

Package ‘spOccupancy’

April 13, 2022

Type Package

Title Single-Species, Multi-Species, and Integrated Spatial Occupancy Models

Version 0.3.1

Author Jeffrey Doser [aut, cre],
Andrew Finley [aut]

Maintainer Jeffrey Doser <doser.jef@msu.edu>

Description Fits single-species, multi-species, and integrated non-spatial and spatial occupancy models using Markov Chain Monte Carlo (MCMC). Models are fit using Polya-Gamma data augmentation detailed in Polson, Scott, and Windle (2013) <[doi:10.1080/01621459.2013.829001](https://doi.org/10.1080/01621459.2013.829001)>. Spatial models are fit using either Gaussian processes or Nearest Neighbor Gaussian Processes (NNGP) for large spatial datasets. Details on NNGP models are given in Datta, Banerjee, Finley, and Gelfand (2016) <[doi:10.1080/01621459.2015.1044091](https://doi.org/10.1080/01621459.2015.1044091)> and Finley, Datta, and Banerjee (2020) <[arXiv:2001.09111](https://arxiv.org/abs/2001.09111)>. Provides functionality for data integration of multiple single-species occupancy data sets using a joint likelihood framework. Details on data integration are given in Miller, Pacifici, Sanderlin, and Reich (2019) <[doi:10.1111/2041-210X.13110](https://doi.org/10.1111/2041-210X.13110)>. Details on single-species and multi-species models are found in MacKenzie, Nichols, Lachman, Droege, Royle, and Langtimm (2002) <[doi:10.1890/0012-9658\(2002\)083\[2248:ESORWD\]2.0.CO;2](https://doi.org/10.1890/0012-9658(2002)083[2248:ESORWD]2.0.CO;2)> and Dorrizio and Royle <[doi:10.1198/016214505000000015](https://doi.org/10.1198/016214505000000015)>, respectively.

fitted.intPGOcc	<i>Extract Model Fitted Values for intPGOcc Object</i>
-----------------	--

Description

Method for extracting model fitted values and detection probability values from a fitted single-species integrated occupancy (intPGOcc) model.

Usage

```
## S3 method for class 'intPGOcc'
fitted(object, ...)
```

Arguments

object	object of class intPGOcc.
...	currently no additional arguments

Details

A method to the generic `fitted` function to extract fitted values and detection probability values for fitted model objects of class intPGOcc.

Value

A list comprised of

y.rep.samples	A list of three-dimensional numeric arrays of fitted values for each individual data source for use in Goodness of Fit assessments.
p.samples	A list of three-dimensional numeric arrays of detection probability values.

fitted.lfJSDM *Extract Model Fitted Values for lfJSDM Object*

Description

Method for extracting model fitted values and probability values from a fitted latent factor joint species distribution model (lfJSDM).

Usage

```
## S3 method for class 'lfJSDM'
fitted(object, ...)
```

Arguments

object object of class lfJSDM.
 ... currently no additional arguments

Details

A method to the generic `fitted` function to extract fitted values and probability values for fitted model objects of class lfJSDM.

Value

A list comprised of:

`z.samples` A three-dimensional numeric array of fitted values for use in Goodness of Fit assessments. Array dimensions correspond to MCMC samples, species, and sites.

`psi.samples` A three-dimensional numeric array of probability values. Array dimensions correspond to MCMC samples, species, and sites.

fitted.lfMsPGOcc *Extract Model Fitted Values for lfMsPGOcc Object*

Description

Method for extracting model fitted values and detection probability values from a fitted latent factor multi-species occupancy (lfMsPGOcc) model.

Usage

```
## S3 method for class 'lfMsPGOcc'
fitted(object, ...)
```

Arguments

object object of class lfMsPGOcc.
 ... currently no additional arguments

Details

A method to the generic `fitted` function to extract fitted values and detection probability values for fitted model objects of class lfMsPGOcc.

Value

A list comprised of:

y.rep.samples A four-dimensional numeric array of fitted values for use in Goodness of Fit assessments. Array dimensions correspond to MCMC samples, species, sites, and replicates.
 p.samples A four-dimensional numeric array of detection probability values. Array dimensions correspond to MCMC samples, species, sites, and replicates.

fitted.msPGOcc	<i>Extract Model Fitted Values for msPGOcc Object</i>
----------------	---

Description

Method for extracting model fitted values and detection probability values from a fitted multi-species occupancy (msPGOcc) model.

Usage

```
## S3 method for class 'msPGOcc'
fitted(object, ...)
```

Arguments

object object of class msPGOcc.
 ... currently no additional arguments

Details

A method to the generic `fitted` function to extract fitted values and detection probability values for fitted model objects of class msPGOcc.

Value

A list comprised of:

- | | |
|----------------------------|--|
| <code>y.rep.samples</code> | A four-dimensional numeric array of fitted values for use in Goodness of Fit assessments. Array dimensions correspond to MCMC samples, species, sites, and replicates. |
| <code>p.samples</code> | A four-dimensional numeric array of detection probability values. Array dimensions correspond to MCMC samples, species, sites, and replicates. |

`fitted.PGOcc`
Extract Model Fitted Values for PGOcc Object

Description

Method for extracting model fitted values and detection probabilities from a fitted single-species occupancy (PGOcc) model.

Usage

```
## S3 method for class 'PGOcc'
fitted(object, ...)
```

Arguments

- | | |
|---------------------|-----------------------------------|
| <code>object</code> | object of class PGOcc. |
| <code>...</code> | currently no additional arguments |

Details

A method to the generic `fitted` function to extract fitted values and detection probabilities for fitted model objects of class PGOcc.

Value

A list comprised of:

- | | |
|----------------------------|--|
| <code>y.rep.samples</code> | A three-dimensional numeric array of fitted values for use in Goodness of Fit assessments. Array dimensions correspond to MCMC samples, sites, and replicates. |
| <code>p.samples</code> | A three-dimensional numeric array of detection probability values. Array dimensions correspond to MCMC samples, sites, and replicates. |

fitted.sfJSDM	<i>Extract Model Fitted Values for sfJSDM Object</i>
---------------	--

Description

Method for extracting model fitted values and probability values from a fitted spatial factor joint species distribution model (sfJSDM).

Usage

```
## S3 method for class 'sfJSDM'
fitted(object, ...)
```

Arguments

object	object of class sfJSDM.
...	currently no additional arguments

Details

A method to the generic `fitted` function to extract fitted values and probability values for fitted model objects of class sfJSDM.

Value

A list comprised of:

z.samples	A three-dimensional numeric array of fitted values for use in Goodness of Fit assessments. Array dimensions correspond to MCMC samples, species, and sites.
psi.samples	A three-dimensional numeric array of probability values. Array dimensions correspond to MCMC samples, species, and sites.

fitted.sfMsPGOcc	<i>Extract Model Fitted Values for sfMsPGOcc Object</i>
------------------	---

Description

Method for extracting model fitted values and detection probability values from a fitted spatial factor multi-species occupancy (sfMsPGOcc) model.

Usage

```
## S3 method for class 'sfMsPGOcc'
fitted(object, ...)
```

Arguments

object object of class sfMsPGOcc.
 ... currently no additional arguments

Details

A method to the generic `fitted` function to extract fitted values and detection probability values for fitted model objects of class sfMsPGOcc.

Value

A list comprised of:

y.rep.samples A four-dimensional numeric array of fitted values for use in Goodness of Fit assessments. Array dimensions correspond to MCMC samples, species, sites, and replicates.
 p.samples A four-dimensional numeric array of detection probability values. Array dimensions correspond to MCMC samples, species, sites, and replicates.

fitted.spIntPGOcc *Extract Model Fitted Values for spIntPGOcc Object*

Description

Method for extracting model fitted values and detection probability values from a fitted single-species integrated spatial occupancy (spIntPGOcc) model.

Usage

```
## S3 method for class 'spIntPGOcc'
fitted(object, ...)
```

Arguments

object object of class spIntPGOcc.
 ... currently no additional arguments

Details

A method to the generic `fitted` function to extract fitted values and detection probability values for fitted model objects of class spIntPGOcc.

Value

A list comprised of

- y.rep.samples A list of three-dimensional numeric arrays of fitted values for each individual data source for use in Goodness of Fit assessments.
- p.samples A list of three-dimensional numeric arrays of detection probability values.

fitted.spMsPGOcc	<i>Extract Model Fitted Values for spMsPGOcc Object</i>
------------------	---

Description

Method for extracting model fitted values and detection probability values from a fitted multi-species spatial occupancy (spMsPGOcc) model.

Usage

```
## S3 method for class 'spMsPGOcc'
fitted(object, ...)
```

Arguments

- object object of class spMsPGOcc.
- ... currently no additional arguments

Details

A method to the generic [fitted](#) function to extract fitted values and detection probability values for fitted model objects of class spMsPGOcc.

Value

A list comprised of:

- y.rep.samples A four-dimensional numeric array of fitted values for use in Goodness of Fit assessments. Array dimensions correspond to MCMC samples, species, sites, and replicates.
- p.samples A four-dimensional numeric array of detection probability values. Array dimensions correspond to MCMC samples, species, sites, and replicates.

fitted.spPGOcc	<i>Extract Model Fitted Values for spPGOcc Object</i>
----------------	---

Description

Method for extracting model fitted values and detection probabilities from a fitted single-species spatial occupancy (spPGOcc) model.

Usage

```
## S3 method for class 'spPGOcc'
fitted(object, ...)
```

Arguments

object	object of class spPGOcc.
...	currently no additional arguments

Details

A method to the generic `fitted` function to extract fitted values and detection probabilities for fitted model objects of class spPGOcc.

Value

A list comprised of:

y.rep.samples	A three-dimensional numeric array of fitted values for use in Goodness of Fit assessments. Array dimensions correspond to MCMC samples, sites, and replicates.
p.samples	A three-dimensional numeric array of detection probability values. Array dimensions correspond to MCMC samples, sites, and replicates.

hbef2015	<i>Detection-nondetection data of 12 foliage gleaning bird species in 2015 in the Hubbard Brook Experimental Forest</i>
----------	---

Description

Detection-nondetection data of 12 foliage gleaning bird species in 2015 in the Hubbard Brook Experimental Forest (HBEF) in New Hampshire, USA. Data were collected at 373 sites over three replicate point counts each of 10 minutes in length, with a detection radius of 100m. Some sites were not visited for all three replicates. The 12 species included in the data set are as follows: (1) AMRE: American Redstart; (2) BAWW: Black-and-white Warbler; (3) BHVI: Blue-headed Vireo; (4) BLBW: Blackburnian Warbler; (5) BLPW: Blackpoll Warbler; (6) BTBW: Black-throated Blue Warbler; (7) BTNW: Black-throated Green Warbler; (8) CAWA: Canada Warbler; (9) MAWA: Magnolia Warbler; (10) NAWA: Nashville Warbler; (11) OVEN: Ovenbird; (12) REVI: Red-eyed Vireo.

Usage

```
data(hbef2015)
```

Format

hbf2015 is a list with four elements:

`y`: a three-dimensional array of detection-nondetection data with dimensions of species (12), sites (373) and replicates (3).

`occ.covs`: a numeric matrix with 373 rows and one column consisting of the elevation at each site.

`det.covs`: a list of two numeric matrices with 373 rows and 3 columns. The first element is the day of year when the survey was conducted for a given site and replicate. The second element is the time of day when the survey was conducted.

`coords`: a numeric matrix with 373 rows and two columns containing the site coordinates (East-ing and Northing) in UTM Zone 19. The proj4string is "+proj=utm +zone=19 +units=m +datum=NAD83".

hbfElev

Elevation in meters extracted at a 30m resolution across the Hubbard Brook Experimental Forest

Description

Elevation in meters extracted at a 30m resolution of the Hubbard Brook Experimental Forest. Data come from the National Elevation Dataset.

Usage

```
data(hbfElev)
```

Format

hbfElev is a data frame with three columns:

val: the elevation value in meters.

Easting: the x coordinate of the point. The proj4string is "+proj=utm +zone=19 +units=m +datum=NAD83".

Northing: the y coordinate of the point. The proj4string is "+proj=utm +zone=19 +units=m +datum=NAD83".

intPGOcc

Function for Fitting Single-Species Integrated Occupancy Models Using Polya-Gamma Latent Variables

Description

Function for fitting single-species integrated occupancy models using Polya-Gamma latent variables. Data integration is done using a joint likelihood framework, assuming distinct detection models for each data source that are each conditional on a single latent occurrence process.

Usage

```
intPGOcc(occ.formula, det.formula, data, inits, priors, n.samples,
         n.omp.threads = 1, verbose = TRUE, n.report = 1000,
         n.burn = round(.10 * n.samples), n.thin = 1, n.chains = 1,
         k.fold, k.fold.threads = 1, k.fold.seed,
         k.fold.data, ...)
```

Arguments

`occ.formula` a symbolic description of the model to be fit for the occurrence portion of the model using R's model syntax. Only right-hand side of formula is specified. See example below.

`det.formula` a list of symbolic descriptions of the models to be fit for the detection portion of the model using R's model syntax for each data set. Each element in the list is a formula for the detection model of a given data set. Only right-hand side of formula is specified. See example below.

data	a list containing data necessary for model fitting. Valid tags are <code>y</code> , <code>occ.covs</code> , <code>det.covs</code> , and <code>sites</code> . <code>y</code> is a list of matrices or data frames for each data set used in the integrated model. Each element of the list has first dimension equal to the number of sites with that data source and second dimension equal to the maximum number of replicates at a given site. <code>occ.covs</code> is a matrix or data frame containing the variables used in the occupancy portion of the model, with the number of rows being the number of sites with at least one data source for each column (variable). <code>det.covs</code> is a list of variables included in the detection portion of the model for each data source. <code>det.covs</code> should have the same number of elements as <code>y</code> , where each element is itself a list. Each element of the list for a given data source is a different detection covariate, which can be site-level or observational-level. Site-level covariates are specified as a vector with length equal to the number of observed sites of that data source, while observation-level covariates are specified as a matrix or data frame with the number of rows equal to the number of observed sites of that data source and number of columns equal to the maximum number of replicates at a given site.
inits	a list with each tag corresponding to a parameter name. Valid tags are <code>z</code> , <code>beta</code> , and <code>alpha</code> . The value portion of tags <code>z</code> and <code>beta</code> is the parameter's initial value. The tag <code>alpha</code> is a list comprised of the initial values for the detection parameters for each data source. Each element of the list should be a vector of initial values for all detection parameters in the given data source or a single value for each data source to assign all parameters for a given data source the same initial value. See <code>priors</code> description for definition of each parameter name. Additionally, the tag <code>fix</code> can be set to <code>TRUE</code> to fix the starting values across all chains. If <code>fix</code> is not specified (the default), starting values are varied randomly across chains.
priors	a list with each tag corresponding to a parameter name. Valid tags are <code>beta.normal</code> and <code>alpha.normal</code> . Occurrence (<code>beta</code>) and detection (<code>alpha</code>) regression coefficients are assumed to follow a normal distribution. For <code>beta</code> hyperparameters of the normal distribution are passed as a list of length two with the first and second elements corresponding to the mean and variance of the normal distribution, which are each specified as vectors of length equal to the number of coefficients to be estimated or of length one if priors are the same for all coefficients. For the detection coefficients <code>alpha</code> , the mean and variance hyperparameters are themselves passed in as lists, with each element of the list corresponding to the specific hyperparameters for the detection parameters in a given data source. If not specified, prior means are set to 0 and prior variances set to 2.72.
n.samples	the number of posterior samples to collect in each chain.
n.omp.threads	a positive integer indicating the number of threads to use for SMP parallel processing. The package must be compiled for OpenMP support. For most Intel-based machines, we recommend setting <code>n.omp.threads</code> up to the number of hyperthreaded cores. Note, <code>n.omp.threads > 1</code> might not work on some systems.
verbose	if <code>TRUE</code> , messages about data preparation, model specification, and progress of the sampler are printed to the screen. Otherwise, no messages are printed.
n.report	the interval to report MCMC progress.

n.burn	the number of samples out of the total n.samples to discard as burn-in. By default, the first 10% of samples is discarded.
n.thin	the thinning interval for collection of MCMC samples. The thinning occurs after the n.burn samples are discarded. Default value is set to 1.
n.chains	the number of chains to run in sequence.
k.fold	specifies the number of k folds for cross-validation. If not specified as an argument, then cross-validation is not performed and k.fold.threads and k.fold.seed are ignored. In k -fold cross-validation, the data specified in data is randomly partitioned into k equal sized subsamples. Of the k subsamples, $k - 1$ subsamples are used to fit the model and the remaining k samples are used for prediction. The cross-validation process is repeated k times (the folds). As a scoring rule, we use the model deviance as described in Hooten and Hobbs (2015). Cross-validation is performed after the full model is fit using all the data. Cross-validation results are reported in the k.fold.deviance object in the return list.
k.fold.threads	number of threads to use for cross-validation. If k.fold.threads > 1 parallel processing is accomplished using the foreach and doParallel packages. Ignored if k.fold is not specified.
k.fold.seed	seed used to split data set into k.fold parts for k-fold cross-validation. Ignored if k.fold is not specified.
k.fold.data	an integer specifying the specific data set to hold out values from. If not specified, data from all data set locations will be incorporated into the k-fold cross-validation.
...	currently no additional arguments

Value

An object of class intPGOcc that is a list comprised of:

beta.samples	a coda object of posterior samples for the occupancy regression coefficients.
alpha.samples	a coda object of posterior samples for the detection regression coefficients for all data sources.
z.samples	a coda object of posterior samples for the latent occupancy values
psi.samples	a coda object of posterior samples for the latent occupancy probability values
rhat	a list of Gelman-Rubin diagnostic values for some of the model parameters.
ESS	a list of effective sample sizes for some of the model parameters.
run.time	execution time reported using proc.time().
k.fold.deviance	scoring rule (deviance) from k-fold cross-validation. A separate deviance value is returned for each data source. Only included if k.fold is specified in function call. Only a single value is returned if k.fold.data is specified.

The return object will include additional objects used for subsequent prediction and/or model fit evaluation. Note that detection probability estimated values are not included in the model object, but can be extracted using fitted().

Note

Some of the underlying code used for generating random numbers from the Polya-Gamma distribution is taken from the **pgdraw** package written by Daniel F. Schmidt and Enes Makalic. Their code implements Algorithm 6 in PhD thesis of Jesse Bennett Windle (2013) <https://repositories.lib.utexas.edu/handle/2152/21842>.

summary(out)

```

Description

Function for fitting a joint species distribution model with species correlations. This model does not explicitly account for imperfect detection (see `lfMsPGOcc()`). We use Polya-gamma latent variables and a factor modeling approach.

Usage

```
lfJSDM(formula, data, inits, priors, n.factors,
        n.samples, n.omp.threads = 1, verbose = TRUE, n.report = 100,
        n.burn = round(.10 * n.samples), n.thin = 1, n.chains = 1,
        k.fold, k.fold.threads = 1, k.fold.seed, ...)
```

Arguments

formula	a symbolic description of the model to be fit for the model using R's model syntax. Only right-hand side of formula is specified. See example below. Random intercepts are allowed using lme4 syntax (Bates et al. 2015).
data	a list containing data necessary for model fitting. Valid tags are <code>y</code> , <code>covs</code> , and <code>coords</code> . <code>y</code> is a two-dimensional array with first dimension equal to the number of species and second dimension equal to the number of sites. Note how this differs from other <code>spOccupancy</code> functions in that <code>y</code> does not have any replicate surveys. This is because <code>lfJSDM</code> does not account for imperfect detection. <code>covs</code> is a matrix or data frame containing the variables used in the model, with J rows for each column (variable). <code>coords</code> is a matrix with J rows and 2 columns consisting of the spatial coordinates of each site in the data. Note that <code>spOccupancy</code> assumes coordinates are specified in a projected coordinate system.
inits	a list with each tag corresponding to a parameter name. Valid tags are <code>beta.comm</code> , <code>beta</code> , <code>tau.sq.beta</code> , <code>sigma.sq.psi</code> , <code>lambda</code> . The value portion of each tag is the parameter's initial value. See <code>priors</code> description for definition of each parameter name. Additionally, the tag <code>fix</code> can be set to <code>TRUE</code> to fix the starting values across all chains. If <code>fix</code> is not specified (the default), starting values are varied randomly across chains.
priors	a list with each tag corresponding to a parameter name. Valid tags are <code>beta.comm.normal</code> , <code>tau.sq.beta.ig</code> , and <code>sigma.sq.psi.ig</code> . Community-level (<code>beta.comm</code>) regression coefficients are assumed to follow a normal distribution. The hyperparameters of the normal distribution are passed as a list of length two with the first and second elements corresponding to the mean and variance of the normal distribution, which are each specified as vectors of length equal to the number of coefficients to be estimated or of length one if priors are the same for all coefficients. If not specified, prior means are set to 0 and prior variances set to 2.72. Community-level variance parameters (<code>tau.sq.beta</code>) are assumed to follow an inverse Gamma distribution. The hyperparameters of the inverse gamma distribution are passed as a list of length two with the first and second elements corresponding to the shape and scale parameters, which are each specified as vectors of length equal to the number of coefficients to be estimated or a single value if all parameters are assigned the same prior. If not specified, prior shape and scale parameters are set to 0.1. The factor model fits <code>n.factors</code> independent latent factors. The priors for the factor loadings matrix <code>lambda</code> are fixed

following standard approaches to ensure parameter identifiability. The upper triangular elements of the $N \times n$. `factors` matrix are fixed at 0 and the diagonal elements are fixed at 1. The lower triangular elements are assigned a standard normal prior (i.e., mean 0 and variance 1). `sigma.sq.psi` is the random effect variance for any random effects, and is assumed to follow an inverse Gamma distribution. The hyperparameters of the inverse-Gamma distribution are passed as a list of length two with first and second elements corresponding to the shape and scale parameters, respectively, which are each specified as vectors of length equal to the number of random intercepts or of length one if priors are the same for all random effect variances.

<code>n.factors</code>	the number of factors to use in the latent factor model approach. Typically, the number of factors is set to be small (e.g., 4-5) relative to the total number of species in the community, which will lead to substantial decreases in computation time. However, the value can be anywhere between 1 and N (the number of species in the community).
<code>n.samples</code>	the number of posterior samples to collect in each chain.
<code>n.omp.threads</code>	a positive integer indicating the number of threads to use for SMP parallel processing. The package must be compiled for OpenMP support. For most Intel-based machines, we recommend setting <code>n.omp.threads</code> up to the number of hyperthreaded cores. Note, <code>n.omp.threads > 1</code> might not work on some systems.
<code>verbose</code>	if TRUE, messages about data preparation, model specification, and progress of the sampler are printed to the screen. Otherwise, no messages are printed.
<code>n.report</code>	the interval to report MCMC progress.
<code>n.burn</code>	the number of samples out of the total <code>n.samples</code> to discard as burn-in for each chain. By default, the first 10% of samples is discarded.
<code>n.thin</code>	the thinning interval for collection of MCMC samples. The thinning occurs after the <code>n.burn</code> samples are discarded. Default value is set to 1.
<code>n.chains</code>	the number of chains to run in sequence.
<code>k.fold</code>	specifies the number of k folds for cross-validation. If not specified as an argument, then cross-validation is not performed and <code>k.fold.threads</code> and <code>k.fold.seed</code> are ignored. In k -fold cross-validation, the data specified in <code>data</code> is randomly partitioned into k equal sized subsamples. Of the k subsamples, $k - 1$ subsamples are used to fit the model and the remaining k samples are used for prediction. The cross-validation process is repeated k times (the folds). As a scoring rule, we use the model deviance as described in Hooten and Hobbs (2015). Cross-validation is performed after the full model is fit using all the data. Cross-validation results are reported in the <code>k.fold.deviance</code> object in the return list.
<code>k.fold.threads</code>	number of threads to use for cross-validation. If <code>k.fold.threads > 1</code> parallel processing is accomplished using the foreach and doParallel packages. Ignored if <code>k.fold</code> is not specified.
<code>k.fold.seed</code>	seed used to split data set into <code>k.fold</code> parts for k -fold cross-validation. Ignored if <code>k.fold</code> is not specified.
<code>...</code>	currently no additional arguments

Value

An object of class lfJSDM that is a list comprised of:

<code>beta.comm.samples</code>	a coda object of posterior samples for the community level occurrence regression coefficients.
<code>tau.sq.beta.samples</code>	a coda object of posterior samples for the occurrence community variance parameters.
<code>beta.samples</code>	a coda object of posterior samples for the species level occurrence regression coefficients.
<code>lambda.samples</code>	a coda object of posterior samples for the latent factor loadings.
<code>psi.samples</code>	a three-dimensional array of posterior samples for the latent probability of occurrence/detection values for each species.
<code>sigma.sq.psi.samples</code>	a coda object of posterior samples for variances of random intercepts included in the occurrence portion of the model. Only included if random intercepts are specified in <code>occ.formula</code> .
<code>w.samples</code>	a three-dimensional array of posterior samples for the latent effects for each latent factor.
<code>beta.star.samples</code>	a coda object of posterior samples for the occurrence random effects. Only included if random intercepts are specified in <code>occ.formula</code> .
<code>like.samples</code>	a three-dimensional array of posterior samples for the likelihood value associated with each site and species. Used for calculating WAIC.
<code>rhat</code>	a list of Gelman-Rubin diagnostic values for some of the model parameters.
<code>ESS</code>	a list of effective sample sizes for some of the model parameters.
<code>run.time</code>	MCMC sampler execution time reported using <code>proc.time()</code> .
<code>k.fold.deviance</code>	vector of scoring rules (deviance) from k-fold cross-validation. A separate value is reported for each species. Only included if <code>k.fold</code> is specified in function call.

The return object will include additional objects used for subsequent prediction and/or model fit evaluation. Note that detection probability estimated values are not included in the model object, but can be extracted using `fitted()`.

Note

Some of the underlying code used for generating random numbers from the Polya-Gamma distribution is taken from the **pgdraw** package written by Daniel F. Schmidt and Enes Makalic. Their code implements Algorithm 6 in PhD thesis of Jesse Bennett Windle (2013) <https://repositories.lib.utexas.edu/handle/2152/21842>.

lfMsPGOcc

*Function for Fitting Latent Factor Multi-Species Occupancy Models***Description**

Function for fitting multi-species occupancy models with species correlations (i.e., a joint species distribution model with imperfect detection). We use Polya-gamma latent variables and a factor modeling approach for dimension reduction.

Usage

```

lfMsPGOcc(occ.formula, det.formula, data, inits, priors, n.factors,
          n.samples, n.omp.threads = 1, verbose = TRUE, n.report = 100,
          n.burn = round(.10 * n.samples), n.thin = 1, n.chains = 1,
          k.fold, k.fold.threads = 1, k.fold.seed, ...)

```

Arguments

`occ.formula` a symbolic description of the model to be fit for the occurrence portion of the model using R's model syntax. Only right-hand side of formula is specified. See

	example below. Random intercepts are allowed using lme4 syntax (Bates et al. 2015).
<code>det.formula</code>	a symbolic description of the model to be fit for the detection portion of the model using R's model syntax. Only right-hand side of formula is specified. See example below. Random intercepts are allowed using lme4 syntax (Bates et al. 2015).
<code>data</code>	a list containing data necessary for model fitting. Valid tags are <code>y</code> , <code>occ.covs</code> , <code>det.covs</code> , and <code>coords</code> . <code>y</code> is a three-dimensional array with first dimension equal to the number of species, second dimension equal to the number of sites, and third dimension equal to the maximum number of replicates at a given site. <code>occ.covs</code> is a matrix or data frame containing the variables used in the occurrence portion of the model, with J rows for each column (variable). <code>det.covs</code> is a list of variables included in the detection portion of the model. Each list element is a different detection covariate, which can be site-level or observational-level. Site-level covariates are specified as a vector of length J while observational-level covariates are specified as a matrix or data frame with the number of rows equal to J and number of columns equal to the maximum number of replicates at a given site. <code>coords</code> is a matrix or data frame with two columns that contain the spatial coordinates of each site. Note that <code>spOccupancy</code> assumes coordinates are specified in a projected coordinate system.
<code>inits</code>	a list with each tag corresponding to a parameter name. Valid tags are <code>alpha.comm</code> , <code>beta.comm</code> , <code>beta</code> , <code>alpha</code> , <code>tau.sq.beta</code> , <code>tau.sq.alpha</code> , <code>lambda</code> , <code>sigma.sq.psi</code> , <code>sigma.sq.p</code> , <code>z</code> . The value portion of each tag is the parameter's initial value. See priors description for definition of each parameter name. Additionally, the tag <code>fix</code> can be set to <code>TRUE</code> to fix the starting values across all chains. If <code>fix</code> is not specified (the default), starting values are varied randomly across chains.
<code>priors</code>	a list with each tag corresponding to a parameter name. Valid tags are <code>beta.comm.normal</code> , <code>alpha.comm.normal</code> , <code>tau.sq.beta.ig</code> , <code>tau.sq.alpha.ig</code> , <code>sigma.sq.psi.ig</code> , and <code>sigma.sq.p.ig</code> . Community-level occurrence (<code>beta.comm</code>) and detection (<code>alpha.comm</code>) regression coefficients are assumed to follow a normal distribution. The hyperparameters of the normal distribution are passed as a list of length two with the first and second elements corresponding to the mean and variance of the normal distribution, which are each specified as vectors of length equal to the number of coefficients to be estimated or of length one if priors are the same for all coefficients. If not specified, prior means are set to 0 and prior variances set to 2.72. Community-level variance parameters for occurrence (<code>tau.sq.beta</code>) and detection (<code>tau.sq.alpha</code>) are assumed to follow an inverse Gamma distribution. The hyperparameters of the inverse gamma distribution are passed as a list of length two with the first and second elements corresponding to the shape and scale parameters, which are each specified as vectors of length equal to the number of coefficients to be estimated or a single value if all parameters are assigned the same prior. If not specified, prior shape and scale parameters are set to 0.1. The factor model fits <code>n.factors</code> independent latent factors. The priors for the factor loadings matrix <code>lambda</code> are fixed following standard approaches to ensure parameter identifiability. The upper triangular elements of the $N \times n.factors$ matrix are fixed at 0 and the diagonal elements are fixed at 1. The lower triangular elements are assigned a standard normal prior (i.e., mean 0 and variance 1). <code>sigma.sq.psi</code> and <code>sigma.sq.p</code> are the random

effect variances for any occurrence or detection random effects, respectively, and are assumed to follow an inverse Gamma distribution. The hyperparameters of the inverse-Gamma distribution are passed as a list of length two with first and second elements corresponding to the shape and scale parameters, respectively, which are each specified as vectors of length equal to the number of random intercepts or of length one if priors are the same for all random effect variances.

n. factors	the number of factors to use in the latent factor model approach. Typically, the number of factors is set to be small (e.g., 4-5) relative to the total number of species in the community, which will lead to substantial decreases in computation time. However, the value can be anywhere between 1 and N (the number of species in the community).
n. samples	the number of posterior samples to collect in each chain.
n. omp. threads	a positive integer indicating the number of threads to use for SMP parallel processing. The package must be compiled for OpenMP support. For most Intel-based machines, we recommend setting n. omp. threads up to the number of hyperthreaded cores. Note, n. omp. threads > 1 might not work on some systems.
verbose	if TRUE, messages about data preparation, model specification, and progress of the sampler are printed to the screen. Otherwise, no messages are printed.
n. report	the interval to report MCMC progress.
n. burn	the number of samples out of the total n. samples to discard as burn-in for each chain. By default, the first 10% of samples is discarded.
n. thin	the thinning interval for collection of MCMC samples. The thinning occurs after the n. burn samples are discarded. Default value is set to 1.
n. chains	the number of chains to run in sequence.
k. fold	specifies the number of k folds for cross-validation. If not specified as an argument, then cross-validation is not performed and k. fold. threads and k. fold. seed are ignored. In k -fold cross-validation, the data specified in data is randomly partitioned into k equal sized subsamples. Of the k subsamples, $k - 1$ subsamples are used to fit the model and the remaining k samples are used for prediction. The cross-validation process is repeated k times (the folds). As a scoring rule, we use the model deviance as described in Hooten and Hobbs (2015). Cross-validation is performed after the full model is fit using all the data. Cross-validation results are reported in the k. fold. deviance object in the return list.
k. fold. threads	number of threads to use for cross-validation. If k. fold. threads > 1 parallel processing is accomplished using the foreach and doParallel packages. Ignored if k. fold is not specified.
k. fold. seed	seed used to split data set into k. fold parts for k-fold cross-validation. Ignored if k. fold is not specified.
...	currently no additional arguments

Value

An object of class lfMsPGOcc that is a list comprised of:

<code>beta.comm.samples</code>	a coda object of posterior samples for the community level occurrence regression coefficients.
<code>alpha.comm.samples</code>	a coda object of posterior samples for the community level detection regression coefficients.
<code>tau.sq.beta.samples</code>	a coda object of posterior samples for the occurrence community variance parameters.
<code>tau.sq.alpha.samples</code>	a coda object of posterior samples for the detection community variance parameters.
<code>beta.samples</code>	a coda object of posterior samples for the species level occurrence regression coefficients.
<code>alpha.samples</code>	a coda object of posterior samples for the species level detection regression coefficients.
<code>lambda.samples</code>	a coda object of posterior samples for the latent factor loadings.
<code>z.samples</code>	a three-dimensional array of posterior samples for the latent occurrence values for each species.
<code>psi.samples</code>	a three-dimensional array of posterior samples for the latent occurrence probability values for each species.
<code>sigma.sq.psi.samples</code>	a coda object of posterior samples for variances of random intercepts included in the occurrence portion of the model. Only included if random intercepts are specified in <code>occ.formula</code> .
<code>sigma.sq.p.samples</code>	a coda object of posterior samples for variances of random intercepts included in the detection portion of the model. Only included if random intercepts are specified in <code>det.formula</code> .
<code>w.samples</code>	a three-dimensional array of posterior samples for the latent effects for each latent factor.
<code>beta.star.samples</code>	a coda object of posterior samples for the occurrence random effects. Only included if random intercepts are specified in <code>occ.formula</code> .
<code>alpha.star.samples</code>	a coda object of posterior samples for the detection random effects. Only included if random intercepts are specified in <code>det.formula</code> .

Function for Fitting Multi-Species Occupancy Models Using Poly-Gamma Latent Variables

Description

Function for fitting multi-species occupancy models using Poly-Gamma latent variables.

Usage

```

msPGOcc(occ.formula, det.formula, data, inits, priors, n.samples,
        n.omp.threads = 1, verbose = TRUE, n.report = 100,
        n.burn = round(.10 * n.samples), n.thin = 1, n.chains = 1,
        k.fold, k.fold.threads = 1, k.fold.seed, ...)

```

Arguments

occ.formula	a symbolic description of the model to be fit for the occurrence portion of the model using R's model syntax. Only right-hand side of formula is specified. See example below. Random intercepts are allowed using lme4 syntax (Bates et al. 2015).
det.formula	a symbolic description of the model to be fit for the detection portion of the model using R's model syntax. Only right-hand side of formula is specified. See example below. Random intercepts are allowed using lme4 syntax (Bates et al. 2015).
data	a list containing data necessary for model fitting. Valid tags are <code>y</code> , <code>occ.covs</code> , and <code>det.covs</code> . <code>y</code> is a three-dimensional array with first dimension equal to the number of species, second dimension equal to the number of sites, and third dimension equal to the maximum number of replicates at a given site. <code>occ.covs</code> is a matrix or data frame containing the variables used in the occurrence portion of the model, with J rows for each column (variable). <code>det.covs</code> is a list of variables included in the detection portion of the model. Each list element is a different detection covariate, which can be site-level or observational-level. Site-level covariates are specified as a vector of length J while observational-level covariates are specified as a matrix or data frame with the number of rows

	equal to J and number of columns equal to the maximum number of replicates at a given site.
<code>inits</code>	a list with each tag corresponding to a parameter name. Valid tags are <code>alpha.comm</code> , <code>beta.comm</code> , <code>beta</code> , <code>alpha</code> , <code>tau.sq.beta</code> , <code>tau.sq.alpha</code> , <code>sigma.sq.psi</code> , <code>sigma.sq.p</code> , and <code>z</code> . The value portion of each tag is the parameter's initial value. See <code>priors</code> description for definition of each parameter name. Additionally, the tag <code>fix</code> can be set to <code>TRUE</code> to fix the starting values across all chains. If <code>fix</code> is not specified (the default), starting values are varied randomly across chains.
<code>priors</code>	a list with each tag corresponding to a parameter name. Valid tags are <code>beta.comm.normal</code> , <code>alpha.comm.normal</code> , <code>tau.sq.beta.ig</code> , <code>tau.sq.alpha.ig</code> , <code>sigma.sq.psi.ig</code> , and <code>sigma.sq.p.ig</code> . Community-level occurrence (<code>beta.comm</code>) and detection (<code>alpha.comm</code>) regression coefficients are assumed to follow a normal distribution. The hyperparameters of the normal distribution are passed as a list of length two with the first and second elements corresponding to the mean and variance of the normal distribution, which are each specified as vectors of length equal to the number of coefficients to be estimated or of length one if priors are the same for all coefficients. If not specified, prior means are set to 0 and prior variances set to 2.72. Community-level variance parameters for occurrence (<code>tau.sq.beta</code>) and detection (<code>tau.sq.alpha</code>) are assumed to follow an inverse Gamma distribution. The hyperparameters of the inverse gamma distribution are passed as a list of length two with the first and second elements corresponding to the shape and scale parameters, which are each specified as vectors of length equal to the number of coefficients to be estimated or a single value if all parameters are assigned the same prior. If not specified, prior shape and scale parameters are set to 0.1. <code>sigma.sq.psi</code> and <code>sigma.sq.p</code> are the random effect variances for any occurrence or detection random effects, respectively, and are assumed to follow an inverse Gamma distribution. The hyperparameters of the inverse-Gamma distribution are passed as a list of length two with first and second elements corresponding to the shape and scale parameters, respectively, which are each specified as vectors of length equal to the number of random intercepts or of length one if priors are the same for all random effect variances.
<code>n.samples</code>	the number of posterior samples to collect in each chain.
<code>n.omp.threads</code>	a positive integer indicating the number of threads to use for SMP parallel processing. The package must be compiled for OpenMP support. For most Intel-based machines, we recommend setting <code>n.omp.threads</code> up to the number of hyperthreaded cores. Note, <code>n.omp.threads > 1</code> might not work on some systems. Currently only relevant for spatial models.
<code>verbose</code>	if <code>TRUE</code> , messages about data preparation, model specification, and progress of the sampler are printed to the screen. Otherwise, no messages are printed.
<code>n.report</code>	the interval to report MCMC progress.
<code>n.burn</code>	the number of samples out of the total <code>n.samples</code> to discard as burn-in for each chain. By default, the first 10% of samples is discarded.
<code>n.thin</code>	the thinning interval for collection of MCMC samples. The thinning occurs after the <code>n.burn</code> samples are discarded. Default value is set to 1.
<code>n.chains</code>	the number of chains to run in sequence.

<code>k.fold</code>	specifies the number of k folds for cross-validation. If not specified as an argument, then cross-validation is not performed and <code>k.fold.threads</code> and <code>k.fold.seed</code> are ignored. In k -fold cross-validation, the data specified in <code>data</code> is randomly partitioned into k equal sized subsamples. Of the k subsamples, $k - 1$ subsamples are used to fit the model and the remaining k samples are used for prediction. The cross-validation process is repeated k times (the folds). As a scoring rule, we use the model deviance as described in Hooten and Hobbs (2015). Cross-validation is performed after the full model is fit using all the data. Cross-validation results are reported in the <code>k.fold.deviance</code> object in the return list.
<code>k.fold.threads</code>	number of threads to use for cross-validation. If <code>k.fold.threads</code> > 1 parallel processing is accomplished using the foreach and doParallel packages. Ignored if <code>k.fold</code> is not specified.
<code>k.fold.seed</code>	seed used to split data set into <code>k.fold</code> parts for k -fold cross-validation. Ignored if <code>k.fold</code> is not specified.
<code>...</code>	currently no additional arguments

Value

An object of class `msPGOcc` that is a list comprised of:

<code>beta.comm.samples</code>	a coda object of posterior samples for the community level occurrence regression coefficients.
<code>alpha.comm.samples</code>	a coda object of posterior samples for the community level detection regression coefficients.
<code>tau.sq.beta.samples</code>	a coda object of posterior samples for the occurrence community variance parameters.
<code>tau.sq.alpha.samples</code>	a coda object of posterior samples for the detection community variance parameters.
<code>beta.samples</code>	a coda object of posterior samples for the species level occurrence regression coefficients.
<code>alpha.samples</code>	a coda object of posterior samples for the species level detection regression coefficients.
<code>z.samples</code>	a three-dimensional array of posterior samples for the latent occurrence values for each species.
<code>psi.samples</code>	a three-dimensional array of posterior samples for the latent occurrence probability values for each species.
<code>sigma.sq.psi.samples</code>	a coda object of posterior samples for variances of random intercepts included in the occurrence portion of the model. Only included if random intercepts are specified in <code>occ.formula</code> .
<code>sigma.sq.p.samples</code>	a coda object of posterior samples for variances of random intercepts included in the detection portion of the model. Only included if random intercepts are specified in <code>det.formula</code> .

<code>beta.star.samples</code>	a coda object of posterior samples for the occurrence random effects. Only included if random intercepts are specified in <code>occ.formula</code> .
<code>alpha.star.samples</code>	a coda object of posterior samples for the detection random effects. Only included if random intercepts are specified in <code>det.formula</code> .
<code>like.samples</code>	a three-dimensional array of posterior samples for the likelihood value associated with each site and species. Used for calculating WAIC.
<code>rhat</code>	a list of Gelman-Rubin diagnostic values for some of the model parameters.
<code>ESS</code>	a list of effective sample sizes for some of the model parameters.
<code>run.time</code>	MCMC sampler execution time reported using <code>proc.time()</code> .
<code>k.fold.deviance</code>	vector of scoring rules (deviance) from k-fold cross-validation. A separate value is reported for each species. Only included if <code>k.fold</code> is specified in function call.

The return object will include additional objects used for subsequent prediction and/or model fit evaluation. Note that detection probability estimated values are not included in the model object, but can be extracted using `fitted()`.

Note

Some of the underlying code used for generating random numbers from the Polya-Gamma distribution is taken from the **pgdraw** package written by Daniel F. Schmidt and Enes Makalic. Their code implements Algorithm 6 in PhD thesis of Jesse Bennett Windle (2013) <https://repositories.lib.utexas.edu/handle/2152/21842>.

neon2015

Detection-nondetection data of 12 foliage gleaning bird species in 2015 in Bartlett Experimental Forest in New Hampshire, USA

Description

Detection-nondetection data of 12 foliage gleaning bird species in 2015 in the Bartlett Experimental Forest in New Hampshire, USA. These data were collected as part of the National Ecological Observatory Network (NEON). Data were collected at 80 sites where observers recorded the number of all bird species observed during a six minute, 125m radius point count survey once during the breeding season. The six minute survey was split into three two-minute intervals following a removal design where the observer recorded the interval during which a species was first observed (if any) with a 1, intervals prior to observation with a 0, and then mentally removed the species from subsequent intervals (marked with NA), which enables modeling of data in an occupancy modeling framework. The 12 species included in the data set are as follows: (1) AMRE: American Redstart; (2) BAWW: Black-and-white Warbler; (3) BHVI: Blue-headed Vireo; (4) BLBW: Blackburnian Warbler; (5) BLPW: Blackpoll Warbler; (6) BTBW: Black-throated Blue Warbler; (7) BTNW: Black-throated Green Warbler; (8) CAWA: Canada Warbler; (9) MAWA: Magnolia Warbler; (10) NAWA: Nashville Warbler; (11) OVEN: Ovenbird; (12) REVI: Red-eyed Vireo.

Usage

```
data(neon2015)
```

Format

neon2015 is a list with four elements:

`y`: a three-dimensional array of detection-nondetection data with dimensions of species (12), sites (80) and replicates (3).

`occ.covs`: a numeric matrix with 80 rows and one column consisting of the elevation at each site.

`det.covs`: a list of two numeric vectors with 80 elements. The first element is the day of year when the survey was conducted for a given site. The second element is the time of day when the survey began.

`coords`: a numeric matrix with 80 rows and two columns containing the site coordinates (East-ing and Northing) in UTM Zone 19. The proj4string is "+proj=utm +zone=19 +units=m +datum=NAD83".

PGOcc

Function for Fitting Single-Species Occupancy Models Using Polya-Gamma Latent Variables

Description

Function for fitting single-species occupancy models using Polya-Gamma latent variables.

Usage

```
PGOcc(occ.formula, det.formula, data, inits, priors, n.samples,
      n.omp.threads = 1, verbose = TRUE, n.report = 100,
      n.burn = round(.10 * n.samples), n.thin = 1, n.chains = 1,
      k.fold, k.fold.threads = 1, k.fold.seed, ...)
```

Arguments

<code>occ.formula</code>	a symbolic description of the model to be fit for the occurrence portion of the model using R's model syntax. Only right-hand side of formula is specified. See example below. Random intercepts are allowed using lme4 syntax (Bates et al. 2015).
<code>det.formula</code>	a symbolic description of the model to be fit for the detection portion of the model using R's model syntax. Only right-hand side of formula is specified. See example below. Random intercepts are allowed using lme4 syntax (Bates et al. 2015).
<code>data</code>	a list containing data necessary for model fitting. Valid tags are <code>y</code> , <code>occ.covs</code> , and <code>det.covs</code> . <code>y</code> is a matrix or data frame with first dimension equal to the number of sites (J) and second dimension equal to the maximum number of replicates at a given site. <code>occ.covs</code> is a matrix or data frame containing the variables used in the occurrence portion of the model, with J rows for each column (variable). <code>det.covs</code> is a list of variables included in the detection portion of the model. Each list element is a different detection covariate, which can be site-level or observational-level. Site-level covariates are specified as a vector of length J while observation-level covariates are specified as a matrix or data frame with the number of rows equal to J and number of columns equal to the maximum number of replicates at a given site.
<code>inits</code>	a list with each tag corresponding to a parameter name. Valid tags are <code>z</code> , <code>beta</code> , <code>alpha</code> , <code>sigma.sq.psi</code> , and <code>sigma.sq.p</code> . The value portion of each tag is the parameter's initial value. <code>sigma.sq.psi</code> and <code>sigma.sq.p</code> are only relevant when including random effects in the occurrence and detection portion of the occupancy model, respectively. See <code>priors</code> description for definition of each parameter name. Additionally, the tag <code>fix</code> can be set to <code>TRUE</code> to fix the starting values across all chains. If <code>fix</code> is not specified (the default), starting values are varied randomly across chains.
<code>priors</code>	a list with each tag corresponding to a parameter name. Valid tags are <code>beta.normal</code> , <code>alpha.normal</code> , <code>sigma.sq.psi.ig</code> , and <code>sigma.sq.p.ig</code> . Occupancy (<code>beta</code>) and detection (<code>alpha</code>) regression coefficients are assumed to follow a normal distribution. The hyperparameters of the normal distribution are passed as a list of length two with the first and second elements corresponding to the mean and variance of the normal distribution, which are each specified as vectors of length equal to the number of coefficients to be estimated or of length one if priors are the same for all coefficients. If not specified, prior means are set to 0 and prior variances set to 2.72. <code>sigma.sq.psi</code> and <code>sigma.sq.p</code> are the random effect variances for any occurrence or detection random effects, respectively, and are assumed to follow an inverse Gamma distribution. The hyperparameters of the inverse-Gamma distribution are passed as a list of length two with first and second elements corresponding to the shape and scale parameters, respectively, which are each specified as vectors of length equal to the number of random intercepts or of length one if priors are the same for all random effect variances.
<code>n.samples</code>	the number of posterior samples to collect in each chain.
<code>n.omp.threads</code>	a positive integer indicating the number of threads to use for SMP parallel processing. The package must be compiled for OpenMP support. For most Intel-based machines, we recommend setting <code>n.omp.threads</code> up to the number of

	hyperthreaded cores. Note, <code>n.omp.threads > 1</code> might not work on some systems. Currently only relevant for spatial models.
<code>verbose</code>	if TRUE, messages about data preparation, model specification, and progress of the sampler are printed to the screen. Otherwise, no messages are printed.
<code>n.report</code>	the interval to report MCMC progress.
<code>n.burn</code>	the number of samples out of the total <code>n.samples</code> to discard as burn-in for each chain. By default, the first 10% of samples is discarded.
<code>n.thin</code>	the thinning interval for collection of MCMC samples. The thinning occurs after the <code>n.burn</code> samples are discarded. Default value is set to 1.
<code>n.chains</code>	the number of chains to run in sequence.
<code>k.fold</code>	specifies the number of k folds for cross-validation. If not specified as an argument, then cross-validation is not performed and <code>k.fold.threads</code> and <code>k.fold.seed</code> are ignored. In k -fold cross-validation, the data specified in <code>data</code> is randomly partitioned into k equal sized subsamples. Of the k subsamples, $k - 1$ subsamples are used to fit the model and the remaining k samples are used for prediction. The cross-validation process is repeated k times (the folds). As a scoring rule, we use the model deviance as described in Hooten and Hobbs (2015). Cross-validation is performed after the full model is fit using all the data. Cross-validation results are reported in the <code>k.fold.deviance</code> object in the return list.
<code>k.fold.threads</code>	number of threads to use for cross-validation. If <code>k.fold.threads > 1</code> parallel processing is accomplished using the foreach and doParallel packages. Ignored if <code>k.fold</code> is not specified.
<code>k.fold.seed</code>	seed used to split data set into <code>k.fold</code> parts for k -fold cross-validation. Ignored if <code>k.fold</code> is not specified.
<code>...</code>	currently no additional arguments

Value

An object of class `PGOcc` that is a list comprised of:

<code>beta.samples</code>	a coda object of posterior samples for the occupancy regression coefficients.
<code>alpha.samples</code>	a coda object of posterior samples for the detection regression coefficients.
<code>z.samples</code>	a coda object of posterior samples for the latent occupancy values
<code>psi.samples</code>	a coda object of posterior samples for the latent occupancy probability values
<code>sigma.sq.psi.samples</code>	a coda object of posterior samples for variances of random intercepts included in the occupancy portion of the model. Only included if random intercepts are specified in <code>occ.formula</code> .
<code>sigma.sq.p.samples</code>	a coda object of posterior samples for variances of random intercepts included in the detection portion of the model. Only included if random intercepts are specified in <code>det.formula</code> .
<code>beta.star.samples</code>	a coda object of posterior samples for the occurrence random effects. Only included if random intercepts are specified in <code>occ.formula</code> .

<code>alpha.star.samples</code>	a coda object of posterior samples for the detection random effects. Only included if random intercepts are specified in <code>det.formula</code> .
<code>like.samples</code>	a coda object of posterior samples for the likelihood value associated with each site. Used for calculating WAIC.
<code>run.time</code>	execution time reported using <code>proc.time()</code> .
<code>k.fold.deviance</code>	scoring rule (deviance) from k-fold cross-validation. Only included if <code>k.fold</code> is specified in function call.

The return object will include additional objects used for subsequent prediction and/or model fit evaluation. Note that detection probability estimated values are not included in the model object, but can be extracted using `fitted()`.

Note

Some of the underlying code used for generating random numbers from the Polya-Gamma distribution is taken from the **pgdraw** package written by Daniel F. Schmidt and Enes Makalic. Their code implements Algorithm 6 in PhD thesis of Jesse Bennett Windle (2013) <https://repositories.lib.utexas.edu/handle/2152/21842>.

ppcOcc

Function for performing posterior predictive checks

Description

Function for performing posterior predictive checks on spOccupancy model objects.

Usage

```
ppcOcc(object, fit.stat, group, ...)
```

Arguments

object	an object of class PGOcc, spPGOcc, msPGOcc, spMsPGOcc, intPGOcc, spIntPGOcc, lfMsPGOcc, or sfMsPGOcc.
--------	---

<code>fit.stat</code>	a quoted keyword that specifies the fit statistic to use in the posterior predictive check. Supported fit statistics are "freeman-tukey" and "chi-squared".
<code>group</code>	a positive integer indicating the way to group the detection-nondetection data for the posterior predictive check. Value 1 will group values by row (site) and value 2 will group values by column (replicate).
<code>...</code>	currently no additional arguments

Details

Standard GoF assessments are not valid for binary data, and posterior predictive checks must be performed on some sort of binned data.

Value

An object of class `ppcOcc` that is a list comprised of:

<code>fit.y</code>	a numeric vector of posterior samples for the fit statistic calculated on the observed data.
<code>fit.y.rep</code>	a numeric vector of posterior samples for the fit statistic calculated on a replicate data set generated from the model.
<code>fit.y.group.quant</code> s	a matrix consisting of posterior quantiles for the fit statistic using the observed data for each unique element the fit statistic is calculated for (i.e., sites when <code>group = 1</code> , replicates when <code>group = 2</code>).
<code>fit.y.rep.group.quant</code> s	a matrix consisting of posterior quantiles for the fit statistic using the model replicated data for each unique element the fit statistic is calculated for (i.e., sites when <code>group = 1</code> , replicates when <code>group = 2</code>).

The return object will include additional objects used for standard extractor functions.

predict.intPGOcc *Function for prediction at new locations for single-species integrated occupancy models*

Description

The function `predict` collects posterior predictive samples for a set of new locations given an object of class `'intPGOcc'`.

Usage

```
## S3 method for class 'intPGOcc'
predict(object, X.0, ...)
```

Arguments

object	an object of class intPGOcc
X.0	the design matrix for prediction locations. This should include a column of 1s for the intercept. Covariates should have the same column names as those used when fitting the model with intPGOcc.
...	currently no additional arguments

Value

An object of class `predict.intPGOcc` that is a list comprised of:

psi.0.samples	a coda object of posterior predictive samples for the latent occurrence probability values.
z.0.samples	a coda object of posterior predictive samples for the latent occurrence values.

The return object will include additional objects used for standard extractor functions.

predict.lfJSDM	<i>Function for prediction at new locations for latent factor joint species distribution models</i>
----------------	---

Description

The function `predict` collects posterior predictive samples for a set of new locations given an object of class 'lfJSDM'.

Usage

```

## S3 method for class 'lfJSDM'
predict(object, X.0, coords.0,
        ignore.RE = FALSE, ...)

```

Arguments

object	an object of class lfJSDM
X.0	the design matrix of covariates at the prediction locations. This should include a column of 1s for the intercept if an intercept is included in the model. If random effects are included in the model, the levels of the random effects at the new locations should be included as a column in the design matrix. The ordering of the levels should match the ordering used to fit the data in lfJSDM. Columns should correspond to the order of how covariates were specified in the formula argument of lfJSDM. Column names of the random effects must match the name of the random effects, if specified in the formula argument of lfJSDM.
coords.0	the spatial coordinates corresponding to X.0. Note that spOccupancy assumes coordinates are specified in a projected coordinate system.
ignore.RE	a logical value indicating whether to include unstructured random effects for prediction. If TRUE, random effects will be ignored and prediction will only use the fixed effects. If FALSE, random effects will be included in the prediction for both observed and unobserved levels of the random effect.
...	currently no additional arguments

Value

A list object of class `predict.lfJSDM` that consists of:

- `psi.0.samples` a three-dimensional array of posterior predictive samples for the latent occurrence probability values.
- `z.0.samples` a three-dimensional array of posterior predictive samples for the latent occurrence values.
- `w.0.samples` a three-dimensional array of posterior predictive samples for the latent factors.

The return object will include additional objects used for standard extractor functions.

Note

When `ignore.RE = FALSE`, both sampled levels and non-sampled levels of random effects are supported for prediction. For sampled levels, the posterior distribution for the random intercept corresponding to that level of the random effect will be used in the prediction. For non-sampled levels, random values are drawn from a normal distribution using the posterior samples of the random effect variance, which results in fully propagated uncertainty in predictions with models that incorporate random effects.

predict.lfMsPGOcc	<i>Function for prediction at new locations for latent factor multi-species occupancy models</i>
-------------------	--

Description

The function `predict` collects posterior predictive samples for a set of new locations given an object of class `'lfMsPGOcc'`. Prediction is possible for both the latent occupancy state as well as detection.

Usage

```
## S3 method for class 'lfMsPGOcc'
predict(object, X.0, coords.0,
        ignore.RE = FALSE, type = 'occupancy', ...)
```

Arguments

<code>object</code>	an object of class <code>lfMsPGOcc</code>
<code>X.0</code>	the design matrix of covariates at the prediction locations. This should include a column of 1s for the intercept if an intercept is included in the model. If random effects are included in the occupancy (or detection if <code>type = 'detection'</code>) portion of the model, the levels of the random effects at the new locations should be included as a column in the design matrix. The ordering of the levels should match the ordering used to fit the data in <code>lfMsPGOcc</code> . Columns should correspond to the order of how covariates were specified in the corresponding formula argument of <code>lfMsPGOcc</code> . Column names of the random effects must match the name of the random effects, if specified in the corresponding formula argument of <code>lfMsPGOcc</code> .
<code>coords.0</code>	the spatial coordinates corresponding to <code>X.0</code> . Note that <code>spOccupancy</code> assumes coordinates are specified in a projected coordinate system.
<code>ignore.RE</code>	a logical value indicating whether to include unstructured random effects for prediction. If <code>TRUE</code> , random effects will be ignored and prediction will only use the fixed effects. If <code>FALSE</code> , random effects will be included in the prediction for both observed and unobserved levels of the random effect.
<code>...</code>	currently no additional arguments
<code>type</code>	a quoted keyword indicating what type of prediction to produce. Valid keywords are <code>'occupancy'</code> to predict latent occupancy probability and latent occupancy values (this is the default), or <code>'detection'</code> to predict detection probability given new values of detection covariates.

Value

A list object of class `predict.lfMsPGOcc`. When `type = 'occupancy'`, the list consists of:

- `psi.0.samples` a three-dimensional array of posterior predictive samples for the latent occurrence probability values.
- `z.0.samples` a three-dimensional array of posterior predictive samples for the latent occurrence values.
- `w.0.samples` a three-dimensional array of posterior predictive samples for the latent factors.

When `type = 'detection'`, the list consists of:

- `p.0.samples` a three-dimensional array of posterior predictive samples for the detection probability values.

The return object will include additional objects used for standard extractor functions.

Note

When `ignore.RE = FALSE`, both sampled levels and non-sampled levels of random effects are supported for prediction. For sampled levels, the posterior distribution for the random intercept corresponding to that level of the random effect will be used in the prediction. For non-sampled levels, random values are drawn from a normal distribution using the posterior samples of the random effect variance, which results in fully propagated uncertainty in predictions with models that incorporate random effects.

predict.msPGOcc	<i>Function for prediction at new locations for multi-species occupancy models</i>
-----------------	--

Description

The function `predict` collects posterior predictive samples for a set of new locations given an object of class `'msPGOcc'`. Prediction is possible for both the latent occupancy state as well as detection.

Usage

```

## S3 method for class 'msPGOcc'
predict(object, X.0, ignore.RE = FALSE, type = 'occupancy', ...)

```

Arguments

object	an object of class <code>msPGOcc</code>
X.0	the design matrix of covariates at the prediction locations. This should include a column of 1s for the intercept if an intercept is included in the model. If random effects are included in the occupancy (or detection if <code>type = 'detection'</code>) portion of the model, the levels of the random effects at the new locations should be included as a column in the design matrix. The ordering of the levels should match the ordering used to fit the data in <code>msPGOcc</code> . Columns should correspond to the order of how covariates were specified in the corresponding formula argument of <code>msPGOcc</code> . Column names of the random effects must match the name of the random effects, if specified in the corresponding formula argument of <code>msPGOcc</code> .
ignore.RE	a logical value indicating whether to include unstructured random effects for prediction. If <code>TRUE</code> , random effects will be ignored and prediction will only use the fixed effects. If <code>FALSE</code> , random effects will be included in the prediction for both observed and unobserved levels of the random effect.
...	currently no additional arguments
type	a quoted keyword indicating what type of prediction to produce. Valid keywords are <code>'occupancy'</code> to predict latent occupancy probability and latent occupancy values (this is the default), or <code>'detection'</code> to predict detection probability given new values of detection covariates.

Value

A list object of class `predict.msPGOcc`. When `type = 'occupancy'`, the list consists of:

`psi.0.samples` a three-dimensional array of posterior predictive samples for the latent occurrence probability values.

`z.0.samples` a three-dimensional array of posterior predictive samples for the latent occurrence values.

When `type = 'detection'`, the list consists of:

`p.0.samples` a three-dimensional array of posterior predictive samples for the detection probability values.

The return object will include additional objects used for standard extractor functions.

Note

When `ignore.RE = FALSE`, both sampled levels and non-sampled levels of random effects are supported for prediction. For sampled levels, the posterior distribution for the random intercept corresponding to that level of the random effect will be used in the prediction. For non-sampled levels, random values are drawn from a normal distribution using the posterior samples of the random effect variance, which results in fully propagated uncertainty in predictions with models that incorporate random effects.

```

predict.PGOcc	<i>Function for prediction at new locations for single-species occupancy models</i>
---------------	---

Description

The function `predict` collects posterior predictive samples for a set of new locations given an object of class 'PGOcc'. Prediction is possible for both the latent occupancy state as well as detection.

Usage

```
## S3 method for class 'PGOcc'
predict(object, X.0, ignore.RE = FALSE, type = 'occupancy', ...)
```

Arguments

<code>object</code>	an object of class <code>PGOcc</code>
<code>X.0</code>	the design matrix of covariates at the prediction locations. This should include a column of 1s for the intercept if an intercept is included in the model. If random effects are included in the occupancy (or detection if <code>type = 'detection'</code>) portion of the model, the levels of the random effects at the new locations should be included as a column in the design matrix. The ordering of the levels should match the ordering used to fit the data in <code>PGOcc</code> . Columns should correspond to the order of how covariates were specified in the corresponding formula argument of <code>PGOcc</code> . Column names of the random effects must match the name of the random effects, if specified in the corresponding formula argument of <code>PGOcc</code> .
<code>ignore.RE</code>	logical value that specifies whether or not to remove random occurrence (or detection if <code>type = 'detection'</code>) effects from the subsequent predictions. If <code>TRUE</code> , random effects will be included. If <code>FALSE</code> , random effects will be set to 0 and predictions will only be generated from the fixed effects.
<code>type</code>	a quoted keyword indicating what type of prediction to produce. Valid keywords are 'occupancy' to predict latent occupancy probability and latent occupancy values (this is the default), or 'detection' to predict detection probability given new values of detection covariates.
<code>...</code>	currently no additional arguments

Value

A list object of class `predict.PGOcc`. When `type = 'occupancy'`, the list consists of:

<code>psi.0.samples</code>	a coda object of posterior predictive samples for the latent occupancy probability values.
----------------------------	--

`z.0.samples` a coda object of posterior predictive samples for the latent occupancy values.

When `type = 'detection'`, the list consists of:

`p.0.samples` a coda object of posterior predictive samples for the detection probability values.

The return object will include additional objects used for standard extractor functions.

Note

When `ignore.RE = FALSE`, both sampled levels and non-sampled levels of random effects are supported for prediction. For sampled levels, the posterior distribution for the random intercept corresponding to that level of the random effect will be used in the prediction. For non-sampled levels, random values are drawn from a normal distribution using the posterior samples of the random effect variance, which results in fully propagated uncertainty in predictions with models that incorporate random effects.

predict.sfJSDM

Function for prediction at new locations for spatial factor joint species distribution model

Description

The function `predict` collects posterior predictive samples for a set of new locations given an object of class 'sfJSDM'.

Usage

```

## S3 method for class 'sfJSDM'
predict(object, X.0, coords.0, n.omp.threads = 1, verbose = TRUE,
        n.report = 100, ignore.RE = FALSE, ...)

```

Arguments

<code>object</code>	an object of class <code>sfJSDM</code>
<code>X.0</code>	the design matrix of covariates at the prediction locations. This should include a column of 1s for the intercept if an intercept is included in the model. If random effects are included in the model, the levels of the random effects at the new locations should be included as a column in the design matrix. The ordering of the levels should match the ordering used to fit the data in <code>sfJSDM</code> . Columns should correspond to the order of how covariates were specified in the formula argument of <code>sfJSDM</code> . Column names of the random effects must match the name of the random effects, if specified in the formula argument of <code>sfJSDM</code> .
<code>coords.0</code>	the spatial coordinates corresponding to <code>X.0</code> . Note that <code>spOccupancy</code> assumes coordinates are specified in a projected coordinate system.
<code>n.omp.threads</code>	a positive integer indicating the number of threads to use for SMP parallel processing. The package must be compiled for OpenMP support. For most Intel-based machines, we recommend setting <code>n.omp.threads</code> up to the number of hyperthreaded cores. Note, <code>n.omp.threads > 1</code> might not work on some systems.
<code>verbose</code>	if TRUE, model specification and progress of the sampler is printed to the screen. Otherwise, nothing is printed to the screen.
<code>n.report</code>	the interval to report sampling progress.
<code>ignore.RE</code>	a logical value indicating whether to include unstructured random effects for prediction. If TRUE, unstructured random effects will be ignored and prediction will only use the fixed effects and the spatial random effects. If FALSE, random effects will be included in the prediction for both observed and unobserved levels of the unstructured random effects.
<code>...</code>	currently no additional arguments

Value

An list object of class `predict.sfJSDM` that consists of:

<code>psi.0.samples</code>	a three-dimensional array of posterior predictive samples for the latent occurrence probability values.
<code>z.0.samples</code>	a three-dimensional array of posterior predictive samples for the latent occurrence values.
<code>w.0.samples</code>	a three-dimensional array of posterior predictive samples for the latent spatial factors.
<code>run.time</code>	execution time reported using <code>proc.time()</code> .

The return object will include additional objects used for standard extractor functions.

Note

When `ignore.RE = FALSE`, both sampled levels and non-sampled levels of random effects are supported for prediction. For sampled levels, the posterior distribution for the random intercept corresponding to that level of the random effect will be used in the prediction. For non-sampled levels,

random values are drawn from a normal distribution using the posterior samples of the random effect variance, which results in fully propagated uncertainty in predictions with models that incorporate random effects.

```

predict.sfMsPGOcc      Function for prediction at new locations for spatial factor multi-
                        species occupancy models

```

Description

The function `predict` collects posterior predictive samples for a set of new locations given an object of class `'sfMsPGOcc'`. Prediction is possible for both the latent occupancy state as well as detection.

Usage

```

## S3 method for class 'sfMsPGOcc'
predict(object, X.0, coords.0, n.omp.threads = 1, verbose = TRUE,
        n.report = 100, ignore.RE = FALSE, type = 'occupancy', ...)

```

Arguments

<code>object</code>	an object of class <code>sfMsPGOcc</code>
<code>X.0</code>	the design matrix of covariates at the prediction locations. This should include a column of 1s for the intercept if an intercept is included in the model. If random effects are included in the occupancy (or detection if <code>type = 'detection'</code>) portion of the model, the levels of the random effects at the new locations should be included as a column in the design matrix. The ordering of the levels should match the ordering used to fit the data in <code>sfMsPGOcc</code> . Columns should correspond to the order of how covariates were specified in the corresponding formula argument of <code>sfMsPGOcc</code> . Column names of the random effects must match the name of the random effects, if specified in the corresponding formula argument of <code>sfMsPGOcc</code> .
<code>coords.0</code>	the spatial coordinates corresponding to <code>X.0</code> . Note that <code>spOccupancy</code> assumes coordinates are specified in a projected coordinate system.
<code>n.omp.threads</code>	a positive integer indicating the number of threads to use for SMP parallel processing. The package must be compiled for OpenMP support. For most Intel-based machines, we recommend setting <code>n.omp.threads</code> up to the number of hyperthreaded cores. Note, <code>n.omp.threads > 1</code> might not work on some systems.
<code>verbose</code>	if <code>TRUE</code> , model specification and progress of the sampler is printed to the screen. Otherwise, nothing is printed to the screen.

<code>n.report</code>	the interval to report sampling progress.
<code>ignore.RE</code>	a logical value indicating whether to include unstructured random effects for prediction. If TRUE, unstructured random effects will be ignored and prediction will only use the fixed effects and the spatial random effects. If FALSE, random effects will be included in the prediction for both observed and unobserved levels of the unstructured random effects.
<code>type</code>	a quoted keyword indicating what type of prediction to produce. Valid keywords are 'occupancy' to predict latent occupancy probability and latent occupancy values (this is the default), or 'detection' to predict detection probability given new values of detection covariates.
<code>...</code>	currently no additional arguments

Value

An list object of class `predict.sfMsPGOcc`. When `type = 'occupancy'`, the list consists of:

<code>psi.0.samples</code>	a three-dimensional array of posterior predictive samples for the latent occurrence probability values.
<code>z.0.samples</code>	a three-dimensional array of posterior predictive samples for the latent occurrence values.
<code>w.0.samples</code>	a three-dimensional array of posterior predictive samples for the latent spatial factors.
<code>run.time</code>	execution time reported using <code>proc.time()</code> .

When `type = 'detection'`, the list consists of:

<code>p.0.samples</code>	a three-dimensional array of posterior predictive samples for the detection probability values.
<code>run.time</code>	execution time reported using <code>proc.time()</code> .

The return object will include additional objects used for standard extractor functions.

Note

When `ignore.RE = FALSE`, both sampled levels and non-sampled levels of random effects are supported for prediction. For sampled levels, the posterior distribution for the random intercept corresponding to that level of the random effect will be used in the prediction. For non-sampled levels, random values are drawn from a normal distribution using the posterior samples of the random effect variance, which results in fully propagated uncertainty in predictions with models that incorporate random effects.

predict.spIntPGOcc *Function for prediction at new locations for single-species integrated spatial occupancy models*

Description

The function `predict` collects posterior predictive samples for a set of new locations given an object of class `'spIntPGOcc'`.

Usage

```

## S3 method for class 'spIntPGOcc'
predict(object, X.0, coords.0, n.omp.threads = 1, verbose = TRUE,
        n.report = 100, ...)

```

Arguments

<code>object</code>	an object of class <code>spIntPGOcc</code> .
<code>X.0</code>	the design matrix for prediction locations. This should include a column of 1s for the intercept. Covariates should have the same column names as those used when fitting the model with <code>spIntPGOcc</code> .
<code>coords.0</code>	the spatial coordinates corresponding to <code>X.0</code> . Note that <code>spOccupancy</code> assumes coordinates are specified in a projected coordinate system.
<code>n.omp.threads</code>	a positive integer indicating the number of threads to use for SMP parallel processing. The package must be compiled for OpenMP support. For most Intel-based machines, we recommend setting <code>n.omp.threads</code> up to the number of hyperthreaded cores. Note, <code>n.omp.threads > 1</code> might not work on some systems.
<code>verbose</code>	if <code>TRUE</code> , model specification and progress of the sampler is printed to the screen. Otherwise, nothing is printed to the screen.
<code>n.report</code>	the interval to report sampling progress.
<code>...</code>	currently no additional arguments

Value

An object of class `predict.spIntPGOcc` that is a list comprised of:

`psi.0.samples` a coda object of posterior predictive samples for the latent occurrence probability values.

`z.0.samples` a coda object of posterior predictive samples for the latent occurrence values.

The return object will include additional objects used for standard extractor functions.

predict.spMsPGOcc	<i>Function for prediction at new locations for multi-species spatial occupancy models</i>
-------------------	--

Description

The function `predict` collects posterior predictive samples for a set of new locations given an object of class `'spMsPGOcc'`. Prediction is possible for both the latent occupancy state as well as detection.

Usage

```

## S3 method for class 'spMsPGOcc'
predict(object, X.0, coords.0, n.omp.threads = 1, verbose = TRUE,
        n.report = 100, ignore.RE = FALSE, type = 'occupancy', ...)

```

Arguments

`object` an object of class `spMsPGOcc`

<code>X.0</code>	the design matrix of covariates at the prediction locations. This should include a column of 1s for the intercept if an intercept is included in the model. If random effects are included in the occupancy (or detection if <code>type = 'detection'</code>) portion of the model, the levels of the random effects at the new locations should be included as a column in the design matrix. The ordering of the levels should match the ordering used to fit the data in <code>spMsPGOcc</code> . Columns should correspond to the order of how covariates were specified in the corresponding formula argument of <code>spMsPGOcc</code> . Column names of the random effects must match the name of the random effects, if specified in the corresponding formula argument of <code>spMsPGOcc</code> .
<code>coords.0</code>	the spatial coordinates corresponding to <code>X.0</code> . Note that <code>sp0occupancy</code> assumes coordinates are specified in a projected coordinate system.
<code>n.omp.threads</code>	a positive integer indicating the number of threads to use for SMP parallel processing. The package must be compiled for OpenMP support. For most Intel-based machines, we recommend setting <code>n.omp.threads</code> up to the number of hyperthreaded cores. Note, <code>n.omp.threads > 1</code> might not work on some systems.
<code>verbose</code>	if TRUE, model specification and progress of the sampler is printed to the screen. Otherwise, nothing is printed to the screen.
<code>n.report</code>	the interval to report sampling progress.
<code>ignore.RE</code>	a logical value indicating whether to include unstructured random effects for prediction. If TRUE, unstructured random effects will be ignored and prediction will only use the fixed effects and the spatial random effects. If FALSE, random effects will be included in the prediction for both observed and unobserved levels of the unstructured random effects.
<code>type</code>	a quoted keyword indicating what type of prediction to produce. Valid keywords are 'occupancy' to predict latent occupancy probability and latent occupancy values (this is the default), or 'detection' to predict detection probability given new values of detection covariates.
<code>...</code>	currently no additional arguments

Value

An list object of class `predict.spMsPGOcc`. When `type = 'occupancy'`, the list consists of:

<code>psi.0.samples</code>	a three-dimensional array of posterior predictive samples for the latent occurrence probability values.
<code>z.0.samples</code>	a three-dimensional array of posterior predictive samples for the latent occurrence values.
<code>w.0.samples</code>	a three-dimensional array of posterior predictive samples for the latent spatial random effects.
<code>run.time</code>	execution time reported using <code>proc.time()</code> .

When `type = 'detection'`, the list consists of:

<code>p.0.samples</code>	a three-dimensional array of posterior predictive samples for the detection probability values.
--------------------------	---

run.time execution time reported using proc.time().

The return object will include additional objects used for standard extractor functions.

Note

When ignore.RE = FALSE, both sampled levels and non-sampled levels of random effects are supported for prediction. For sampled levels, the posterior distribution for the random intercept corresponding to that level of the random effect will be used in the prediction. For non-sampled levels, random values are drawn from a normal distribution using the posterior samples of the random effect variance, which results in fully propagated uncertainty in predictions with models that incorporate random effects.

predict.spPGOcc	<i>Function for prediction at new locations for single-species spatial occupancy models</i>
-----------------	---

Description

The function `predict` collects posterior predictive samples for a set of new locations given an object of class `'spPGOcc'`. Prediction is possible for both the latent occupancy state as well as detection.

Usage

```

## S3 method for class 'spPGOcc'
predict(object, X.0, coords.0, n.omp.threads = 1, verbose = TRUE,
  n.report = 100, ignore.RE = FALSE, type = 'occupancy', ...)

```

Arguments

<code>object</code>	an object of class <code>spPGOcc</code>
<code>X.0</code>	the design matrix of covariates at the prediction locations. This should include a column of 1s for the intercept if an intercept is included in the model. If random effects are included in the occupancy (or detection if <code>type = 'detection'</code>) portion of the model, the levels of the random effects at the new locations should be included as a column in the design matrix. The ordering of the levels should match the ordering used to fit the data in <code>spPGOcc</code> . Columns should correspond

	to the order of how covariates were specified in the corresponding formula argument of spPGOcc. Column names of the random effects must match the name of the random effects, if specified in the corresponding formula argument of spPGOcc.
coords.0	the spatial coordinates corresponding to $X.0$. Note that spOccupancy assumes coordinates are specified in a projected coordinate system.
n.omp.threads	a positive integer indicating the number of threads to use for SMP parallel processing. The package must be compiled for OpenMP support. For most Intel-based machines, we recommend setting n.omp.threads up to the number of hyperthreaded cores. Note, n.omp.threads > 1 might not work on some systems.
verbose	if TRUE, model specification and progress of the sampler is printed to the screen. Otherwise, nothing is printed to the screen.
ignore.RE	a logical value indicating whether to include unstructured random effects for prediction. If TRUE, unstructured random effects will be ignored and prediction will only use the fixed effects and the spatial random effects. If FALSE, random effects will be included in the prediction for both observed and unobserved levels of the unstructured random effects.
n.report	the interval to report sampling progress.
type	a quoted keyword indicating what type of prediction to produce. Valid keywords are 'occupancy' to predict latent occupancy probability and latent occupancy values (this is the default), or 'detection' to predict detection probability given new values of detection covariates.
...	currently no additional arguments

Value

A list object of class predict.spPGOcc. When type = 'occupancy', the list consists of:

psi.0.samples	a coda object of posterior predictive samples for the latent occurrence probability values.
z.0.samples	a coda object of posterior predictive samples for the latent occurrence values.
w.0.samples	a coda object of posterior predictive samples for the latent spatial random effects.
run.time	execution time reported using proc.time().

When type = 'detection', the list consists of:

p.0.samples	a coda object of posterior predictive samples for the detection probability values.
run.time	execution time reported using proc.time().

The return object will include additional objects used for standard extractor functions.

Note

When `ignore.RE = FALSE`, both sampled levels and non-sampled levels of random effects are supported for prediction. For sampled levels, the posterior distribution for the random intercept corresponding to that level of the random effect will be used in the prediction. For non-sampled levels, random values are drawn from a normal distribution using the posterior samples of the random effect variance, which results in fully propagated uncertainty in predictions with models that incorporate random effects.

summary(out)

# Predict at new locations -----
out.pred <- predict(out, X.0, coords.0, verbose = FALSE)

```

Description

The function `sfJSDM` fits a spatially-explicit joint species distribution model. This model does not explicitly account for imperfect detection (see `sfMsPGOcc()`). We use Polya-Gamma latent variables and a spatial factor modeling approach. Currently, models are implemented using a Nearest Neighbor Gaussian Process. Future development will allow for running the models using a full Gaussian Process.

Usage

```
sfJSDM(formula, data, inits, priors, tuning,
        cov.model = 'exponential', NNGP = TRUE,
        n.neighbors = 15, search.type = 'cb', n.factors, n.batch,
        batch.length, accept.rate = 0.43, n.omp.threads = 1,
        verbose = TRUE, n.report = 100,
        n.burn = round(.10 * n.batch * batch.length), n.thin = 1,
        n.chains = 1, k.fold, k.fold.threads = 1, k.fold.seed, ...)
```

Arguments

<code>formula</code>	a symbolic description of the model to be fit for the model using R's model syntax. Only right-hand side of formula is specified. See example below. Random intercepts are allowed using lme4 syntax (Bates et al. 2015).
<code>data</code>	a list containing data necessary for model fitting. Valid tags are <code>y</code> , <code>covs</code> , and <code>coords</code> . <code>y</code> is a two-dimensional array with first dimension equal to the number of species and second dimension equal to the number of sites. Note how this differs from other <code>spOccupancy</code> functions in that <code>y</code> does not have any replicate surveys. This is because <code>sfJSDM</code> does not account for imperfect detection. <code>covs</code> is a matrix or data frame containing the variables used in the model, with J rows for each column (variable). <code>coords</code> is a matrix with J rows and 2 columns consisting of the spatial coordinates of each site in the data. Note that <code>spOccupancy</code> assumes coordinates are specified in a projected coordinate system.
<code>inits</code>	a list with each tag corresponding to a parameter name. Valid tags are <code>beta.comm</code> , <code>beta</code> , <code>tau.sq.beta</code> , <code>phi</code> , <code>lambda</code> , <code>sigma.sq.psi</code> , and <code>nu</code> . <code>nu</code> is only specified if <code>cov.model = "matern"</code> . <code>sigma.sq.psi</code> is only specified if random intercepts are included in formula. The value portion of each tag is the parameter's initial value. See <code>priors</code> description for definition of each parameter name. Additionally, the tag <code>fix</code> can be set to <code>TRUE</code> to fix the starting values across all chains. If <code>fix</code> is not specified (the default), starting values are varied randomly across chains.
<code>priors</code>	a list with each tag corresponding to a parameter name. Valid tags are <code>beta.comm.normal</code> , <code>tau.sq.beta.ig</code> , <code>phi.unif</code> , <code>nu.unif</code> , and <code>sigma.sq.psi.ig</code> . Community-level occurrence (<code>beta.comm</code>) regression coefficients are assumed to follow a normal distribution. The hyperparameters of the normal distribution are passed as a list of length two with the first and second elements corresponding to the mean and variance of the normal distribution, which are each specified as vectors of length equal to the number of coefficients to be estimated or of length one if priors are the same for all coefficients. If not specified, prior means are

set to 0 and prior variances set to 2.73. Community-level variance parameters ($\tau \cdot \text{sq} \cdot \beta$) are assumed to follow an inverse Gamma distribution. The hyperparameters of the inverse gamma distribution are passed as a list of length two with the first and second elements corresponding to the shape and scale parameters, which are each specified as vectors of length equal to the number of coefficients to be estimated or a single value if priors are the same for all parameters. If not specified, prior shape and scale parameters are set to 0.1. The spatial factor model fits $n \cdot \text{factors}$ independent spatial processes. The spatial decay ϕ and smoothness ν parameters for each latent factor are assumed to follow Uniform distributions. The hyperparameters of the Uniform are passed as a list with two elements, with both elements being vectors of length $n \cdot \text{factors}$ corresponding to the lower and upper support, respectively, or as a single value if the same value is assigned for all factors. The priors for the factor loadings matrix λ are fixed following the standard spatial factor model to ensure parameter identifiability (Christensen and Amemlya 2002). The upper triangular elements of the $N \times n \cdot \text{factors}$ matrix are fixed at 0 and the diagonal elements are fixed at 1. The lower triangular elements are assigned a standard normal prior (i.e., mean 0 and variance 1). $\sigma \cdot \text{sq} \cdot \psi$ is the random effect variance for any random effects, and is assumed to follow an inverse Gamma distribution. The hyperparameters of the inverse-Gamma distribution are passed as a list of length two with first and second elements corresponding to the shape and scale parameters, respectively, which are each specified as vectors of length equal to the number of random intercepts or of length one if priors are the same for all random effect variances.

tuning	a list with each tag corresponding to a parameter name. Valid tags are ϕ and ν . The value portion of each tag defines the initial variance of the adaptive sampler. We assume the initial variance of the adaptive sampler is the same for each species, although the adaptive sampler will adjust the tuning variances separately for each species. See Roberts and Rosenthal (2009) for details.
cov.model	a quoted keyword that specifies the covariance function used to model the spatial dependence structure among the observations. Supported covariance model key words are: "exponential", "matern", "spherical", and "gaussian".
NNGP	if TRUE, model is fit with an NNGP. If FALSE, a full Gaussian process is used. See Datta et al. (2016) and Finley et al. (2019) for more information. For spatial factor models, only NNGP = TRUE is currently supported.
n.neighbors	number of neighbors used in the NNGP. Only used if NNGP = TRUE. Datta et al. (2016) showed that 15 neighbors is usually sufficient, but that as few as 5 neighbors can be adequate for certain data sets, which can lead to even greater decreases in run time. We recommend starting with 15 neighbors (the default) and if additional gains in computation time are desired, subsequently compare the results with a smaller number of neighbors using WAIC or k-fold cross-validation.
search.type	a quoted keyword that specifies the type of nearest neighbor search algorithm. Supported method key words are: "cb" and "brute". The "cb" should generally be much faster. If locations do not have identical coordinate values on the axis used for the nearest neighbor ordering then "cb" and "brute" should produce identical neighbor sets. However, if there are identical coordinate values

	on the axis used for nearest neighbor ordering, then "cb" and "brute" might produce different, but equally valid, neighbor sets, e.g., if data are on a grid.
n.factors	the number of factors to use in the spatial factor model approach. Typically, the number of factors is set to be small (e.g., 4-5) relative to the total number of species in the community, which will lead to substantial decreases in computation time. However, the value can be anywhere between 1 and N (the number of species in the community).
n.batch	the number of MCMC batches in each chain to run for the Adaptive MCMC sampler. See Roberts and Rosenthal (2009) for details.
batch.length	the length of each MCMC batch to run for the Adaptive MCMC sampler. See Roberts and Rosenthal (2009) for details.
accept.rate	target acceptance rate for Adaptive MCMC. Default is 0.43. See Roberts and Rosenthal (2009) for details.
n.omp.threads	a positive integer indicating the number of threads to use for SMP parallel processing. The package must be compiled for OpenMP support. For most Intel-based machines, we recommend setting n.omp.threads up to the number of hyperthreaded cores. Note, n.omp.threads > 1 might not work on some systems.
verbose	if TRUE, messages about data preparation, model specification, and progress of the sampler are printed to the screen. Otherwise, no messages are printed.
n.report	the interval to report Metropolis sampler acceptance and MCMC progress. Note this is specified in terms of batches and not overall samples for spatial models.
n.burn	the number of samples out of the total n.samples to discard as burn-in for each chain. By default, the first 10% of samples is discarded.
n.thin	the thinning interval for collection of MCMC samples. The thinning occurs after the n.burn samples are discarded. Default value is set to 1.
n.chains	the number of chains to run in sequence.
k.fold	specifies the number of k folds for cross-validation. If not specified as an argument, then cross-validation is not performed and k.fold.threads and k.fold.seed are ignored. In k -fold cross-validation, the data specified in data is randomly partitioned into k equal sized subsamples. Of the k subsamples, $k - 1$ subsamples are used to fit the model and the remaining k samples are used for prediction. The cross-validation process is repeated k times (the folds). As a scoring rule, we use the model deviance as described in Hooten and Hobbs (2015). Cross-validation is performed after the full model is fit using all the data. Cross-validation results are reported in the k.fold.deviance object in the return list.
k.fold.threads	number of threads to use for cross-validation. If k.fold.threads > 1 parallel processing is accomplished using the foreach and doParallel packages. Ignored if k.fold is not specified.
k.fold.seed	seed used to split data set into k.fold parts for k-fold cross-validation. Ignored if k.fold is not specified.
...	currently no additional arguments

Value

An object of class sfJSDM that is a list comprised of:

<code>beta.comm.samples</code>	a coda object of posterior samples for the community level occurrence regression coefficients.
<code>tau.sq.beta.samples</code>	a coda object of posterior samples for the occurrence community variance parameters.
<code>beta.samples</code>	a coda object of posterior samples for the species level occurrence regression coefficients.
<code>theta.samples</code>	a coda object of posterior samples for the species level correlation parameters.
<code>lambda.samples</code>	a coda object of posterior samples for the latent spatial factor loadings.
<code>psi.samples</code>	a three-dimensional array of posterior samples for the latent occurrence probability values for each species.
<code>w.samples</code>	a three-dimensional array of posterior samples for the latent spatial random effects for each latent factor.
<code>sigma.sq.psi.samples</code>	a coda object of posterior samples for variances of random intercepts included in the occurrence portion of the model. Only included if random intercepts are specified in formula.
<code>beta.star.samples</code>	a coda object of posterior samples for the occurrence random effects. Only included if random intercepts are specified in formula.
<code>like.samples</code>	a three-dimensional array of posterior samples for the likelihood value associated with each site and species. Used for calculating WAIC.
<code>rhat</code>	a list of Gelman-Rubin diagnostic values for some of the model parameters.
<code>ESS</code>	a list of effective sample sizes for some of the model parameters.
<code>run.time</code>	MCMC sampler execution time reported using <code>proc.time()</code> .
<code>k.fold.deviance</code>	vector of scoring rules (deviance) from k-fold cross-validation. A separate value is reported for each species. Only included if <code>k.fold</code> is specified in function call.

The return object will include additional objects used for subsequent prediction and/or model fit evaluation. Note that detection probability estimated values are not included in the model object, but can be extracted using `fitted()`.

Note

Some of the underlying code used for generating random numbers from the Polya-Gamma distribution is taken from the **pgdraw** package written by Daniel F. Schmidt and Enes Makalic. Their code implements Algorithm 6 in PhD thesis of Jesse Bennett Windle (2013) <https://repositories.lib.utexas.edu/handle/2152/21842>.

sfMsPGOcc

Function for Fitting Spatial Factor Multi-Species Occupancy Models

Description

The function `sfMsPGOcc` fits multi-species spatial occupancy models with species correlations (i.e., a spatially-explicit joint species distribution model with imperfect detection). We use Polya-Gamma latent variables and a spatial factor modeling approach. Currently, models are implemented using a Nearest Neighbor Gaussian Process. Future development will allow for running the models using full Gaussian Processes.

Usage

```

sfMsPGOcc(occ.formula, det.formula, data, inits, priors, tuning,
cov.model = 'exponential', NNGP = TRUE,
n.neighbors = 15, search.type = 'cb', n.factors, n.batch,
batch.length, accept.rate = 0.43, n.omp.threads = 1,
verbose = TRUE, n.report = 100,
n.burn = round(.10 * n.batch * batch.length), n.thin = 1,
n.chains = 1, k.fold, k.fold.threads = 1, k.fold.seed, ...)

```

Arguments

<code>occ.formula</code>	a symbolic description of the model to be fit for the occurrence portion of the model using R's model syntax. Random intercepts are allowed using lme4 syntax (Bates et al. 2015). Only right-hand side of formula is specified. See example below.
<code>det.formula</code>	a symbolic description of the model to be fit for the detection portion of the model using R's model syntax. Only right-hand side of formula is specified. See example below. Random intercepts are allowed using lme4 syntax (Bates et al. 2015).
<code>data</code>	a list containing data necessary for model fitting. Valid tags are <code>y</code> , <code>occ.covs</code> , <code>det.covs</code> , <code>coords</code> . <code>y</code> is a three-dimensional array with first dimension equal to the number of species, second dimension equal to the number of sites, and third dimension equal to the maximum number of replicates at a given site. <code>occ.covs</code> is a matrix or data frame containing the variables used in the occurrence portion of the model, with J rows for each column (variable). <code>det.covs</code> is a list of variables included in the detection portion of the model. Each list element is a different detection covariate, which can be site-level or observational-level.

Site-level covariates are specified as a vector of length J while observation-level covariates are specified as a matrix or data frame with the number of rows equal to J and number of columns equal to the maximum number of replicates at a given site. `coords` is a $J \times 2$ matrix of the observation coordinates. Note that `spOccupancy` assumes coordinates are specified in a projected coordinate system.

<code>inits</code>	a list with each tag corresponding to a parameter name. Valid tags are <code>alpha.comm</code> , <code>beta.comm</code> , <code>beta</code> , <code>alpha</code> , <code>tau.sq.beta</code> , <code>tau.sq.alpha</code> , <code>sigma.sq.psi</code> , <code>sigma.sq.p</code> , <code>z</code> , <code>phi</code> , <code>lambda</code> , and <code>nu</code> . <code>nu</code> is only specified if <code>cov.model = "matern"</code> , and <code>sigma.sq.psi</code> and <code>sigma.sq.p</code> are only specified if random effects are included in <code>occ.formula</code> or <code>det.formula</code> , respectively. The value portion of each tag is the parameter's initial value. See <code>priors</code> description for definition of each parameter name. Additionally, the tag <code>fix</code> can be set to <code>TRUE</code> to fix the starting values across all chains. If <code>fix</code> is not specified (the default), starting values are varied randomly across chains.
<code>priors</code>	a list with each tag corresponding to a parameter name. Valid tags are <code>beta.comm.normal</code> , <code>alpha.comm.normal</code> , <code>tau.sq.beta.ig</code> , <code>tau.sq.alpha.ig</code> , <code>sigma.sq.psi</code> , <code>sigma.sq.p</code> , <code>phi.unif</code> , and <code>nu.unif</code> . Community-level occurrence (<code>beta.comm</code>) and detection (<code>alpha.comm</code>) regression coefficients are assumed to follow a normal distribution. The hyperparameters of the normal distribution are passed as a list of length two with the first and second elements corresponding to the mean and variance of the normal distribution, which are each specified as vectors of length equal to the number of coefficients to be estimated or of length one if priors are the same for all coefficients. If not specified, prior means are set to 0 and prior variances set to 2.73. Community-level variance parameters for occupancy (<code>tau.sq.beta</code>) and detection (<code>tau.sq.alpha</code>) are assumed to follow an inverse Gamma distribution. The hyperparameters of the inverse gamma distribution are passed as a list of length two with the first and second elements corresponding to the shape and scale parameters, which are each specified as vectors of length equal to the number of coefficients to be estimated or a single value if priors are the same for all parameters. If not specified, prior shape and scale parameters are set to 0.1. The spatial factor model fits <code>n.factors</code> independent spatial processes. The spatial decay <code>phi</code> and smoothness <code>nu</code> parameters for each latent factor are assumed to follow Uniform distributions. The hyperparameters of the Uniform are passed as a list with two elements, with both elements being vectors of length <code>n.factors</code> corresponding to the lower and upper support, respectively, or as a single value if the same value is assigned for all factors. The priors for the factor loadings matrix <code>lambda</code> are fixed following the standard spatial factor model to ensure parameter identifiability (Christensen and Amemlya 2002). The upper triangular elements of the $N \times n.factors$ matrix are fixed at 0 and the diagonal elements are fixed at 1. The lower triangular elements are assigned a standard normal prior (i.e., mean 0 and variance 1). <code>sigma.sq.psi</code> and <code>sigma.sq.p</code> are the random effect variances for any occurrence or detection random effects, respectively, and are assumed to follow an inverse Gamma distribution. The hyperparameters of the inverse-Gamma distribution are passed as a list of length two with first and second elements corresponding to the shape and scale parameters, respectively, which are each specified as vectors of length equal to the number of random intercepts or of length one if priors are the same

	for all random effect variances.
tuning	a list with each tag corresponding to a parameter name. Valid tags are phi and nu. The value portion of each tag defines the initial variance of the adaptive sampler. We assume the initial variance of the adaptive sampler is the same for each species, although the adaptive sampler will adjust the tuning variances separately for each species. See Roberts and Rosenthal (2009) for details.
cov.model	a quoted keyword that specifies the covariance function used to model the spatial dependence structure among the observations. Supported covariance model key words are: "exponential", "matern", "spherical", and "gaussian".
NNGP	if TRUE, model is fit with an NNGP. If FALSE, a full Gaussian process is used. See Datta et al. (2016) and Finley et al. (2019) for more information. For spatial factor models, only NNGP = TRUE is currently supported.
n.neighbors	number of neighbors used in the NNGP. Only used if NNGP = TRUE. Datta et al. (2016) showed that 15 neighbors is usually sufficient, but that as few as 5 neighbors can be adequate for certain data sets, which can lead to even greater decreases in run time. We recommend starting with 15 neighbors (the default) and if additional gains in computation time are desired, subsequently compare the results with a smaller number of neighbors using WAIC or k-fold cross-validation.
search.type	a quoted keyword that specifies the type of nearest neighbor search algorithm. Supported method key words are: "cb" and "brute". The "cb" should generally be much faster. If locations do not have identical coordinate values on the axis used for the nearest neighbor ordering then "cb" and "brute" should produce identical neighbor sets. However, if there are identical coordinate values on the axis used for nearest neighbor ordering, then "cb" and "brute" might produce different, but equally valid, neighbor sets, e.g., if data are on a grid.
n.factors	the number of factors to use in the spatial factor model approach. Typically, the number of factors is set to be small (e.g., 4-5) relative to the total number of species in the community, which will lead to substantial decreases in computation time. However, the value can be anywhere between 1 and N (the number of species in the community).
n.batch	the number of MCMC batches in each chain to run for the Adaptive MCMC sampler. See Roberts and Rosenthal (2009) for details.
batch.length	the length of each MCMC batch to run for the Adaptive MCMC sampler. See Roberts and Rosenthal (2009) for details.
accept.rate	target acceptance rate for Adaptive MCMC. Default is 0.43. See Roberts and Rosenthal (2009) for details.
n.omp.threads	a positive integer indicating the number of threads to use for SMP parallel processing. The package must be compiled for OpenMP support. For most Intel-based machines, we recommend setting n.omp.threads up to the number of hyperthreaded cores. Note, n.omp.threads > 1 might not work on some systems.
verbose	if TRUE, messages about data preparation, model specification, and progress of the sampler are printed to the screen. Otherwise, no messages are printed.
n.report	the interval to report Metropolis sampler acceptance and MCMC progress. Note this is specified in terms of batches and not overall samples for spatial models.

n.burn	the number of samples out of the total n.samples to discard as burn-in for each chain. By default, the first 10% of samples is discarded.
n.thin	the thinning interval for collection of MCMC samples. The thinning occurs after the n.burn samples are discarded. Default value is set to 1.
n.chains	the number of chains to run in sequence.
k.fold	specifies the number of k folds for cross-validation. If not specified as an argument, then cross-validation is not performed and k.fold.threads and k.fold.seed are ignored. In k -fold cross-validation, the data specified in data is randomly partitioned into k equal sized subsamples. Of the k subsamples, $k - 1$ subsamples are used to fit the model and the remaining k samples are used for prediction. The cross-validation process is repeated k times (the folds). As a scoring rule, we use the model deviance as described in Hooten and Hobbs (2015). Cross-validation is performed after the full model is fit using all the data. Cross-validation results are reported in the k.fold.deviance object in the return list.
k.fold.threads	number of threads to use for cross-validation. If k.fold.threads > 1 parallel processing is accomplished using the foreach and doParallel packages. Ignored if k.fold is not specified.
k.fold.seed	seed used to split data set into k.fold parts for k-fold cross-validation. Ignored if k.fold is not specified.
...	currently no additional arguments

Value

An object of class sfMsPGOcc that is a list comprised of:

beta.comm.samples	a coda object of posterior samples for the community level occurrence regression coefficients.
alpha.comm.samples	a coda object of posterior samples for the community level detection regression coefficients.
tau.sq.beta.samples	a coda object of posterior samples for the occurrence community variance parameters.
tau.sq.alpha.samples	a coda object of posterior samples for the detection community variance parameters.
beta.samples	a coda object of posterior samples for the species level occurrence regression coefficients.
alpha.samples	a coda object of posterior samples for the species level detection regression coefficients.
theta.samples	a coda object of posterior samples for the species level correlation parameters.
lambda.samples	a coda object of posterior samples for the latent spatial factor loadings.
z.samples	a three-dimensional array of posterior samples for the latent occurrence values for each species.

<code>psi.samples</code>	a three-dimensional array of posterior samples for the latent occupancy probability values for each species.
<code>w.samples</code>	a three-dimensional array of posterior samples for the latent spatial random effects for each latent factor.
<code>sigma.sq.psi.samples</code>	a coda object of posterior samples for variances of random intercepts included in the occurrence portion of the model. Only included if random intercepts are specified in <code>occ.formula</code> .
<code>sigma.sq.p.samples</code>	a coda object of posterior samples for variances of random intercepts included in the detection portion of the model. Only included if random intercepts are specified in <code>det.formula</code> .
<code>beta.star.samples</code>	a coda object of posterior samples for the occurrence random effects. Only included if random intercepts are specified in <code>occ.formula</code> .
<code>alpha.star.samples</code>	a coda object of posterior samples for the detection random effects. Only included if random intercepts are specified in <code>det.formula</code> .
<code>like.samples</code>	a three-dimensional array of posterior samples for the likelihood value associated with each site and species. Used for calculating WAIC.
<code>rhat</code>	a list of Gelman-Rubin diagnostic values for some of the model parameters.
<code>ESS</code>	a list of effective sample sizes for some of the model parameters.
<code>run.time</code>	MCMC sampler execution time reported using <code>proc.time()</code> .
<code>k.fold.deviance</code>	vector of scoring rules (deviance) from k-fold cross-validation. A separate value is reported for each species. Only included if <code>k.fold</code> is specified in function call.

The return object will include additional objects used for subsequent prediction and/or model fit evaluation. Note that detection probability estimated values are not included in the model object, but can be extracted using `fitted()`.

Note

Some of the underlying code used for generating random numbers from the Polya-Gamma distribution is taken from the **pgdraw** package written by Daniel F. Schmidt and Enes Makalic. Their code implements Algorithm 6 in PhD thesis of Jesse Bennett Windle (2013) <https://repositories.lib.utexas.edu/handle/2152/21842>.

simIntOcc	<i>Simulate Single-Species Detection-Nondetection Data from Multiple Data Sources</i>
-----------	---

Description

The function `simIntOcc` simulates single-species detection-nondetection data from multiple data sources for simulation studies, power assessments, or function testing of integrated occupancy models. Data can optionally be simulated with a spatial Gaussian Process on the occurrence process.

Usage

```

simIntOcc(n.data, J.x, J.y, J.obs, n.rep, beta, alpha,
  sp = FALSE, cov.model, sigma.sq, phi, nu, ...)

```

Arguments

n.data	an integer indicating the number of detection-nondetection data sources to simulate.
J.x	a single numeric value indicating the number of sites across the region of interest along the horizontal axis. Total number of sites across the simulated region of interest is $J.x \times J.y$.
J.y	a single numeric value indicating the number of sites across the region of interest along the vertical axis. Total number of sites across the simulated region of interest is $J.x \times J.y$.
J.obs	a numeric vector of length n.data containing the number of sites to simulate each data source at. Data sources can be obtained at completely different sites, the same sites, or anywhere inbetween. Maximum number of sites a given data source is available at is equal to $J = J.x \times J.y$.
n.rep	a list of length n.data. Each element is a numeric vector with length corresponding to the number of sites that given data source is observed at (in J.obs). Each vector indicates the number of repeat visits at each of the sites for a given data source.
beta	a numeric vector containing the intercept and regression coefficient parameters for the occurrence portion of the single-species occupancy model.
alpha	a list of length n.data. Each element is a numeric vector containing the intercept and regression coefficient parameters for the detection portion of the single-species occupancy model for each data source.
sp	a logical value indicating whether to simulate a spatially-explicit occupancy model with a Gaussian process. By default set to FALSE.
cov.model	a quoted keyword that specifies the covariance function used to model the spatial dependence structure among the latent occurrence values. Supported covariance model key words are: "exponential", "matern", "spherical", and "gaussian".
sigma.sq	a numeric value indicating the spatial variance parameter. Ignored when sp = FALSE.
phi	a numeric value indicating the spatial range parameter. Ignored when sp = FALSE.
nu	a numeric value indicating the spatial smoothness parameter. Only used when sp = TRUE and cov.model = "matern".
...	currently no additional arguments

Value

A list comprised of:

X.obs	a numeric design matrix for the occurrence portion of the model. This matrix contains the intercept and regression coefficients for only the observed sites.
X.pred	a numeric design matrix for the occurrence portion of the model at sites where there are no observed data sources.

X.p	a list of design matrices for the detection portions of the integrated occupancy model. Each element in the list is a design matrix of detection covariates for each data source.
coords.obs	a numeric matrix of coordinates of each observed site. Required for spatial models.
coords.pred	a numeric matrix of coordinates of each site in the study region without any data sources. Only used for spatial models.
D.obs	a distance matrix of observed sites. Only used for spatial models.
D.pred	a distance matrix of sites in the study region without any observed data. Only used for spatial models.
w.obs	a matrix of the spatial random effects at observed locations. Only used to simulate data when <code>sp = TRUE</code>
.	.
w.pred	a matrix of the spatial random random effects at locations without any observation.
psi.obs	a matrix of the occurrence probabilities for each observed site.
psi.pred	a matrix of the occurrence probabilities for sites without any observations.
z.obs	a vector of the latent occurrence states at each observed site.
z.pred	a vector of the latent occurrence states at each site without any observations.
p	a list of detection probability matrices for each of the <code>n.data</code> data sources.
y	a list of matrices of the raw detection-nondetection data for each site and replicate combination.

  n.rep = n.rep, beta = beta, alpha = alpha, sp = TRUE,
  cov.model = 'gaussian', sigma.sq = sigma.sq, phi = phi)

```

simMsOcc

Simulate Multi-Species Detection-Nondetection Data

Description

The function `simMsOcc` simulates multi-species detection-nondetection data for simulation studies, power assessments, or function testing. Data can be optionally simulated with a spatial Gaussian Process in the occurrence portion of the model, as well as an option to allow for species correlations using a factor modeling approach. Non-spatial random intercepts can also be included in the detection or occurrence portions of the occupancy model.

Usage

```

simMsOcc(J.x, J.y, n.rep, N, beta, alpha, psi.RE = list(),
  p.RE = list(), sp = FALSE, cov.model, sigma.sq, phi, nu,
  factor.model = FALSE, n.factors, ...)

```

Arguments

<code>J.x</code>	a single numeric value indicating the number of sites to simulate detection-nondetection data along the horizontal axis. Total number of sites with simulated data is $J.x \times J.y$.
<code>J.y</code>	a single numeric value indicating the number of sites to simulate detection-nondetection data along the vertical axis. Total number of sites with simulated data is $J.x \times J.y$.
<code>n.rep</code>	a numeric vector of length $J = J.x \times J.y$ indicating the number of repeat visits at each of the J sites.
<code>N</code>	a single numeric value indicating the number of species to simulate detection-nondetection data.

beta	a numeric matrix with N rows containing the intercept and regression coefficient parameters for the occurrence portion of the multi-species occupancy model. Each row corresponds to the regression coefficients for a given species.
alpha	a numeric matrix with N rows containing the intercept and regression coefficient parameters for the detection portion of the multi-species occupancy model. Each row corresponds to the regression coefficients for a given species.
psi.RE	a list used to specify the non-spatial random intercepts included in the occurrence portion of the model. The list must have two tags: <code>levels</code> and <code>sigma.sq.psi</code> . <code>levels</code> is a vector of length equal to the number of distinct random intercepts to include in the model and contains the number of levels there are in each intercept. <code>sigma.sq.psi</code> is a vector of length equal to the number of distinct random intercepts to include in the model and contains the variances for each random effect. If not specified, no random effects are included in the occurrence portion of the model.
p.RE	a list used to specify the non-spatial random intercepts included in the detection portion of the model. The list must have two tags: <code>levels</code> and <code>sigma.sq.p</code> . <code>levels</code> is a vector of length equal to the number of distinct random intercepts to include in the model and contains the number of levels there are in each intercept. <code>sigma.sq.p</code> is a vector of length equal to the number of distinct random intercepts to include in the model and contains the variances for each random effect. If not specified, no random effects are included in the detection portion of the model.
sp	a logical value indicating whether to simulate a spatially-explicit occupancy model with a Gaussian process. By default set to FALSE.
cov.model	a quoted keyword that specifies the covariance function used to model the spatial dependence structure among the latent occurrence values. Supported covariance model key words are: "exponential", "matern", "spherical", and "gaussian".
sigma.sq	a numeric vector of length N containing the spatial variance parameter for each species. Ignored when <code>sp = FALSE</code> or when <code>factor.model = TRUE</code> .
phi	a numeric vector of length N containing the spatial range parameter for each species. Ignored when <code>sp = FALSE</code> . If <code>factor.model = TRUE</code> , this should be of length <code>n.factors</code> .
nu	a numeric vector of length N containing the spatial smoothness parameter for each species. Only used when <code>sp = TRUE</code> and <code>cov.model = 'matern'</code> . If <code>factor.model = TRUE</code> , this should be of length <code>n.factors</code> .
factor.model	a logical value indicating whether to simulate data following a factor modeling approach that explicitly incorporates species correlations. If <code>sp = TRUE</code> , the latent factors are simulated from independent spatial processes. If <code>sp = FALSE</code> , the latent factors are simulated from standard normal distributions.
n.factors	a single numeric value specifying the number of latent factors to use to simulate the data if <code>factor.model = TRUE</code> .
...	currently no additional arguments

Value

A list comprised of:

<code>X</code>	a $J \times p.occ$ numeric design matrix for the occurrence portion of the model.
<code>X.p</code>	a three-dimensional numeric array with dimensions corresponding to sites, repeat visits, and number of detection regression coefficients. This is the design matrix used for the detection portion of the occupancy model.
<code>coords</code>	a $J \times J$ numeric matrix of coordinates of each occupancy site. Required for spatial models.
<code>w</code>	a $N \times J$ matrix of the spatial random effects for each species. Only used to simulate data when <code>sp = TRUE</code> . If <code>factor.model = TRUE</code> , the first dimension is <code>n.factors</code> .
<code>psi</code>	a $N \times J$ matrix of the occurrence probabilities for each species at each site.
<code>z</code>	a $N \times J$ matrix of the latent occurrence states for each species at each site.
<code>p</code>	a $N \times J \times \max(n.rep)$ array of the detection probabilities for each species at each site and replicate combination. Sites with fewer than <code>max(n.rep)</code> replicates will contain NA values.
<code>y</code>	a $N \times J \times \max(n.rep)$ array of the raw detection-nondetection data for each species at each site and replicate combination. Sites with fewer than <code>max(n.rep)</code> replicates will contain NA values.
<code>X.p.re</code>	a three-dimensional numeric array containing the levels of any detection random effect included in the model. Only relevant when detection random effects are specified in <code>p.RE</code> .
<code>X.lambda.re</code>	a numeric matrix containing the levels of any occurrence random effect included in the model. Only relevant when occurrence random effects are specified in <code>psi.RE</code> .
<code>alpha.star</code>	a numeric matrix where each row contains the simulated detection random effects for each given level of the random effects included in the detection model. Only relevant when detection random effects are included in the model.
<code>beta.star</code>	a numeric matrix where each row contains the simulated occurrence random effects for each given level of the random effects included in the occurrence model. Only relevant when occurrence random effects are included in the model.

simOcc

Simulate Single-Species Detection-Nondetection Data

Description

The function `simOcc` simulates single-species occurrence data for simulation studies, power assessments, or function testing. Data can be optionally simulated with a spatial Gaussian Process in the occurrence portion of the model. Non-spatial random intercepts can also be included in the detection or occurrence portions of the occupancy model.

Usage

```

simOcc(J.x, J.y, n.rep, beta, alpha, psi.RE = list(),
       p.RE = list(), sp = FALSE, cov.model, sigma.sq, phi, nu, ...)

```

Arguments

`J.x` a single numeric value indicating the number of sites to simulate detection-nondetection data along the horizontal axis. Total number of sites with simulated data is $J.x \times J.y$.

<code>J.y</code>	a single numeric value indicating the number of sites to simulate detection-nondetection data along the vertical axis. Total number of sites with simulated data is $J.x \times J.y$.
<code>n.rep</code>	a numeric vector of length $J = J.x \times J.y$ indicating the number of repeat visits at each of the J sites.
<code>beta</code>	a numeric vector containing the intercept and regression coefficient parameters for the occupancy portion of the single-species occupancy model.
<code>alpha</code>	a numeric vector containing the intercept and regression coefficient parameters for the detection portion of the single-species occupancy model.
<code>psi.RE</code>	a list used to specify the non-spatial random intercepts included in the occupancy portion of the model. The list must have two tags: <code>levels</code> and <code>sigma.sq.psi</code> . <code>levels</code> is a vector of length equal to the number of distinct random intercepts to include in the model and contains the number of levels there are in each intercept. <code>sigma.sq.psi</code> is a vector of length equal to the number of distinct random intercepts to include in the model and contains the variances for each random effect. If not specified, no random effects are included in the occupancy portion of the model.
<code>p.RE</code>	a list used to specify the non-spatial random intercepts included in the detection portion of the model. The list must have two tags: <code>levels</code> and <code>sigma.sq.p</code> . <code>levels</code> is a vector of length equal to the number of distinct random intercepts to include in the model and contains the number of levels there are in each intercept. <code>sigma.sq.p</code> is a vector of length equal to the number of distinct random intercepts to include in the model and contains the variances for each random effect. If not specified, no random effects are included in the detection portion of the model.
<code>sp</code>	a logical value indicating whether to simulate a spatially-explicit occupancy model with a Gaussian process. By default set to FALSE.
<code>cov.model</code>	a quoted keyword that specifies the covariance function used to model the spatial dependence structure among the latent occurrence values. Supported covariance model key words are: "exponential", "matern", "spherical", and "gaussian".
<code>sigma.sq</code>	a numeric value indicating the spatial variance parameter. Ignored when <code>sp = FALSE</code> .
<code>phi</code>	a numeric value indicating the spatial range parameter. Ignored when <code>sp = FALSE</code> .
<code>nu</code>	a numeric value indicating the spatial smoothness parameter. Only used when <code>sp = TRUE</code> and <code>cov.model = "matern"</code> .
<code>...</code>	currently no additional arguments

Value

A list comprised of:

<code>X</code>	a $J \times p.occ$ numeric design matrix for the occupancy portion of the model.
----------------	--

X.p	a three-dimensional numeric array with dimensions corresponding to sites, repeat visits, and number of detection regression coefficients. This is the design matrix used for the detection portion of the occupancy model.
coords	a $J \times J$ numeric matrix of coordinates of each occupancy site. Required for spatial models.
w	a $J \times 1$ matrix of the spatial random effects. Only used to simulate data when <code>sp = TRUE</code> .
psi	a $J \times 1$ matrix of the occupancy probabilities for each site.
z	a length J vector of the latent occupancy states at each site.
p	a $J \times \max(\text{n.rep})$ matrix of the detection probabilities for each site and replicate combination. Sites with fewer than $\max(\text{n.rep})$ replicates will contain NA values.
y	a $J \times \max(\text{n.rep})$ matrix of the raw detection-nondetection data for each site and replicate combination.
X.p.re	a three-dimensional numeric array containing the levels of any detection random effect included in the model. Only relevant when detection random effects are specified in <code>p.RE</code> .
X.lambda.re	a numeric matrix containing the levels of any occurrence random effect included in the model. Only relevant when occurrence random effects are specified in <code>psi.RE</code> .
alpha.star	a numeric vector that contains the simulated detection random effects for each given level of the random effects included in the detection model. Only relevant when detection random effects are included in the model.
beta.star	a numeric vector that contains the simulated occurrence random effects for each given level of the random effects included in the occurrence model. Only relevant when occurrence random effects are included in the model.

spIntPGOcc	<i>Function for Fitting Single-Species Integrated Spatial Occupancy Models Using Polya-Gamma Latent Variables</i>
------------	---

Description

The function `spIntPGOcc` fits single-species integrated spatial occupancy models using Polya-Gamma latent variables. Models can be fit using either a full Gaussian process or a Nearest Neighbor Gaussian Process for large data sets. Data integration is done using a joint likelihood framework, assuming distinct detection models for each data source that are each conditional on a single latent occupancy process.

Usage

```
spIntPGOcc(occ.formula, det.formula, data, inits, priors,
  tuning, cov.model = "exponential", NNGP = TRUE,
  n.neighbors = 15, search.type = 'cb', n.batch,
  batch.length, accept.rate = 0.43, n.omp.threads = 1,
  verbose = TRUE, n.report = 100,
  n.burn = round(.10 * n.batch * batch.length),
  n.thin = 1, n.chains = 1, k.fold, k.fold.threads = 1,
  k.fold.seed, k.fold.data, ...)
```

Arguments

<code>occ.formula</code>	a symbolic description of the model to be fit for the occurrence portion of the model using R's model syntax. Only right-hand side of formula is specified. See example below.
<code>det.formula</code>	a list of symbolic descriptions of the models to be fit for the detection portion of the model using R's model syntax for each data set. Each element in the list is a formula for the detection model of a given data set. Only right-hand side of formula is specified. See example below.
<code>data</code>	a list containing data necessary for model fitting. Valid tags are <code>y</code> , <code>occ.covs</code> , <code>det.covs</code> , <code>sites</code> and <code>coords</code> . <code>y</code> is a list of matrices or data frames for each data set used in the integrated model. Each element of the list has first dimension equal to the number of sites with that data source and second dimension equal to the maximum number of replicates at a given site. <code>occ.covs</code> is a matrix or data frame containing the variables used in the occurrence portion of the model, with the number of rows being the number of sites with at least one data source for each column (variable). <code>det.covs</code> is a list of variables included in the detection portion of the model for each data source. <code>det.covs</code> should have the same number of elements as <code>y</code> , where each element is itself a list. Each element of the list for a given data source is a different detection covariate, which can be site-level or observational-level. Site-level covariates are specified as a

vector with length equal to the number of observed sites of that data source, while observation-level covariates are specified as a matrix or data frame with the number of rows equal to the number of observed sites of that data source and number of columns equal to the maximum number of replicates at a given site. `coords` is a matrix of the observation site coordinates. Note that `spOccupancy` assumes coordinates are specified in a projected coordinate system.

<code>inits</code>	a list with each tag corresponding to a parameter name. Valid tags are <code>z</code> , <code>beta</code> , <code>alpha</code> , <code>sigma.sq</code> , <code>phi</code> , <code>w</code> , and <code>nu</code> . The value portion of all tags except <code>alpha</code> is the parameter's initial value. The tag <code>alpha</code> is a list comprised of the initial values for the detection parameters for each data source. Each element of the list should be a vector of initial values for all detection parameters in the given data source or a single value for each data source to assign all parameters for a given data source the same initial value. See <code>priors</code> description for definition of each parameter name. Additionally, the tag <code>fix</code> can be set to <code>TRUE</code> to fix the starting values across all chains. If <code>fix</code> is not specified (the default), starting values are varied randomly across chains.
<code>priors</code>	a list with each tag corresponding to a parameter name. Valid tags are <code>beta.normal</code> , <code>alpha.normal</code> , <code>phi.unif</code> , <code>sigma.sq.ig</code> , and <code>nu.unif</code> . Occurrence (<code>beta</code>) and detection (<code>alpha</code>) regression coefficients are assumed to follow a normal distribution. For <code>beta</code> hyperparameters of the normal distribution are passed as a list of length two with the first and second elements corresponding to the mean and variance of the normal distribution, which are each specified as vectors of length equal to the number of coefficients to be estimated or of length one if <code>priors</code> are the same for all coefficients. For the detection coefficients <code>alpha</code> , the mean and variance hyperparameters are themselves passed in as lists, with each element of the list corresponding to the specific hyperparameters for the detection parameters in a given data source. If not specified, prior means are set to 0 and prior variances set to 2.73 for normal priors. The spatial variance parameter, <code>sigma.sq</code> , is assumed to follow an inverse-Gamma distribution, whereas the spatial decay <code>phi</code> and smoothness <code>nu</code> parameters are assumed to follow Uniform distributions. The hyperparameters of the inverse-Gamma are passed as a vector of length two, with the first and second elements corresponding to the <i>shape</i> and <i>scale</i> , respectively. The hyperparameters of the Uniform are also passed as a vector of length two with the first and second elements corresponding to the lower and upper support, respectively.
<code>tuning</code>	a list with each tag corresponding to a parameter name. Valid tags are <code>phi</code> and <code>nu</code> . The value portion of each tag defines the initial variance of the Adaptive sampler. See Roberts and Rosenthal (2009) for details.
<code>cov.model</code>	a quoted keyword that specifies the covariance function used to model the spatial dependence structure among the observations. Supported covariance model keywords are: "exponential", "matern", "spherical", and "gaussian".
<code>NNGP</code>	if <code>TRUE</code> , model is fit with an NNGP. If <code>FALSE</code> , a full Gaussian process is used. See Datta et al. (2016) and Finley et al. (2019) for more information.
<code>n.neighbors</code>	number of neighbors used in the NNGP. Only used if <code>NNGP = TRUE</code> . Datta et al. (2016) showed that 15 neighbors is usually sufficient, but that as few as 5 neighbors can be adequate for certain data sets, which can lead to even greater decreases in run time. We recommend starting with 15 neighbors (the default)

and if additional gains in computation time are desired, subsequently compare the results with a smaller number of neighbors using WAIC or k-fold cross-validation.

search.type	a quoted keyword that specifies the type of nearest neighbor search algorithm. Supported method key words are: "cb" and "brute". The "cb" should generally be much faster. If locations do not have identical coordinate values on the axis used for the nearest neighbor ordering then "cb" and "brute" should produce identical neighbor sets. However, if there are identical coordinate values on the axis used for nearest neighbor ordering, then "cb" and "brute" might produce different, but equally valid, neighbor sets, e.g., if data are on a grid.
n.batch	the number of MCMC batches to run for each chain for the Adaptive MCMC sampler. See Roberts and Rosenthal (2009) for details.
batch.length	the length of each MCMC batch to run for the Adaptive MCMC sampler. See Roberts and Rosenthal (2009) for details.
accept.rate	target acceptance rate for Adaptive MCMC. Default is 0.43. See Roberts and Rosenthal (2009) for details.
n.omp.threads	a positive integer indicating the number of threads to use for SMP parallel processing. The package must be compiled for OpenMP support. For most Intel-based machines, we recommend setting n.omp.threads up to the number of hyperthreaded cores. Note, n.omp.threads > 1 might not work on some systems.
verbose	if TRUE, messages about data preparation, model specification, and progress of the sampler are printed to the screen. Otherwise, no messages are printed.
n.report	the interval to report Metropolis sampler acceptance and MCMC progress. Note this is specified in terms of batches and not overall samples for spatial models.
n.burn	the number of samples out of the total n.batch * batch.length samples to discard as burn-in. By default, the first 10% of samples is discarded.
n.thin	the thinning interval for collection of MCMC samples. The thinning occurs after the n.burn samples are discarded. Default value is set to 1.
n.chains	the number of chains to run in sequence.
k.fold	specifies the number of k folds for cross-validation. If not specified as an argument, then cross-validation is not performed and k.fold.threads and k.fold.seed are ignored. In k -fold cross-validation, the data specified in data is randomly partitioned into k equal sized subsamples. Of the k subsamples, $k - 1$ subsamples are used to fit the model and the remaining k samples are used for prediction. The cross-validation process is repeated k times (the folds). As a scoring rule, we use the model deviance as described in Hooten and Hobbs (2015). Cross-validation is performed after the full model is fit using all the data. Cross-validation results are reported in the k.fold.deviance object in the return list.
k.fold.threads	number of threads to use for cross-validation. If k.fold.threads > 1 parallel processing is accomplished using the foreach and doParallel packages. Ignored if k.fold is not specified.
k.fold.seed	seed used to split data set into k.fold parts for k-fold cross-validation. Ignored if k.fold is not specified.

k.fold.data	an integer specifying the specific data set to hold out values from. If not specified, data from all data set locations will be incorporated into the k-fold cross-validation.
...	currently no additional arguments

Value

An object of class spIntPGOcc that is a list comprised of:

beta.samples	a coda object of posterior samples for the occurrence regression coefficients.
alpha.samples	a coda object of posterior samples for the detection regression coefficients for all data sources.
z.samples	a coda object of posterior samples for the latent occurrence values
psi.samples	a coda object of posterior samples for the latent occurrence probability values
theta.samples	a coda object of posterior samples for covariance parameters.
w.samples	a coda object of posterior samples for latent spatial random effects.
rhat	a list of Gelman-Rubin diagnostic values for some of the model parameters.
ESS	a list of effective sample sizes for some of the model parameters.
run.time	execution time reported using <code>proc.time()</code> .
k.fold.deviance	scoring rule (deviance) from k-fold cross-validation. A separate deviance value is returned for each data source. Only included if <code>k.fold</code> is specified in function call. Only a single value is returned if <code>k.fold.data</code> is specified.

The return object will include additional objects used for subsequent prediction and/or model fit evaluation. Note that detection probability estimated values are not included in the model object, but can be extracted using `fitted()`.

Note

Some of the underlying code used for generating random numbers from the Polya-Gamma distribution is taken from the **pgdraw** package written by Daniel F. Schmidt and Enes Makalic. Their code implements Algorithm 6 in PhD thesis of Jesse Bennett Windle (2013) <https://repositories.lib.utexas.edu/handle/2152/21842>.

*Function for Fitting Multi-Species Spatial Occupancy Models Using
Polya-Gamma Latent Variables*

Description

The function `spMsPGOcc` fits multi-species spatial occupancy models using Polya-Gamma latent variables. Models can be fit using either a full Gaussian process or a Nearest Neighbor Gaussian Process for large data sets.

Usage

```

spMsPGOcc(occ.formula, det.formula, data, inits, priors, tuning,
          cov.model = 'exponential', NNGP = TRUE,
          n.neighbors = 15, search.type = 'cb', n.batch,
          batch.length, accept.rate = 0.43, n.omp.threads = 1,
          verbose = TRUE, n.report = 100,
          n.burn = round(.10 * n.batch * batch.length), n.thin = 1,
          n.chains = 1, k.fold, k.fold.threads = 1, k.fold.seed, ...)

```

Arguments

`occ.formula` a symbolic description of the model to be fit for the occurrence portion of the model using R's model syntax. Only right-hand side of formula is specified. See example below. Random intercepts are allowed using lme4 syntax (Bates et al. 2015).

det.formula	a symbolic description of the model to be fit for the detection portion of the model using R's model syntax. Only right-hand side of formula is specified. See example below. Random intercepts are allowed using lme4 syntax (Bates et al. 2015).
data	a list containing data necessary for model fitting. Valid tags are <code>y</code> , <code>occ.covs</code> , <code>det.covs</code> , <code>coords</code> . <code>y</code> is a three-dimensional array with first dimension equal to the number of species, second dimension equal to the number of sites, and third dimension equal to the maximum number of replicates at a given site. <code>occ.covs</code> is a matrix or data frame containing the variables used in the occurrence portion of the model, with J rows for each column (variable). <code>det.covs</code> is a list of variables included in the detection portion of the model. Each list element is a different detection covariate, which can be site-level or observational-level. Site-level covariates are specified as a vector of length J while observational-level covariates are specified as a matrix or data frame with the number of rows equal to J and number of columns equal to the maximum number of replicates at a given site. <code>coords</code> is a $J \times 2$ matrix of the observation coordinates. Note that spOccupancy assumes coordinates are specified in a projected coordinate system.
inits	a list with each tag corresponding to a parameter name. Valid tags are <code>alpha.comm</code> , <code>beta.comm</code> , <code>beta</code> , <code>alpha</code> , <code>tau.sq.beta</code> , <code>tau.sq.alpha</code> , <code>sigma.sq.psi</code> , <code>sigma.sq.p</code> , <code>z</code> , <code>sigma.sq</code> , <code>phi</code> , <code>w</code> , and <code>nu</code> . <code>nu</code> is only specified if <code>cov.model = "matern"</code> , <code>sigma.sq.psi</code> is only specified if there are random intercepts in <code>occ.formula</code> , and <code>sigma.sq.p</code> is only specified if there are random intercepts in <code>det.formula</code> . The value portion of each tag is the parameter's initial value. See <code>priors</code> description for definition of each parameter name. Additionally, the tag <code>fix</code> can be set to TRUE to fix the starting values across all chains. If <code>fix</code> is not specified (the default), starting values are varied randomly across chains.
priors	a list with each tag corresponding to a parameter name. Valid tags are <code>beta.comm.normal</code> , <code>alpha.comm.normal</code> , <code>tau.sq.beta.ig</code> , <code>tau.sq.alpha.ig</code> , <code>phi.unif</code> , <code>sigma.sq.ig</code> , <code>nu.unif</code> , <code>sigma.sq.psi</code> , <code>sigma.sq.p</code> . Community-level occurrence (<code>beta.comm</code>) and detection (<code>alpha.comm</code>) regression coefficients are assumed to follow a normal distribution. The hyperparameters of the normal distribution are passed as a list of length two with the first and second elements corresponding to the mean and variance of the normal distribution, which are each specified as vectors of length equal to the number of coefficients to be estimated or of length one if priors are the same for all coefficients. If not specified, prior means are set to 0 and prior variances set to 2.73. Community-level variance parameters for occupancy (<code>tau.sq.beta</code>) and detection (<code>tau.sq.alpha</code>) are assumed to follow an inverse Gamma distribution. The hyperparameters of the inverse gamma distribution are passed as a list of length two with the first and second elements corresponding to the shape and scale parameters, which are each specified as vectors of length equal to the number of coefficients to be estimated or a single value if priors are the same for all parameters. If not specified, prior shape and scale parameters are set to 0.1. The species-specific spatial variance parameter, <code>sigma.sq</code> , is assumed to follow an inverse-Gamma distribution, whereas the spatial decay <code>phi</code> and smoothness <code>nu</code> parameters are assumed to follow Uniform distributions. The hyperparameters of the inverse-Gamma are passed as a list of length two, with the list elements being vectors of length N correspond-

	<p>ing to the species-specific shape and scale parameters, respectively, or a single value if the same value is assigned for all species. The hyperparameters of the Uniform are also passed as a list with two elements, with both elements being vectors of length N corresponding to the lower and upper support, respectively, or as a single value if the same value is assigned for all species. <code>sigma.sq.psi</code> and <code>sigma.sq.p</code> are the random effect variances for any occurrence or detection random effects, respectively, and are assumed to follow an inverse Gamma distribution. The hyperparameters of the inverse-Gamma distribution are passed as a list of length two with first and second elements corresponding to the shape and scale parameters, respectively, which are each specified as vectors of length equal to the number of random intercepts or of length one if priors are the same for all random effect variances.</p>
<code>tuning</code>	<p>a list with each tag corresponding to a parameter name. Valid tags are <code>phi</code> and <code>nu</code>. The value portion of each tag defines the initial variance of the adaptive sampler. We assume the initial variance of the adaptive sampler is the same for each species, although the adaptive sampler will adjust the tuning variances separately for each species. See Roberts and Rosenthal (2009) for details.</p>
<code>cov.model</code>	<p>a quoted keyword that specifies the covariance function used to model the spatial dependence structure among the observations. Supported covariance model keywords are: "exponential", "matern", "spherical", and "gaussian".</p>
<code>NNGP</code>	<p>if TRUE, model is fit with an NNGP. If FALSE, a full Gaussian process is used. See Datta et al. (2016) and Finley et al. (2019) for more information.</p>
<code>n.neighbors</code>	<p>number of neighbors used in the NNGP. Only used if <code>NNGP = TRUE</code>. Datta et al. (2016) showed that 15 neighbors is usually sufficient, but that as few as 5 neighbors can be adequate for certain data sets, which can lead to even greater decreases in run time. We recommend starting with 15 neighbors (the default) and if additional gains in computation time are desired, subsequently compare the results with a smaller number of neighbors using WAIC or k-fold cross-validation.</p>
<code>search.type</code>	<p>a quoted keyword that specifies the type of nearest neighbor search algorithm. Supported method keywords are: "cb" and "brute". The "cb" should generally be much faster. If locations do not have identical coordinate values on the axis used for the nearest neighbor ordering then "cb" and "brute" should produce identical neighbor sets. However, if there are identical coordinate values on the axis used for nearest neighbor ordering, then "cb" and "brute" might produce different, but equally valid, neighbor sets, e.g., if data are on a grid.</p>
<code>n.batch</code>	<p>the number of MCMC batches in each chain to run for the Adaptive MCMC sampler. See Roberts and Rosenthal (2009) for details.</p>
<code>batch.length</code>	<p>the length of each MCMC batch to run for the Adaptive MCMC sampler. See Roberts and Rosenthal (2009) for details.</p>
<code>accept.rate</code>	<p>target acceptance rate for Adaptive MCMC. Default is 0.43. See Roberts and Rosenthal (2009) for details.</p>
<code>n.omp.threads</code>	<p>a positive integer indicating the number of threads to use for SMP parallel processing. The package must be compiled for OpenMP support. For most Intel-based machines, we recommend setting <code>n.omp.threads</code> up to the number of hyperthreaded cores. Note, <code>n.omp.threads > 1</code> might not work on some systems.</p>

<code>verbose</code>	if TRUE, messages about data preparation, model specification, and progress of the sampler are printed to the screen. Otherwise, no messages are printed.
<code>n.report</code>	the interval to report Metropolis sampler acceptance and MCMC progress. Note this is specified in terms of batches and not overall samples for spatial models.
<code>n.burn</code>	the number of samples out of the total <code>n.samples</code> to discard as burn-in for each chain. By default, the first 10% of samples is discarded.
<code>n.thin</code>	the thinning interval for collection of MCMC samples. The thinning occurs after the <code>n.burn</code> samples are discarded. Default value is set to 1.
<code>n.chains</code>	the number of chains to run in sequence.
<code>k.fold</code>	specifies the number of k folds for cross-validation. If not specified as an argument, then cross-validation is not performed and <code>k.fold.threads</code> and <code>k.fold.seed</code> are ignored. In k -fold cross-validation, the data specified in <code>data</code> is randomly partitioned into k equal sized subsamples. Of the k subsamples, $k - 1$ subsamples are used to fit the model and the remaining k samples are used for prediction. The cross-validation process is repeated k times (the folds). As a scoring rule, we use the model deviance as described in Hooten and Hobbs (2015). Cross-validation is performed after the full model is fit using all the data. Cross-validation results are reported in the <code>k.fold.deviance</code> object in the return list.
<code>k.fold.threads</code>	number of threads to use for cross-validation. If <code>k.fold.threads</code> > 1 parallel processing is accomplished using the foreach and doParallel packages. Ignored if <code>k.fold</code> is not specified.
<code>k.fold.seed</code>	seed used to split data set into <code>k.fold</code> parts for k -fold cross-validation. Ignored if <code>k.fold</code> is not specified.
<code>...</code>	currently no additional arguments

Value

An object of class `spMsPGOcc` that is a list comprised of:

<code>beta.comm.samples</code>	a coda object of posterior samples for the community level occurrence regression coefficients.
<code>alpha.comm.samples</code>	a coda object of posterior samples for the community level detection regression coefficients.
<code>tau.sq.beta.samples</code>	a coda object of posterior samples for the occurrence community variance parameters.
<code>tau.sq.alpha.samples</code>	a coda object of posterior samples for the detection community variance parameters.
<code>beta.samples</code>	a coda object of posterior samples for the species level occurrence regression coefficients.
<code>alpha.samples</code>	a coda object of posterior samples for the species level detection regression coefficients.
<code>theta.samples</code>	a coda object of posterior samples for the species level covariance parameters.

<code>z.samples</code>	a three-dimensional array of posterior samples for the latent occurrence values for each species.
<code>psi.samples</code>	a three-dimensional array of posterior samples for the latent occupancy probability values for each species.
<code>w.samples</code>	a three-dimensional array of posterior samples for the latent spatial random effects for each species.
<code>sigma.sq.psi.samples</code>	a coda object of posterior samples for variances of random intercepts included in the occurrence portion of the model. Only included if random intercepts are specified in <code>occ.formula</code> .
<code>sigma.sq.p.samples</code>	a coda object of posterior samples for variances of random intercepts included in the detection portion of the model. Only included if random intercepts are specified in <code>det.formula</code> .
<code>alpha.star.samples</code>	a coda object of posterior samples for the detection random effects. Only included if random intercepts are specified in <code>det.formula</code> .
<code>beta.star.samples</code>	a coda object of posterior samples for the occurrence random effects. Only included if random intercepts are specified in <code>occ.formula</code> .
<code>like.samples</code>	a three-dimensional array of posterior samples for the likelihood value associated with each site and species. Used for calculating WAIC.
<code>rhat</code>	a list of Gelman-Rubin diagnostic values for some of the model parameters.
<code>ESS</code>	a list of effective sample sizes for some of the model parameters.
<code>run.time</code>	MCMC sampler execution time reported using <code>proc.time()</code> .
<code>k.fold.deviance</code>	vector of scoring rules (deviance) from k-fold cross-validation. A separate value is reported for each species. Only included if <code>k.fold</code> is specified in function call.

The return object will include additional objects used for subsequent prediction and/or model fit evaluation. Note that detection probability estimated values are not included in the model object, but can be extracted using `fitted()`.

Note

Some of the underlying code used for generating random numbers from the Poly-Gamma distribution is taken from the **pgdraw** package written by Daniel F. Schmidt and Enes Makalic. Their code implements Algorithm 6 in PhD thesis of Jesse Bennett Windle (2013) <https://repositories.lib.utexas.edu/handle/2152/21842>.

spPGOcc

Function for Fitting Single-Species Spatial Occupancy Models Using Poly-Gamma Latent Variables

Description

The function `spPGOcc` fits single-species spatial occupancy models using Poly-Gamma latent variables. Models can be fit using either a full Gaussian process or a Nearest Neighbor Gaussian Process for large data sets.

Usage

```

spPGOcc(occ.formula, det.formula, data, inits, priors,
        tuning, cov.model = "exponential", NNGP = TRUE,
        n.neighbors = 15, search.type = "cb", n.batch,
        batch.length, accept.rate = 0.43,
        n.omp.threads = 1, verbose = TRUE, n.report = 100,
        n.burn = round(.10 * n.batch * batch.length),
        n.thin = 1, n.chains = 1, k.fold, k.fold.threads = 1,
        k.fold.seed = 100, ...)

```

Arguments

- | | |
|--------------------------|---|
| <code>occ.formula</code> | a symbolic description of the model to be fit for the occurrence portion of the model using R's model syntax. Only right-hand side of formula is specified. See example below. Random intercepts are allowed using lme4 syntax (Bates et al. 2015). |
| <code>det.formula</code> | a symbolic description of the model to be fit for the detection portion of the model using R's model syntax. Only right-hand side of formula is specified. See example below. Random intercepts are allowed using lme4 syntax (Bates et al. 2015). |
| <code>data</code> | a list containing data necessary for model fitting. Valid tags are <code>y</code> , <code>occ.covs</code> , <code>det.covs</code> , and <code>coords</code> . <code>y</code> is the detection-nondetection data matrix or data |

frame with first dimension equal to the number of sites (J) and second dimension equal to the maximum number of replicates at a given site. `occ.covs` is a matrix or data frame containing the variables used in the occupancy portion of the model, with J rows for each column (variable). `det.covs` is a list of variables included in the detection portion of the model. Each list element is a different detection covariate, which can be site-level or observational-level. Site-level covariates are specified as a vector of length J while observation-level covariates are specified as a matrix or data frame with the number of rows equal to J and number of columns equal to the maximum number of replicates at a given site. `coords` is a $J \times 2$ matrix of the observation coordinates. Note that spOccupancy assumes coordinates are specified in a projected coordinate system.

<code>inits</code>	a list with each tag corresponding to a parameter name. Valid tags are <code>z</code> , <code>beta</code> , <code>alpha</code> , <code>sigma.sq</code> , <code>phi</code> , <code>w</code> , <code>nu</code> , <code>sigma.sq.psi</code> , <code>sigma.sq.p</code> . <code>nu</code> is only specified if <code>cov.model = "matern"</code> , <code>sigma.sq.p</code> is only specified if there are random effects in <code>det.formula</code> , and <code>sigma.sq.psi</code> is only specified if there are random effects in <code>occ.formula</code> . The value portion of each tag is the parameter's initial value. See <code>priors</code> description for definition of each parameter name. Additionally, the tag <code>fix</code> can be set to <code>TRUE</code> to fix the starting values across all chains. If <code>fix</code> is not specified (the default), starting values are varied randomly across chains.
<code>priors</code>	a list with each tag corresponding to a parameter name. Valid tags are <code>beta.normal</code> , <code>alpha.normal</code> , <code>phi.unif</code> , <code>sigma.sq.ig</code> , <code>nu.unif</code> , <code>sigma.sq.psi.ig</code> , and <code>sigma.sq.p.ig</code> . Occurrence (<code>beta</code>) and detection (<code>alpha</code>) regression coefficients are assumed to follow a normal distribution. The hyperparameters of the normal distribution are passed as a list of length two with the first and second elements corresponding to the mean and variance of the normal distribution, which are each specified as vectors of length equal to the number of coefficients to be estimated or of length one if priors are the same for all coefficients. If not specified, prior means are set to 0 and prior variances set to 2.73. The spatial variance parameter, <code>sigma.sq</code> , is assumed to follow an inverse-Gamma distribution, whereas the spatial decay <code>phi</code> and smoothness <code>nu</code> parameters are assumed to follow Uniform distributions. The hyperparameters of the inverse-Gamma for <code>sigma.sq</code> are passed as a vector of length two, with the first and second elements corresponding to the <i>shape</i> and <i>scale</i> , respectively. The hyperparameters of the Uniform are also passed as a vector of length two with the first and second elements corresponding to the lower and upper support, respectively. <code>sigma.sq.psi</code> and <code>sigma.sq.p</code> are the random effect variances for any occurrence or detection random effects, respectively, and are assumed to follow an inverse-Gamma distribution. The hyperparameters of the inverse-Gamma distribution are passed as a list of length two with the first and second elements corresponding to the shape and scale parameters, respectively, which are each specified as vectors of length equal to the number of random intercepts or of length one if priors are the same for all random effect variances.
<code>cov.model</code>	a quoted keyword that specifies the covariance function used to model the spatial dependence structure among the observations. Supported covariance model keywords are: "exponential", "matern", "spherical", and "gaussian".
<code>tuning</code>	a list with each tag corresponding to a parameter name. Valid tags are <code>phi</code> and

	nu. The value portion of each tag defines the initial variance of the Adaptive sampler. See Roberts and Rosenthal (2009) for details.
NNGP	if TRUE, model is fit with an NNGP. If FALSE, a full Gaussian process is used. See Datta et al. (2016) and Finley et al. (2019) for more information.
n.neighbors	number of neighbors used in the NNGP. Only used if NNGP = TRUE. Datta et al. (2016) showed that 15 neighbors is usually sufficient, but that as few as 5 neighbors can be adequate for certain data sets, which can lead to even greater decreases in run time. We recommend starting with 15 neighbors (the default) and if additional gains in computation time are desired, subsequently compare the results with a smaller number of neighbors using WAIC or k-fold cross-validation.
search.type	a quoted keyword that specifies the type of nearest neighbor search algorithm. Supported method key words are: "cb" and "brute". The "cb" should generally be much faster. If locations do not have identical coordinate values on the axis used for the nearest neighbor ordering then "cb" and "brute" should produce identical neighbor sets. However, if there are identical coordinate values on the axis used for nearest neighbor ordering, then "cb" and "brute" might produce different, but equally valid, neighbor sets, e.g., if data are on a grid.
n.batch	the number of MCMC batches in each chain to run for the Adaptive MCMC sampler. See Roberts and Rosenthal (2009) for details.
batch.length	the length of each MCMC batch in each chain to run for the Adaptive MCMC sampler. See Roberts and Rosenthal (2009) for details.
accept.rate	target acceptance rate for Adaptive MCMC. Default is 0.43. See Roberts and Rosenthal (2009) for details.
n.omp.threads	a positive integer indicating the number of threads to use for SMP parallel processing. The package must be compiled for OpenMP support. For most Intel-based machines, we recommend setting n.omp.threads up to the number of hyperthreaded cores. Note, n.omp.threads > 1 might not work on some systems.
verbose	if TRUE, messages about data preparation, model specification, and progress of the sampler are printed to the screen. Otherwise, no messages are printed.
n.report	the interval to report Metropolis sampler acceptance and MCMC progress.
n.burn	the number of samples out of the total n.batch * batch.length samples in each chain to discard as burn-in. By default, the first 10% of samples is discarded.
n.thin	the thinning interval for collection of MCMC samples. The thinning occurs after the n.burn samples are discarded. Default value is set to 1.
n.chains	the number of MCMC chains to run in sequence.
k.fold	specifies the number of k folds for cross-validation. If not specified as an argument, then cross-validation is not performed and k.fold.threads and k.fold.seed are ignored. In k -fold cross-validation, the data specified in data is randomly partitioned into k equal sized subsamples. Of the k subsamples, $k - 1$ subsamples are used to fit the model and the remaining k samples are used for prediction. The cross-validation process is repeated k times (the folds). As a scoring rule, we use the model deviance as described in Hooten and Hobbs (2015).

Cross-validation is performed after the full model is fit using all the data. Cross-validation results are reported in the `k.fold.deviance` object in the return list.

<code>k.fold.threads</code>	number of threads to use for cross-validation. If <code>k.fold.threads > 1</code> parallel processing is accomplished using the foreach and doParallel packages. Ignored if <code>k.fold</code> is not specified.
<code>k.fold.seed</code>	seed used to split data set into <code>k.fold</code> parts for k-fold cross-validation. Ignored if <code>k.fold</code> is not specified.
<code>...</code>	currently no additional arguments

Value

An object of class `spPGOcc` that is a list comprised of:

<code>beta.samples</code>	a coda object of posterior samples for the occurrence regression coefficients.
<code>alpha.samples</code>	a coda object of posterior samples for the detection regression coefficients.
<code>z.samples</code>	a coda object of posterior samples for the latent occurrence values
<code>psi.samples</code>	a coda object of posterior samples for the latent occurrence probability values
<code>theta.samples</code>	a coda object of posterior samples for covariance parameters.
<code>w.samples</code>	a coda object of posterior samples for latent spatial random effects.
<code>sigma.sq.psi.samples</code>	a coda object of posterior samples for variances of random intercepts included in the occupancy portion of the model. Only included if random intercepts are specified in <code>occ.formula</code> .
<code>sigma.sq.p.samples</code>	a coda object of posterior samples for variances of random intercepts included in the detection portion of the model. Only included if random intercepts are specified in <code>det.formula</code> .
<code>beta.star.samples</code>	a coda object of posterior samples for the occurrence random effects. Only included if random intercepts are specified in <code>occ.formula</code> .
<code>alpha.star.samples</code>	a coda object of posterior samples for the detection random effects. Only included if random intercepts are specified in <code>det.formula</code> .
<code>like.samples</code>	a coda object of posterior samples for the likelihood value associated with each site. Used for calculating WAIC.
<code>rhat</code>	a list of Gelman-Rubin diagnostic values for some of the model parameters.
<code>ESS</code>	a list of effective sample sizes for some of the model parameters.
<code>run.time</code>	execution time reported using <code>proc.time()</code> .
<code>k.fold.deviance</code>	scoring rule (deviance) from k-fold cross-validation. Only included if <code>k.fold</code> is specified in function call.

The return object will include additional objects used for subsequent prediction and/or model fit evaluation. Note that detection probability values are not included in the model object, but can be extracted using `fitted()`.

```

summary.intPGOcc

Methods for intPGOcc Object

Description

Methods for extracting information from fitted single species integrated occupancy (intPGOcc) model.

Usage

```
## S3 method for class 'intPGOcc'
summary(object, quantiles = c(0.025, 0.5, 0.975),
        digits = max(3L, getOption("digits") - 3L), ...)
## S3 method for class 'intPGOcc'
print(x, ...)
```

Arguments

object, x	object of class intPGOcc.
quantiles	for summary, posterior distribution quantiles to compute.
digits	for summary, number of digits to report.
...	currently no additional arguments

Details

A set of standard extractor functions for fitted model objects of class intPGOcc, including methods to the generic functions [print](#) and [summary](#).

Value

No return value, called to display summary information of a intPGOcc object.

summary.lfJSDM	<i>Methods for lfJSDM Object</i>
----------------	----------------------------------

Description

Methods for extracting information from a fitted latent factor joint species distribution model (lfJSDM).

Usage

```
## S3 method for class 'lfJSDM'
summary(object, level = 'both', quantiles = c(0.025, 0.5, 0.975),
        digits = max(3L, getOption("digits") - 3L), ...)
## S3 method for class 'lfJSDM'
print(x, ...)
```

Arguments

object, x	object of class lfJSDM.
level	a quoted keyword that indicates the level to summarize the model results. Valid key words are: "community", "species", or "both".
quantiles	for summary, posterior distribution quantiles to compute.
digits	for summary, number of digits to report.
...	currently no additional arguments

Details

A set of standard extractor functions for fitted model objects of class lfJSDM, including methods to the generic functions [print](#) and [summary](#).

Value

No return value, called to display summary information of a lfJSDM object.

summary.lfMsPGOcc *Methods for lfMsPGOcc Object*

Description

Methods for extracting information from a fitted latent factor multi-species occupancy model (lfMsPGOcc).

Usage

```
## S3 method for class 'lfMsPGOcc'
summary(object, level = 'both', quantiles = c(0.025, 0.5, 0.975),
        digits = max(3L, getOption("digits") - 3L), ...)
## S3 method for class 'lfMsPGOcc'
print(x, ...)
```

Arguments

object, x	object of class lfMsPGOcc.
level	a quoted keyword that indicates the level to summarize the model results. Valid key words are: "community", "species", or "both".
quantiles	for summary, posterior distribution quantiles to compute.
digits	for summary, number of digits to report.
...	currently no additional arguments

Details

A set of standard extractor functions for fitted model objects of class lfMsPGOcc, including methods to the generic functions [print](#) and [summary](#).

Value

No return value, called to display summary information of a lfMsPGOcc object.

summary.msPGOcc *Methods for msPGOcc Object*

Description

Methods for extracting information from fitted multi-species occupancy (msPGOcc) model.

Usage

```
## S3 method for class 'msPGOcc'
summary(object, level = 'both', quantiles = c(0.025, 0.5, 0.975),
        digits = max(3L, getOption("digits") - 3L), ...)
## S3 method for class 'msPGOcc'
print(x, ...)
```

Arguments

object, x	object of class msPGOcc.
level	a quoted keyword that indicates the level to summarize the model results. Valid key words are: "community", "species", or "both".
quantiles	for summary, posterior distribution quantiles to compute.
digits	for summary, number of digits to report.
...	currently no additional arguments

A set of standard extractor functions for fitted model objects of class msPGOcc, including methods to the generic functions [print](#) and [summary](#).

Value

No return value, called to display summary information of a msPGOcc object.

summary.PGOcc *Methods for PGOcc Object*

Description

Methods for extracting information from fitted single-species occupancy (PGOcc) model.

Usage

```
## S3 method for class 'PGOcc'
summary(object, quantiles = c(0.025, 0.5, 0.975),
        digits = max(3L, getOption("digits") - 3L), ...)
## S3 method for class 'PGOcc'
print(x, ...)
```

Arguments

object, x	object of class PGOcc.
quantiles	for summary, posterior distribution quantiles to compute.
digits	for summary, number of digits to report.
...	currently no additional arguments

Details

A set of standard extractor functions for fitted model objects of class PGOcc, including methods to the generic functions [print](#) and [summary](#).

Value

No return value, called to display summary information of a PGOcc object.

summary.ppcOcc	<i>Methods for ppcOcc Object</i>
----------------	----------------------------------

Description

Methods for extracting information from posterior predictive check objects of class ppcOcc.

Usage

```
## S3 method for class 'ppcOcc'
summary(object, level, digits = max(3L, getOption("digits") - 3L), ...)
```

Arguments

object	object of class ppcOcc.
level	a quoted keyword for multi-species models that indicates the level to summarize the posterior predictive check. Valid key words are: "community", "species", or "both".
digits	number of digits to report.
...	currently no additional arguments

Details

A set of standard extractor functions for fitted posterior predictive check objects of class ppcOcc, including methods to the generic function [summary](#).

Value

No return value, called to display summary information of a ppcOcc object.

summary.sfJSDM *Methods for sfJSDM Object*

Description

Methods for extracting information from fitted spatial factor joint species distribution models (sfJSDM).

Usage

```
## S3 method for class 'sfJSDM'
summary(object, level, quantiles = c(0.025, 0.5, 0.975),

print(x, ...)
```

Arguments

object, x	object of class spIntPGOcc.
quantiles	for summary, posterior distribution quantiles to compute.
digits	for summary, number of digits to report.
...	currently no additional arguments

Details

A set of standard extractor functions for fitted model objects of class spIntPGOcc, including methods to the generic functions [print](#) and [summary](#).

Value

No return value, called to display summary information of a spIntPGOcc object.

summary.spMsPGOcc *Methods for spMsPGOcc Object*

Description

Methods for extracting information from fitted multi-species spatial occupancy (spMsPGOcc) model.

Usage

```
## S3 method for class 'spMsPGOcc'
summary(object, level, quantiles = c(0.025, 0.5, 0.975),
        digits = max(3L, getOption("digits") - 3L), ...)
## S3 method for class 'spMsPGOcc'
print(x, ...)
```

Arguments

object, x	object of class spMsPGOcc.
level	a quoted keyword that indicates the level to summarize the model results. Valid key words are: "community", "species", or "both".
quantiles	for summary, posterior distribution quantiles to compute.
digits	for summary, number of digits to report.
...	currently no additional arguments

Details

A set of standard extractor functions for fitted model objects of class spMsPGOcc, including methods to the generic functions [print](#) and [summary](#).

Value

No return value, called to display summary information of a spMsPGOcc object.

summary.spPGOcc	<i>Methods for spPGOcc Object</i>
-----------------	-----------------------------------

Description

Methods for extracting information from fitted single-species spatial occupancy (spPGOcc) model.

Usage

```
## S3 method for class 'spPGOcc'
summary(object, quantiles = c(0.025, 0.5, 0.975),
        digits = max(3L, getOption("digits") - 3L), ...)
## S3 method for class 'spPGOcc'
print(x, ...)
```

Arguments

object, x	object of class spPGOcc.
quantiles	for summary, posterior distribution quantiles to compute.
digits	for summary, number of digits to report.
...	currently no additional arguments

Details

A set of standard extractor functions for fitted model objects of class spPGOcc, including methods to the generic functions [print](#) and [summary](#).

Value

No return value, called to display summary information of a spPGOcc object.

waicOcc	<i>Compute Widely Applicable Information Criterion for spOccupancy Model Objects</i>
---------	--

Description

Function for computing the Widely Applicable Information Criterion (WAIC; Watanabe 2010) for spOccupancy model objects.

Usage

```
waicOcc(object, ...)
```

Arguments

object an object of class PGOcc, spPGOcc, msPGOcc, spMsPGOcc, intPGOcc, spIntPGOcc, lfJSDM, sfJSDM, lfMsPGOcc, or sfMsPGOcc.
 ... currently no additional arguments

Details

The effective number of parameters is calculated following the recommendations of Gelman et al. (2014).

Value

When object is of class PGOcc, spPGOcc, msPGOcc, spMsPGOcc, lfJSDM, sfJSDM, lfMsPGOcc, or sfMsPGOcc, returns a vector with three elements corresponding to estimates of the expected log pointwise predictive density (elpd), the effective number of parameters (pD), and the WAIC. When object is of class intPGOcc or spIntPGOcc, returns a data frame with columns elpd, pD, and WAIC, with each row corresponding to the estimated values for each data source in the integrated model.
