Package ‘spb babel’

April 7, 2020

Type  Package
Version  0.5.1
Title  Convert Spatial Data Using Tidy Tables
Description  Tools to convert from specific formats to more general forms of spatial data. Using tables to store the actual entities present in spatial data provides flexibility, and the functions here deliberately minimize the level of interpretation applied, leaving that for specific applications. Includes support for simple features, round-trip for 'Spatial' classes and long-form tables, analogous to 'ggplot2::fortify'. There is also a more 'normal form' representation that decomposes simple features and their kin to tables of objects, parts, and unique coordinates.

URL  https://mdsumner.github.io/spbabel

BugReports  https://github.com/mdsumner/spbabel/issues

Depends  R (>= 3.2.3)
Imports  dplyr, methods, sp, tibble, rlang
Suggests  testthat, ggplot2, maptools, raster, rmarkdown, knitr, covr, broom, ggpolypath, maps, sf, trip, viridis

VignetteBuilder  knitr
LazyData  yes
License  GPL-3
RoxygenNote  7.1.0
ByteCompile  TRUE
NeedsCompilation  no

Author  Michael D. Sumner [aut, cre]
Maintainer  Michael D. Sumner <mdsumner@gmail.com>
Repository  CRAN
Date/Publication  2020-04-07 11:50:03 UTC
R topics documented:

**spbabel-package**

Convert between different types of spatial objects.

**Description**

Facilities for converting between different types of spatial objects, including an in-place method to modify the underlying geometry of 'Spatial' classes using data frame idioms. The spbabel package provides functions to round-trip a Spatial object to a single table and back.

**Details**

- `sptable<-` modify a Spatial object in-place
- `sptable` create a **tibble** from Spatial DataFrame object
- `sp` create Spatial DataFrame object from table

**as_tibble.sfg**

Individual geometries as tibbles.

**Description**

Individual geometries as tibbles.

**Usage**

```r
## S3 method for class 'sfg'
as_tibble(x)
```
**Arguments**

- `x`: sf geometry of type sf

**Value**

- `tibble`

**Examples**

```r
tibble::as_tibble(sf::st_point(c(1, 1, 1)))
```

---

**Description**

A `feature_table` is a normal form for simple features, where all branches are recorded in one table with attributes `object_`, `branch_`, `type_`, `parent_`. All instances of `parent_` are NA except for the holes in multipolygon.

**Usage**

```r
feature_table(x, ...)
```

**Arguments**

- `x`: sf object
- `...`: ignored

**Details**

There is wasted information stored this way, but that’s because this is intended as a lowest common denominator format.

There are three tables, objects (the feature attributes and ID), branches (the parts), coordinates (the X, Y, Z, M values).

---

**holey**

*Multi-part, multi-holed, neighbouring, not completely topological polygons.*

---

**Description**

Created in `/data-raw/` from a manual drawing built in Manifold GIS.
map_table

*A decomposition of 'vector' map data structures to tables.*

**Description**

Creates a set of related tables to store the appropriate entities in spatial map data.

**Usage**

```
map_table(x, ...)
```

**Arguments**

- `x` : object to tidy
- `...` : arguments passed to methods

**Details**

The basic entities behind spatial data, and hence the "map tables" are:

- **vertices** : the positions in geometric space, e.g. x, y, z, time, long, lat, salinity etc.
- **branches** : a single connected chain of vertices, or "parts"
- **objects** : a collection of branches aligned to a row of metadata

This is the basic "topology" of traditional GIS vector data, for points, lines, polygons and their multi-counterparts. By default map_tables will produce these tables and also de-duplicated the input vertices, adding a fourth table to link vertices to branches.

Other topology types such as triangle or quad meshes can extend this four-entity model, or exist without the branches at all. See "mesh_table"?? These are currently classed as object_table, branch_table, branch_link_vertex_table, and vertex_table. But there are no methods.

**Value**

list of tibbles

---

**mpoint1**

*MultiPointsDataFrame data set*

**Description**

MultiPointsDataFrame data set
semap  "South-east" map data.

Description

Created in /data-raw/ semap is the sptable version of some of wrld_simpl, and seatt is the matching attribute data, linked by 'object_'.

Created in /data-raw/.

Examples

# recreate as sp object
mp <- sp(semap, attr_tab = seatt, crs = "+proj=longlat +ellps=WGS84")

sf  TBD Convert from dplyr tbl form to simple features.

Description

Not yet implemented.

Usage

sf(x, ...)

## S3 method for class 'data.frame'
sf(x, attr_tab = NULL, crs, ...)

Arguments

x  tibble as created by sptable
...
attr_tab  remaining data from the attributes
crs  projection, defaults to NA_character_

Value

sf
show, SpatialPolygonsDataFrame-method

sp methods

Description

Sp methods

Usage

```r
## S4 method for signature 'SpatialPolygonsDataFrame'
show(object)

## S4 method for signature 'SpatialLinesDataFrame'
show(object)

## S4 method for signature 'SpatialPointsDataFrame'
show(object)

## S4 method for signature 'Spatial'
print(x, ...)
```

Arguments

- `object`: Spatial object
- `x`: Spatial object
- `...`: ignored

sp

Convert from dplyr tbl form to Spatial*DataFrame.

Description

Convert from dplyr tbl form to Spatial*DataFrame.

Usage

```r
sp(x, ...)

## S3 method for class 'data.frame'
sp(x, attr_tab = NULL, crs, ...)
```
Arguments

- **x**: tibble as created by `sptable`
- **attr_tab**: unused
- **crs**: remaining data from the attributes
- **projection**, defaults to `NA_character_`

Value

`Spatial*`

Examples

```r
library(dplyr)
semap1 <- semap %>% dplyr::filter(y_ > -89.9999)
sp_obj <- sp(semap1, attr_tab = seatt, crs = "+proj=longlat +ellps=WGS84")
## look, seamless Antarctica!
## library(rgdal); plot(spTransform(sp_obj, "+proj=laea +lat_0=-70"))
```

Description

Convert from various forms to a table.

Decompose a `Spatial` or `sf` object to a single table structured as a row for every coordinate in all the sub-geometries, including duplicated coordinates that close polygonal rings, close lines and shared vertices between objects.

Usage

```r
## S3 method for class 'SpatialPolygons'
sptable(x, ...)

## S3 method for class 'SpatialLines'
sptable(x, ...)

## S3 method for class 'SpatialPointsDataFrame'
sptable(x, ...)

## S3 method for class 'SpatialMultiPointsDataFrame'
sptable(x, ...)

sptable(object) <- value

sptable(x, ...)

## S3 method for class 'trip'
map_table(x, ...)
```
Arguments

x  Spatial object  
...  ignored  
object  Spatial object  
value  modified sptable version of object  

Details

Input can be a of type sf SpatialPolygonsDataFrame, SpatialLinesDataFrame, SpatialMultiPointsDataFrame or a SpatialPointsDataFrame. For simplicity sptable and its inverses sp and sf assume that all geometry can be encoded with object, branch, island, order, x and y. and that the type of topology is identified by which of these are present.

For simple features objects with mixed types of topology the result is consistent, but probably not useful. Columns that aren’t present in one type will be present, padded with NA. (This is work in progress).

This is analogous to the following but in spbabel provides a consistent way to round-trip back to Spatial classes and other forms.

- sp_tidiers (replacement of ‘ggplot2::fortify’).
- geom
- SpatialPolygonsDataFrame-class with its ‘as(as(x, "SpatialLinesDataFrame"), "SpatialPointsDataFrame")’ work flow.

Value

Spatial object  
tibble with columns

- SpatialPolygonsDataFrame "object_" "branch_" "island_" "order_" "x" "y_"
- SpatialLinesDataFrame "object_" "branch_" "order_" "x_" "y_"
- SpatialPointsDataFrame "object_" "x_" "y_"
- SpatialMultiPointsDataFrame "object_" "branch_" "x_" "y_"
- sf some combination of the above

Examples

## holey is a decomposed SpatialPolygonsDataFrame  
spdata <- sp(holey)
library(sp)
plot(spdata, col = rainbow(nrow(spdata), alpha = 0.4))
points(holey$x_, holey$y_, cex = 4)
holes <- subset(holey, !island_)  
## add the points that only belong to holes  
points(holes$x_, holes$y_, pch = "*", cex = 2)
## manipulate based on topology
## convert to not-holes
notahole <- holes
notahole$island_ <- TRUE
# also convert to singular objects - note that this now means we have an overlapping pair of polys
# because the door had a hole filled by another object
notahole$object_ <- notahole$branch_
plot(sp(notahole), add = TRUE, col = "red")

## example using in-place modification with sptable<-
library(maptools)
data(wrld_simpl)
spdata2 <- spdata
library(dplyr)
# modify the geometry on this object without separating the vertices from the objects
sptable(spdata2) <- sptable(spdata2) %>% dplyr::mutate(x_ = x_ + 10, y_ = y_ + 5)

---

**track**

*Multi-object track with x, y, z, and time.*

**Description**

Created in /data-raw/track.r
