Package ‘sperrorest’

March 27, 2018

Type Package

Title Perform Spatial Error Estimation and Variable Importance in Parallel

Description Implements spatial error estimation and permutation-based variable importance measures for predictive models using spatial cross-validation and spatial block bootstrap.

Version 2.1.5

Date 2018-03-26

BugReports https://github.com/pat-s/sperrorest/issues

Depends R (>= 2.10)

Suggests ipred, nnet, RSAGA, knitr, testthat, pacman, rmarkdown

Imports pbapply, pbmcapply, magrittr, future.apply, future, doFuture, foreach, ROCR, parallel, graphics, stats, rpart, purrr, stringr, gdata, glue

License GPL-3

This package implements spatial error estimation and permutation-based spatial variable importance using different spatial cross-validation and spatial block bootstrap methods. To cite ‘sperrorest’ in publications, reference the paper by Brenning (2012).
add.distance

References

add.distance

Add distance information to resampling objects

Description

Add distance information to resampling objects

Usage

add.distance(object, ...)

## S3 method for class 'resampling'
add.distance(object, data, coords = c("x", "y"), ...)

## S3 method for class 'represampling'
add.distance(object, ..., )

Arguments

object resampling or represampling object.

... Additional arguments to dataset_distance and add.distance.resampling, respectively.

data data.frame containing at least the columns specified by coords.

coords (ignored by partition_cv)

Details

Nearest-neighbour distances are calculated for each sample in the test set. These nrow(test) nearest-neighbour distances are then averaged. Aggregation methods other than mean can be chosen using the fun argument, which will be passed on to dataset_distance.
Value

A `resampling` or `represampling` object containing an additional `$distance` component in each `resampling` object. The distance component is a single numeric value indicating, for each train/test pair, the (by default, mean) nearest-neighbour distance between the two sets.

See Also

dataset_distance represampling resampling

Examples

data(ecuador) # Muenchow et al. (2012), see ?ecuador
nsp.parti <- partition_cv(ecuador)
sp.parti <- partition_kmeans(ecuador)
nsp.parti <- add.distance(nsp.parti, ecuador)
sp.parti <- add.distance(sp.parti, ecuador)
# non-spatial partitioning: very small test-training distance:
  nsp.parti[[1]][[1]]$distance
# spatial partitioning: more substantial distance, depending on number of
# folds etc.
sp.parti[[1]][[1]]$distance

as_represampling

Resampling objects with repetition, i.e. sets of partitionings or bootstrap samples

Description

Functions for handling represampling objects, i.e. lists of `resampling` objects.

Usage

as_represampling(object, ...)

## S3 method for class 'list'
as_represampling(object, ...)

## S3 method for class 'represampling'
print(x, ...)

is_represampling(object)

Arguments

object object of class represampling, or a list to be coerced to this class.
...
currently not used.
x object of class represampling.
Details

represampling objects are (names) lists of represampling objects. Such objects are typically created by partition_cv, partition_kmeans, represampling_disc_bootstrap and related functions.

In r-repeated k-fold cross-validation, for example, the corresponding represampling object has length r, and each of its r represampling objects has length k.

as.resampling_list coerces object to class represampling while coercing its elements to represampling objects. Some validity checks are performed.

Value

as.represampling methods return an object of class represampling with the contents of object.

See Also

resampling, partition_cv, partition_kmeans, represampling_disc_bootstrap, etc.

Examples

data(ecuador) # Muenchow et al. (2012), see ?ecuador
# Partitioning by elevation classes in 200 m steps:
fac <- factor( as.character( floor( ecuador$dem / 300 ) ) )
summary(fac)
parti <- as.resampling(fac)
# a list of lists specifying sets of training and test sets,
# using each factor at a time as the test set:
str(parti)
summary(parti)
as.resampling(object, ...)  

validate.resampling(object)  

is.resampling(x, ...)  

## S3 method for class 'resampling'  
print(x, ...)  

Arguments  

object  
depending on the function/method, a list or a vector of type factor defining a partitioning of the dataset.  

...  
currently not used.  

x  
object of class resampling.  

Details  

A resampling object is a list of lists defining a set of training and test samples.  

In the case of k-fold cross-validation partitioning, for example, the corresponding resampling object would be of length k, i.e. contain k lists. Each of these k lists defines a training set of size \( n(k-1)/k \) (where \( n \) is the overall sample size), and a test set of size \( n/k \). The resampling object does, however, not contain the data itself, but only indices between 1 and \( n \) identifying the selection (see Examples).  

Another example is bootstrap resampling. represampling_bootstrap with argument oob = TRUE generates resampling objects with indices of a bootstrap sample in the train component and indices of the out-of-bag sample in the test component (see Examples below).  

as.resampling.factor: For each factor level of the input variable, as.resampling.factor determines the indices of samples in this level (= test samples) and outside this level (= training samples). Empty levels of object are dropped without warning.  

as.resampling_list checks if the list in object has a valid resampling object structure (with components train and test etc.) and assigns the class attribute 'resampling' if successful.  

Value  

as.resampling methods: An object of class resampling.  

See Also  

represampling, partition_cv, partition_kmeans, represampling_bootstrap, etc.  

Examples  

data(ecuador) # Muenchow et al. (2012), see ?ecuador  

# Partitioning by elevation classes in 200 m steps:  
parti <- factor( as.character( floor( ecuador$dem / 200 ) ) )  
smp <- as.resampling(parti)
as.tilename

Summary

Functions for generating and handling alphanumeric tile names of the form 'X2:Y7' as used by partition_tiles and represampling_tile_bootstrap.

Usage

as.tilename(x, ...)

## S3 method for class 'numeric'
as.tilename(x, ...)

## S3 method for class 'tilename'
as.character(x, ...)

## S3 method for class 'tilename'
as.numeric(x, ...)

## S3 method for class 'tilename'
as.tilename(x, ...)

## S3 method for class 'tilename'
print(x, ...)
Arguments

- `x` object of class `tilename`, `character`, or `numeric` (of length 2).
- ... additional arguments (currently ignored).

Value

object of class `tilename`, `character`, or `numeric` vector of length 2

See Also

`partition_tiles`, `represampling`, `represampling_tile_bootstrap`

Examples

```r
tnm <- as.tilename(c(2,3))
tnm # 'X2:Y3'
as.numeric(tnm) # c(2,3)
```

---

**dataset_distance**

*Calculate mean nearest-neighbour distance between point datasets*

Description

dataset_distance calculates Euclidean nearest-neighbour distances between two point datasets and summarizes these distances using some function, by default the mean.

Usage

```r
dataset_distance(d1, d2, x_name = "x", y_name = "y", fun = mean, method = "euclidean", ...)
```

Arguments

- `d1` a data.frame with (at least) columns with names given by `x_name` and `y_name`; these contain the x and y coordinates, respectively.
- `d2` see `d1` - second set of points
- `x_name` name of column in `d1` and `d2` containing the x coordinates of points.
- `y_name` same for y coordinates
- `fun` function to be applied to the vector of nearest-neighbor distances of `d1` from `d2`.
- `method` type of distance metric to be used; only 'euclidean' is currently supported.
- ... additional arguments to `fun`.

Details

Nearest-neighbour distances are calculated for each point in `d1`, resulting in a vector of length `nrow(d1)`, and `fun` is applied to this vector.
**Value**

depends on fun; typically (e.g., mean) a numeric vector of length 1

**See Also**

add.distance

**Examples**

```r
df <- data.frame(x = rnorm(100), y = rnorm(100))
dataset_distance(df, df) # == 0
```

**Description**

Calculate a variety of accuracy measures from observations and predictions of numerical and categorical response variables.

**Usage**

```r
err_default(obs, pred)
```

**Arguments**

- `obs`: factor, logical, or numeric vector with observations
- `pred`: factor, logical, or numeric vector with predictions. Must be of same type as `obs` with the exception that `pred` may be numeric if `obs` is factor or logical (‘soft’ classification).

**Value**

A list with (currently) the following components, depending on the type of prediction problem:

- **‘hard’ classification**
  - misclassification error, overall accuracy; if two classes, sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), kappa
- **‘soft’ classification**
  - area under the ROC curve, error and accuracy at a obs>0.5 dichotomization, false-positive rate (FPR; 1-specificity) at 70, 80 and 90 percent sensitivity, true-positive rate (sensitivity) at 80, 90 and 95 percent specificity
- **regression**
  - bias, standard deviation, mean squared error, MAD (mad), median, interquartile range (IQR) of residuals
get_small_tiles

Identify small partitions that need to be fixed.

Description

get_small_tiles identifies partitions (tiles) that are too small according to some defined criterion / criteria (minimum number of samples in tile and/or minimum fraction of entire dataset).

Usage

get_small_tiles(tile, min_n = NULL, min_frac = 0, ignore = c())

Arguments

tile factor: tile/partition names for all samples; names must be coercible to class tilename, i.e. of the form 'X4:Y2' etc.

min_n integer (optional): minimum number of samples per partition_

min_frac numeric >0, <1: minimum relative size of partition as percentage of sample.

ignore character vector: names of tiles to be ignored, i.e. to be retained even if the inclusion criteria are not met.

Value

character vector: names of tiles that are considered 'small' according to these criteria

See Also

partition_tiles, tilename
Examples

data(ecuador) # Muenchow et al. (2012), see ?ecuador
# Rectangular partitioning without removal of small tiles:
parti <- partition_tiles(ecuador, nsplit = c(10, 10), reassign = FALSE)
summary(parti)
length(parti[[1]])
# Same in factor format for the application of get_small_tiles:
parti_fac <- partition_tiles(ecuador, nsplit = c(10, 10), reassign = FALSE,
return_factor = TRUE)
get_small_tiles(parti_fac[[1]], min_n = 20) # tiles with less than 20 samples
parti2 <- partition_tiles(ecuador, nsplit = c(10, 10), reassign = TRUE,
min_n = 20, min_frac = 0)
length(parti2[[1]]) < length(parti[[1]])

Description

partition_cv creates a represampling object for length(repetition)-repeated nfold-fold cross-validation.

Usage

partition_cv(data, coords = c("x", "y"), nfold = 10, repetition = 1,
seed1 = NULL, return_factor = FALSE)

Arguments

data data.frame containing at least the columns specified by coords
coords (ignored by partition_cv)
nfold number of partitions (folds) in nfold-fold cross-validation partitioning
repetition numeric vector: cross-validation repetitions to be generated. Note that this is not the number of repetitions, but the indices of these repetitions. E.g., use repetition = c(1:100) to obtain the 'first' 100 repetitions, and repetition = c(101:200) to obtain a different set of 100 repetitions.
seed1 seed1+i is the random seed that will be used by set.seed in repetition i (i in repetition) to initialize the random number generator before sampling from the data set.
return_factor if FALSE (default), return a represampling object; if TRUE (used internally by other sperrorest functions), return a list containing factor vectors (see Value)

Details

This function does not actually perform a cross-validation or partition the data set itself; it simply creates a data structure containing the indices of training and test samples.
Value

If `return_factor = FALSE` (the default), a `represampling` object. Specifically, this is a (named) list of length(`repetition`) resampling objects. Each of these `resampling` objects is a list of length `nfold` corresponding to the folds. Each fold is represented by a list of containing the components `train` and `test`, specifying the indices of training and test samples (row indices for `data`). If `return_factor = TRUE` (mainly used internally), a (named) list of length `length(repetition)`. Each component of this list is a vector of length `nrow(data)` of type `factor`, specifying for each sample the fold to which it belongs. The factor levels are `factor(1:nfold)`.

See Also

`sperrorest`, `represampling`

Examples

data(ecuador)
## non-spatial cross-validation:
resamp <- partition_cv(ecuador, nfold = 5, repetition = 5)
# plot(resamp, ecuador)
# first repetition, second fold, test set indices:
idx <- resamp[[1]][[2]]$test
# test sample used in this particular repetition and fold:
ecuador[idx, ]

---

**partition_cv_strat**  
*Partition the data for a stratified (non-spatial) cross-validation*

Description

`partition_cv_strat` creates a set of sample indices corresponding to cross-validation test and training sets.

Usage

`partition_cv_strat(data, coords = c("x", "y"), nfold = 10,`
`return_factor = FALSE, repetition = 1, seed1 = NULL, strat)`

Arguments

- `data`: data.frame containing at least the columns specified by `coords`
- `coords`: vector of length 2 defining the variables in `data` that contain the x and y coordinates of sample locations
- `nfold`: number of partitions (folds) in `nfold`-fold cross-validation partitioning
- `return_factor`: if FALSE (default), return a `represampling` object; if TRUE (used internally by other `sperrorest` functions), return a list containing factor vectors (see Value)
partition_disc

repetition numeric vector: cross-validation repetitions to be generated. Note that this is not the number of repetitions, but the indices of these repetitions. E.g., use repetition = c(1:100) to obtain (the 'first') 100 repetitions, and repetition = c(101:200) to obtain a different set of 100 repetitions.

seed1 seed1+i is the random seed that will be used by set.seed in repetition i (i in repetition) to initialize the random number generator before sampling from the data set.

strat character: column in data containing a factor variable over which the partitioning should be stratified; or factor vector of length nrow(data): variable over which to stratify

Value

A represampling object, see also partition_cv, partition_strat_cv, however, stratified with respect to the variable data[,strat]; i.e., cross-validation partitioning is done within each set data[datat, strat]=i,] (i in levels(data[, strat]), and the ith folds of all levels are combined into one cross-validation fold.

See Also

sperrorest, as_resampling, resample_strat_uniform

Examples

data(ecuador)
 parti <- partition_cv_strat(ecuador, strat = 'slides', nfold = 5, repetition = 1)
 idx <- parti[['1']]$train
 mean(ecuador$slides[idx] == 'TRUE') / mean(ecuador$slides == 'TRUE')
 # always == 1
 # Non-stratified cross-validation:
 parti <- partition_cv(ecuador, nfold = 5, repetition = 1)
 idx <- parti[['1']]$train
 mean(ecuador$slides[idx] == 'TRUE') / mean(ecuador$slides == 'TRUE')
 # close to 1 because of large sample size, but with some random variation

partition_disc Leave-one-disc-out cross-validation and leave-one-out cross-validation

Description

partition_disc partitions the sample into training and tests set by selecting circular test areas (possibly surrounded by an exclusion buffer) and using the remaining samples as training samples (leave-one-disc-out cross-validation). partition_loo creates training and test sets for leave-one-out cross-validation with (optional) buffer.
Usage

```
partition_disc(data, coors = c("x", "y"), radius, buffer = NULL,
    ndisc = nrow(data), seed1 = NULL, return_train = TRUE, prob = NULL,
    replace = FALSE, repetition = 1)
```

```
partition_loo(data, ndisc = nrow(data), replace = FALSE, ...)
```

Arguments

- **data**: `data.frame` containing at least the columns specified by `coords`
- **coords**: vector of length 2 defining the variables in `data` that contain the x and y coordinates of sample locations.
- **radius**: radius of test area discs; performs leave-one-out resampling if radius <0.
- **buffer**: radius of additional 'neutral area' around test area discs that is excluded from training and test sets; defaults to 0, i.e. all samples are either in the test area or in the training area.
- **ndisc**: Number of discs to be randomly selected; each disc constitutes a separate test set. Defaults to `nrow(data)`, i.e. one disc around each sample.
- **seed1**: `seed1+i` is the random seed that will be used by `set.seed` in repetition `i` (i in `repetition`) to initialize the random number generator before sampling from the data set.
- **return_train**: If `FALSE`, returns only test sample; if `TRUE`, also the training area.
- **prob**: optional argument to `sample`.
- **replace**: optional argument to `sample`: sampling with or without replacement?
- **repetition**: see `partition_cv`; however, see Note below: `repetition` should normally be = 1 in this function.
- **...**: arguments to be passed to `partition_disc`

Value

A `resampling` object. Contains `length(repetition)` resampling objects. Each of these contains `ndisc` lists with indices of test and (if `return_train = TRUE`) training sets.

Note

Test area discs are centered at (random) samples, not at general random locations. Test area discs may (and likely will) overlap independently of the value of `replace`. `replace` only controls the replacement of the center point of discs when drawing center points from the samples.

- `radius < 0` does leave-one-out resampling with an optional buffer. `radius = 0` is similar except that samples with identical coordinates would fall within the test area disc.

References

**partition_factor**

See Also

sperrorest, partition_cv, partition_kmeans

Examples

```r
data(ecuador)
parti <- partition_disc(ecuador, radius = 200, buffer = 200,
                        ndisc = 5, repetition = 1:2)
# plot(parti,ecuador)
summary(parti)

# leave-one-out with buffer:
parti.loo <- partition_loo(ecuador, buffer = 200)
summary(parti)
```

**partition_factor**

Partition the data for a (non-spatial) leave-one-factor-out cross-validation based on a given, fixed partitioning

Description

`partition_factor` creates a represampling object, i.e. a set of sample indices defining cross-validation test and training sets.

Usage

```r
partition_factor(data, coords = c("x", "y"), fac, return_factor = FALSE,
                 repetition = 1)
```

Arguments

- **data** `data.frame` containing at least the columns specified by `coords`
- **coords** vector of length 2 defining the variables in `data` that contain the x and y coordinates of sample locations.
- **fac** either the name of a variable (column) in `data`, or a vector of type factor and length `nrow(data)` that contains the partitions to be used for defining training and test samples.
- **return_factor** if FALSE (default), return a represampling object; if TRUE (used internally by other sperrorest functions), return a list containing factor vectors (see Value)
- **repetition** numeric vector: cross-validation repetitions to be generated. Note that this is not the number of repetitions, but the indices of these repetitions. E.g., use `repetition = c(1:100)` to obtain (the 'first') 100 repetitions, and `repetition = c(101:200)` to obtain a different set of 100 repetitions.

Value

A represampling object, see also `partition_cv` for details.
**Note**

In this partitioning approach, all repetitions are identical and therefore pseudo-replications.

**See Also**

`sperrorest, partition_cv, as.resampling.factor`

**Examples**

```r
data(ecuador)
# I don't recommend using this partitioning for cross-validation,
# this is only for demonstration purposes:
breaks <- quantile(ecuador$dem, seq(0, 1, length = 6))
ecuador$zclass <- cut(ecuador$dem, breaks, include.lowest = TRUE)
summary(ecuador$zclass)
parti <- partition_factor(ecuador, fac = 'zclass')
# plot(parti, ecuador)
summary(parti)
```

---

**partition_factor_cv**  
*Partition the data for a (non-spatial) k-fold cross-validation at the group level*

**Description**

`partition_factor_cv` creates a *represampling* object, i.e. a set of sample indices defining cross-validation test and training sets, where partitions are obtained by resampling at the level of groups of observations as defined by a given factor variable. This can be used, for example, to resample agricultural data that is grouped by fields, at the agricultural field level in order to preserve spatial autocorrelation within fields.

**Usage**

```r
partition_factor_cv(data, coords = c("x", "y"), fac, nfold = 10,
                    repetition = 1, seed = NULL, return_factor = FALSE)
```

**Arguments**

- **data**  
  data frame containing at least the columns specified by `coords`

- **coords**  
  vector of length 2 defining the variables in `data` that contain the x and y coordinates of sample locations.

- **fac**  
  either the name of a variable (column) in `data`, or a vector of type factor and length `nrow(data)` that defines groups or clusters of observations.

- **nfold**  
  number of partitions (folds) in `nfold`-fold cross-validation partitioning
repetition numeric vector: cross-validation repetitions to be generated. Note that this is not the number of repetitions, but the indices of these repetitions. E.g., use repetition = c(1:100) to obtain (the 'first') 100 repetitions, and repetition = c(101:200) to obtain a different set of 100 repetitions.

seed1 seed1+i is the random seed that will be used by set.seed in repetition i (i in repetition) to initialize the random number generator before sampling from the data set.

return_factor if FALSE (default), return a represampling object; if TRUE (used internally by other sperrorest functions), return a list containing factor vectors (see Value)

Value

A represampling object, see also partition_cv for details.

Note

In this partitioning approach, the number of factor levels in fac must be large enough for this factor-level resampling to make sense.

See Also

sperrorest, partition_cv, partition_factor, as.resampling.factor

Description

partition_kmeans divides the study area into irregularly shaped spatial partitions based on k-means (kmeans) clustering of spatial coordinates.

Usage

partition_kmeans(data, coords = c("x", "y"), nfold = 10, repetition = 1, seed1 = NULL, return_factor = FALSE, balancing_steps = 1, order_clusters = TRUE, ...)

Arguments

data data.frame containing at least the columns specified by coords

coords vector of length 2 defining the variables in data that contain the x and y coordinates of sample locations.

nfold number of cross-validation folds, i.e. parameter k in k-means clustering.

repetition numeric vector: cross-validation repetitions to be generated. Note that this is not the number of repetitions, but the indices of these repetitions. E.g., use repetition = c(1:100) to obtain (the 'first') 100 repetitions, and repetition = c(101:200) to obtain a different set of 100 repetitions.
seed

seed1+i is the random seed that will be used by `set.seed` in repetition i (i in repetition) to initialize the random number generator before sampling from the data set.

return_factor

if FALSE (default), return a `represampling` object; if TRUE (used internally by other sperrorest functions), return a list containing factor vectors (see Value)

balancing_steps

if > 1, perform nfold-means clustering balancing_steps times, and pick the clustering that minimizes the Gini index of the sample size distribution among the partitions. The idea is that ‘degenerate’ partitions will be avoided, but this also has the side effect of reducing variation among partitioning repetitions. More meaningful constraints (e.g., minimum number of positive and negative samples within each partition should be added in the future.

order_clusters

if TRUE, clusters are ordered by increasing x coordinate of center point.

... additional arguments to `kmeans`.

Value

A `represampling` object, see also `partition_cv` for details.

Note

Default parameter settings may change in future releases.

References

`sperrorest, partition_cv, partition_disc, partition_tiles, kmeans`

Examples

data(ecuador)
resamp <- partition_kmeans(ecuador, nfold = 5, repetition = 2)
# plot(resamp, ecuador)
**partition_tiles**  
*Partition the study area into rectangular tiles*

**Description**

**partition_tiles** divides the study area into a specified number of rectangular tiles. Optionally small partitions can be merged with adjacent tiles to achieve a minimum number or percentage of samples in each tile.

**Usage**

```r
partition_tiles(data, coords = c("x", "y"), dsplit = NULL, nsplit = NULL, rotation = c("none", "random", "user"), user_rotation, offset = c("none", "random", "user"), user_offset, reassign = TRUE, min_frac = 0.025, min_n = 5, iterate = 1, return_factor = FALSE, repetition = 1, seed1 = NULL)
```

**Arguments**

- **data**  
  data.frame containing at least the columns specified by `coords`.

- **coords**  
  vector of length 2 defining the variables in `data` that contain the x and y coordinates of sample locations.

- **dsplit**  
  optional vector of length 2: equidistance of splits in (possibly rotated) x direction (`dsplit[1]`) and y direction (`dsplit[2]`) used to define tiles. If `dsplit` is of length 1, its value is recycled. Either `dsplit` or `nsplit` must be specified.

- **nsplit**  
  optional vector of length 2: number of splits in (possibly rotated) x direction (`nsplit[1]`) and y direction (`nsplit[2]`) used to define tiles. If `nsplit` is of length 1, its value is recycled.

- **rotation**  
  indicates whether and how the rectangular grid should be rotated; random rotation is only between −45 and +45 degrees.

- **user_rotation**  
  if `rotation='user'`, angles (in degrees) by which the rectangular grid is to be rotated in each repetition. Either a vector of same length as `repetition`, or a single number that will be replicated `length(repetition)` times.

- **offset**  
  indicates whether and how the rectangular grid should be shifted by an offset.

- **user_offset**  
  if `offset='user'`, a list (or vector) of two components specifying a shift of the rectangular grid in (possibly rotated) x and y direction. The offset values are relative values, a value of 0.5 resulting in a one-half tile shift towards the left, or upward. If this is a list, its first (second) component refers to the rotated x (y) direction, and both components must have same length as `repetition` (or length 1). If a vector of length 2 (or list components have length 1), the two values will be interpreted as relative shifts in (rotated) x and y direction, respectively, and will therefore be recycled as needed (`length(repetition)` times each).
reassign logical (default TRUE): if TRUE, 'small' tiles (as per min_frac and min_n arguments and get_small_tiles) are merged with (smallest) adjacent tiles. If FALSE, small tiles are 'eliminated', i.e. set to NA.

min_frac numeric >=0, <1: minimum relative size of partition as percentage of sample; argument passed to get_small_tiles. Will be ignored if NULL.

min_n integer >=0: minimum number of samples per partition; argument passed to get_small_tiles. Will be ignored if NULL.

iterate argument to be passed to tile_neighbors

return_factor if FALSE (default), return a represampling object; if TRUE (used internally by other sperrorest functions), return a list containing factor vectors (see Value)

repetition numeric vector: cross-validation repetitions to be generated. Note that this is not the number of repetitions, but the indices of these repetitions. E.g., use repetition = c(1:100) to obtain (the 'first') 100 repetitions, and repetition = c(101:200) to obtain a different set of 100 repetitions.

seed1 seed1+i is the random seed that will be used by set.seed in repetition i (i in repetition) to initialize the random number generator before sampling from the data set.

Value

A represampling object. Contains length(repetition) resampling objects as repetitions. The exact number of folds / test-set tiles within each resampling objects depends on the spatial configuration of the data set and possible cleaning steps (see min_frac, min_n).

Note

Default parameter settings may change in future releases. This function, especially the rotation and shifting part of it and the algorithm for cleaning up small tiles is still a bit experimental. Use with caution. For non-zero offsets (offsetA‘none’), the number of tiles may actually be greater than nsplit[1]*nsplit[2] because of fractional tiles lurking into the study region. reassign=TRUE with suitable thresholds is therefore recommended for non-zero (including random) offsets.

sperrorest, as.resampling.factor, get_small_tiles, tile_neighbors

Examples

data(ecuador)
parti <- partition_tiles(ecuador, nsplit = c(4, 3), reassign = FALSE)
# plot(parti,ecuador)
summary(parti) # tile A4 has only 55 samples
# same partitioning, but now merge tiles with less than 100 samples to
# adjacent tiles:
parti2 <- partition_tiles(ecuador, nsplit = c(4,3), reassign = TRUE,
min_n = 100)
# plot(parti2,ecuador)
summary(parti2)
# tile B4 (in 'parti') was smaller than A3, therefore A4 was merged with B4,
# not with A3
# now with random rotation and offset, and tiles of 2000 m length:
parti3 <- partition_tiles(ecuador, dsplit = 2000, offset = 'random',
rotation = 'random', reassign = TRUE, min_n = 100)
# plot(parti3, ecuador)
summary(parti3)

plot.represampling  Plot spatial resampling objects

Description
plot.represampling displays the partitions or samples corresponding arising from the resampling
of a data set.

Usage
## S3 method for class 'represampling'
plot(x, data, coords = c("x", "y"), pch = "+",
wiggle_sd = 0, ...)

## S3 method for class 'resampling'
plot(x, ...)

Arguments
x
  a represampling resp. resampling object.
data
  a data.frame of samples containing at least the x and y coordinates of samples
  as specified by coords.
coords
  vector of length 2 defining the variables in data that contain the x and y coordi-
nates of sample locations.
pch
  point symbol (to be passed to points).
wiggle_sd
  'wiggle' the point locations in x and y direction to avoid overplotting of sam-
  ples drawn multiple times by bootstrap methods; this is a standard deviation (in
  the units of the x/y coordinates) of a normal distribution and defaults to 0 (no
  wiggling).
...
  additional arguments to plot.

Note
This function is not intended for samples obtained by resampling with replacement (e.g., bootstrap)
because training and test points will be overplotted in that case. The size of the plotting region will
also limit the number of maps that can be displayed at once, i.e., the number of rows (repetitions)
and fields (columns).
Examples

data(ecuador)
# non-spatial cross-validation:
resamp <- partition_cv(ecuador, nfold = 5, repetition = 1:2)
# plot(resamp, ecuador)
# spatial cross-validation using k-means clustering:
resamp <- partition_kmeans(ecuador, nfold = 5, repetition = 1:2)
# plot(resamp, ecuador)

represampling_bootstrap

Non-spatial bootstrap resampling

Description

represampling_bootstrap draws a bootstrap random sample (with replacement) from data.

Usage

represampling_bootstrap(data, coords = c("x", "y"), nboot = nrow(data),
  repetition = 1, seed1 = NULL, oob = FALSE)

Arguments

data  data.frame containing at least the columns specified by coords
coords vector of length 2 defining the variables in data that contain the x and y coordinates of sample locations.
nboot  Size of bootstrap sample
repetition numeric vector: cross-validation repetitions to be generated. Note that this is not the number of repetitions, but the indices of these repetitions. E.g., use repetition = c(1:100) to obtain the 'first' 100 repetitions, and repetition = c(101:200) to obtain a different set of 100 repetitions.
seed1  seed1+i is the random seed that will be used by set.seed in repetition i (i in repetition) to initialize the random number generator before sampling from the data set.
oob logical (default FALSE): if TRUE, use the out-of-bag sample as the test sample; if FALSE, draw a second bootstrap sample of size nboot independently to obtain a test sample.

Value

A represampling object. This is a (named) list containing length(repetition). resampling objects. Each of these contains only one list with indices of training and test samples. Indices are row indices for data.
represampling_disc_bootstrap

Description

represampling_disc_bootstrap performs a spatial block bootstrap by resampling at the level of rectangular partitions or 'tiles' generated by partition_tiles.

Usage

represampling_disc_bootstrap(data, coords = c("x", "y"), nboot, repetition = 1, seed1 = NULL, oob = FALSE, ...)

Arguments

data: data.frame containing at least the columns specified by coords
coords: vector of length 2 defining the variables in data that contain the x and y coordinates of sample locations.
nboot: number of bootstrap samples; you may specify different values for the training sample (nboot[1]) and for the test sample (nboot[2]).
repetition: numeric vector: cross-validation repetitions to be generated. Note that this is not the number of repetitions, but the indices of these repetitions. E.g., use repetition = c(1:100) to obtain (the 'first') 100 repetitions, and repetition = c(101:200) to obtain a different set of 100 repetitions.
seed1: seed1+i is the random seed that will be used by set.seed in repetition i (i in repetition) to initialize the random number generator before sampling from the data set.
oob: logical (default FALSE): if TRUE, use the out-of-bag sample as the test sample (the complement of the nboot[1] test set discs, minus the buffer area as specified in the ... arguments to partition_disc); if FALSE, draw a second bootstrap sample of size nboot independently to obtain a test sample (sets of overlapping discs drawn with replacement).
...: additional arguments to be passed to partition_disc; note that a buffer argument has not effect if oob=FALSE; see example below
Note

Performs nboot out of nrow(data) resampling of circular discs. This is an overlapping spatial block bootstrap where the blocks are circular.

Examples

data(ecuador)
# Overlapping disc bootstrap:
parti <- represampling_disc_bootstrap(ecuador, radius = 200, nboot = 20, oob = FALSE)
# plot(parti, ecuador)
# Note that a 'buffer' argument would make no difference because bootstrap sets of discs are drawn independently for the training and test sample.
#
# Overlapping disc bootstrap for training sample, out-of-bag sample as test sample:
parti <- represampling_disc_bootstrap(ecuador, radius = 200, buffer = 200, nboot = 10, oob = TRUE)
# plot(parti,ecuador)

represampling_factor_bootstrap

Bootstrap at an aggregated level

Description

represampling_factor_bootstrap resamples partitions defined by a factor variable. This can be used for non-overlapping block bootstraps and similar.

Usage

represampling_factor_bootstrap(data, fac, repetition = 1, nboot = -1, seed1 = NULL, oob = FALSE)

Arguments

data: data.frame containing at least the columns specified by coords
fac: defines a grouping or partitioning of the samples in data; three possible types: (1) the name of a variable in data (coerced to factor if not already a factor variable); (2) a factor variable (or a vector that can be coerced to factor); (3) a list of factor variables (or vectors that can be coerced to factor); this list must be of length length(repetition), and if it is named, the names must be equal to as.character(repetition); this list will typically be generated by a partition.* function with return_factor = TRUE (see Examples below)
represampling_factor_bootstrap

repetition numeric vector: cross-validation repetitions to be generated. Note that this is not the number of repetitions, but the indices of these repetitions. E.g., use repetition = c(1:100) to obtain (the 'first') 100 repetitions, and repetition = c(101:200) to obtain a different set of 100 repetitions.

nboot number of bootstrap replications used for generating the bootstrap training sample (nboot[1]) and the test sample (nboot[2]); nboot[2] is ignored (with a warning) if oob = TRUE. A value of -1 will be substituted with the number of levels of the factor variable, corresponding to an n out of n bootstrap at the grouping level defined by fac.

seed1 seed1+i is the random seed that will be used by set.seed in repetition i (i in repetition) to initialize the random number generator before sampling from the data set.

oob if TRUE, the test sample will be the out-of-bag sample; if FALSE (default), the test sample is an independently drawn bootstrap sample of size nboot[2].

Details

nboot refers to the number of groups (as defined by the factors) to be drawn with replacement from the set of groups. I.e., if fac is a factor variable, nboot would normally not be greater than nlevels(fac), nlevels(fac) being the default as per nboot = -1.

represampling_disc_bootstrap, represampling_tile_bootstrap

Examples

data(ecuador)
# a dummy example for demonstration, performing bootstrap
# at the level of an arbitrary factor variable:
parti <- represampling_factor_bootstrap(ecuador,
                                          factor(floor(ecuador$dem / 100)),
                                          oob = TRUE)

# plot(parti, ecuador)

# using the factor bootstrap for a non-overlapping block bootstrap
# (see also represampling_tile_bootstrap):
fac <- partition_tiles(ecuador, return_factor = TRUE, repetition = c(1:3),
                        dsplit = 500, min_n = 200, rotation = 'random',
                        offset = 'random')
parti <- represampling_factor_bootstrap(ecuador, fac, oob = TRUE,
                                         repetition = c(1:3))
# plot(parti, ecuador)
represampling_kmeans_bootstrap

Spatial block bootstrap at the level of spatial k-means clusters

Description

represampling_kmeans_bootstrap performs a non-overlapping spatial block bootstrap by resampling at the level of irregularly-shaped partitions generated by partition_kmeans.

Usage

represampling_kmeans_bootstrap(data, coords = c("x", "y"), repetition = 1, nfold = 10, nboot = nfold, seed1 = NULL, oob = FALSE, ...)

Arguments

data: data.frame containing at least the columns specified by coords
coords: vector of length 2 defining the variables in data that contain the x and y coordinates of sample locations.
repetition: numeric vector: cross-validation repetitions to be generated. Note that this is not the number of repetitions, but the indices of these repetitions. E.g., use repetition = c(1:100) to obtain (the 'first') 100 repetitions, and repetition = c(101:200) to obtain a different set of 100 repetitions.
nfold: see partition_kmeans
nboot: see represampling_factor_bootstrap
seed1: seed1+i is the random seed that will be used by set.seed in repetition i (i in repetition) to initialize the random number generator before sampling from the data set.
oob: see represampling_factor_bootstrap
...: additional arguments to be passed to partition_kmeans

represampling_tile_bootstrap

Spatial block bootstrap using rectangular blocks

Description

represampling_tile_bootstrap performs a non-overlapping spatial block bootstrap by resampling at the level of rectangular partitions or 'tiles' generated by partition_tiles.

Usage

represampling_tile_bootstrap(data, coords = c("x", "y"), repetition = 1, nboot = -1, seed1 = NULL, oob = FALSE, ...)

Arguments

data: data.frame containing at least the columns specified by coords
coords: vector of length 2 defining the variables in data that contain the x and y coordinates of sample locations.
repetition: numeric vector: cross-validation repetitions to be generated. Note that this is not the number of repetitions, but the indices of these repetitions. E.g., use repetition = c(1:100) to obtain (the 'first') 100 repetitions, and repetition = c(101:200) to obtain a different set of 100 repetitions.
nfold: see partition_kmeans
nboot: see represampling_factor_bootstrap
seed1: seed1+i is the random seed that will be used by set.seed in repetition i (i in repetition) to initialize the random number generator before sampling from the data set.
oob: see represampling_factor_bootstrap
...: additional arguments to be passed to partition_kmeans
resample_factor

Arguments

- **data**: data.frame containing at least the columns specified by `coords`.
- **coords**: vector of length 2 defining the variables in `data` that contain the x and y coordinates of sample locations.
- **repetition**: numeric vector: cross-validation repetitions to be generated. Note that this is not the number of repetitions, but the indices of these repetitions. E.g., use `repetition = c(1:100)` to obtain the first 100 repetitions, and `repetition = c(101:200)` to obtain a different set of 100 repetitions.
- **nboot**: see `represampling_factor_bootstrap`.
- **seed**: seed + i is the random seed that will be used by `set.seed` in repetition i (i in repetition) to initialize the random number generator before sampling from the data set.
- **oob**: see `represampling_factor_bootstrap`.
- **...**: additional arguments to be passed to `partition_tiles`.

---

**resample_factor**

*Draw uniform random (sub)sample at the group level*

---

**Description**

`resample_factor` draws a random (sub)sample (with or without replacement) of the groups or clusters identified by the `fac` argument.

**Usage**

```
resample_factor(data, param = list(fac = "class", n = Inf, replace = FALSE))
```

**Arguments**

- **data**: a `data.frame`, rows represent samples
- **param**: a list with the following components: `fac` is a factor variable of length `nrow(data)` or the name of a factor variable in `data`; `n` is a numeric value specifying the size of the subsample (in terms of groups, not observations); `replace` determines if resampling of groups is to be done with or without replacement.

**Details**

If `param$replace=FALSE`, a subsample of `min(param$n,nlevel(data[,fac]))` groups will be drawn from `data`. If `param$replace=TRUE`, the number of groups to be drawn is `param$n`.

**Value**

a `data.frame` containing a subset of the rows of `data`.

**See Also**

`resample_strat_uniform()`, `sample()`
resample_strat_uniform

Draw stratified random sample

Description

resample_strat_uniform draws a stratified random sample (with or without replacement) from the samples in data. Stratification is over the levels of data[, param$response]. The same number of samples is drawn within each level.

Usage

resample_strat_uniform(data, param = list(strat = "class", nstrat = Inf, replace = FALSE))

Arguments

data a data.frame, rows represent samples
param a list with the following components: strat is either the name of a factor variable in data that defines the stratification levels, or a vector of type factor and length nrow(data); n is a numeric value specifying the size of the subsample; replace determines if sampling is with or without replacement

Details

If param$replace=FALSE, a subsample of size min(param$n, nrow(data)) will be drawn from data. If param$replace=TRUE, the size of the subsample is param$n.

Value

a data.frame containing a subset of the rows of data.

See Also

resample_uniform(), sample()

Examples

data(ecuador) # Muenchow et al. (2012), see ?ecuador
d <- resample_strat_uniform(ecuador,
                         param = list(strat = 'slides', nstrat = 100))
nrow(d) # == 200
sum(d$slides == 'TRUE') # == 100
resample_uniform

Desciption

resample_uniform draws a random (sub)sample (with or without replacement) from the samples in data.

Usage

resample_uniform(data, param = list(n = Inf, replace = FALSE))

Arguments

data a data.frame, rows represent samples

param a list with the following components: n is a numeric value specifying the size of the subsample; replace determines if sampling is with or without replacement

Details

If param$replace=FALSE, a subsample of size min(param$n, nrow(data)) will be drawn from data. If param$replace=TRUE, the size of the subsample is param$n.

Value

a data.frame containing a subset of the rows of data.

See Also

resample_strat_uniform(), sample()

Examples

data(ecuador) # Muenchow et al. (2012), see ?ecuador
d <- resample_uniform(ecuador, param = list(strat = 'slides', n = 200))
nrow(d) # == 200  
sum(d$slides == 'TRUE')
sperrorest

Perform spatial error estimation and variable importance assessment in parallel

Description

sperrorest is a flexible interface for multiple types of parallelized spatial and non-spatial cross-validation and bootstrap error estimation and parallelized permutation-based assessment of spatial variable importance.

Usage

sperrorest(formula, data, coords = c("x", "y"), model_fun, model_args = list(), pred_fun = NULL, pred_args = list(), smp_fun = partition_cv, smp_args = list(), train_fun = NULL, train_param = NULL, test_fun = NULL, test_param = NULL, err_fun = err_default, imp_variables = NULL, imp_permutations = 1000, importance = !is.null(imp_variables), distance = FALSE, par_args = list(par_mode = "foreach", par_units = NULL, par_option = NULL), do_gc = 1, progress = "all", out_progress = "", benchmark = FALSE, ...

Arguments

formula  A formula specifying the variables used by the model. Only simple formulas without interactions or nonlinear terms should be used, e.g. y~x1+x2+x3 but not y~x1*x2+log(x3). Formulas involving interaction and nonlinear terms may possibly work for error estimation but not for variable importance assessment, but should be used with caution.

data  a data.frame with predictor and response variables. Training and test samples will be drawn from this data set by train_fun and test_fun, respectively.

coords  vector of length 2 defining the variables in data that contain the x and y coordinates of sample locations.

model_fun  Function that fits a predictive model, such as glm or rpart. The function must accept at least two arguments, the first one being a formula and the second a data.frame with the learning sample.

model_args  Arguments to be passed to model_fun (in addition to the formula and data argument, which are provided by sperrorest).

pred_fun  Prediction function for a fitted model object created by model. Must accept at least two arguments: the fitted object and a data.frame newdata with data on which to predict the outcome.

pred_args  (optional) Arguments to pred_fun (in addition to the fitted model object and the newdata argument, which are provided by sperrorest).

smp_fun  A function for sampling training and test sets from data. E.g. partition_kmeans for spatial cross-validation using spatial k-means clustering.
sperrorest

smp_args (optional) Arguments to be passed to smp_fun.

train_fun (optional) A function for resampling or subsampling the training sample in order to achieve, e.g., uniform sample sizes on all training sets, or maintaining a certain ratio of positives and negatives in training sets. E.g. resample_uniform or resample_strat_uniform.

train_param (optional) Arguments to be passed to resample_fun.

test_fun (optional) Like train_fun but for the test set.

test_param (optional) Arguments to be passed to test_fun.

err_fun A function that calculates selected error measures from the known responses in data and the model predictions delivered by pred_fun. E.g. err_default (the default).

imp_variables (optional; used if importance = TRUE). Variables for which permutation-based variable importance assessment is performed. If importance = TRUE and imp_variables == NULL, all variables in formula will be used.

imp_permutations (optional; used if importance = TRUE). Number of permutations used for variable importance assessment.

importance logical (default: FALSE): perform permutation-based variable importance assessment?

distance logical (default: FALSE): if TRUE, calculate mean nearest-neighbour distances from test samples to training samples using add.distance.represampling.

par_args list of parallelization parameters:

- par_mode: the parallelization mode. See details.
- par_units: the number of parallel processing units.
- par_option: optional future settings for par_mode = "future" or par_mode = "foreach".

do_gc numeric (default: 1): defines frequency of memory garbage collection by calling gc; if < 1, no garbage collection; if >= 1, run a gc after each repetition; if >= 2, after each fold.

progress character (default: all): Whether to show progress information (if possible). Default shows repetition, fold and (if enabled) variable importance progress for par_mode = "foreach" or par_mode = "sequential". Set to "rep" for repetition information only or FALSE for no progress information.

out_progress only used if par_mode = foreach: Write progress output to a file instead of console output. The default ("") results in console output for Unix-systems and file output ('sperrorest.progress.txt') in the current working directory for Windows systems. No console output is possible on Windows systems.

benchmark (optional) logical (default: FALSE): if TRUE, perform benchmarking and return sperrorestbenchmark object.

... Further options passed to makeCluster for par_mode = "foreach".

Details

By default sperrorest runs in parallel on all cores using foreach with the future backend. If this is not desired, specify par_units in par_args or set par_mode = "sequential".
Available parallelization modes include \texttt{par\_mode = "apply"} (calls \texttt{pbmclapply} on Unix, \texttt{parApply} on Windows) and \texttt{future} (\texttt{future\_lapply}). For the latter and \texttt{par\_mode = "foreach"}, \texttt{par\_option} (default to \texttt{multiprocess} and \texttt{cluster}, respectively) can be specified. See \texttt{plan} for further details.

**Value**

A list (object of class \texttt{sperrorest}) with (up to) six components:

- \texttt{error\_rep} a \texttt{sperrorestreperror} object containing predictive performances at the repetition level
- \texttt{error\_fold} a \texttt{sperroresterror} object containing predictive performances at the fold level
- \texttt{represampling} a \texttt{represampling()} object
- \texttt{importance} a \texttt{sperrorestimportance} object containing permutation-based variable importances at the fold level
- \texttt{benchmark} a \texttt{sperrorestbenchmark} object containing information on the system the code is running on, starting and finishing times, number of available CPU cores, parallelization mode, number of parallel units, and runtime performance
- \texttt{package\_version} a \texttt{sperrorestpackageversion} object containing information about the \texttt{sperrorest} package version

**Note**

Custom predict functions passed to \texttt{pred\_fun}, which consist of multiple custom defined child functions, must be defined in one function.

**summary.represampling**  
*Summary statistics for a resampling objects*

**Description**

Calculates sample sizes of training and test sets within repetitions and folds of a resampling or represampling object.

**Usage**

```r
## S3 method for class 'represampling'
summary(object, ...)
```

```r
## S3 method for class 'resampling'
summary(object, ...)
```

**Arguments**

- `object` A resampling or represampling object.
- `...` currently ignored.
Summary ofesperresterror

Value

A list of data.frames summarizing the sample sizes of training and test sets in each fold of each repetition.

Description

summary.sperroresterror calculates mean, standard deviation, median etc. of the calculated error measures at the specified level (overall, repetition, or fold). summary.sperrorestrepeerror does the same with the pooled error, at the overall or repetition level.

Usage

## S3 method for class 'sperroresterror'
summary(object, level = 0, pooled = TRUE,
na.rm = TRUE, ...)

Arguments

- `object`: sperroresterror resp. sperrorestcombinederror error object calculated by sperrorest
- `level`: Level at which errors are summarized: 0: overall; 1: repetition; 2: fold
- `pooled`: If TRUE (default), mean and standard deviation etc are calculated between fold-level error estimates. If FALSE, apply first a weighted.mean among folds before calculating mean, standard deviation etc among repetitions. See also Details.
- `na.rm`: Remove NA values? See mean etc.
- `...`: additional arguments (currently ignored)

Details

Let’s use an example to explain the error_rep argument. E.g., assume we are using 100-repeated 10-fold cross-validation. If error_rep = TRUE (default), the mean and standard deviation calculated when summarizing at level = 0 are calculated across the error estimates obtained for each of the 100*10 = 1000 folds. If error_rep = FALSE, mean and standard deviation are calculated across the 100 repetitions, using the weighted average of the fold-level errors to calculate an error value for the entire sample. This will essentially not affect the mean value but of course the standard deviation of the error. error_rep = FALSE is not recommended, it is mainly for testing purposes; when the test sets are small (as in leave-one-out cross-validation, in the extreme case), consider running sperrorest with error_rep = TRUE and examine only the error_rep component of its result.
Value

Depending on the level of aggregation, a list or data.frame with mean, and at level 0 also standard deviation, median and IQR of the error measures.

See Also

sperrorest

Description

summary.sperrorestimportance calculated mean, standard deviation, median etc. of the calculated error measures at the specified level (overall, repetition, or fold).

Usage

## S3 method for class 'sperrorestimportance'
summary(object, level = 0, na.rm = TRUE,
    which = NULL, ...)

Arguments

  object             sperrorestimportance object calculated by sperrorest called with argument importance = TRUE
  level              Level at which errors are summarized: 0: overall; 1: repetition; 2: fold
  na.rm              Remove NA values? See mean etc.
  which              optional character vector specifying selected variables for which the importances should be summarized (to do: check implementation)
  ...                additional arguments (currently ignored)

Value

a list or data.frame, depending on the level of aggregation
Summary methods provide varying level of detail while print methods provide full details.

## Usage

```r
## S3 method for class 'sperrorestreerror'
summary(object, level = 0, na.rm = TRUE, ...)

## S3 method for class 'sperrorest'
summary(object, ...)

## S3 method for class 'sperrorestimportance'
print(x, ...)

## S3 method for class 'sperroresterror'
print(x, ...)

## S3 method for class 'sperrorestreerror'
print(x, ...)

## S3 method for class 'sperrorest'
print(x, ...)

## S3 method for class 'sperrorestbenchmarks'
print(x, ...)

## S3 method for class 'sperrorestpackageversion'
print(x, ...)
```

### Arguments

- **object**: a `sperrorest` object
- **level**: Level at which errors are summarized: 0: overall; 1: repetition; 2: fold
- **na.rm**: Remove NA values? See `mean` etc.
- **...**: additional arguments for `summary.sperroresterror` or `summary.sperrorestimportance`
- **x**: Depending on method, a `sperrorest`, `sperroresterror` or `sperrorestimportance` object

- `sperrorest`, `summary.sperroresterror`, `summary.sperrorestimportance`
tile_neighbors

Determine the names of neighbouring tiles in a rectangular pattern

Description

This based on 'counting' up and down based on the tile name.

Usage

tile_neighbors(nm, tileset, iterate = 0, diagonal = FALSE)

Arguments

nm        Character string or factor: name of a tile, e.g., 'X4:Y6'
tileset   Admissible tile names; if missing and nm is a factor variable, then levels(nm) is used as a default for tileset.
iterate   internal - do not change default: to control behaviour in an interactive call to this function.
diagonal  if TRUE, diagonal neighbours are also considered neighbours.

Value

Character string.
