Package ‘statsExpressions’

March 20, 2024

Type Package

Title Tidy Dataframes and Expressions with Statistical Details

Version 1.5.4

Maintainer Indrajeet Patil <patilindrajeet.science@gmail.com>

Description Utilities for producing dataframes with rich details for the most common types of statistical approaches and tests: parametric, nonparametric, robust, and Bayesian t-test, one-way ANOVA, correlation analyses, contingency table analyses, and meta-analyses. The functions are pipe-friendly and provide a consistent syntax to work with tidy data. These dataframes additionally contain expressions with statistical details, and can be used in graphing packages. This package also forms the statistical processing backend for 'ggstatsplot'. References: Patil (2021) <doi:10.21105/joss.03236>.

LazyData true
add_expression_col

Template for expressions with statistical details

Description

Creates an expression from a data frame containing statistical details. Ideally, this data frame would come from having run `tidy_model_parameters` function on your model object.

This function is currently not stable and should not be used outside of this package context.
Usage

add_expression_col(
  data,
  paired = FALSE,
  statistic.text = NULL,
  effsize.text = NULL,
  prior.type = NULL,
  n = NULL,
  n.text = ifelse(paired, list(quote(italic("n")["pairs"])),
                  list(quote(italic("n")["obs"]))),
  digits = 2L,
  digits.df = 0L,
  digits.df.error = digits.df,
  ...
)

Arguments

data A data frame containing details from the statistical analysis and should contain some or all of the following columns:
  • statistic: the numeric value of a statistic.
  • df.error: the numeric value of a parameter being modeled (often degrees of freedom for the test); note that if there are no degrees of freedom (e.g., for non-parametric tests), this column will be irrelevant.
  • df: relevant only if the statistic in question has two degrees of freedom.
  • p.value: the two-sided p-value associated with the observed statistic.
  • method: method describing the test carried out.
  • effectsize: name of the effect size (if not present, same as method).
  • estimate: estimated value of the effect size.
  • conf.level: width for the confidence intervals.
  • conf.low: lower bound for effect size estimate.
  • conf.high: upper bound for effect size estimate.
  • bf10: Bayes Factor value (if bayesian = TRUE).

paired Logical that decides whether the experimental design is repeated measures/within-subjects or between-subjects. The default is FALSE.

statistic.text A character that specifies the relevant test statistic. For example, for tests with t-statistic, statistic.text = "t".

effsize.text A character that specifies the relevant effect size.

prior.type The type of prior.

n An integer specifying the sample size used for the test.

n.text A character that specifies the design, which will determine what the n stands for. It defaults to quote(italic("n")["pairs"]) if paired = TRUE, and to quote(italic("n")["obs"]) if paired = FALSE. If you wish to customize this further, you will need to provide object of language type.
digits, digits.df, digits.df.error
   Number of decimal places to display for the parameters (default: 0L).

... Currently ignored.

Examples

set.seed(123)

# creating a data frame with stats results
stats_df <- cbind.data.frame(
  statistic = 5.494,
  df = 29.234,
  p.value = 0.00001,
  estimate = -1.980,
  conf.level = 0.95,
  conf.low = -2.873,
  conf.high = -1.088,
  method = "Student's t-test"
)

# expression for *t*-statistic with Cohen's *d* as effect size
# note that the plotmath expressions need to be quoted
add_expression_col(
  data = stats_df,
  statistic.text = list(quote(italic("t"))),
  effsize.text = list(quote(italic("d"))),
  n = 32L,
  n.text = list(quote(italic("n"))["no.obs"]),
  digits = 3L,
  digits.df = 3L
)

bugs_long Tidy version of the "Bugs" dataset.

Description

Tidy version of the "Bugs" dataset.

Usage

bugs_long

Format

A data frame with 372 rows and 6 variables

- subject. Dummy identity number for each participant.
- gender. Participant’s gender (Female, Male).
• region. Region of the world the participant was from.
• education. Level of education.
• condition. Condition of the experiment the participant gave rating for (LDLF: low freighteningness and low disgustingness; LFHD: low freighteningness and high disgustingness; HFHD: high freighteningness and low disgustingness; HFHD: high freighteningness and high disgustingness).
• desire. The desire to kill an arthropod was indicated on a scale from 0 to 10.

Details
This data set, "Bugs", provides the extent to which men and women want to kill arthropods that vary in freighteningness (low, high) and disgustingness (low, high). Each participant rates their attitudes towards all anthropods. Subset of the data reported by Ryan et al. (2013).

Source

Examples
dim(bugs_long)
head(bugs_long)
dplyr::glimpse(bugs_long)

centrality_description

Data frame and expression for distribution properties

Description
Parametric, non-parametric, robust, and Bayesian measures of centrality.

Usage
centrality_description(
  data,
  x,
  y,
  type = "parametric",
  conf.level = NULL,
  tr = 0.2,
  digits = 2L,
  ...
)

Arguments

data  A data frame (or a tibble) from which variables specified are to be taken. Other data types (e.g., matrix, table, array, etc.) will not be accepted. Additionally, grouped data frames from {dplyr} should be ungrouped before they are entered as data.

x    The grouping (or independent) variable in data.

y    The response (or outcome or dependent) variable from data.

type A character specifying the type of statistical approach:

- "parametric"
- "nonparametric"
- "robust"
- "bayes"

You can specify just the initial letter.

conf.level  Scalar between 0 and 1 (default: 95% confidence/credible intervals, 0.95). If NULL, no confidence intervals will be computed.

tr    Trim level for the mean when carrying out robust tests. In case of an error, try reducing the value of tr, which is by default set to 0.2. Lowering the value might help.

digits Number of digits for rounding or significant figures. May also be "signif" to return significant figures or "scientific" to return scientific notation. Control the number of digits by adding the value as suffix, e.g. digits = "scientific4" to have scientific notation with 4 decimal places, or digits = "signif5" for 5 significant figures (see also signif()).

... Currently ignored.

Details

This function describes a distribution for y variable for each level of the grouping variable in x by a set of indices (e.g., measures of centrality, dispersion, range, skewness, kurtosis, etc.). It additionally returns an expression containing a specified centrality measure. The function internally relies on datawizard::describe_distribution() function.

Centrality measures

The table below provides summary about:

- statistical test carried out for inferential statistics
- type of effect size estimate and a measure of uncertainty for this estimate
- functions used internally to compute these details

<table>

set.seed(123)

# ----------------------- parametric -----------------------
centrality_description(iris, Species, Sepal.Length, type = "parametric")

# ----------------------- non-parametric -------------------
centrality_description(mtcars, am, wt, type = "nonparametric")

# ----------------------- robust ---------------------------
centrality_description(ToothGrowth, supp, len, type = "robust")

# ----------------------- Bayesian -------------------------
centrality_description(sleep, group, extra, type = "bayes")

contingency_table

Description

Parametric and Bayesian one-way and two-way contingency table analyses.

Usage

contingency_table(
  data,
  x,
  y = NULL,
  paired = FALSE,
  type = "parametric",
  counts = NULL,
  ratio = NULL,
  alternative = "two.sided",
  digits = 2L,
  conf.level = 0.95,
  sampling.plan = "indepMulti",
  fixed.margin = "rows",
  prior.concentration = 1,
  ...
)
Arguments

**data**
A data frame (or a tibble) from which variables specified are to be taken. Other data types (e.g., matrix, table, array, etc.) will **not** be accepted. Additionally, grouped data frames from `{dplyr}` should be ungrouped before they are entered as data.

**x**
The variable to use as the **rows** in the contingency table.

**y**
The variable to use as the **columns** in the contingency table. Default is **NULL**. If **NULL**, one-sample proportion test (a goodness of fit test) will be run for the x variable.

**paired**
Logical indicating whether data came from a within-subjects or repeated measures design study (Default: **FALSE**).

**type**
A character specifying the type of statistical approach:
- "parametric"
- "nonparametric"
- "robust"
- "bayes"

You can specify just the initial letter.

**counts**
The variable in data containing counts, or **NULL** if each row represents a single observation.

**ratio**
A vector of proportions: the expected proportions for the proportion test (should sum to 1). Default is **NULL**, which means the null is equal theoretical proportions across the levels of the nominal variable. E.g., ratio = c(0.5, 0.5) for two levels, ratio = c(0.25, 0.25, 0.25, 0.25) for four levels, etc.

**alternative**
A character string specifying the alternative hypothesis; Controls the type of CI returned: "two.sided" (default, two-sided CI), "greater" or "less" (one-sided CI). Partial matching is allowed (e.g., "g", "l", "two"...). See section One-Sided CIs in the `effectsize_CIs` vignette.

**digits**
Number of digits for rounding or significant figures. May also be "signif" to return significant figures or "scientific" to return scientific notation. Control the number of digits by adding the value as suffix, e.g. digits = "scientific4" to have scientific notation with 4 decimal places, or digits = "signif5" for 5 significant figures (see also `signif()`).

**conf.level**
Scalar between 0 and 1 (default: 95% confidence/credible intervals, 0.95). If **NULL**, no confidence intervals will be computed.

**sampling.plan**
Character describing the sampling plan. Possible options are "indepMulti" (independent multinomial; default), "poisson", "jointMulti" (joint multinomial), "hypergeom" (hypergeometric). For more, see `{BayesFactor}:contingencyTableBF()`.

**fixed.margin**
For the independent multinomial sampling plan, which margin is fixed ("rows" or "cols"). Defaults to "rows".

**prior.concentration**
Specifies the prior concentration parameter, set to 1 by default. It indexes the expected deviation from the null hypothesis under the alternative, and corresponds to Gunel and Dickey’s (1974) "a" parameter.

**...**
Additional arguments (currently ignored).
Value

The returned tibble data frame can contain some or all of the following columns (the exact columns will depend on the statistical test):

- **statistic**: the numeric value of a statistic
- **df**: the numeric value of a parameter being modeled (often degrees of freedom for the test)
- **df.error** and **df**: relevant only if the statistic in question has two degrees of freedom (e.g. anova)
- **p.value**: the two-sided \( p \)-value associated with the observed statistic
- **method**: the name of the inferential statistical test
- **estimate**: estimated value of the effect size
- **conf.low**: lower bound for the effect size estimate
- **conf.high**: upper bound for the effect size estimate
- **conf.level**: width of the confidence interval
- **conf.method**: method used to compute confidence interval
- **conf.distribution**: statistical distribution for the effect
- **effectsize**: the name of the effect size
- **n.obs**: number of observations
- **expression**: pre-formatted expression containing statistical details

For examples, see data frame output vignette.

Contingency table analyses

The table below provides summary about:

- statistical test carried out for inferential statistics
- type of effect size estimate and a measure of uncertainty for this estimate

)

# ------------------------ Bayesian -------------------------------------
set.seed(123)
contingency_table(
  data = as.data.frame(HairEyeColor),
  x = Eye,
  counts = Freq,
  ratio = c(0.2, 0.2, 0.3, 0.3),
  type = "bayes"
)
```
Description

Parametric, non-parametric, robust, and Bayesian correlation test.

Usage

corr_test(
  data,
  x,
  y,
  type = "parametric",
  digits = 2L,
  conf.level = 0.95,
  tr = 0.2,
  bf.prior = 0.707,
  ...
)

Arguments

data: A data frame (or a tibble) from which variables specified are to be taken. Other data types (e.g., matrix, table, array, etc.) will not be accepted. Additionally, grouped data frames from \{dplyr\} should be ungrouped before they are entered as data.

x: The column in data containing the explanatory variable to be plotted on the x-axis.

y: The column in data containing the response (outcome) variable to be plotted on the y-axis.

type: A character specifying the type of statistical approach:
- "parametric"
- "nonparametric"
- "robust"
- "bayes"

You can specify just the initial letter.

digits: Number of digits for rounding or significant figures. May also be "signif" to return significant figures or "scientific" to return scientific notation. Control the number of digits by adding the value as suffix, e.g. digits = "scientific4" to have scientific notation with 4 decimal places, or digits = "signif5" for 5 significant figures (see also \texttt{signif()}).

conf.level: Scalar between 0 and 1 (default: 95% confidence/credible intervals, 0.95). If \texttt{NULL}, no confidence intervals will be computed.

tr: Trim level for the mean when carrying out robust tests. In case of an error, try reducing the value of \texttt{tr}, which is by default set to 0.2. Lowering the value might help.

bf.prior: A number between 0.5 and 2 (default 0.707), the prior width to use in calculating Bayes factors and posterior estimates. In addition to numeric arguments,
several named values are also recognized: "medium", "wide", and "ultrawide", corresponding to $r$ scale values of $1/2$, $\sqrt{2}/2$, and $1$, respectively. In case of an ANOVA, this value corresponds to scale for fixed effects.

Additional arguments (currently ignored).

Value

The returned tibble data frame can contain some or all of the following columns (the exact columns will depend on the statistical test):

- **statistic**: the numeric value of a statistic
- **df**: the numeric value of a parameter being modeled (often degrees of freedom for the test)
- **df.error** and **df**: relevant only if the statistic in question has two degrees of freedom (e.g. anova)
- **p.value**: the two-sided $p$-value associated with the observed statistic
- **method**: the name of the inferential statistical test
- **estimate**: estimated value of the effect size
- **conf.low**: lower bound for the effect size estimate
- **conf.high**: upper bound for the effect size estimate
- **conf.level**: width of the confidence interval
- **conf.method**: method used to compute confidence interval
- **conf.distribution**: statistical distribution for the effect
- **effectsize**: the name of the effect size
- **n.obs**: number of observations
- **expression**: pre-formatted expression containing statistical details

For examples, see data frame output vignette.

Correlation analyses

The table below provides summary about:

- statistical test carried out for inferential statistics
- type of effect size estimate and a measure of uncertainty for this estimate

corr_test(mtcars, wt, mpg, type = "robust")

# ----------------------- Bayesian -------------------------
corr_test(mtcars, wt, mpg, type = "bayes")
```

---

**iris_long**  
*Edgar Anderson's Iris Data in long format.*

Description

Edgar Anderson’s Iris Data in long format.

Usage

`iris_long`

Format

A data frame with 600 rows and 5 variables

- id. Dummy identity number for each flower (150 flowers in total).
- Species. The species are *Iris setosa*, *versicolor*, and *virginica*.
- attribute. What attribute is being measured ("Sepal" or "Pepal").
- measure. What aspect of the attribute is being measured ("Length" or "Width").
- value. Value of the measurement.

Details

This famous (Fisher’s or Anderson’s) iris data set gives the measurements in centimeters of the variables sepal length and width and petal length and width, respectively, for 50 flowers from each of 3 species of iris. The species are *Iris setosa*, versicolor, and virginica.  
This is a modified dataset from datasets package.
long_to_wide_converter

Examples

```r
dim(iris_long)
head(iris_long)
dplyr::glimpse(iris_long)
```

---

long_to_wide_converter

*Convert long/tidy data frame to wide format*

---

**Description**

This conversion is helpful mostly for repeated measures design, where removing NAs by participant can be a bit tedious.

**Usage**

```r
long_to_wide_converter(
  data,
  x,
  y,
  subject.id = NULL,
  paired = TRUE,
  spread = TRUE,
  ...
)
```

**Arguments**

- **data**: A data frame (or a tibble) from which variables specified are to be taken. Other data types (e.g., matrix, table, array, etc.) will not be accepted. Additionally, grouped data frames from `{dplyr}` should be ungrouped before they are entered as data.

- **x**: The grouping (or independent) variable from data. In case of a repeated measures or within-subjects design, if `subject.id` argument is not available or not explicitly specified, the function assumes that the data has already been sorted by such an id by the user and creates an internal identifier. So if your data is not sorted, the results can be inaccurate when there are more than two levels in `x` and there are NAs present. The data is expected to be sorted by user in `subject-1, subject-2, ..., pattern`.

- **y**: The response (or outcome or dependent) variable from data.

- **subject.id**: Relevant in case of a repeated measures or within-subjects design (paired = TRUE, i.e.), it specifies the subject or repeated measures identifier. **Important**: Note that if this argument is NULL (which is the default), the function assumes that the data has already been sorted by such an id by the user and creates an internal identifier. So if your data is not sorted and you leave this argument unspecified, the results can be inaccurate when there are more than two levels in `x` and there are NAs present.
paired Logical that decides whether the experimental design is repeated measures/within-subjects or between-subjects. The default is FALSE.

spread Logical that decides whether the data frame needs to be converted from long/tidy to wide (default: TRUE).

... Currently ignored.

Value
A data frame with NAs removed while respecting the between-or-within-subjects nature of the dataset.

Examples

# for reproducibility
library(statsExpressions)
set.seed(123)

# repeated measures design
long_to_wide_converter(
  bugs_long,
  condition,
  desire,
  subject.id = subject,
  paired = TRUE
)

# independent measures design
long_to_wide_converter(mtcars, cyl, wt, paired = FALSE)

# Random-effects meta-analysis

meta_analysis Random-effects meta-analysis

Description
Parametric, non-parametric, robust, and Bayesian random-effects meta-analysis.

Usage

meta_analysis(
  data,
  type = "parametric",
  random = "mixture",
  digits = 2L,
  conf.level = 0.95,
  ...
)

Arguments

data A data frame. It must contain columns named estimate (effect sizes or outcomes) and std.error (corresponding standard errors). These two columns will be used:
  • as yi and sei arguments in metafor::rma() (for parametric test) or metaplus::metaplus() (for robust test)
  • as y and SE arguments in metaBMA::meta_random() (for Bayesian test).

type A character specifying the type of statistical approach:
  • "parametric"
  • "nonparametric"
  • "robust"
  • "bayes"
You can specify just the initial letter.

random The type of random effects distribution. One of "normal", "t-dist", "mixture", for standard normal, t-distribution or mixture of normals respectively.

digits Number of digits for rounding or significant figures. May also be "signif" to return significant figures or "scientific" to return scientific notation. Control the number of digits by adding the value as suffix, e.g. digits = "scientific4" to have scientific notation with 4 decimal places, or digits = "signif5" for 5 significant figures (see also signif()).

conf.level Scalar between 0 and 1 (default: 95% confidence/credible intervals, 0.95). If NULL, no confidence intervals will be computed.

... Additional arguments passed to the respective meta-analysis function.

Value

The returned tibble data frame can contain some or all of the following columns (the exact columns will depend on the statistical test):
  • statistic: the numeric value of a statistic
  • df: the numeric value of a parameter being modeled (often degrees of freedom for the test)
  • df.error and df: relevant only if the statistic in question has two degrees of freedom (e.g. anova)
  • p.value: the two-sided p-value associated with the observed statistic
  • method: the name of the inferential statistical test
  • estimate: estimated value of the effect size
  • conf.low: lower bound for the effect size estimate
  • conf.high: upper bound for the effect size estimate
  • conf.level: width of the confidence interval
  • conf.method: method used to compute confidence interval
  • conf.distribution: statistical distribution for the effect
  • effectsize: the name of the effect size
Random-effects meta-analysis

The table below provides summary about:

- statistical test carried out for inferential statistics
- type of effect size estimate and a measure of uncertainty for this estimate
- functions used internally to compute these details

### Note

**Important**: The function assumes that you have already downloaded the needed package (`{metafor}`, `{metaplus}`, or `{metaBMA}`) for meta-analysis. If they are not available, you will be asked to install them.

### Examples

```r
# setup
set.seed(123)
library(statsExpressions)

# let's use `mag` dataset from `{metaplus}`
data(mag, package = "metaplus")
dat <- dplyr::rename(mag, estimate = yi, std.error = sei)

# ----------------------- parametric -------------------------------------
meta_analysis(dat)

# ----------------------- robust ----------------------------------
meta_analysis(dat, type = "random", random = "normal")
```
movies_long

# ----------------------- Bayesian ----------------------------------
suppressWarnings(meta_analysis(dat, type = "bayes")

movies_long

Movie information and user ratings from IMDB.com (long format).

Description

Movie information and user ratings from IMDB.com (long format).

Usage

movies_long

Format

A data frame with 1,579 rows and 8 variables

- title. Title of the movie.
- year. Year of release.
- budget. Total budget (if known) in US dollars
- length. Length in minutes.
- rating. Average IMDB user rating.
- votes. Number of IMDB users who rated this movie.
- mpaa. MPAA rating.
- genre. Different genres of movies (action, animation, comedy, drama, documentary, romance, short).

Details

Modified dataset from ggplot2movies package.

The internet movie database, https://imdb.com/, is a website devoted to collecting movie data supplied by studios and fans. It claims to be the biggest movie database on the web and is run by amazon.

Movies were are identical to those selected for inclusion in movies_wide but this dataset has been constructed such that every movie appears in one and only one genre category.

Source

https://CRAN.R-project.org/package=ggplot2movies
movies_wide

Examples

dim(movies_long)
head(movies_long)
dplyr::glimpse(movies_long)

movies_wide

Movie information and user ratings from IMDB.com (wide format).

Description

Movie information and user ratings from IMDB.com (wide format).

Usage

movies_wide

Format

A data frame with 1,579 rows and 13 variables

- title. Title of the movie.
- year. Year of release.
- budget. Total budget in millions of US dollars
- length. Length in minutes.
- rating. Average IMDB user rating.
- votes. Number of IMDB users who rated this movie.
- mpaa. MPAA rating.
- action, animation, comedy, drama, documentary, romance, short. Binary variables representing if movie was classified as belonging to that genre.
- NumGenre. The number of different genres a film was classified in an integer between one and four.

Details

Modified dataset from ggplot2movies package.

The internet movie database, https://imdb.com/, is a website devoted to collecting movie data supplied by studios and fans. It claims to be the biggest movie database on the web and is run by amazon.

Movies were selected for inclusion if they had a known length and had been rated by at least one IMDB user. Small categories such as documentaries and NC-17 movies were removed.

https://CRAN.R-project.org/package=ggplot2movies
Examples

```r
dim(movies_wide)
head(movies_wide)
dplyr::glimpse(movies_wide)
```

---

**oneway_anova**  
*One-way analysis of variance (ANOVA)*

**Description**

Parametric, non-parametric, robust, and Bayesian one-way ANOVA.

**Usage**

```r
oneway_anova(
  data,
  x,
  y,
  subject.id = NULL,
  type = "parametric",
  paired = FALSE,
  digits = 2L,
  conf.level = 0.95,
  effsize.type = "omega",
  var.equal = FALSE,
  bf.prior = 0.707,
  tr = 0.2,
  nboot = 100L,
  ...
)
```

**Arguments**

- **data**  
  A data frame (or a tibble) from which variables specified are to be taken. Other data types (e.g., matrix, table, array, etc.) will not be accepted. Additionally, grouped data frames from `{dplyr}` should be ungrouped before they are entered as data.

- **x**  
  The grouping (or independent) variable from data. In case of a repeated measures or within-subjects design, if `subject.id` argument is not available or not explicitly specified, the function assumes that the data has already been sorted by such an id by the user and creates an internal identifier. So if your data is not sorted, the results can be inaccurate when there are more than two levels in x and there are NAs present. The data is expected to be sorted by user in subject-1, subject-2, ..., pattern.

- **y**  
  The response (or outcome or dependent) variable from data.
subject.id Relevant in case of a repeated measures or within-subjects design (paired = TRUE, i.e.), it specifies the subject or repeated measures identifier. **Important:** Note that if this argument is NULL (which is the default), the function assumes that the data has already been sorted by such an id by the user and creates an internal identifier. So if your data is not sorted and you leave this argument unspecified, the results can be inaccurate when there are more than two levels in x and there are NAs present.

type A character specifying the type of statistical approach:
- "parametric"
- "nonparametric"
- "robust"
- "bayes"

You can specify just the initial letter.

paired Logical that decides whether the experimental design is repeated measures/within-subjects or between-subjects. The default is FALSE.

digits Number of digits for rounding or significant figures. May also be "signif" to return significant figures or "scientific" to return scientific notation. Control the number of digits by adding the value as suffix, e.g. digits = "scientific4" to have scientific notation with 4 decimal places, or digits = "signif5" for 5 significant figures (see also `signif()`).

conf.level Scalar between 0 and 1 (default: 95% confidence/credible intervals, 0.95). If NULL, no confidence intervals will be computed.

effsize.type Type of effect size needed for parametric tests. The argument can be "eta" (partial eta-squared) or "omega" (partial omega-squared).

var.equal a logical variable indicating whether to treat the two variances as being equal. If TRUE then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used.

bf.prior A number between 0.5 and 2 (default 0.707), the prior width to use in calculating Bayes factors and posterior estimates. In addition to numeric arguments, several named values are also recognized: "medium", "wide", and "ultrawide", corresponding to r scale values of 1/2, sqrt(2)/2, and 1, respectively. In case of an ANOVA, this value corresponds to scale for fixed effects.

tr Trim level for the mean when carrying out robust tests. In case of an error, try reducing the value of tr, which is by default set to 0.2. Lowering the value might help.

nboot Number of bootstrap samples for computing confidence interval for the effect size (Default: 100L).

... Additional arguments (currently ignored).

**Value**

The returned tibble data frame can contain some or all of the following columns (the exact columns will depend on the statistical test):

- **statistic**: the numeric value of a statistic
• df: the numeric value of a parameter being modeled (often degrees of freedom for the test)
• df.error and df: relevant only if the statistic in question has two degrees of freedom (e.g. anova)
• p.value: the two-sided p-value associated with the observed statistic
• method: the name of the inferential statistical test
• estimate: estimated value of the effect size
• conf.low: lower bound for the effect size estimate
• conf.high: upper bound for the effect size estimate
• conf.level: width of the confidence interval
• conf.method: method used to compute confidence interval
• conf.distribution: statistical distribution for the effect
• effectsize: the name of the effect size
• n.obs: number of observations
• expression: pre-formatted expression containing statistical details

For examples, see data frame output vignette.

    type      = "bayes"
)
One-sample tests

Description

Parametric, non-parametric, robust, and Bayesian one-sample tests.

Usage

one_sample_test(
  data,  
  x, 
  type = "parametric", 
  test.value = 0, 
  alternative = "two.sided", 
  digits = 2L, 
  conf.level = 0.95, 
  tr = 0.2, 
  bf.prior = 0.707, 
  effsize.type = "g", 
  ...
)

Arguments

data A data frame (or a tibble) from which variables specified are to be taken. Other data types (e.g., matrix, table, array, etc.) will not be accepted. Additionally, grouped data frames from {dplyr} should be ungrouped before they are entered as data.

x A numeric variable from the data frame data.

type A character specifying the type of statistical approach:
  • "parametric"
  • "nonparametric"
  • "robust"
  • "bayes"
You can specify just the initial letter.

test.value A number indicating the true value of the mean (Default: 0).

alternative a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.

digits Number of digits for rounding or significant figures. May also be "signif" to return significant figures or "scientific" to return scientific notation. Control the number of digits by adding the value as suffix, e.g. digits = "scientific4" to have scientific notation with 4 decimal places, or digits = "signif5" for 5 significant figures (see also signif()).
conf.level  Scalar between 0 and 1 (default: 95% confidence/credible intervals, 0.95). If NULL, no confidence intervals will be computed.

tr  Trim level for the mean when carrying out robust tests. In case of an error, try reducing the value of tr, which is by default set to 0.2. Lowering the value might help.

bf.prior  A number between 0.5 and 2 (default 0.707), the prior width to use in calculating Bayes factors and posterior estimates. In addition to numeric arguments, several named values are also recognized: "medium", "wide", and "ultrawide", corresponding to r scale values of 1/2, sqrt(2)/2, and 1, respectively. In case of an ANOVA, this value corresponds to scale for fixed effects.

effsize.type  Type of effect size needed for parametric tests. The argument can be "d" (for Cohen's d) or "g" (for Hedge's g).

...  Currently ignored.

Value

The returned tibble data frame can contain some or all of the following columns (the exact columns will depend on the statistical test):

- statistic: the numeric value of a statistic
- df: the numeric value of a parameter being modeled (often degrees of freedom for the test)
- df.error and df: relevant only if the statistic in question has two degrees of freedom (e.g. anova)
- p.value: the two-sided p-value associated with the observed statistic
- method: the name of the inferential statistical test
- estimate: estimated value of the effect size
- conf.low: lower bound for the effect size estimate
- conf.high: upper bound for the effect size estimate
- conf.level: width of the confidence interval
- conf.method: method used to compute confidence interval
- conf.distribution: statistical distribution for the effect
- effectsize: the name of the effect size
- n.obs: number of observations
- expression: pre-formatted expression containing statistical details

For examples, see data_frame_output vignette.

# ----------------------- Bayesian -------------------------
one_sample_test(mtcars, wt, test.value = 3, type = "bayes")
```

Description

Calculate parametric, non-parametric, robust, and Bayes Factor pairwise comparisons between group levels with corrections for multiple testing.
pairwise_comparisons

Usage

pairwise_comparisons(
  data,
  x,
  y,
  subject.id = NULL,
  type = "parametric",
  paired = FALSE,
  var.equal = FALSE,
  tr = 0.2,
  bf.prior = 0.707,
  p.adjust.method = "holm",
  digits = 2L,
  ...)

Arguments

data A data frame (or a tibble) from which variables specified are to be taken. Other
data types (e.g., matrix, table, array, etc.) will not be accepted. Additionally,
grouped data frames from \{dplyr\} should be ungrouped before they are entered
as data.

x The grouping (or independent) variable from data. In case of a repeated mea-
sures or within-subjects design, if subject.id argument is not available or not
explicitly specified, the function assumes that the data has already been sorted
by such an id by the user and creates an internal identifier. So if your data is
not sorted, the results can be inaccurate when there are more than two levels
in x and there are NAs present. The data is expected to be sorted by user in
subject-1, subject-2, ..., pattern.

y The response (or outcome or dependent) variable from data.

subject.id Relevant in case of a repeated measures or within-subjects design (paired =
TRUE, i.e.), it specifies the subject or repeated measures identifier. Important:
Note that if this argument is NULL (which is the default), the function assumes
that the data has already been sorted by such an id by the user and creates an
internal identifier. So if your data is not sorted and you leave this argument
unspecified, the results can be inaccurate when there are more than two levels
in x and there are NAs present.

type A character specifying the type of statistical approach:

- "parametric"
- "nonparametric"
- "robust"
- "bayes"

You can specify just the initial letter.

paired Logical that decides whether the experimental design is repeated measures/within-
subjects or between-subjects. The default is FALSE.
pairwise_comparisons

var.equal  
a logical variable indicating whether to treat the two variances as being equal. If TRUE then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used.

tr  
Trim level for the mean when carrying out robust tests. In case of an error, try reducing the value of tr, which is by default set to 0.2. Lowering the value might help.

bf.prior  
A number between 0.5 and 2 (default 0.707), the prior width to use in calculating Bayes factors and posterior estimates. In addition to numeric arguments, several named values are also recognized: "medium", "wide", and "ultrawide", corresponding to r scale values of 1/2, sqrt(2)/2, and 1, respectively. In case of an ANOVA, this value corresponds to scale for fixed effects.

p.adjust.method  
Adjustment method for p-values for multiple comparisons. Possible methods are: "holm" (default), "hochberg", "hommel", "bonferroni", "BH", "BY", "fdr", "none".

digits  
Number of digits for rounding or significant figures. May also be "signif" to return significant figures or "scientific" to return scientific notation. Control the number of digits by adding the value as suffix, e.g. digits = "scientific4" to have scientific notation with 4 decimal places, or digits = "signif5" for 5 significant figures (see also signif()).

...  
Additional arguments passed to other methods.

Value

The returned tibble data frame can contain some or all of the following columns (the exact columns will depend on the statistical test):

- statistic: the numeric value of a statistic
- df: the numeric value of a parameter being modeled (often degrees of freedom for the test)
- df.error and df: relevant only if the statistic in question has two degrees of freedom (e.g. anova)
- p.value: the two-sided p-value associated with the observed statistic
- method: the name of the inferential statistical test
- estimate: estimated value of the effect size
- conf.low: lower bound for the effect size estimate
- conf.high: upper bound for the effect size estimate
- conf.level: width of the confidence interval
- conf.method: method used to compute confidence interval
- conf.distribution: statistical distribution for the effect
- effectsize: the name of the effect size
- n.obs: number of observations
- expression: pre-formatted expression containing statistical details

For examples, see data frame output vignette.

**p_adjust_text**  
**p-value adjustment method text**

**Description**

Preparing text to describe which *p*-value adjustment method was used
Usage

\texttt{p\_adjust\_text(p\_adjust.method)}

Arguments

\texttt{p\_adjust.method}

Adjustment method for \( p\)-values for multiple comparisons. Possible methods are: "holm" (default), "hochberg", "hommel", "bonferroni", "BH", "BY", "fdr", "none".

Value

Standardized text description for what method was used.

Examples

\begin{verbatim}
  p_adjust_text("none")
  p_adjust_text("BY")
\end{verbatim}

---

\textbf{stats_type_switch} \hspace{1cm} \textit{Switch the type of statistics.}

Description

Relevant mostly for \texttt{ggstatsplot} and \texttt{statsExpressions} packages, where different statistical approaches are supported via this argument: parametric, non-parametric, robust, and Bayesian. This switch function converts strings entered by users to a common pattern for convenience.

Usage

\texttt{stats_type_switch(type)}

Arguments

\texttt{type}

A character specifying the type of statistical approach:

- "parametric"
- "nonparametric"
- "robust"
- "bayes"

You can specify just the initial letter.

Examples

\begin{verbatim}
  stats_type_switch("p")
  stats_type_switch("bf")
\end{verbatim}
tidy_model_expressions

Expressions with statistics for tidy regression data frames

Description

Expressions with statistics for tidy regression data frames

Usage

```r
tidy_model_expressions(
  data,
  statistic = NULL,
  digits = 2L,
  effsize.type = "omega",
  ...
)
```

Arguments

- `data` A tidy data frame from regression model object (see `statsExpressions:::tidy_model_parameters()`).
- `statistic` Which statistic is to be displayed (either "t" or "f" or "z" or "chi") in the expression.
- `digits` Number of digits for rounding or significant figures. May also be "signif" to return significant figures or "scientific" to return scientific notation. Control the number of digits by adding the value as suffix, e.g. `digits = "scientific4"` to have scientific notation with 4 decimal places, or `digits = "signif5"` for 5 significant figures (see also `signif()`).
- `effsize.type` Type of effect size needed for parametric tests. The argument can be "eta" (partial eta-squared) or "omega" (partial omega-squared).
- `...` Currently ignored.

Details

When any of the necessary numeric column values (estimate, statistic, p.value) are missing, for these rows, a NULL is returned instead of an expression with empty strings.

Note

This is an experimental function and may change in the future. Please do not use it yet in your workflow.
Examples

```r
# setup
set.seed(123)
library(statsExpressions)

# extract a tidy data frame
df <- tidy_model_parameters(lm(wt ~ am * cyl, mtcars))

# create a column containing expression; the expression will depend on `statistic`
tidy_model_expressions(df, statistic = "t")
tidy_model_expressions(df, statistic = "z")
tidy_model_expressions(df, statistic = "chi")
```

---

tidy_model_parameters  Convert `parameters` package output to `tidyverse` conventions

Description

Convert `parameters` package output to `tidyverse` conventions

Usage

```r
tidy_model_parameters(model, ...)
```

Arguments

- `model`  Statistical Model.
- `...`  Arguments passed to or from other methods. Non-documented arguments are `digits`, `p_digits`, `ci_digits` and `footer_digits` to set the number of digits for the output. If `s_value = TRUE`, the p-value will be replaced by the S-value in the output (cf. Rafi and Greenland 2020). `pd` adds an additional column with the probability of direction (see `bayestestR::p_direction()` for details). `groups` can be used to group coefficients. It will be passed to the print-method, or can directly be used in `print()`, see documentation in `print.parameters_model()`. Furthermore, see 'Examples' in `model_parameters.default()`. For developers, whose interest mainly is to get a "tidy" data frame of model summaries, it is recommended to set `pretty_names = FALSE` to speed up computation of the summary table.

Examples

```r
model <- lm(mpg ~ wt + cyl, data = mtcars)
tidy_model_parameters(model)
```
two_sample_test

Two-sample tests

Description

Parametric, non-parametric, robust, and Bayesian two-sample tests.

Usage

two_sample_test(
  data,
  x,
  y,
  subject.id = NULL,
  type = "parametric",
  paired = FALSE,
  alternative = "two.sided",
  digits = 2L,
  conf.level = 0.95,
  effsize.type = "g",
  var.equal = FALSE,
  bf.prior = 0.707,
  tr = 0.2,
  nboot = 100L,
  ...
)

Arguments

data A data frame (or a tibble) from which variables specified are to be taken. Other data types (e.g., matrix, table, array, etc.) will not be accepted. Additionally, grouped data frames from {dplyr} should be ungrouped before they are entered as data.

x The grouping (or independent) variable from data. In case of a repeated measures or within-subjects design, if subject.id argument is not available or not explicitly specified, the function assumes that the data has already been sorted by such an id by the user and creates an internal identifier. So if your data is not sorted, the results can be inaccurate when there are more than two levels in x and there are NAs present. The data is expected to be sorted by user in subject-1,subject-2,...,pattern.

y The response (or outcome or dependent) variable from data.

subject.id Relevant in case of a repeated measures or within-subjects design (paired = TRUE, i.e.), it specifies the subject or repeated measures identifier. Important: Note that if this argument is NULL (which is the default), the function assumes that the data has already been sorted by such an id by the user and creates an internal identifier. So if your data is not sorted and you leave this argument
two_sample_test

unspefied, the results can be inaccurate when there are more than two levels in x and there are NAs present.

type A character specifying the type of statistical approach:
  • "parametric"
  • "nonparametric"
  • "robust"
  • "bayes"

You can specify just the initial letter.

paired Logical that decides whether the experimental design is repeated measures/within-subjects or between-subjects. The default is FALSE.

alternative a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.

digits Number of digits for rounding or significant figures. May also be "signif" to return significant figures or "scientific" to return scientific notation. Control the number of digits by adding the value as suffix, e.g. digits = "scientific4" to have scientific notation with 4 decimal places, or digits = "signif5" for 5 significant figures (see also signif()).

conf.level Scalar between 0 and 1 (default: 95% confidence/credible intervals, 0.95). If NULL, no confidence intervals will be computed.

effsize.type Type of effect size needed for parametric tests. The argument can be "d" (for Cohen’s d) or "g" (for Hedge’s g).

var.equal a logical variable indicating whether to treat the two variances as being equal. If TRUE then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used.

bf.prior A number between 0.5 and 2 (default 0.707), the prior width to use in calculating Bayes factors and posterior estimates. In addition to numeric arguments, several named values are also recognized: "medium", "wide", and "ultrawide", corresponding to r scale values of 1/2, sqrt(2)/2, and 1, respectively. In case of an ANOVA, this value corresponds to scale for fixed effects.

tr Trim level for the mean when carrying out robust tests. In case of an error, try reducing the value of tr, which is by default set to 0.2. Lowering the value might help.

nboot Number of bootstrap samples for computing confidence interval for the effect size (Default: 100L).

... Currently ignored.

Value

The returned tibble data frame can contain some or all of the following columns (the exact columns will depend on the statistical test):

• statistic: the numeric value of a statistic
• df: the numeric value of a parameter being modeled (often degrees of freedom for the test)
• df.error and df: relevant only if the statistic in question has two degrees of freedom (e.g. anova)
• p.value: the two-sided p-value associated with the observed statistic
• method: the name of the inferential statistical test
• estimate: estimated value of the effect size
• conf.low: lower bound for the effect size estimate
• conf.high: upper bound for the effect size estimate
• conf.level: width of the confidence interval
• conf.method: method used to compute confidence interval
• conf.distribution: statistical distribution for the effect
• effectsize: the name of the effect size
• n.obs: number of observations
• expression: pre-formatted expression containing statistical details

For examples, see data frame output vignette.

Two-sample tests

The table below provides summary about:

• statistical test carried out for inferential statistics
• type of effect size estimate and a measure of uncertainty for this estimate
• functions used internally to compute these details
