Package ‘shapley’
November 7, 2023

Type Package
Title Weighted Mean SHAP for Feature Selection in ML Grid and Ensemble
Version 0.1
Depends R (>= 3.5.0),

Description This R package introduces an innovative method for calculating SHapley Additive exPlanations (SHAP) values for a grid of fine-tuned base-learner machine learning models as well as stacked ensembles, a method not previously available due to the common reliance on single best-performing models. By integrating the weighted mean SHAP values from individual base-learners comprising the ensemble or individual base-learners in a tuning grid search, the package weights SHAP contributions according to each model’s performance, assessed by the Area Under the Precision-Recall Curve (AUCPR) for binary classifiers (currently implemented). It further extends this framework to implement weighted confidence intervals for weighted mean SHAP values, offering a more comprehensive and robust feature importance evaluation over a grid of machine learning models, instead of solely computing SHAP values for the best-performing model. This methodology is particularly beneficial for addressing the severe class imbalance (class rarity) problem by providing a transparent, generalized measure of feature importance that mitigates the risk of reporting SHAP values for an overfitted or biased model and maintains robustness under severe class imbalance, where there is no universal criteria of identifying the absolute best model. Furthermore, the package implements hypothesis testing to ascertain the statistical significance of SHAP values for individual features, as well as comparative significance testing of SHAP contributions between features. Additionally, it tackles a critical gap in feature selection literature by presenting criteria for the automatic feature selection of the most important features across a grid of models or stacked ensembles, eliminating the need for arbitrary determination of the
number of top features to be extracted. This utility is invaluable for researchers analyzing feature significance, particularly within severely imbalanced outcomes where conventional methods fall short. In addition, it is also expected to report democratic feature importance across a grid of models, resulting in a more comprehensive and generalizable feature selection. The package further implements a novel method for visualizing SHAP values both at subject level and feature level as well as a plot for feature selection based on the weighted mean SHAP ratios.

h2o.get_ids

Description
extracts the model IDs from H2O AutoML object or H2O grid

Usage
h2o.get_ids(automl)

Arguments
automl a h2o "AutoML" grid object

Value
a character vector of trained models’ names (IDs)

Author(s)
E. F. Haghish

Examples
## Not run:
library(h2o)
h2o.init(ignore_config = TRUE, nthreads = 2, bind_to_localhost = FALSE, insecure = TRUE)
prostate_path <- system.file("extdata", "prostate.csv", package = "h2o")
prostate <- h2o.importFile(path = prostate_path, header = TRUE)
y <- "CAPSULE"
prostate[,y] <- as.factor(prostate[,y]) #convert to factor for classification
aml <- h2o.automl(y = y, training_frame = prostate, max_runtime_secs = 30)

# get the model IDs
ids <- h2o.ids(aml)

## End(Not run)
normalize

*Normalize a vector based on specified minimum and maximum values*

**Description**

This function normalizes a vector based on specified minimum and maximum values. If the minimum and maximum values are not specified, the function will use the minimum and maximum values of the vector.

**Usage**

```r
normalize(x, min = NULL, max = NULL)
```

**Arguments**

- `x`: numeric vector
- `min`: minimum value
- `max`: maximum value

**Value**

normalized numeric vector

**Author(s)**

E. F. Haghigh

**shapley**

*Weighted average of SHAP values and weighted SHAP confidence intervals for a grid of fine-tuned models or base-learners of a stacked ensemble model*

**Description**

Weighted average of SHAP values and weighted SHAP confidence intervals provide a measure of feature importance for a grid of fine-tuned models or base-learners of a stacked ensemble model. Instead of reporting relative SHAP contributions for a single model, this function takes the variability in feature importance of multiple models into account and computes weighted mean and confidence intervals for each feature, taking the performance metric of each model as the weight. The function also provides a plot of the weighted SHAP values and confidence intervals. Currently only models trained by h2o machine learning software or autoEnsemble package are supported.
shapley(
    models,
    newdata,
    plot = TRUE,
    family = "binary",
    performance_metric = c("aucpr"),
    method = c("lowerCI"),
    cutoff = 0.01,
    top_n_features = NULL,
    normalize_to = "upperCI"
)

Arguments

models H2O search grid, AutoML grid, or a character vector of H2O model IDs. the "h2o.get_ids" function from "h2otools" can retrieve the IDs from grids.

newdata h2o frame (data.frame). the data.frame must be already uploaded on h2o server (cloud). when specified, this dataset will be used for evaluating the models. if not specified, model performance on the training dataset will be reported.

plot logical. if TRUE, the weighted mean and confidence intervals of the SHAP values are plotted. The default is TRUE.

family character. currently only "binary" classification models trained by h2o machine learning are supported.

performance_metric character, specifying the performance metric to be used for weighting the SHAP values (mean and 95 "aucpr" (area under the precision-recall curve). Other options include "auc" (area under the ROC curve), "mcc" (Matthews correlation coefficient), and "f2" (F2 score).

method character, specifying the method used for identifying the most important features according to their weighted SHAP values. The default selection method is "lowerCI", which includes features whose lower weighted confidence interval exceeds the predefined 'cutoff' value (default is relative SHAP of 1 Alternatively, the "mean" option can be specified, indicating any feature with normalized weighted mean SHAP contribution above the specified 'cutoff' should be selected. Another alternative options is "shapratio", a method that filters for features where the proportion of their relative weighted SHAP value exceeds the 'cutoff'. This approach calculates the relative contribution of each feature's weighted SHAP value against the aggregate of all features, with those surpassing the 'cutoff' being selected as top feature.

cutoff numeric, specifying the cutoff for the method used for selecting the top features.

top_n_features integer. if specified, the top n features with the highest weighted SHAP values will be selected, overruling the 'cutoff' and 'method' arguments.

normalize_to character. The default value is "upperCI", which sets the feature with the maximum SHAP value to one, allowing the higher CI to go beyond one. Setting
this value is mainly for aesthetic reason to adjust the Plot, but also, it can influence the feature selection process, depending on the method in use, because it changes how the SHAP values should be normalized. The alternative is 'feature', specifying that in the normalization of the SHAP values, the maximum confidence interval of the weighted SHAP values should be equal to "1", in order to limit the plot values to maximum of one.

Value

a list including the GGPlot2 object, the data frame of SHAP values, and performance metric of all models, as well as the model IDs.

Examples

```r
## Not run:
# load the required libraries for building the base-learners and the ensemble models
library(h2o)  # shapley supports h2o models
library(shapley)

# initiate the h2o server
h2o.init(ignore_config = TRUE, nthreads = 2, bind_to_localhost = FALSE, insecure = TRUE)

# upload data to h2o cloud
prostate_path <- system.file("extdata", "prostate.csv", package = "h2o")
prostate <- h2o.importFile(path = prostate_path, header = TRUE)
set.seed(10)

### H2O provides 2 types of grid search for tuning the models, which are
### AutoML and Grid. Below, I demonstrate how weighted mean shapley values
### can be computed for both types.

#######################################################
### PREPARE AutoML Grid (takes a couple of minutes)
#######################################################
# run AutoML to tune various models (GBM) for 60 seconds
y <- "CAPSULE"
prostate[,y] <- as.factor(prostate[,y])  # convert to factor for classification
aml <- h2o.automl(y = y, training_frame = prostate, max_runtime_secs = 120,
                   include_algos=c("GBM"),
                   seed = 2023, nfolds = 10,
                   keep_cross_validation_predictions = TRUE)

### call 'shapley' function to compute the weighted mean and weighted confidence intervals
### of SHAP values across all trained models.
```
### Note that the 'newdata' should be the testing dataset!
result <- shapley(models = aml, newdata = prostate, plot = TRUE)

### PREPARE H2O Grid (takes a couple of minutes)
# make sure equal number of "nfolds" is specified for different grids
grid <- h2o.grid(algorithm = "gbm", y = y, training_frame = prostate,
hyper_params = list(ntrees = seq(1,50,1)),
grid_id = "ensemble_grid",
# this setting ensures the models are comparable for building a meta learner
seed = 2023, fold_assignment = "Modulo", nfolds = 10,
keep_cross_validation_predictions = TRUE)
result2 <- shapley(models = grid, newdata = prostate, plot = TRUE)

### PREPARE autoEnsemble STACKED ENSEMBLE MODEL
### get the models' IDs from the AutoML and grid searches.
### this is all that is needed before building the ensemble,
### i.e., to specify the model IDs that should be evaluated.
library(autoEnsemble)
ids <- c(h2o.get_ids(aml), h2o.get_ids(grid))
autoSearch <- ensemble(models = ids, training_frame = prostate, strategy = "search")
result3 <- shapley(models = autoSearch, newdata = prostate, plot = TRUE)

## End(Not run)

shapley.plot

Plot weighted SHAP contributions

Description

This function applies different criteria to visualize SHAP contributions

Usage

shapley.plot(
  shapley,
  plot = "bar",
  legendstyle = "continuous",
  scale_colour_gradient = NULL
)
Arguments

- **shapley**: object of class 'shapley', as returned by the 'shapley' function
- **plot**: character, specifying the type of the plot, which can be either 'bar', 'waffle', or 'shap'. The default is 'bar'.
- **legendstyle**: character, specifying the style of the plot legend, which can be either 'continuous' (default) or 'discrete'. The continuous legend is only applicable to 'shap' plots and other plots only use 'discrete' legend.
- **scale_colour_gradient**: character vector for specifying the color gradients for the plot.

Value

`ggplot` object

**shapley.test**

*Normalize a vector based on specified minimum and maximum values*

**Description**

This function normalizes a vector based on specified minimum and maximum values. If the minimum and maximum values are not specified, the function will use the minimum and maximum values of the vector.

**Usage**

```
shapley.test(shapley, features, n = 5000)
```

**Arguments**

- `shapley` object of class 'shapley', as returned by the 'shapley' function
- `features` character, name of two features to be compared with permutation test
- `n` integer, number of permutations

**Value**

normalized numeric vector

shapley.top 
Select top features in a model
Description

This function applies different criteria simultaneously to identify the most important features in a model. The criteria include: 1) minimum limit of lower weighted confidence intervals of SHAP values relative to the feature with highest SHAP value. 2) minimum limit of percentage of weighted mean SHAP values relative to over all SHAP values of all features. These are specified with two different cutoff values.

Usage

shapley.top(shapley, lowerci = 0.01, shapratio = 0.005)

Arguments

shapley object of class 'shapley', as returned by the 'shapley' function
lowerci numeric, specifying the lower limit of weighted confidence intervals of SHAP values relative to the feature with highest SHAP value. the default is 0.01
shapratio numeric, specifying the lower limit of percentage of weighted mean SHAP values relative to over all SHAP values of all features. the default is 0.005

Value
data.frame of selected features

### Description

This function performs a weighted permutation test to determine if there is a significant difference between the means of two weighted numeric vectors. It tests the null hypothesis that the difference in means is zero against the alternative that it is not zero.

### Usage

test(var1, var2, weights, n = 2000)

### Arguments

- var1: A numeric vector.
- var2: A numeric vector of the same length as var1.
- weights: A numeric vector of weights, assumed to be the same for both var1 and var2.
- n: The number of permutations to perform (default is 1000).

### Value

A list containing the observed difference in means and the p-value of the test.
