Package ‘spatialsample’

May 17, 2023

Title  Spatial Resampling Infrastructure

Version  0.4.0

Description  Functions and classes for spatial resampling to use with the
'sample' package, such as spatial cross-validation (Brenning, 2012)
<doi:10.1109/IGARSS.2012.6352393>. The scope of 'sample' and
'spatialsample' is to provide the basic building blocks for creating
and analyzing resamples of a spatial data set, but neither package
includes functions for modeling or computing statistics. The resampled
spatial data sets created by 'spatialsample' do not contain much
overhead in memory.

**R topics documented:**

- autoplot.spatial_rset ........................................... 2
- boston_canopy .................................................. 3
- spatial_block_cv .............................................. 5
- spatial_buffer_vfold_cv ...................................... 6
- spatial_clustering_cv .......................................... 8
- spatial_nndm_cv ................................................ 10

**Index**

- autoplot.spatial_rset  Create a ggplot for spatial resamples. 13

**Description**

This method provides a good visualization method for spatial resampling.

**Usage**

```r
## S3 method for class 'spatial_rset'
autoplot(object, ..., alpha = 0.6)

## S3 method for class 'spatial_block_cv'
autoplot(object, show_grid = TRUE, ..., alpha = 0.6)
```

**Arguments**

- `object`  A spatial_rset object or a spatial_rsplit object. Note that only resamples made from sf objects create spatial_rset and spatial_rsplit objects; this function will not work for resamples made with non-spatial tibbles or data.frames.
- `...`  Options passed to `ggplot2::geom_sf()`.
- `alpha`  Opacity, passed to `ggplot2::geom_sf()`. Values of alpha range from 0 to 1, with lower values corresponding to more transparent colors.
- `show_grid`  When plotting spatial_block_cv objects, should the grid itself be drawn on top of the data? Set to FALSE to remove the grid.
**Details**

The plot method for spatial_rset displays which fold each observation is assigned to. Note that if data is assigned to multiple folds (which is common if resamples were created with a non-zero radius) only the "last" fold for each observation will appear on the plot. Consider adding ggplot2::facet_wrap(~ fold) to visualize all members of each fold separately. Alternatively, consider plotting each split using the spatial_rsplit method (for example, via lapply(object$splits, autoplot)).

**Value**

A ggplot object with each fold assigned a color, made using ggplot2::geom_sf().

**Examples**

```r
boston_block <- spatial_block_cv(boston_canopy, v = 2)
autoplot(boston_block)
autoplot(boston_block$splits[[1]])
```

---

**boston_canopy**

*Boston tree canopy and heat index data.*

**Description**

A dataset containing data on tree canopy coverage and change for the city of Boston, Massachusetts from 2014-2019, as well as temperature and heat index data for July 2019. Data is aggregated to a grid of regular 25 hectare hexagons, clipped to city boundaries. This data is made available under the Public Domain Dedication and License v1.0 whose full text can be found at: [https://opendatacommons.org/licenses/pddl/1-0/](https://opendatacommons.org/licenses/pddl/1-0/).

**Usage**

```r
boston_canopy
```

**Format**

A data frame (of class sf, tbl_df, tbl, and data.frame) containing 682 records of 22 variables:

- **grid_id** Unique identifier for each hexagon. Letters represent the hexagon’s X position in the grid (ordered West to East), while numbers represent the Y position (ordered North to South).
- **land_area** Area excluding water bodies
- **canopy_gain** Area of canopy gain between the two years
- **canopy_loss** Area of canopy loss between the two years
- **canopy_no_change** Area of no canopy change between the two years
- **canopy_area_2014** 2014 total canopy area (baseline)
canopy_area_2019  2019 total canopy area
change_canopy_area  The change in area of tree canopy between the two years
change_canopy_percentage  Relative change calculation used in economics is the gain or loss of tree canopy relative to the earlier time period: (2019 Canopy-2014 Canopy)/(2014 Canopy)
canopy_percentage_2014  2014 canopy percentage
canopy_percentage_2019  2019 canopy percentage
change_canopy_absolute  Absolute change. Magnitude of change in percent tree canopy from 2014 to 2019 (% 2019 Canopy - % 2014 Canopy)
mean_temp_morning  Mean temperature for July 2019 from 6am - 7am
mean_temp_evening  Mean temperature for July 2019 from 7pm - 8pm
mean_temp  Mean temperature for July 2019 from 6am - 7am, 3pm - 4pm, and 7pm - 8pm (combined)
mean_heat_index_morning  Mean heat index for July 2019 from 6am - 7am
mean_heat_index_evening  Mean heat index for July 2019 from 7pm - 8pm
mean_heat_index  Mean heat index for July 2019 from 6am - 7am, 3pm - 4pm, and 7pm - 8pm (combined)
gameometry  Geometry of each hexagon, encoded using EPSG:2249 as a coordinate reference system (NAD83 / Massachusetts Mainland (ftUS)). Note that the linear units of this CRS are in US feet.

Details

Note that this dataset is in the EPSG:2249 (NAD83 / Massachusetts Mainland (ftUS)) coordinate reference system (CRS), which may not be installed by default on your computer. Before working with boston_canopy, run:

- sf::sf_proj_network(TRUE) to install the CRS itself
- sf::sf_add_proj_units() to add US customary units to your units database

These steps only need to be taken once per computer (or per PROJ installation).

Source

Spatial block cross-validation

Description

Block cross-validation splits the area of your data into a number of grid cells, or "blocks", and then assigns all data into folds based on the blocks their centroid falls into.

Usage

```r
spatial_block_cv(
  data,
  method = c("random", "snake", "continuous"),
  v = 10,
  relevant_only = TRUE,
  radius = NULL,
  buffer = NULL,
  ..., 
  repeats = 1
)
```

Arguments

- `data`: An object of class `sf` or `sfc`.
- `method`: The method used to sample blocks for cross validation folds. Currently supports "random", which randomly assigns blocks to folds, "snake", which labels the first row of blocks from left to right, then the next from right to left, and repeats from there, and "continuous", which labels each row from left to right, moving from the bottom row up.
- `v`: The number of partitions for the resampling. Set to `NULL` or `Inf` for the maximum sensible value (for leave-one-X-out cross-validation).
- `relevant_only`: For systematic sampling, should only blocks containing data be included in fold labeling?
- `radius`: Numeric: points within this distance of the initially-selected test points will be assigned to the assessment set. If `NULL`, no radius is applied.
- `buffer`: Numeric: points within this distance of any point in the test set (after `radius` is applied) will be assigned to neither the analysis or assessment set. If `NULL`, no buffer is applied.
- `...`: Arguments passed to `sf::st_make_grid()`.
- `repeats`: The number of times to repeat the V-fold partitioning.

Details

The grid blocks can be controlled by passing arguments to `sf::st_make_grid()` via `...`. Some particularly useful arguments include:
spatial_buffer_vfold_cv

- **cellsize**: Target cellsize, expressed as the "diameter" (shortest straight-line distance between opposing sides; two times the apothem) of each block, in map units.
- **n**: The number of grid blocks in the x and y direction (columns, rows).
- **square**: A logical value indicating whether to create square (TRUE) or hexagonal (FALSE) cells.

If both `cellsize` and `n` are provided, then the number of blocks requested by `n` of sizes specified by `cellsize` will be returned, likely not lining up with the bounding box of data. If only `cellsize` is provided, this function will return as many blocks of size `cellsize` as fit inside the bounding box of data. If only `n` is provided, then `cellsize` will be automatically adjusted to create the requested number of cells.

**Value**

A tibble with classes `spatial_block_cv`, `spatial_rset`, `rset`, `tbl_df`, `tbl`, and `data.frame`. The results include a column for the data split objects and an identification variable `id`.

**References**

**Examples**

```r
spatial_block_cv(boston_canopy, v = 3)
```

---

V-fold cross-validation (also known as k-fold cross-validation) randomly splits the data into V groups of roughly equal size (called "folds"). A resample of the analysis data consists of V-1 of the folds while the assessment set contains the final fold. These functions extend `rsample::vfold_cv()` and `rsample::group_vfold_cv()` to also apply an inclusion radius and exclusion buffer to the assessment set, ensuring that your analysis data is spatially separated from the assessment set. In basic V-fold cross-validation (i.e. no repeats), the number of resamples is equal to V.
spatial_buffer_vfold_cv

Usage

spatial_buffer_vfold_cv(
  data,
  radius,
  buffer,
  v = 10,
  repeats = 1,
  strata = NULL,
  breaks = 4,
  pool = 0.1,
  ...
)

spatial_leave_location_out_cv(
  data,
  group,
  v = NULL,
  radius = NULL,
  buffer = NULL,
  ..., repeats = 1
)

Arguments

data A data frame.
radius Numeric: points within this distance of the initially-selected test points will be assigned to the assessment set. If NULL, no radius is applied.
buffer Numeric: points within this distance of any point in the test set (after radius is applied) will be assigned to neither the analysis or assessment set. If NULL, no buffer is applied.
v The number of partitions for the resampling. Set to NULL or Inf for the maximum sensible value (for leave-one-X-out cross-validation).
repeats The number of times to repeat the V-fold partitioning.
strata A variable in data (single character or name) used to conduct stratified sampling. When not NULL, each resample is created within the stratification variable. Numeric strata are binned into quartiles.
breaks A single number giving the number of bins desired to stratify a numeric stratification variable.
pool A proportion of data used to determine if a particular group is too small and should be pooled into another group. We do not recommend decreasing this argument below its default of 0.1 because of the dangers of stratifying groups that are too small.
... Not currently used.
group A variable in data (single character or name) used to create folds. For leave-location-out CV, this should be a variable containing the locations to group
observations by, for leave-time-out CV the time blocks to group by, and for leave-location-and-time-out the spatiotemporal blocks to group by.

Details

When `radius` and `buffer` are both `NULL`, `spatial_buffer_vfold_cv` is equivalent to `rsample::vfold_cv()` and `spatial_leave_location_out_cv` is equivalent to `rsample::group_vfold_cv()`.

spatial_clustering_cv  Spatial Clustering Cross-Validation

Description

Spatial clustering cross-validation splits the data into V groups of disjointed sets by clustering points based on their spatial coordinates. A resample of the analysis data consists of V-1 of the folds/clusters while the assessment set contains the final fold/cluster.
spatial_clustering_cv

Usage

spatial_clustering_cv(
  data,
  v = 10,
  cluster_function = c("kmeans", "hclust"),
  radius = NULL,
  buffer = NULL,
  ...,
  repeats = 1,
  distance_function = function(x) as.dist(sf::st_distance(x))
)

Arguments

data An sf object (often from sf::read_sf() or sf::st_as_sf()) to split into folds.
v The number of partitions of the data set.
cluster_function Which function should be used for clustering? Options are either "kmeans" (to use stats::kmeans()) or "hclust" (to use stats::hclust()). You can also provide your own function; see Details.
radius Numeric: points within this distance of the initially-selected test points will be assigned to the assessment set. If NULL, no radius is applied.
buffer Numeric: points within this distance of any point in the test set (after radius is applied) will be assigned to neither the analysis or assessment set. If NULL, no buffer is applied.
... Extra arguments passed on to stats::kmeans() or stats::hclust().
repeats The number of times to repeat the clustered partitioning.
distance_function Which function should be used for distance calculations? Defaults to sf::st_distance(), with the output matrix converted to a stats::dist() object. You can also provide your own function; see Details.

Details

Clusters are created based on the distances between observations if data is an sf object. Each cluster is used as a fold for cross-validation. Depending on how the data are distributed spatially, there may not be an equal number of observations in each fold.

You can optionally provide a custom function to distance_function. The function should take an sf object and return a stats::dist() object with distances between data points.

You can optionally provide a custom function to cluster_function. The function must take three arguments:

- dists, a stats::dist() object with distances between data points
- v, a length-1 numeric for the number of folds to create
- ..., to pass any additional named arguments to your function
The function should return a vector of cluster assignments of length `nrow(data)`, with each element of the vector corresponding to the matching row of the data frame.

Value

A tibble with classes `spatial_clustering_cv`, `spatial_rset`, `rset`, `tbl_df`, `tbl`, and `data.frame`. The results include a column for the data split objects and an identification variable `id`. Resamples created from non-sf objects will not have the `spatial_rset` class.

Changes in `spatialsample 0.3.0`

As of `spatialsample` version 0.3.0, this function no longer accepts non-sf objects as arguments to `data`. In order to perform clustering with non-spatial data, consider using `rsample::clustering_cv()`.

Also as of version 0.3.0, this function now calculates edge-to-edge distance for non-point geometries, in line with the rest of the package. Earlier versions relied upon between-centroid distances.

References

Examples

data(Smithsonian, package = "modeldata")

`smithsonian_sf <- sf::st_as_sf(
    Smithsonian,
    coords = c("longitude", "latitude"),
    # Set CRS to WGS84
    crs = 4326
)

# When providing sf objects, coords are inferred automatically
spatial_clustering_cv(smithsonian_sf, v = 5)

# Can use hclust instead:
spatial_clustering_cv(smithsonian_sf, v = 5, cluster_function = "hclust")
Description

NNDM is a variant of leave-one-out cross-validation which assigns each observation to a single assessment fold, and then attempts to remove data from each analysis fold until the nearest neighbor distance distribution between assessment and analysis folds matches the nearest neighbor distance distribution between training data and the locations a model will be used to predict. Proposed by Milà et al. (2022), this method aims to provide accurate estimates of how well models will perform in the locations they will actually be predicting. This method was originally implemented in the CAST package.

Usage

```r
spatial_nndm_cv(
  data,
  prediction_sites,
  ..., 
  autocorrelation_range = NULL,
  prediction_sample_size = 1000,
  min_analysis_proportion = 0.5
)
```

Arguments

data An object of class sf or sfc.
prediction_sites An sf or sfc object describing the areas to be predicted. If prediction_sites are all points, then those points are treated as the intended prediction points when calculating target nearest neighbor distances. If any element of prediction_sites is not a single point, then points are sampled from within the bounding box of prediction_sites and those points are then used as the intended prediction points.
...
Additional arguments passed to `sf::st_sample()`. Note that the number of points to sample is controlled by `prediction_sample_size`; trying to pass `size` via ... will cause an error.

autocorrelation_range A numeric of length 1 representing the landscape autocorrelation range ("phi" in the terminology of Milà et al. (2022)). If NULL, the default, the autocorrelation range is assumed to be the distance between the opposite corners of the bounding box of prediction_sites.

prediction_sample_size A numeric of length 1: the number of points to sample when prediction_sites is not only composed of points. Note that this argument is passed to size in `sf::st_sample()`, meaning that no elements of ... can be named size.

min_analysis_proportion The minimum proportion of data that must remain after removing points to match nearest neighbor distances. This function will stop removing data from analysis sets once only min_analysis_proportion of the original data remains
spatial_nndm_cv

in analysis sets, even if the nearest neighbor distances between analysis and as-
se ssment sets are still lower than those between training and prediction loca-
tions.

Details

Note that, as a form of leave-one-out cross-validation, this method can be rather slow for larger data
(and fitting models to these resamples will be even slower).

Value

A tibble with classes spatial_nndm_cv, spatial_rset, rset, tbl_df, tbl, and data.frame. The
results include a column for the data split objects and an identification variable id.
