()` function. To preserve the numbered list structure when indenting roxygen2 comments with Ctrl+Shift+/, leave empty lines between the pasted output and the rest of the block.

### Usage

```r
write_doc_audit(sample_output, name_test)
```

### Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sample_output</code></td>
<td>Data frame. Result of a call to <code>audit()</code> on a data frame that resulted from a call to the mapper function for which you wrote the <code>audit()</code> method, such as <code>audit(grim_map(pigs1))</code> or <code>audit(debit_map(pigs3))</code>.</td>
</tr>
<tr>
<td><code>name_test</code></td>
<td>String (length 1). Name of the consistency test which the mapper function applies, such as &quot;GRIM&quot; or &quot;DEBIT&quot;.</td>
</tr>
</tbody>
</table>

### Value

A string vector formatted by `glue::glue()`.

### Examples

```r
# Start by running `audit()`:
out_grim <- audit(grim_map(pigs1))
out_debit <- audit(debit_map(pigs3))

out_grim
out_debit

# Documenting the `audit()` method for `grim_map()`:
write_doc_audit(sample_output = out_grim, name_test = "GRIM")

# Documenting the `audit()` method for `debit_map()`:
write_doc_audit(sample_output = out_debit, name_test = "DEBIT")
```
write_doc_audit_seq  Documentation template for audit_seq()

Description

write_doc_audit_seq() creates a roxygen2 block section to be inserted into the documentation of functions created with `function_map_seq()`. The section informs users about the ways in which `audit_seq()` summarizes the results of the manufactured *_map_seq() function.

Copy the output from your console and paste it into the roxygen2 block of your *_map_seq() function. To preserve the bullet-point structure when indenting roxygen2 comments with Ctrl+Shift+/, leave empty lines between the pasted output and the rest of the block.

Usage

write_doc_audit_seq(key_args, name_test)

Arguments

key_args  String vector with the names of the key columns that are tested for consistency by the *_map_seq() function. The values need to have the same order as in that function's output.

name_test  String (length 1). Name of the consistency test which the *_map_seq() function applies, such as "GRIM".

Value

A string vector formatted by glue::glue().

See Also

The sister function `write_doc_audit_total_n()` and, for context, vignette("consistency-tests-in-depth").

Examples

# For GRIM and `grim_map_seq()`:  
write_doc_audit_seq(key_args = c("x", "n"), name_test = "GRIM")

# For DEBIT and `debit_map_seq()`:  
write_doc_audit_seq(key_args = c("x", "sd", "n"), name_test = "DEBIT")
Description

write_doc_audit_total_n() creates a roxygen2 block section to be inserted into the documentation of functions created with function_map_total_n(). The section informs users about the ways in which audit_seq() summarizes the results of the manufactured *_map_total_n() function.

Copy the output from your console and paste it into the roxygen2 block of your *_map_total_n() function. To preserve the bullet-point structure when indenting roxygen2 comments with Ctrl+Shift+/ , leave empty lines between the pasted output and the rest of the block.

Usage

write_doc_audit_total_n(key_args, name_test)

Arguments

key_args  String vector with the names of the key columns that are tested for consistency by the *_map_seq() function. (These are the original variable names, without “1” and “2” suffixes.) The values need to have the same order as in that function’s output.

name_test  String (length 1). Name of the consistency test which the *_map_seq() function applies, such as “GRIM”.

Value

A string vector formatted by glue::glue().

See Also

The sister function write_doc_audit_seq() and, for context, vignette(“consistency-tests-in-depth”).

Examples

# For GRIM and `grim_map_total_n()`:
write_doc_audit_total_n(key_args = c("x", "n"), name_test = "GRIM")

# For DEBIT and `debit_map_total_n()`:
write_doc_audit_total_n(key_args = c("x", "sd", "n"), name_test = "DEBIT")
**write_doc_factory_map_conventions**

*Documentation template for function factory conventions*

**Description**

`write_doc_factory_map_conventions()` creates a roxygen2 block section to be inserted into the documentation of a function factory such as `function_map_seq()` or `function_map_total_n()`. It lays out the naming guidelines that users of your function factory should follow when creating new manufactured functions.

Copy the output from your console and paste it into the roxygen2 block of your function factory.

**Usage**

```r
write_doc_factory_map_conventions(
  ending,
  name_test1 = "GRIM",
  name_test2 = "GRIMMER",
  scrutiny_prefix = FALSE
)
```

**Arguments**

- **ending**
  - String (length 1). The part of your function factory’s name after `function_map_`.
- **name_test1, name_test2**
  - Strings (length 1 each). Plain-text names of example consistency tests. Defaults are "GRIM" and "GRIMMER", respectively.
- **scrutiny_prefix**
  - Logical (length 1). Should the scrutiny functions mentioned in the output have a `scrutiny::` namespace specification? Set this to `TRUE` if the output will go into another package’s documentation. Default is `FALSE`.

**Value**

A string vector formatted by `glue::glue()`.

**See Also**

For context, see *Implementing consistency tests*.

**Examples**

```r
# For `function_map_seq()`:
write_doc_factory_map_conventions(ending = "seq")

# For `function_map_total_n()`:
write_doc_factory_map_conventions(ending = "total_n")
```
