Package ‘tensorflow’

October 2, 2019

Type Package
Title R Interface to 'TensorFlow'
Version 2.0.0
Description Interface to 'TensorFlow' <https://www.tensorflow.org/>, an open source software library for numerical computation using data flow graphs. Nodes in the graph represent mathematical operations, while the graph edges represent the multidimensional data arrays (tensors) communicated between them. The flexible architecture allows you to deploy computation to one or more 'CPUs' or 'GPUs' in a desktop, server, or mobile device with a single 'API'. 'TensorFlow' was originally developed by researchers and engineers working on the Google Brain Team within Google's Machine Intelligence research organization for the purposes of conducting machine learning and deep neural networks research, but the system is general enough to be applicable in a wide variety of other domains as well.
License Apache License 2.0
URL https://github.com/rstudio/tensorflow
BugReports https://github.com/rstudio/tensorflow/issues
SystemRequirements TensorFlow (https://www.tensorflow.org/)
Encoding UTF-8
LazyData true
Depends R (>= 3.1)
Imports config, jsonlite (>= 1.2), processx, reticulate (>= 1.10), tfruns (>= 1.0), utils, yaml, rstudioapi (>= 0.7)
Suggests testthat, keras, tfestimators
RoxygenNote 6.1.1
NeedsCompilation no

all_dims

Description

This function returns an object that can be used when subsetting tensors with \[
\]. If you are familiar with python\., this is equivalent to the python Ellipsis \..., (not to be confused with \... in R).

Usage

all_dims()
evaluate

Examples

```r
## Not run:
# in python, if x is a numpy array or tensorflow tensor
x[..., i]
# the ellipsis means "expand to match number of dimension of x".
# to translate the above python expression to R, write:
x[all_dims(), i]

## End(Not run)
```

evaluate

Evaluate a Model

Description

Evaluate a model object. See implementations in the keras and tfestimators packages.

Usage

```r
evaluate(object, ...)
```

Arguments

- `object` An evaluable R object.
- `...` Optional arguments passed on to implementing methods.

Implementations

- keras
- tfestimators

exportSavedModel

Export a Saved Model

Description

Serialize a model to disk. See implementations in the keras and tfestimators packages.

Usage

```r
exportSavedModel(object, export_dir_base, ...)
```
install_tensorflow

Arguments

- object: An R object.
- export_dir_base: A string containing a directory in which to export the SavedModel.

Value

The path to the exported directory, as a string.

Implementations

- keras
- tfestimators

install_tensorflow Install TensorFlow and its dependencies

Description

Install TensorFlow and its dependencies

Usage

install_tensorflow(method = c("auto", "virtualenv", "conda"),
conda = "auto", version = "default", envname = NULL,
extra_packages = NULL, restart_session = TRUE,
conda_python_version = "3.6", ...)

Arguments

- method: Installation method. By default, "auto" automatically finds a method that will work in the local environment. Change the default to force a specific installation method. Note that the "virtualenv" method is not available on Windows (as this isn’t supported by TensorFlow). Note also that since this command runs without privilege the "system" method is available only on Windows.
- conda: Path to conda executable (or "auto" to find conda using the PATH and other conventional install locations).
- version: TensorFlow version to install. Specify "default" to install the CPU version of the latest release. Specify "gpu" to install the GPU version of the latest release. You can also provide a full major.minor.patch specification (e.g. "1.1.0"), appending "-gpu" if you want the GPU version (e.g. "1.1.0-gpu"). Alternatively, you can provide the full URL to an installer binary (e.g. for a nightly binary).
- envname: Name of Python environment to install within
install_tensorflow_extras

**Install additional Python packages alongside TensorFlow**

### Description

This function is deprecated. Use the `extra_packages` argument to `install_tensorflow()` to install additional packages.

### Usage

```r
install_tensorflow_extras(packages, conda = "auto")
```

#### Arguments

- **packages**
  - Python packages to install
- **conda**
  - Path to conda executable (or "auto" to find conda using the PATH and other conventional install locations). Only used when TensorFlow is installed within a conda environment.

---

**parse_arguments**

**Parse Command Line Arguments**

### Description

Parse command line arguments of the form `--key=value` and `--key value`. The values are assumed to be valid yaml and will be converted using `yaml.load()`.

### Usage

```r
parse_arguments(arguments = NULL)
```

#### Arguments

- **arguments**
  - A vector of command line arguments. When NULL (the default), the command line arguments received by the current R process are used.
parse_flags

Parse Configuration Flags for a TensorFlow Application

Description
Parse configuration flags for a TensorFlow application. Use this to parse and unify the configuration(s) specified through a flags.yml configuration file, alongside other arguments set through the command line.

Usage

parse_flags(config = Sys.getenv("R_CONFIG_ACTIVE", unset = "default"),
            file = "flags.yml", arguments = commandArgs(TRUE))

Arguments

- **config**: The configuration to use. Defaults to the active configuration for the current environment (as specified by the R_CONFIG_ACTIVE environment variable), or default when unset.
- **file**: The configuration file to read.
- **arguments**: The command line arguments (as a character vector) to be parsed.

Value
A named R list, mapping configuration keys to values.

Examples

```r
# Not run:
# examine an example configuration file provided by tensorflow
file <- system.file("examples/config/flags.yml", package = "tensorflow")
cat(readLines(file), sep = "\n")

# read the default configuration
FLAGS <- tensorflow::parse_flags("default", file = file)
str(FLAGS)

# read the alternate configuration: note that
# the default configuration is inherited, but
# we override the 'string' configuration here
FLAGS <- tensorflow::parse_flags("alternate", file = file)
str(FLAGS)

# override configuration values using command
# line arguments (normally, these would be
# passed in through the command line invocation
# used to start the process)
FLAGS <- tensorflow::parse_flags("alternate", file = file)
```
shape

"alternate",
file = file,
arguments = c("--foo=1")
)
str(FLAGS)

## End(Not run)

---

<table>
<thead>
<tr>
<th>shape</th>
<th>Tensor shape</th>
</tr>
</thead>
</table>

**Description**

Tensor shape

**Usage**

```r
shape(...)```

**Arguments**

```
... Tensor dimensions
```

---

<table>
<thead>
<tr>
<th>tensorboard</th>
<th>TensorBoard Visualization Tool</th>
</tr>
</thead>
</table>

**Description**

TensorBoard is a tool inspecting and understanding your TensorFlow runs and graphs.

**Usage**

```r
tensorboard(log_dir, action = c("start", "stop"), host = "127.0.0.1",
port = "auto",
launch_browser =getOption("tensorflow.tensorboard.browser",
interactive()), reload_interval = 5, purge_orphaned_data = TRUE)
```

**Arguments**

```
log_dir Directory to scan for training logs. If this is a named character vector then the
specified names will be used as aliases within TensorBoard.
action Specify whether to start or stop TensorBoard (TensorBoard will be stopped au-
tomatically when the R session from which it is launched is terminated).
host Host for serving TensorBoard
```
Port for serving TensorBoard. If "auto" is specified (the default) then an unused port will be chosen automatically.

launch_browser
Open a web browser for TensorBoard after launching. Defaults to TRUE in interactive sessions. When running under RStudio uses an RStudio window by default (pass a function e.g. utils::browseURL() to open in an external browser). Use the tensorflow.tensorboard.browser option to establish a global default behavior.

reload_interval
How often the backend should load more data.

purge_orphaned_data
Whether to purge data that may have been orphaned due to TensorBoard restarts. Disabling purge_orphaned_data can be used to debug data disappearance.

Details
When TensorBoard is passed a logdir at startup, it recursively walks the directory tree rooted at logdir looking for subdirectories that contain tfevents data. Every time it encounters such a subdirectory, it loads it as a new run, and the frontend will organize the data accordingly.

The TensorBoard process will be automatically destroyed when the R session in which it is launched exits. You can pass action = "stop" to manually terminate TensorBoard.

Value
URL for browsing TensorBoard (invisibly).

tensorflow

TensorFlow for R

Description
TensorFlow is an open source software library for numerical computation using data flow graphs. Nodes in the graph represent mathematical operations, while the graph edges represent the multidimensional data arrays (tensors) communicated between them. The flexible architecture allows you to deploy computation to one or more CPUs or GPUs in a desktop, server, or mobile device with a single API.

Details
The TensorFlow API is composed of a set of Python modules that enable constructing and executing TensorFlow graphs. The tensorflow package provides access to the complete TensorFlow API from within R.

For additional documentation on the tensorflow package see https://tensorflow.rstudio.com
tf

Main TensorFlow module

Description

Interface to main TensorFlow module. Provides access to top level classes and functions as well as sub-modules (e.g. tf$nn, tf$contrib$learn, etc.).

Usage

tf

Format

TensorFlow module

Examples

```r
## Not run:
library(tensorflow)

hello <- tf$constant('Hello, TensorFlow!')
zeros <- tf$Variable(tf$zeros(shape(1L)))

sess <- tf$Session()
sess$run(tf$global_variables_initializer())
sess$run(hello)
sess$run(zeros)

## End(Not run)
```

tfe_enable_eager_execution

Enables, for the rest of the lifetime of this program, eager execution.

Description

If not called immediately on startup risks creating breakage and bugs.

Usage

tfe_enable_eager_execution(config = NULL, device_policy = c("explicit", "warn", "silent"))
**Arguments**

config (Optional) A `tf$ConfigProto()` protocol buffer with configuration options for the Context. Note that a lot of these options may be currently unimplemented or irrelevant when eager execution is enabled.

device_policy (Optional) What policy to use when trying to run an operation on a device with inputs which are not on that device. Valid values: "explicit": raises an error if the placement is not correct. "warn": copies the tensors which are not on the right device but raises a warning. "silent": silently copies the tensors. This might hide performance problems.

**Details**

After eager execution is enabled, operations are executed as they are defined and tensors hold concrete values, and can be accessed as R matrices or arrays with `as.matrix()`, `as.array()`, `as.double()`, etc.

**Examples**

```r
## Not run:
# load tensorflow and enable eager execution
library(tensorflow)
tfe_enable_eager_execution()

# create a random 10x10 matrix
x <- tf$random_normal(shape(10, 10))

# use it in R via as.matrix()
heatmap(as.matrix(x))
## End(Not run)
```

---

### tf_extract_opts

**Tensor extract options**

**Description**

Tensor extract options

**Usage**

```r
tf_extract_opts(style = getOption("tensorflow.extract.style"), ..., one_based = getOption("tensorflow.extract.one_based", TRUE), inclusive_stop = getOption("tensorflow.extract.inclusive_stop", TRUE), disallow_out_of_bounds = getOption("tensorflow.extract.disallow_out_of_bounds", TRUE), warn_tensors_passed_asis = getOption("tensorflow.extract.warn_tensors_passed_asis",
```
tf_extract_opts

TRUE),
warn_negatives_pythonic = getOption("tensorflow.extract.warn_negatives_pythonic", TRUE))

Arguments

style one of NULL (the default) "R" or "python". If supplied, this overrides all other options. "python" is equivalent to all the other arguments being FALSE. "R" is equivalent to warn_tensors_passed_asis and warn_negatives_pythonic set to FALSE

... ignored

one_based TRUE or FALSE, if one-based indexing should be used

inclusive_stop TRUE or FALSE, if slices like start:stop should be inclusive of stop

disallow_out_of_bounds TRUE or FALSE, whether checks are performed on the slicing index to ensure it is within bounds.

warn_tensors_passed_asis TRUE or FALSE, whether to emit a warning the first time a tensor is supplied to [ that tensors are passed as-is, with no R to python translation

warn_negatives_pythonic TRUE or FALSE, whether to emit a warning the first time a negative number is supplied to [ about the non-standard (python-style) interpretation

Value

an object with class "tf_extract_opts", suitable for passing to [.tensorflow.tensor()

Examples

## Not run:
x <- tf$constant(1:10)

opts <- tf_extract_opts("R")
x[1, options = opts]

# or for more fine-grained control
opts <- tf_extract_opts(
    one_based = FALSE,
    warn_tensors_passed_asis = FALSE,
    warn_negatives_pythonic = FALSE
)
x[0:2, options = opts]

## End(Not run)
tf_function

Creates a callable TensorFlow graph from an R function.

**Description**

tf_function constructs a callable that executes a TensorFlow graph created by tracing the TensorFlow operations in f. This allows the TensorFlow runtime to apply optimizations and exploit parallelism in the computation defined by f.

**Usage**

tf_function(f, input_signature = NULL, autograph = FALSE, experimental_autograph_options = NULL)

**Arguments**

- **f**
  the function to be compiled

- **input_signature**
  A possibly nested sequence of tf$TensorSpec objects specifying the shapes and dtypes of the tensors that will be supplied to this function. If NULL, a separate function is instantiated for each inferred input signature. If input_signature is specified, every input to f must be a tensor.

- **autograph**
  Whether autograph should be applied on f before tracing a graph. This allows for dynamic control flow (if’s, loops etc.) in the traced graph. See https://www.tensorflow.org/guide/autograph for more information. Note: We set the default to FALSE until this functionality is available from R.

- **experimental_autograph_options**
  Experimental knobs (in the form of a tuple of tf$autograph$Feature values) to control behavior when autograph = TRUE.

**tf_probability**

TensorFlow Probability Module

**Description**

TensorFlow Probability Module

**Usage**

tf_probability()

**Value**

Reference to TensorFlow Probability functions and classes
Examples

```r
## Not run:
library(tensorflow)
tfp <- tf_probability()
tfp$distributions$Normal(loc=0, scale=1)
## End(Not run)
```

---

train  

## Train a Model

### Description
Train a model object. See implementation in the tfestimators package.

### Usage

```r
train(object, ...)
```

### Arguments

- **object**: A trainable R object.
- **...**: Optional arguments passed on to implementing methods.

### Implementations
- tfestimators

---

train_and_evaluate  

## Simultaneously Train and Evaluate a Model

### Description
Train and evaluate a model object. See implementation in the tfestimators package.

### Usage

```r
train_and_evaluate(object, ...)
```

### Arguments

- **object**: An R object.
- **...**: Optional arguments passed on to implementing methods.

### Implementations
- tfestimators
**use_compat**  
*Use Compatibility*

**Description**

Enables TensorFlow to run under a different API version for compatibility with previous versions. For instance, this is useful to run TensorFlow 1.x code when using TensorFlow 2.x.

**Usage**

```r
use_compat(version = c("v1", "v2"))
```

**Arguments**

- `version`  
  The version to activate. Must be "v1" or "v2"

**Examples**

```r
## Not run:
library(tensorflow)
use_compat("v1")
## End(Not run)
```

---

**use_session_with_seed**  
*Use a session with a random seed*

**Description**

Set various random seeds required to ensure reproducible results. The provided seed value will establish a new random seed for R, Python, NumPy, and TensorFlow. GPU computations and CPU parallelism will also be disabled by default.

**Usage**

```r
use_session_with_seed(seed, disable_gpu = TRUE, disable_parallel_cpu = TRUE, quiet = FALSE)
```

**Arguments**

- `seed`  
  A single value, interpreted as an integer
- `disable_gpu`  
  TRUE to disable GPU execution (see Parallelism below).
- `disable_parallel_cpu`  
  TRUE to disable CPU parallelism (see Parallelism below).
- `quiet`  
  TRUE to suppress printing of messages.
view_savedmodel

Details
This function must be called at the very top of your script (i.e. immediately after library(tensorflow),
library(keras), etc.). Any existing TensorFlow session is torn down via tf$reset_default_graph().
This function takes all measures known to promote reproducible results from TensorFlow sessions,
however it’s possible that various individual TensorFlow features or dependent libraries escape its
effects. If you encounter non-reproducible results please investigate the possible sources of the
problem, contributions via pull request are very welcome!
Packages which need to be notified before and after the seed is set can register for the "tensorflow:on_before_use_session" and "tensorflow:on_use_session" hooks (see setHook()) for additional
details on hooks).

Value
TensorFlow session object, invisibly

Parallelism
By default the use_session_with_seed() function disables GPU and CPU parallelism, since both
can result in non-deterministic execution patterns (see https://stackoverflow.com/questions/42022950/). You can optionally enable GPU or CPU parallelism by setting the disable_gpu and/or
disable_parallel_cpu parameters to FALSE.

Examples
```r
## Not run:
library(tensorflow)
use_session_with_seed(42)
## End(Not run)
```

view_savedmodel View a Saved Model

Description
View a serialized model from disk.

Usage
view_savedmodel(model_dir)

Arguments

model_dir The path to the exported model, as a string.

Value
URL for browsing TensorBoard (invisibly).
Subset tensors with [

Description

Subset tensors with [

Usage

## S3 method for class 'tensorflow.tensor'
x[...], drop = TRUE,
    style = getOption("tensorflow.extract.style"),
    options = tf_extract_opts(style)

Arguments

x Tensorflow tensor
...
slicing specs. See examples and details.
drop whether to drop scalar dimensions
style One of "python" or "R".
options An object returned by tf_extract_opts()

Examples

## Not run:
sess <- tf$Session()

x <- tf$constant(1:15, shape = c(3, 5))
sess$run(x)
# by default, numerics supplied to `...` are interpreted R style
sess$run( x[,1] ) # first column
sess$run( x[1:2,] ) # first two rows
sess$run( x[,1, drop = FALSE] )

# strided steps can be specified in R syntax or python syntax
sess$run( x[, seq(1, 5, by = 2)] )
sess$run( x[, 1:5:2] )
# if you are unfamiliar with python-style strided steps, see:
# https://docs.scipy.org/doc/numpy-1.13.0/reference/arrays.indexing.html#basic-slicing-and-indexing

# missing arguments for python syntax are valid, but they must by backticked
# or supplied as NULL
sess$run( x[, `::2`] )
sess$run( x[, NULL::NULL:2] )
sess$run( x[, `2:`] )

# Another python feature that is available is a python style ellipsis `...`
# (not to be confused with R dots `...' )
# a all_dims() expands to the shape of the tensor
y <- tf$constant(1:(3^5), shape = c(3,3,3,3,3))
identical(
  sess$run( y[all_dims(), 1] ),
  sess$run( y[,,,,1] )
)

# tf$newaxis are valid
sess$run( x[,, tf$newaxis] )

# negative numbers are always interpreted python style
# The first time a negative number is supplied to `\[`, a warning is issued
# about the non-standard behavior.
sess$run( x[-1,] ) # last row, with a warning
sess$run( x[-1,] ) # the warning is only issued once

# specifying 'style = 'python'' changes the following:
# + zero-based indexing is used
# + slice sequences in the form of `start:stop` do not include `stop`
#   in the returned value
# + out-of-bounds indices in a slice are valid

# The style argument can be supplied to individual calls of `\[` or set
# as a global option

# example of zero based indexing
sess$run( x[0, , style = 'python'] ) # first row
sess$run( x[1, , style = 'python'] ) # second row

# example of slices with exclusive stop
options(tensorflow.extract.style = 'python')
sess$run( x[ , 0:1] ) # just the first column
sess$run( x[ , 0:2] ) # first and second column

# example of out-of-bounds index
sess$run( x[ , 0:10] )
options(tensorflow.extract.style = NULL)

# slicing with tensors is valid too, but note, tensors are never
# translated and are always interpreted python-style.
# A warning is issued the first time a tensor is passed to `\['
sess$run( x[ , tf$constant(0L):tf$constant(2L)] )
# just as in python, only scalar tensors are valid
# https://www.tensorflow.org/api_docs/python/tf/Tensor#__getitem__

# To silence the warnings about tensors being passed as-is and negative numbers
# being interpreted python-style, set
options(tensorflow.extract.style = 'R')

# clean up from examples
options(tensorflow.extract.style = NULL)

## End(Not run)
