Package ‘srvyr’

January 20, 2019

Type  Package
Title  'dplyr'-Like Syntax for Summary Statistics of Survey Data
Description  Use piping, verbs like 'group_by' and 'summarize', and other 'dplyr' inspired syntactic style when calculating summary statistics on survey data using functions from the 'survey' package.
Version  0.3.4
Date  2019-01-19
BugReports  https://github.com/gergness/srvyr/issues
Depends  R (>= 3.1.2)
Imports  dplyr (>= 0.7), magrittr, rlang, survey, tibble
License  GPL-2 | GPL-3
LazyData  TRUE
Suggests  convey, DBI, dplyr, ggplot2, knitr, Matrix, rmarkdown, pander, RSQLite, MonetDBLite, survival, testthat, vardpoor
VignetteBuilder  knitr
RoxygenNote  6.1.1
NeedsCompilation  no
Author  Greg Freedman Ellis [aut, cre], Thomas Lumley [ctb]
Maintainer  Greg Freedman Ellis <greg.freedman@gmail.com>
Repository  CRAN
Date/Publication  2019-01-20 17:00:03 UTC

R topics documented:

  as_survey_rep  .......................................................... 6
as_survey

Create a tbl_svy from a data.frame

Description

as_survey can be used to create a tbl_svy using design information (as_survey_design), replicate weights (as_survey_rep), or a two phase design (as_survey_twophase), or an object created by the survey package.

Usage

as_survey(.data, ...)

## S3 method for class 'data.frame'
as_survey(.data, ...)

## S3 method for class 'tbl_lazy'
as_survey(.data, ...)

## S3 method for class 'survey.design2'
as_survey(.data, ...)

## S3 method for class 'svyrep.design'
as_survey

as_survey(.data, ...)

## S3 method for class 'twophase2'
as_survey(.data, ...)

Arguments

.data a data.frame or an object from the survey package
...
other arguments, see other functions for details

Details

See vignette("databases", package = "dplyr") for more information on setting up databases in dplyr.

Value

a tbl_svy

Examples

# Examples from ?survey::svydesign
library(survey)
library(dplyr)
data(api)

# stratified sample
dstrata <- apistrat %>%
  as_survey(strata = stype, weights = pw)

# Examples from ?survey::svrepdesign
data(scd)
# use BRR replicate weights from Levy and Lemeshow
scd$rep1 <- 2 * c(1, 0, 1, 0, 1, 0)
scd$rep2 <- 2 * c(1, 0, 0, 1, 0, 1)
scd$rep3 <- 2 * c(0, 1, 1, 0, 0, 1)
scd$rep4 <- 2 * c(0, 1, 0, 1, 1, 0)

cdrep <- scd %>%
  as_survey(type = "BRR", repweights = starts_with("rep"),
            combined_weights = FALSE)

# Examples from ?survey::twophase
# two-phase simple random sampling.
data(pbc, package="survival")

pbc <- pbc %>%
  mutate(randomized = !is.na(trt) & trt > 0,
         id = row_number())
d2pbc <- pbc %>%
  as_survey(id = list(id, id), subset = randomized)
as_survey_design

Create a tbl_svy survey object using sampling design

Description

Create a survey object with a survey design.

Usage

as_survey_design(.data, ...)

## S3 method for class 'data.frame'
as_survey_design(.data, ids = NULL, probs = NULL,
    strata = NULL, variables = NULL, fpc = NULL, nest = FALSE,
    check_strata = !nest, weights = NULL, pps = FALSE,
    variance = c("HT", "YG"), ...)

## S3 method for class 'survey.design2'
as_survey_design(.data, ...)

## S3 method for class 'tbl_lazy'
as_survey_design(.data, ids = NULL, probs = NULL,
    strata = NULL, variables = NULL, fpc = NULL, nest = FALSE,
    check_strata = !nest, weights = NULL, pps = FALSE,
    variance = c("HT", "YG"), ...)

Arguments

.data A data frame (which contains the variables specified below)

... ignored

.ids Variables specifying cluster ids from largest level to smallest level (leaving
    the argument empty, NULL, 1, or 0 indicate no clusters).

.probs Variables specifying cluster sampling probabilities.

.strata Variables specifying strata.

.variables Variables specifying variables to be included in survey. Defaults to all variables
    in .data

.fpc Variables specifying a finite population correct, see svydesign for more details.

.nest If TRUE, relabel cluster ids to enforce nesting within strata.
check_strata If TRUE, check that clusters are nested in strata.
weights Variables specifying weights (inverse of probability).
pps "brewer" to use Brewer's approximation for PPS sampling without replacement.
"overton" to use Overton's approximation. An object of class HR to use the Hartley-Rao approximation. An object of class ppsmat to use the Horvitz-Thompson estimator.
variance For pps without replacement, use variance="YG" for the Yates-Grundy estimator instead of the Horvitz-Thompson estimator

Details
If provided a data.frame, it is a wrapper around svydesign. All survey variables must be included in the data.frame itself. Variables are selected by using bare column names, or convenience functions described in select.
If provided a survey.design2 object from the survey package, it will turn it into a srvyr object, so that srvyr functions will work with it

Value
An object of class tbl_svy

Examples
# Examples from ?survey::svydesign
library(survey)
data(api)

# stratified sample
dstrata <- apistrat %>%
  as_survey_design(strata = stype, weights = pw)

# one-stage cluster sample
dclus1 <- apiclus1 %>%
  as_survey_design(dnum, weights = pw, fpc = fpc)

# two-stage cluster sample: weights computed from population sizes.
dclus2 <- apiclus2 %>%
  as_survey_design(c(dnum, snum), fpc = c(fpc1, fpc2))

## multistage sampling has no effect when fpc is not given, so
## these are equivalent.
dclus2wr <- apiclus2 %>%
dplyr::mutate(weights = weights(dclus2)) %>%
  as_survey_design(c(dnum, snum), weights = weights)

dclus2wr2 <- apiclus2 %>%
dplyr::mutate(weights = weights(dclus2)) %>%
  as_survey_design(c(dnum), weights = weights)

## syntax for stratified cluster sample
## though the data weren't really sampled this way
apistrat %>% as_survey_design(dnum, strata = stype, weights = pw, nest = TRUE)

## PPS sampling without replacement
data(election)
dpps <- election_pps %>%
as_survey_design(fpc = p, pps = "brewer")

# dplyr 0.7 introduced new style of NSE called quosures
# See `vignette("programming", package = "dplyr")` for details
st <- quo(stype)
wt <- quo(pw)
dstrata <- apistrat %>%
as_survey_design(strata = !!st, weights = !!wt)

---

**as_survey_rep**

Create a tbl_svy survey object using replicate weights

### Description

Create a survey object with replicate weights.

### Usage

```r
as_survey_rep(.data, ...)
```

#### S3 method for class 'data.frame'

```r
as_survey_rep(.data, variables = NULL, repweights = NULL, weights = NULL, type = c("BRR", "Fay", "JK1", "JKn", "bootstrap", "other"), combined_weights = TRUE, rho = NULL, bootstrap_average = NULL, scale = NULL, rscales = NULL, fpc = NULL, fpctype = c("fraction", "correction"), mse = getOption("survey.replicates.mse"), ...)
```

#### S3 method for class 'tbl_lazy'

```r
as_survey_rep(.data, variables = NULL, repweights = NULL, weights = NULL, type = c("BRR", "Fay", "JK1", "JKn", "bootstrap", "other"), combined_weights = TRUE, rho = NULL, bootstrap_average = NULL, scale = NULL, rscales = NULL, fpc = NULL, fpctype = c("fraction", "correction"), mse = getOption("survey.replicates.mse"), ...)
```

#### S3 method for class 'svyrep.design'

```r
as_survey_rep(.data, ...)
```

#### S3 method for class 'survey.design2'

```r
as_survey_rep(.data, ...)
```
Arguments

.data    A data frame (which contains the variables specified below)
...     ignored
variables Variables to include in the design (default is all)
repweights Variables specifying the replication weight variables
weights Variables specifying sampling weights
type     Type of replication weights
combined_weights TRUE if the repweights already include the sampling weights. This is usually the case.
rho     Shrinkage factor for weights in Fay’s method
bootstrap_average For type = "bootstrap", if the bootstrap weights have been averaged, gives the number of iterations averaged over.
scale, rscales Scaling constant for variance, see svrepdesign for more information.
fpc, fpctype Finite population correction information
mse     if TRUE, compute variances based on sum of squares around the point estimate, rather than the mean of the replicates
compress if TRUE, store replicate weights in compressed form (if converting from design)

Details

If provided a data.frame, it is a wrapper around svrepdesign. All survey variables must be included in the data.frame itself. Variables are selected by using bare column names, or convenience functions described in select.

If provided a svyrep.design object from the survey package, it will turn it into a srvyr object, so that srvyr functions will work with it.

If provided a survey design (survey.design2 or tbl_svy), it is a wrapper around as.svrepdesign, and will convert from a survey design to replicate weights.

Value

An object of class tbl_svy
as_survey_twophase

Create a tbl_svy survey object using two phase design

Description

Create a survey object by specifying the survey’s two phase design. It is a wrapper around \texttt{twophase}. All survey variables must be included in the data.frame itself. Variables are selected by using bare column names, or convenience functions described in \texttt{select}.

Usage

\begin{verbatim}
as_survey_twophase(.data, ...)

## S3 method for class 'data.frame'
as_survey_twophase(.data, id, strata = NULL,
  probs = NULL, weights = NULL, fpc = NULL, subset,
  method = c("full", "approx", "simple"), ...)

## S3 method for class 'twophase2'
as_survey_twophase(.data, ...)
\end{verbatim}

Arguments

\texttt{.data} \hspace{1cm} A data frame (which contains the variables specified below)
... ignored
id list of two sets of variable names for sampling unit identifiers
strata list of two sets of variable names (or NULLs) for stratum identifiers
probs list of two sets of variable names (or NULLs) for sampling probabilities
weights Only for method = "approx", list of two sets of variable names (or NULLs) for sampling weights
fpc list of two sets of variables (or NULLs for finite population corrections
subset bare name of a variable which specifies which observations are selected in phase 2
method "full" requires (much) more memory, but gives unbiased variance estimates for general multistage designs at both phases. "simple" or "approx" use less memory, and is correct for designs with simple random sampling at phase one and stratified randoms sampling at phase two. See twophase for more details.

Value
An object of class tbl_svy

Examples

# Examples from ?survey::twophase
# two-phase simple random sampling.
data(pbc, package="survival")
library(dplyr)

pbc <- pbc %>%
  mutate(randomized = !is.na(trt) & trt > 0,
  id = row_number())
d2pbc <- pbc %>%
  as_survey_twophase(id = list(id, id), subset = randomized)

d2pbc %>% summarize(mean = survey_mean(bili))

# two-stage sampling as two-phase
library(survey)
data(mu284)

mu284_1 <- mu284 %>%
dplyr::slice(c(1:15, rep(1:5, n2[1:5] - 3))) %>%
  mutate(id = row_number(),
  sub = rep(c(TRUE, FALSE), c(15, 34-15)))

dmu284 <- mu284 %>%
  as_survey_design(ids = c(id1, id2), fpc = c(n1, n2))
# first phase cluster sample, second phase stratified within cluster
d2mu284 <- mu284_1 %>%
  as_survey_twophase(id = list(id1, id), strata = list(NULL, id1),
  fpc = list(n1, NULL), subset = sub)
dmu284 %>%
# dplyr 0.7 introduced new style of NSE called quosures
# See `vignette("programming", package = "dplyr")` for details

```r
ids <- quo(list(id, id))
d2pbc <- pbc %>%
  as_survey_twophase(id = !!ids, subset = "randomized")
```

## as_tibble

Coerce survey variables to a data frame (tibble)

**Description**

Coerce survey variables to a data frame (tibble)

**Arguments**

- **x**
  - A tbl_svy object

## cascade

Summarise multiple values into cascading groups

**Description**

cascade is similar to `summarise`, but calculates a summary statistics for the total of a group in addition to each group.

**Usage**

`cascade(.data, ..., .dots, .fill = NA)`

**Arguments**

- **.data**, tbl A tbl_svy object
- **...** Name-value pairs of summary functions
- **.dots** Used to work around non-standard evaluation. See vignette("nse", package = "dplyr") for details.
- **.fill** Value to fill in for group summaries
collect

Examples

```r
library(survey)
data(api)

dstrata <- apistrat %>%
  as_survey_design(strata = stype, weights = pw)

dstrata_grp <- dstrata %>%
  group_by(stype)

dstrata_grp %>%
cascade(api99 = survey_mean(api99),
       api00 = survey_mean(api00),
       api_diff = survey_mean(api00 - api99))
```

---

collect  \hspace{1cm} \textit{Force computation of a database query}

---

current_svy  \hspace{1cm} \textit{Get the survey data for the current context}

---

Description

Collect retrieves data from a database query (and when run on a tbl_svy object adjusts weights accordingly). Use collect when you want to run a function from the survey package on a srvyr db backed object. `compute` stores results in a remote temporary table.

---

Usage

```r
current_svy()
```

Value

a tbl_svy (or error if called with no survey context)
**Description**

These are data manipulation functions designed to work on tbl_svy objects.

**Details**

- `mutate` and `transmute` can add or modify variables. See `mutate` for more details.
- `select` and `rename` keep or rename variables. See `select` for more details.
- `filter` keeps certain observations. See `filter` for more details.
- `arrange` is not implemented for tbl_svy objects. Nor are any two table verbs such as `bind_rows`, `bind_cols` or any of the joins (full_join, left_join, etc.). These data manipulations may require modifications to the survey variable specifications and so cannot be done automatically. Instead, use dplyr to perform them while the data is still stored in data.frames.

**get_var_est**

*Get the variance estimates for a survey estimate*

**Description**

This is a helper to allow srvyr's syntactic style. In general, users will not have to worry about getting survey variance estimates directly unless they are trying to extend srvyr. This function helps convert from the result of a survey function into a data.frame with an estimate and measures of variance around it in a way that summarize expects. See vignette("extending-srvyr") for more details.

**Usage**

```r
get_var_est(stat, vartype, grps = "", level = 0.95, df = Inf, 
pre_calc_ci = FALSE, deff = FALSE)
```

**Arguments**

- `stat`: A survey statistic object, usually the result of a function from the survey package or svyby.
- `vartype`: A vector indicating which variance estimates to calculate (options are se for standard error, ci for confidence interval, var for variance or cv for coefficient of variation). Multiples are allowed.
- `grps`: A vector indicating the names of the grouping variables for grouped surveys ("" indicates no groups).
- `level`: One or more levels to calculate a confidence interval.
Degrees of freedom, many survey functions default to Inf, but srvyr functions generally default to the result of calling `degf` on the survey object.

Whether the confidence interval is pre-calculated (as in `svyciprop`)

Whether to return the design effect (calculated using `survey::deff`)

Get/set the grouping variables for tbl.

These functions do not perform non-standard evaluation, and so are useful when programming against tbl objects. `ungroup` is a convenient inline way of removing existing grouping.

A tbl_df or tbl_svy object.

`group_by` function takes an existing table (or `svy_table`) and converts it to a grouped version, where operations are performed "by group".

Variables to group by. All tbls accept variable names, some will also accept functions of variables. Duplicated groups will be silently dropped.

By default, when `add = FALSE`, `group_by` will override existing groups. To instead add to the existing groups, use `add = TRUE`.

Used to work around non-standard evaluation. See `vignette("nse", package = "dplyr")` for details.
Details

See `group_by` for more information about grouping regular data tables. On `tbl_svy` objects, `group_by` sets up the object for operations similar to those allowed in `svyby`.

See Also

`group_by` for information about `group_by` on normal data tables.

Examples

```r
# examples of svy_tbl group_by
library(survey)
data(api)
dstrata <- apistrat%%
as_survey_design(strata = stype, weights = pw)%%
group_by(stype)

dstrata%%
summarise(api_diff = survey_mean(api00 - api99))
```

---

**set_survey_vars**  
Set the variables for the current survey variable

Description

This is a helper to allow srvyr's syntactic style. In general, users will not have to worry about setting variables in a survey object unless they are trying to extend srvyr. This function helps convert a vector to a variable in the correct part of a survey object’s structure so that functions can refer to it using the survey package’s formula notation. See vignette("extending-srvyr") for more details.

Usage

```r
set_survey_vars(.svy, x, name = "__SRVYR_TEMP_VAR__", add = FALSE)
```

Arguments

- `.svy`  
  A survey object

- `x`  
  A vector to be included in the variables portion of the survey object

- `name`  
  The name of the variable once it is added. Defaults to `__SRVYR_TEMP_VAR__` which is formatted weirdly to avoid name collisions.

- `add`  
  FALSE, the default, overwrite all current variables. If TRUE, will add this variable instead.

Value

a `tbl_svy` with the variables modified
Description

The srvyr package provides a new way of calculating summary statistics on survey data, based on the dplyr package. There are three stages to using srvyr functions, creating a survey object, manipulating the data, and calculating survey statistics.

Functions to create a survey object

`as_survey_design`, `as_survey_rep`, and `as_survey_twophase` are used to create surveys based on a data.frame and design variables, replicate weights or two phase design respectively. Each is based on a function in the survey package (`svydesign`, `svrepdesign`, `twophase`), and it is easy to modify code that uses the survey package so that it works with the srvyr package. See vignette(`srvyr_vs_survey`) for more details.

The function `as_survey` will choose between the other three functions based on the arguments given to save some typing.

Functions to manipulate data in a survey object

Once you’ve created a survey object, you can manipulate the data as you would using dplyr with a data.frame. `mutate` modifies or creates a variable, `select` and `rename` select or rename variables, and `filter` keeps certain observations.

Note that `arrange` and two table verbs such as `bind_rows`, `bind_cols`, or any of the joins are not usable on survey objects because they might require modifications to the definition of your survey. If you need to use these functions, you should do so before you convert the data.frame to a survey object.

Functions to summarize a survey object

Now that you have your data set up correctly, you can calculate summary statistics. To get the statistic over the whole population, use `summarise`, or to calculate it over a set of groups, use `group_by` first.

You can calculate the mean, (with `survey_mean`), the total (`survey_total`), the quantile (`survey_quantile`), or a ratio (`survey_ratio`). By default, srvyr will return the statistic and the standard error around it in a data.frame, but with the `vartype` parameter, you can also get a confidence interval ("ci"), variance ("var"), or coefficient of variation ("cv").

Within summarise, you can also use `unweighted`, which calculates a function without taking into consideration the survey weighting.
srvy-se-deprecated

**Deprecated SE versions of main srvyr verbs**

**Description**

srvyr has updated it's standard evaluation semantics to match dplyr 0.7, so these underscore functions are no longer required (but are still supported for backward compatibility reasons). See `se-deprecated` or the dplyr vignette on programming (vignette("programming", package = "dplyr")) for more details.

**Usage**

```
as_survey(.data, ...)                       
as_survey_design(.data, ids = NULL, probs = NULL, strata = NULL, 
                  variables = NULL, fpc = NULL, nest = FALSE, check_strata = !nest, 
                  weights = NULL, pps = FALSE, variance = c("HT", "YG"))
as_survey_rep(.data, variables = NULL, repweights = NULL, 
               weights = NULL, type = c("BRR", "Fay", "JK1", "JKn", "bootstrap", 
               "other"), combined_weights = TRUE, rho = NULL, 
               bootstrap_average = NULL, scale = NULL, rscales = NULL, 
               fpc = NULL, fpctype = c("fraction", "correction"), 
               mse = getOption("survey.replicates.mse"))
as_survey_twophase(.data, id, strata = NULL, probs = NULL, 
                   weights = NULL, fpc = NULL, subset, method = c("full", "approx", 
                   "simple"))
cascade(.data, ..., .dots, .fill = NA)
```

**Arguments**

- `.data` a data.frame or an object from the survey package
- `...` other arguments, see other functions for details
- `ids` Variables specifying cluster ids from largest level to smallest level (leaving the argument empty, NULL, 1, or 0 indicate no clusters).
- `probs` Variables specifying cluster sampling probabilities.
- `strata` Variables specifying strata.
- `variables` Variables specifying variables to be included in survey. Defaults to all variables in `.data`
- `fpc` Variables specifying a finite population correct, see `svydesign` for more details.
- `nest` If TRUE, relabel cluster ids to enforce nesting within strata.
- `check_strata` If TRUE, check that clusters are nested in strata.
weights: Variables specifying weights (inverse of probability).

pps: "brewer" to use Brewer's approximation for PPS sampling without replacement. "overton" to use Overton's approximation. An object of class HR to use the Hartley-Rao approximation. An object of class ppsmat to use the Horvitz-Thompson estimator.

variance: For pps without replacement, use variance="YG" for the Yates-Grundy estimator instead of the Horvitz-Thompson estimator.

repweights: Variables specifying the replication weight variables.

type: Type of replication weights.

combined_weights: TRUE if the repweights already include the sampling weights. This is usually the case.

rho: Shrinkage factor for weights in Fay's method.

bootstrap_average: For type = "bootstrap", if the bootstrap weights have been averaged, gives the number of iterations averaged over.

scale: Scaling constant for variance, see svrepdesign for more information.

rscales: Scaling constant for variance, see svrepdesign for more information.

fpctype: Finite population correction information.

mse: if TRUE, compute variances based on sum of squares around the point estimate, rather than the mean of the replicates.

id: list of two sets of variable names for sampling unit identifiers.

subset: bare name of a variable which specifies which observations are selected in phase 2.

method: "full" requires (much) more memory, but gives unbiased variance estimates for general multistage designs at both phases. "simple" or "approx" use less memory, and is correct for designs with simple random sampling at phase one and stratified randoms sampling at phase two. See twophase for more details.

.dots: Used to work around non-standard evaluation. See vignette("nse", package = "dplyr") for details.

.fill: Value to fill in for group summaries.

---

**summarise**

Summarise multiple values to a single value.

**Description**

Summarise multiple values to a single value.

**Usage**

summarise(.data, ...)

summarize(.data, ...)
Arguments

$data, tbl A tbl_svy object

Details

Summarise for tbl_svy objects accepts several specialized functions. Each of the functions a variable (or two, in the case of survey_ratio), from the data.frame and default to providing the measure and its standard error.

The argument vartype can choose one or more measures of uncertainty, se for standard error, ci for confidence interval, var for variance, and cv for coefficient of variation. level specifies the level for the confidence interval.

The other arguments correspond to the analogous function arguments from the survey package.

The available functions from srvyr are:

- `survey_mean` Calculate the survey mean of the entire population or by groups. Based on `svymean`.
- `survey_total` Calculate the survey total of the entire population or by groups. Based on `svytotal`.
- `survey_ratio` Calculate the ratio of 2 variables in the entire population or by groups. Based on `svyratio`.
- `survey_quantile` Calculate quantiles in the entire population or by groups. Based on `svyquantile`.
- `survey_median` Calculate the median in the entire population or by groups. `svyquantile`.
- `unweighted` Calculate an unweighted estimate as you would on a regular tbl_df. Based on dplyr’s `summarise`.

Examples

```r
library(survey)
data(api)

dstrata <- apistrat %>%
  as_survey_design(strata = stype, weights = pw)

dstrata %>%
  summarise(api99 = survey_mean(api99),
            api00 = survey_mean(api00),
            api_diff = survey_mean(api00 - api99))

dstrata_grp <- dstrata %>%
  group_by(stype)

dstrata_grp %>%
  summarise(api99 = survey_mean(api99),
            api00 = survey_mean(api00),
            api_diff = survey_mean(api00 - api99))
```
summarise_all  Manipulate multiple columns.

Description

See summarise_all for more details. *_each functions will be deprecated in favor of *_all/*_if/*_at functions.

survey_mean  Calculate the mean and its variation using survey methods

Description

Calculate means and proportions from complex survey data. A wrapper around svymean, or if proportion = TRUE, svyciprop. survey_mean should always be called from summarise.

Usage

survey_mean(x, na.rm = FALSE, vartype = c("se", "ci", "var", "cv"),
level = 0.95, proportion = FALSE, prop_method = c("logit",
"likelihood", "asin", "beta", "mean"), deff = FALSE, df = NULL,
.svy = current_svy(), ...)

Arguments

x  A variable or expression, or empty
na.rm  A logical value to indicate whether missing values should be dropped
vartype  Report variability as one or more of: standard error ("se", default), confidence interval ("ci"), variance ("var") or coefficient of variation ("cv").
level  (For vartype = "ci" only) A single number or vector of numbers indicating the confidence level
proportion  Use methods to calculate the proportion that may have more accurate confidence intervals near 0 and 1. Based on svyciprop.
prop_method  Type of proportion method to use if proportion is TRUE. See svyciprop for details.
deff  A logical value to indicate whether the design effect should be returned.
df  (For vartype = "ci" only) A numeric value indicating the degrees of freedom for t-distribution. The default (NULL) uses degf, but Inf is the usual survey package’s default (except in svyciprop).
.svy  A tbl_svy object. When called from inside a summarize function the default automatically sets the survey to the current survey.
...  Ignored
Examples

library(survey)
data(api)

dstrata <- apistrat %>%
  as_survey_design(strata = stype, weights = pw)

dstrata %>%
  summarise(api99 = survey_mean(api99),
            api_diff = survey_mean(api00 - api99, vartype = c("ci", "cv")))

dstrata %>%
  group_by(awards) %>%
  summarise(api00 = survey_mean(api00))

# Leave x empty to calculate the proportion in each group
dstrata %>%
  group_by(awards) %>%
  summarise(pct = survey_mean())

# Setting proportion = TRUE uses a different method for calculating confidence intervals
# level takes a vector for multiple levels of confidence intervals

dstrata %>%
  summarise(high_api = survey_mean(api00 > 875, proportion = TRUE, vartype = "ci"))

comparison <- survey::svymean(~api99, dstrata)
confint(comparison) # survey's default
confint(comparison, df = survey::degf(dstrata)) # srvyr's default

---

**survey_quantile**

*Calculate the quantile and its variation using survey methods*

**Description**

Calculate quantiles from complex survey data. A wrapper around `svyquantile`. `survey_quantile` and `survey_median` should always be called from `summarise`. 
Usage

\[
\text{survey quantile}(x, \text{quantiles, na.rm} = \text{FALSE}, \text{vartype} = \text{NULL}, \\
\text{level} = 0.95, \text{q.method} = \text{"linear"}, f = 1, \\
\text{interval.type} = \text{c("Wald", "score", "betaWald", "probability", 
\text{"quantile"}), ties = c("discrete", "rounded"), df = Inf, 
\text{.svy} = \text{current.svy}(), ...})
\]

\[
\text{survey median}(x, \text{na.rm} = \text{FALSE}, \text{vartype} = \text{NULL}, \text{level} = 0.95, \\
\text{q.method} = \text{"linear"}, f = 1, \text{interval.type} = \text{c("Wald", "score", 
\text{"betaWald", "probability", "quantile"}), ties = c("discrete", 
\text{"rounded"}), df = Inf, \text{.svy} = \text{current.svy}(), ...})
\]

Arguments

- \(x\) A variable or expression
- \(\text{quantiles}\) A vector of quantiles to calculate
- \(\text{na.rm}\) A logical value to indicate whether missing values should be dropped
- \(\text{vartype}\) NULL to report no variability (default), otherwise one or more of: standard error ("se") confidence interval ("ci") (variance and coefficient of variation not available).
- \(\text{level}\) A single number indicating the confidence level (only one level allowed)
- \(\text{q.method}\) See "method" in \text{approxfun}
- \(f\) See \text{approxfun}
- \(\text{interval.type}\) See \text{svyquantile}
- \(\text{ties}\) See \text{svyquantile}
- \(\text{df}\) A number indicating the degrees of freedom for t-distribution. The default, Inf uses the normal distribution (matches the survey package). Also, has no effect for type = "betaWald".
- \(\text{.svy}\) A tbl\_svy object. When called from inside a summarize function the default automatically sets the survey to the current survey.
- ... Ignored

Examples

```r
library(survey)
data(api)
dstrata <- apistrat %>%
  as_survey_design(strata = stype, weights = pw)
dstrata %>%
  summarise(api99 = survey quantile(api99, c(0.25, 0.5, 0.75)), 
            api00 = survey median(api00, vartype = c("ci")))
dstrata %>%
group_by(awards) %>%
```

```r
```
Calculate the ratio and its variation using survey methods

```
survey_ratio(api00 = survey_median(api00))
```

Description

Calculate ratios from complex survey data. A wrapper around `svyratio`. `survey_ratio` should always be called from `summarise`.

Usage

```
survey_ratio(numerator, denominator, na.rm = FALSE, vartype = c("se", "ci", "var", "cv"), level = 0.95, deff = FALSE, df = NULL, .svy = current_svy(), ...)
```

Arguments

- `numerator`: The numerator of the ratio
- `denominator`: The denominator of the ratio
- `na.rm`: A logical value to indicate whether missing values should be dropped
- `vartype`: Report variability as one or more of: standard error ("se", default), confidence interval ("ci"), variance ("var") or coefficient of variation ("cv").
- `level`: A single number or vector of numbers indicating the confidence level
- `deff`: A logical value to indicate whether the design effect should be returned.
- `df`: (For `vartype` = "ci" only) A numeric value indicating the degrees of freedom for t-distribution. The default (NULL) uses `deff`, but Inf is the usual survey package's default (except in `svyciprop`).
- `.svy`: A tbl_svy object. When called from inside a summarize function the default automatically sets the survey to the current survey.
- `...`: Ignored

Examples

```
library(survey)
data(api)

dstrata <- apistrat %>%
  as_survey_design(strata = stype, weights = pw)

dstrata %>%
  summarise(enroll = survey_ratio(api00, api99, vartype = c("ci", "cv")))

dstrata %>%
  group_by(awards) %>%
```
survey_total

Calculate the total and its variation using survey methods

Description

Calculate totals from complex survey data. A wrapper around svytotal. survey_total should always be called from summarise.

Usage

survey_total(x = NULL, na.rm = FALSE, vartype = c("se", "ci", "var", "cv"), level = 0.95, deff = FALSE, df = NULL, .svy = current_svy(), ...)

Arguments

- **x**: A variable or expression, or empty
- **na.rm**: A logical value to indicate whether missing values should be dropped
- **vartype**: Report variability as one or more of: standard error ("se", default), confidence interval ("ci"), variance ("var") or coefficient of variation ("cv").
- **level**: A single number or vector of numbers indicating the confidence level
- **deff**: A logical value to indicate whether the design effect should be returned.
- **df**: (For vartype = "ci" only) A numeric value indicating the degrees of freedom for t-distribution. The default (NULL) uses deff, but Inf is the usual survey package's default.
- **.svy**: A tbl_svy object. When called from inside a summarize function the default automatically sets the survey to the current survey.
- **...**: Ignored
svychisq

Chisquared tests of association for survey data.

Description

Chisquared tests of association for survey data.

Arguments

formula Model formula specifying margins for the table (using + only)
design survey object
formula See details in svychisq
**Description**

A `tbl_svy` wraps a locally stored svydesign and adds methods for dplyr single-table verbs like `mutate`, `group_by` and `summarise`. Create a `tbl_svy` using `as_survey_design`.

**Methods**

`tbl_df` implements these methods from dplyr.

- **select or rename** Select or rename variables in a survey’s dataset.
- **mutate or transmute** Modify and create variables in a survey’s dataset.
- **group_by and summarise** Get descriptive statistics from survey.

**Examples**

```r
library(survey)
library(dplyr)
data(api)
svy <- as_survey_design(apistrat, strata = stype, weights = pw)
svy

# Data manipulation verbs -----------------------------------------------
filter(svy, pcttest > 95)
select(svy, starts_with("acs")) # variables used in survey design are automatically kept
summarise(svy, col.grad = survey_mean(col.grad))
mutate(svy, api_diff = api00 - api99)

# Group by operations ---------------------------------------------------
# To calculate survey
svy_group <- group_by(svy, dname)

summarise(svy, col.grad = survey_mean(col.grad),
api00 = survey_mean(api00, vartype = "ci"))
```
### tbl_vars

List variables produced by a tbl.

**Arguments**

- **x**: A tbl object

### unweighted

Calculate the an unweighted summary statistic from a survey

**Description**

Calculate unweighted summaries from a survey dataset, just as on a normal data.frame with `summarise`.

**Usage**

```r
unweighted(x, .svy = current_svy(), ...)
```

**Arguments**

- **x**: A variable or expression
- **.svy**: A tbl_svy object. When called from inside a summarize function the default automatically sets the survey to the current survey.
- **...**: Ignored

**Examples**

```r
library(survey)
library(dplyr)
data(api)

dstrata <- apistrat %>%
  as_survey_design(strata = stype, weights = pw)

dstrata %>%
  summarise(api99_unw = unweighted(mean(api99)),
            n = unweighted(n()))

dstrata %>%
  group_by(stype) %>%
  summarise(api_diff_unw = unweighted(mean(api00 - api99)))
```
