Package ‘tfrmt’

July 6, 2024

Title Applies Display Metadata to Analysis Results Datasets

Version 0.1.2

Description Creates a framework to store and apply display metadata to Analysis Results Datasets (ARDs). The use of ‘tfrmt’ allows users to define table format and styling without the data, and later apply the format to the data.

<table>
<thead>
<tr>
<th>apply_frmt</th>
<th>Apply formatting</th>
</tr>
</thead>
</table>

Description

Apply formatting
apply_frmt

Usage

apply_frmt(frmt_def, .data, value, mock = FALSE, ...)

## S3 method for class 'frmt'
apply_frmt(frmt_def, .data, value, mock = FALSE, ...)

## S3 method for class 'frmt_combine'
apply_frmt(
  frmt_def,
  .data,
  value,
  mock = FALSE,
  param,
  column,
  label,
  group,
  ...
)

## S3 method for class 'frmt_when'
apply_frmt(frmt_def, .data, value, mock = FALSE, ...)

Arguments

frmt_def formatting to be applied
.data data, but only what is getting changed
value value symbol should only be one
mock Logical value is this is for a mock or not. By default FALSE
... additional arguments for methods
param param column as a quosure
column column columns as a list of quosures
label label column as a quosure
group group column as a list of quosures

Value

formatted dataset

Examples

library(tibble)
library(dplyr)
# Set up data
df <- tibble(x = c(20.12, 34.54, 12.34))

apply_frmt(
  frmt_def = frmt("XX.X"),
Description

Big N structure allows you to specify which values should become the subject totals ("big N" values) and how they should be formatted in the table's column labels. Values are specified by providing the value(s) of the param column for which the values are big N's. This will remove these from the body of the table and place them into columns matching the values in the column column(s). The default formatting is \( N = xx \), on its own line, but that can be changed by providing a different frmt() to n_frmt.

Usage

big_n_structure(param_val, n_frmt = frmt("\nN = xx"), by_page = FALSE)

Arguments

param_val row value(s) of the parameter column for which the values are big n's
n_frmt frmt() to control the formatting of the big n's
by_page Option to include different big Ns for each group-defined set of pages (defined by any variables set to ".default" in the page_plan). Default is FALSE, meaning only the overall Ns are applied

Value

big_n_structure object

See Also

Link to related article
Description

Define the formatting of the body contents of the table through a series of fmt_structures. Structures get applied in order from bottom up, so the last added structure is the first applied.

Usage

body_plan(...)

Arguments

... list of fmt_structures defining the body formatting

Value

body_plan object

See Also

fmt_structure() defines which rows the formats will be applied to, and fmt(), fmt_combine(), and fmt_when() define the format semantics.

Link to related article

Examples

tfrmt_spec<- tfrmt(
  title = "Table Title",
  body_plan = body_plan(
    fmt_structure(
      group_val = c("group1"),
      label_val = ".default",
      fmt("XXX")
    )
  )
)
Define the Column Plan & Span Structures

**Description**

Using `<tidy-select>` expressions and a series span_structures, define the order of the columns. The selection follows "last selected" principals, meaning columns are moved to the last selection as opposed to preserving the first location.

**Usage**

```r
col_plan(..., .drop = FALSE)
span_structure(...)
```

**Arguments**

- `...`: For a `col_plan` and `span_structure`, `<tidy-select>` arguments, unquoted expressions separated by commas, and span_structures. span_structures must have the arguments named to match the name the column in the input data has to identify the correct columns. See the examples.
- `.drop`: Boolean. Should un-listed columns be dropped from the data. Defaults to `FALSE`.

**Details**

**Column Selection:**

When `col_plan` gets applied and is used to create the output table, the underlying logic sorts out which column specifically is being selected. If a column is selected twice, the last instance in which the column is selected will be the location it gets rendered.

Avoid beginning the `col_plan()` column selection with a deselection (i.e. `col_plan(-col1)`, `col_plan(-starts_with("value")))`. This will result in the table preserving all columns not "de-selected" in the statement, and the order of the columns not changed. It is preferred when creating the `col_plan()` to identify all the columns planned on preserving in the order they are wished to appear, or if `<tidy-select>` arguments - such as `everything`- are used, identify the de-selection after the positive-selection.

Alternatively, once the gt table is produced, use the `cols_hide` function to remove un-wanted columns.

**Value**

- `col_plan` object
- `span_structure` object

**Images**

Here are some example outputs:

Examples

library(dplyr)

## select col_1 as the first column, remove col_last, then create spanning
## structures that have multiple levels
##
## examples also assume the tfrmt has the column argument set to c(c1, c2, c3)
##
## spanning_col_plan_ex <- col_plan(
##  col_1,
##  -col_last,
##  span_structure(
##    c1 = "Top Label Level 1",
##    c2 = "Second Label Level 1.1",
##    c3 = c(col_3, col_4)
##  ),
##  span_structure(
##    c1 = "Top Label Level 1",
##    c2 = "Second Label Level 1.2",
##    c3 = starts_with("B")
##  ),
##  span_structure(
##    c1 = "Top Label Level 1",
##    c3 = col_5
##  ),
##  span_structure(
##    c2 = "Top Label Level 2",
##    c3 = c(col_6, col_7)
##  )
## )

## select my_col_1 as the first column, then
## rename col_2 to new_col_1 and put as the
## second column, then select the rest of the columns
renaming_col_plan_ex <- col_plan(
  my_col_1,
  new_col_1 = col_2,
  everything()
 )

renaming_col_plan_ex2 <- col_plan(
  my_col_1,
  new_col_1 = col_2,
  span_structure(
    c1 = c("My Favorite span name" = "Top Label Level 1"),
    c3 = c("the results column" = col_5)
  )
)
Description

Define how the columns of the table body should be aligned, whether left, right or on a specific character(s).

Usage

```r
col_style_plan(...)```

Arguments

```r
... series of col_style_structure objects```

Value

`col_style_plan` object

See Also

`col_style_structure()` for more information on how to specify how to and which columns to align.

Link to related article

Examples

```r
plan <- col_style_plan(
  col_style_structure(col = "my_var", align = "left", width = 100),
  col_style_structure(col = vars(four), align = "right"),
  col_style_structure(col = vars(two, three), align = c(".", ",", " "))
)```
col_style_structure

Description

Column Style Structure

Usage

col_style_structure(
  col,
  align = NULL,
  type = c("char", "pos"),
  width = NULL,
  ...
)

Arguments

col       Column value to align on from column variable. May be a quoted or unquoted column name, a tidyselect semantic, or a span_structure.
align     Alignment to be applied to column. Defaults to left alignment. See details for acceptable values.
type      Type of alignment: "char" or "pos", for character alignment (default), and positional alignment, respectively. Positional alignment allows for aligning over multiple positions in the column.
width     Width to apply to the column in number of characters. Acceptable values include a numeric value, or a character string of a number.
...

These dots are for future extensions and must be empty

Details

Supports alignment and width setting of data value columns (values found in the column column). Row group and label columns are left-aligned by default. Acceptable input values for align differ by type = "char" or "pos":

Character alignment (type = "char")::

  • "left" for left alignment
  • "right" for right alignment
  • supply a vector of character(s) to align on. If more than one character is provided, alignment will be based on the first occurrence of any of the characters. For alignment based on white space, leading white spaces will be ignored.

Positional alignment (type = "pos")::

supply a vector of strings covering all formatted cell values, with numeric values represented as x’s. These values can be created manually or obtained by utilizing the helper display_val_frmts().
Alignment positions will be represented by vertical bars. For example, with starting values:
c("12.3", "(5%)", "2.35 (10.23)"") we can align all of the first sets of decimals and parentheses by providing align = c("xx.lx", "ll(x%)", "xl.xxx l")

Value
col_style_structure object

See Also
col_style_plan() for more information on how to combine col_style_structure()'s together to form a plan.

Link to related article

Examples

```r
plan <- col_style_plan(
  col_style_structure(col = "my_var",
    align = c("xx| |(xx%)",
        "xx.lx |(xx.x - xx.x)"),
    type = "pos", width = 100),
  col_style_structure(col = vars(four), align = "right", width = 200),
  col_style_structure(col = vars(two, three), align = c(".", ",", ", ")),
  col_style_structure(col = c(two, three), width = 25),
  col_style_structure(col = two, width = 25),
  col_style_structure(col = span_structure(span = value, col = val2),
    width = 25)
)
```

data_ae  

*Adverse Events Analysis Results Data*

**Description**

A dataset containing the results needed for an AE table. Using the CDISC pilot data.

**Usage**

data_ae

**Format**

A data frame with 2,794 rows and 8 variables:

- **AEBODSYS** highest level row labels: System Organ Class
- **AETERM** more specific row labels: Preferred Term
- **col2** higher level column names (spanners)
data_demog

- **col1** lower level column names
- **param** parameter to explain each value
- **value** values to put in a table
- **ord1** controls ordering
- **ord2** more ordering controls

---

**Description**

A dataset containing the results needed for a demography table. Using the CDISC pilot data.

**Usage**

data_demog

**Format**

A data frame with 386 rows and 7 variables:

- **rowlbl1** highest level row labels
- **rowlbl2** more specific row labels
- **param** parameter to explain each value
- **grp** grouping column used to distinguish continuous and categorical
- **ord1** controls ordering
- **ord2** more ordering controls
- **column** column names
- **value** values to put in a table

---

**Description**

A dataset containing the results needed for an Efficacy table. Using the CDISC pilot data for ADAS-Cog(11).

**Usage**

data_efficacy
**Format**

A data frame with 70 rows and 7 variables:

- **group** highest level row labels
- **label** more specific row labels
- **column** column names
- **param** parameter to explain each value
- **value** values to put in a table
- **ord1** controls ordering
- **ord2** more ordering controls

---

### data_labs

**Labs Analysis Results Data**

---

**Description**

A dataset containing the results needed for an labs results table. Using the CDISC pilot data.

**Usage**

data_labs

**Format**

A data frame with 4,950 rows and 7 variables:

- **group1** highest level row labels: Lab value class
- **group2** more specific row labels: Lab parameter
- **rowlbl** most specific row labels: Study visit
- **col1** higher level column names (spanners)
- **col2** lower level column names
- **param** parameter to explain each value
- **value** values to put in a table
- **ord1** controls ordering
- **ord2** more ordering controls
- **ord3** more ordering controls
display_row_frmts  

Display formatting applied to each row

Description

Used when debugging formatting, it is an easy way to allow you to see which formats are applied to each row in your dataset.

Usage

display_row_frmts(tfrmt, .data, convert_to_txt = TRUE)

display_row_frmts(tfrmt, .data, convert_to_txt = TRUE)

Arguments

- `tfrmt`: tfrmt object to apply to the data
- `.data`: Data to apply the tfrmt to
- `convert_to_txt`: Logical value converting formatting to text, by default `TRUE`

Value

formatted tibble

Examples

library(dplyr)
library(tidyr)

tfrmt_spec <- tfrmt(
  label = label,
  column = column,
  param = param,
  value = value,
  body_plan = body_plan(
    frmt_structure(group_val = ".default", label_val = ".default",
    frmt_combine(
      "\{count\} \{percent\}",
      count = frmt("xxx"),
      percent = frmt_when("==100" ~ frmt(""),
        
        "==0" ~ ",
        "TRUE" ~ frmt("xx.x%") )))
  )
)

# Create data
df <- crossing(label = c("label 1", "label 2"),
    column = c("placebo", "trt1"),
    param = c("count", "percent")) %>%
    mutate(value=c(24,19,2400/48,1900/38,5,1,500/48,100/38))

display_row_frmts(tfrmt_spec,df)
library(dplyr)
library(tidyr)

tfrmt_spec <- tfrmt(
    label = label,
    column = column,
    param = param,
    value=value,
    body_plan = body_plan(
        frmt_structure(group_val = ".default", label_val = ".default",
            frmt_combine(
                "[count] {percent}",
                count = frmt("xxx"),
                percent = frmt_when("==100"~ frmt(""),
                    "==0"~ "",
                    "TRUE" ~ frmt("(xx.x%)"))))
    ))

# Create data
df <- crossing(label = c("label 1", "label 2"),
    column = c("placebo", "trt1"),
    param = c("count", "percent")) %>%
    mutate(value=c(24,19,2400/48,1900/38,5,1,500/48,100/38))

display_row_frmts(tfrmt_spec,df)

display_val_frmts

Display formatted values

Description

A helper for creating positional-alignment specifications for the col_style_plan. Returns all unique formatted values to appear in the column(s) specified. Numeric values are represented by x’s.

Usage

display_val_frmts(tfrmt, .data, mock = FALSE, col = NULL)

Arguments

tfrmt tfrmt object to apply to the data
.data Data to apply the tfrmt to
mock Mock table? TRUE or FALSE (default)
col

Column value to align on from column variable. May be a quoted or unquoted column name, a tidyselect semantic, or a span_structure.

Value

text representing character vector of formatted values to be copied and modified in the col_style_plan

Examples

tf_spec <- tfrmt(
group = c(rowlbl1,grp),
label = rowlbl2,
column = column,
param = param,
value = value,
sorting_cols = c(ord1, ord2),
body_plan = body_plan(
  frmt_structure(group_val = ".default", label_val = ".default", frmt_combine("(n) ([pct] %)",
    n = frmt("xxx"),
    pct = frmt("xx.x"))),
  frmt_structure(group_val = ".default", label_val = "n", frmt("xxx")),
  frmt_structure(group_val = ".default", label_val = c("Mean", "Median", "Min", "Max"),
    frmt("xxx.x")),
  frmt_structure(group_val = ".default", label_val = "SD", frmt("xxx.xx")),
  frmt_structure(group_val = ".default", label_val = ".default",
    p = frmt_when(">0.99" ~">0.99",
    "<0.15" ~"<0.15",
    TRUE ~ frmt("x.xxx", missing = "")))
  )
)

display_val_frlmts(tf_spec, data_demog, col = vars(everything()))
display_val_frlmts(tf_spec, data_demog, col = "p-value")

Description

Element block

Usage

element_block(post_space = c(NULL, " ", "-"), fill = TRUE)

Arguments

post_space Values to show in a new line created after the group block
fill Whether to recycle the value of post_space to match width of the data. Defaults to TRUE
element_row_grp_loc

Value

element block object

See Also

row_grp_plan() for more details on how to group row group structures, row_grp_structure() for more details on how to specify row group structures, element_row_grp_loc() for more details on how to specify whether row group titles span the entire table or collapse.

Examples

tfrmt_spec <- tfrmt(
  group = grp1,
  label = label,
  param = param,
  value = value,
  column = column,
  row_grp_plan = row_grp_plan(
    row_grp_structure(group_val = ".default", element_block(post_space = " ")),
    body_plan = body_plan(
      fmt_structure(group_val = ".default", label_val = ".default", fmt("xx"))
    )
  )
)

element_row_grp_loc   Element Row Group Location

Description

Element Row Group Location

Usage

element_row_grp_loc(
  location = c("indented", "spanning", "column", "noprint", "gtdefault"),
  indent = " "
)

Arguments

location Location of the row group labels. Specifying 'indented' combines all group and label variables into a single column with each sub-group indented under its parent. 'spanning' and 'column' retain the highest level group variable in its own column and combine all remaining group and label variables into a single column with sub-groups indented. The highest level group column will either be printed as a spanning header or in its own column in the gt. The 'noprint' option allows the user to suppress group values from being printed. Finally, the
'gtdefault' option allows users to use the 'gt' defaults for styling multiple group columns.

**Value**

- `element_row_grp_loc` object

**Images**

- Here are some example outputs:

**See Also**

- `row_grp_plan()` for more details on how to group row group structures,
- `row_grp_structure()` for more details on how to specify row group structures,
- `element_block()` for more details on how to specify spacing between each group.

**Link to related article**

**Examples**

```r
tfrmt_spec <- tfrmt(
  group = c(grp1, grp2),
  label = label,
  param = param,
  value = value,
  column = column,
  row_grp_plan = row_grp_plan(label_loc = element_row_grp_loc(location = "noprint")),
  body_plan = body_plan(
    fmt_structure(group_val = ".default", label_val = ".default", fmt("xx"))
  )
)
```

---

**Description**

- Defining the location and content of footnotes with a series of footnote structures. Each structure is a footnote and can be applied in multiple locations.

**Usage**

```r
footnote_plan(..., marks = c("numbers", "letters", "standard", "extended"))
```
Arguments

... a series of `footnote_structure()` separated by commas

`marks` type of marks required for footnotes, properties inherited from `tab_footnote` in `gt`. Available options are "numbers", "letters", "standard" and "extended" (standard for a traditional set of 4 symbols, extended for 6 symbols). The default option is set to "numbers".

Value

footnote plan object

Examples

```r
# Adds a footnote indicated by letters rather than numbers to Group 1
footnote_plan <- footnote_plan(
  footnote_structure(footnote_text = "Source Note", group_val = "Group 1"),
  marks="letters")

# Adds a footnote to the 'Placebo' column
footnote_plan <- footnote_plan(
  footnote_structure(footnote_text = "footnote", column_val = "Placebo"),
  marks="numbers")
```

### `footnote_structure` Footnote Structure

**Description**

Footnote Structure

**Usage**

```r
footnote_structure(
  footnote_text,
  column_val = NULL,
  group_val = NULL,
  label_val = NULL
)
```

**Arguments**

- `footnote_text` string with text for footnote
- `column_val` string or a named list of strings which represent the column to apply the footnote to
- `group_val` string or a named list of strings which represent the value of group to apply the footnote to
- `label_val` string which represents the value of label to apply the footnote to
**frmt**

**Value**

footnote structure object

**Examples**

```r
# Adds a source note aka a footnote without a symbol in the table
footnote_structure <- footnote_structure(footnote_text = "Source Note")

# Adds a footnote to the 'Placebo' column
footnote_structure <- footnote_structure(footnote_text = "Text",
                         column_val = "Placebo")

# Adds a footnote to either 'Placebo' or 'Treatment groups' depending on which
# which is last to appear in the column vector
footnote_structure <- footnote_structure(footnote_text = "Text",
                         column_val = list(col1 = "Placebo", col2 = "Treatment groups"))

# Adds a footnote to the 'Adverse Event' label.
footnote_structure <- footnote_structure("Text", label_val = "Adverse Event")
```

---

**frmt**

Table Value Formatting

**Description**

These functions provide an abstracted way to approach to define formatting of table contents. By defining in this way, the formats can be layered to be more specific and general cell styling can be done first.

frmt() is the base definition of a format. This defines spacing, rounding, and missing behaviour.

frmt_combine() is used when two or more rows need to be combined into a single cell in the table. Each of the rows needs to have a defined frmt() and need to share a label.

frmt_when() is used when a rows format behaviour is dependent on the value itself and is written similarly to dplyr::case_when(). The left hand side of the equation is a "TRUE"for the default case or the right hand side of a boolean expression ">50".

**Usage**

```r
frmt(expression, missing = NULL, scientific = NULL, transform = NULL, ...)
frmt_combine(expression, ..., missing = NULL)
frmt_when(..., missing = NULL)
```
Arguments

expression: this is the string representing the intended format. See details: expression for
more a detailed description.

missing: when a value is missing that is intended to be formatted, what value to place.
See details: missing for more a detailed description.

scientific: a string representing the intended scientific notation to be appended to the ex-
pression. Ex. "e^XX" or " x10^XX".

transform: this is what should happen to the value prior to formatting. It should be a formula
or function. Ex. ~.*100 if you want to convert a percent from a decimal prior to
rounding

... See details: ... for a detailed description.

Details

expression:

• fmt() All numbers are represented by "x". Any additional character are printed as-is. If
additional X's present to the left of the decimal point than the value, they will be represented
as spaces.

• fmt_combine() defines how the parameters will be combined as a glue::glue() state-
ment. Parameters need to be equal to the values in the param column and defined in the
expression as "\{param1\} {param2}".

missing:

• fmt() Value to enter when the value is missing. When NULL, the value is "".

• fmt_combine() defines how when all values to be combined are missing. When NULL the
value is "".

...:

• fmt() These dots are for future extensions and must be empty.

• fmt_combine() accepts named arguments defining the fmt() to be applied to which pa-
rameters before being combined.

• fmt_when() accepts a series of equations separated by commas, similar to dplyr::case_when().
The left hand side of the equation is a "TRUE"for the default case or the right hand side of a
boolean expression ">50". The right hand side of the equation is the fmt() to apply when
the left side evaluates to TRUE.

Value

fmt object

See Also

body_plan() combines the fmt_structures to be applied to the table body, and fmt_structure()
defines which rows the formats will be applied to.

frmt_structure

Examples

frmt("XXX %")

frmt("XX.XXX")

frmt("xx.xx", scientific = "x10^xx")

frmt_combine(
    "{param1} {param2}"
    param1 = frmt("XXX %"),
    param2 = frmt("XX.XXX")
)

frmt_when(
    ">3" ~ frmt("(X.X%)"),
    "<=3" ~ frmt("Undetectable")
)

frmt_when(
    "==100"~ frmt(""),
    "==0"~ "",
    "TRUE" ~ frmt("(XXX.X%)")
)

________________________________________________________________________

frmt_structure  Format Structure Object

Description

Function needed to create a frmt_structure object, which is a building block of body_plan(). This specifies the rows the format will be applied to.

Usage

frmt_structure(group_val = ".default", label_val = ".default", ...)

Arguments

group_val  A string or a named list of strings which represent the value of group should be when the given fmt is implemented

label_val  A string which represent the value of label should be when the given fmt is implemented

...  either a frmt(), frmt_combine(), or a frmt_when() object. This can be named to also specify the parameter value

Value

frmt_structure object
is_frmt

Check if input is a frmt

Description
Check if input is a frmt
Check if input is a frmt_combine
Check if input is a frmt_when
Check if input is a frmt_structure
Check if input is a row_grp_structure

Usage
is_frmt(x)

is_frmt_combine(x)

is_frmt_when(x)

is_frmt_structure(x)

is_row_grp_structure(x)
Arguments

x  Object to check

Value

‘TRUE’ if yes, ‘FALSE’ if no

Examples

x1 <- frmt("XXX.XX")
is_frmt(x1)

x2 <- frmt_combine("XXX %","XX,XXX")
is_frmt_combine(x2)

x2 <- frmt_when(
  ">3" ~ frmt("(X.XX)",
  "<=3" ~ frmt("Undetectable")
)
is_frmt_when(x2)

x3 <- frmt_structure(
  group_val = c("group1"),
  label_val = ".default",
  frmt("XXX")
)
is_frmt_structure(x3)

x4 <- rowgrp_structure(group_val = c("A","C"), element_block(post_space = "---"))
is_rowgrp_structure(x4)

Description

Reader to read JSON files/objects into tfrmt objects

Usage

json_to_tfrmt(path = NULL, json = NULL)

Arguments

path  location of the json file to read in
json  json object to read in. By default this is null. This function will read in json object preferentially. So if both a path and a json object are supplied the json object will be read in.
layer_tfrmt

Layer tfrmt objects together

Description

Provide utility for layering tfrmt objects together. If both tfrmt’s have values, it will preferentially choose the second tfrmt by default. This is an alternative to piping together tfrmt’s

Usage

layer_tfrmt(x, y, ..., join_body_plans = TRUE)

Arguments

x, y  
tfrmt objects that need to be combined

...  
arguments passed to layer_tfrmt_arg functions for combining different tfrmt elements

join_body_plans  
should the body_plans be combined, or just keep styling in y. See details: join_body_plans for more details.

Details

join_body_plan:

When combining two body_plans, the body plans will stack together, first the body plan from x tfrmt then y tfrmt. This means that fmt_structures in y will take priority over those in x.

Combining two tfrmt with large body_plans can lead to slow table evaluation. Consider setting join_body_plan to FALSE. Only the y body_plan will be preserved.

Value

tfrmt object

Examples

tfrmt_1 <- tfrmt(title = "title1")
tfrmt_2 <- tfrmt(title = "title2", subtitle = "subtitle2")
layered_table_format <- layer_tfrmt(tfrmt_1, tfrmt_2)
**make_mock_data**

*Make mock data for display shells*

**Description**

Make mock data for display shells

**Usage**

```r
make_mock_data(tfrmt, .default = 1:3, n_cols = NULL)
```

**Arguments**

- `tfrmt`: tfrmt object
- `.default`: Number of unique levels to create for group/label values set to ".default"
- `n_cols`: Number of columns in the output table (not including group/label variables). If not supplied it will default to using the `col_plan` from the `tfrmt`. If neither are available it will use 3.

**Value**

tibble containing mock data

**Examples**

```r
tfrmt_spec <- tfrmt(
  label = label,
  column = column,
  param = param,
  value=value,
  body_plan = body_plan(
    frmt_structure(group_val=".default", label_val=".default", frmt("xx.x"))
  )
)
make_mock_data(tfrmt_spec)
```

---

**page_plan**

*Page Plan*

**Description**

Defining the location and/or frequency of page splits with a series of `page_structure`'s and the `row_every_n` argument, respectively.
Usage

```r
page_plan(
  ..., 
  note_loc = c("noprint", "preheader", "subtitle", "source_note"),
  max_rows = NULL
)
```

Arguments

- `...`: a series of `page_structure()` separated by commas
- `note_loc`: Location of the note describing each table's subset value(s). Useful if the `page_structure` contains only "default" values (meaning the table is split by every unique level of a grouping variable), and that variable is dropped in the `col_plan`. `preheader` only available for rtf output.
- `max_rows`: Option to set a maximum number of rows per page. Takes a numeric value.

Value

- `page_plan` object

Examples

```r
# use of `page_struct`
page_plan(
  page_structure(group_val = "grp1", label_val = "lbl1")
)

# use of `# rows`
page_plan(
  max_rows = 5
)
```

---

### page_structure

**Page structure**

**Description**

Page structure

**Usage**

```r
page_structure(group_val = NULL, label_val = NULL)
```
param_set

Arguments

- **group_val**
  - string or a named list of strings which represent the value of group to split after. Set to ".default" if the split should occur after every unique value of the variable.

- **label_val**
  - string which represents the value of label to split after. Set to ".default" if the split should occur after every unique value of the variable.

Value

- page structure object

Examples

- # split page after every unique level of the grouping variable
  - page_structure(group_val = ".default", label_val = NULL)

- # split page after specific levels
  - page_structure(group_val = "grp1", label_val = "lbl3")

---

param_set

*Set custom parameter-level significant digits rounding*

Description

Set custom parameter-level significant digits rounding

Usage

- param_set(

Arguments

- ...
  - Series of name-value pairs, optionally formatted using glue::glue() syntax (note glue syntax is required for combined parameters). The name represents the parameter and the value represents the number of places to round the parameter to. For combined parameters (e.g., ":min", "max"), value should be a vector of the same length (e.g., c(1,1)).

Details

- Type `param_set()` in console to view package defaults. Use of the function will add to the defaults and/or override included defaults of the same name. For values that are integers, use NA so no decimal places will be added.

Value

- list of default parameter-level significant digits rounding
Examples

# View included defaults
param_set()

# Update the defaults
param_set("(mean) ([sd])" = c(2,3), "pct" = 1)

# Separate mean and SD to different lines
param_set("mean" = 2, "sd" = 3)

# Add formatting using the glue syntax
param_set("(pct) %" = 1)

print_mock_gt 

---

print_mock_gt  

*Print mock table to GT*

Description

Print mock table to GT

Usage

```r
print_mock_gt(
  tfrmt,
  .data = NULL,
  .default = 1:3,
  n_cols = NULL,
  .unicode_ws = TRUE
)
```

Arguments

- **tfrmt**: 
  tfrmt the mock table will be based off of

- **.data**: 
  Optional data. If this is missing, group values, labels values and parameter values will be estimated based on the tfrmt

- **.default**: 
  sequence to replace the default values if a dataset isn’t provided

- **n_cols**: 
  the number of columns. This will only be used if mock data isn’t provided. If not supplied, it will default to using the col_plan from the tfrmt. If neither are available it will use 3.

- **.unicode_ws**: 
  Whether to convert white space to unicode in preparation for output

Value

a stylized gt object
print_to_ggplot

Examples

# Create tfrmt specification

tfrmt_spec <- tfrmt(label = label, column = column, param = param, body_plan = body_plan(
  frmt_structure(group_val = "\default", label_val = "\default", frmt_combine("{count} {percent}",
  count = frmt("xxx"), percent = frmt_when("==100"~ frmt(""), "==0"~ ",
  "TRUE" ~ frmt("(xx.x%)"))))
))

# Print mock table using default
print_mock_gt(tfrmt = tfrmt_spec)

# Create mock data
df <- crossing(label = c("label 1", "label 2", "label 3"), column = c("placebo", "trt1", "trt2"), param = c("count", "percent"))

# Print mock table using mock data
print_mock_gt(tfrmt_spec, df)

print_to_ggplot

Description

Print to ggplot

Usage

print_to_ggplot(tfrmt, .data, ...)

Arguments

  tfrmt  tfrmt object that will dictate the structure of the ggplot object
  .data  Data to style in order to make the ggplot object
  ...   Inputs to geom_text to modify the style of the table body

Value

  a stylized ggplot object
Examples

# Create data
risk <- tibble(time = c(rep(c(0, 1000, 2000, 3000), 3)),
                label = c(rep("Obs", 4), rep("Lev", 4), rep("Lev+5FU", 4)),
                value = c(630, 372, 256, 11, 620, 360, 266, 8, 608, 425, 328, 14),
                param = rep("n", 12))

table <- tfrmt(
              label = label,
              column = time,
              param = param,
              value = value) %>%
          print_to_ggplot(risk)

table

print_to_gt

Description

Print to gt

Usage

print_to_gt(tfrmt, .data, .unicode_ws = TRUE)

Arguments

tfrmt tfrmt object that will dictate the structure of the table
.data Data to style in order to make the table
.unicode_ws Whether to convert white space to unicode in preparation for output

Value

a stylized gt object

Examples

library(dplyr)
# Create tfrmt specification
tfrmt_spec <- tfrmt(
              label = label,
              column = column,
              param = param,
value = value,
body_plan = body_plan(
  frmt_structure(group_val = ".default", label_val = ".default",
  frmt_combine(
    "{count} {percent}",
    count = frmt("xxx"),
    percent = frmt_when("==100" ~ frmt(""),
                 "==0" ~ "",
                 "TRUE" ~ frmt("(xx.x%)")))
))

# Create data
df <- crossing(label = c("label 1", "label 2"),
  column = c("placebo", "trt1"),
  param = c("count", "percent")) %>%
  mutate(value = c(24, 19, 2400/48, 1900/38, 5, 1, 500/48, 100/38))

print_to_gt(tfrmt_spec, df)

---

**row_grp_plan**

### Description

Define the look of the table groups on the output. This function allows you to add spaces after blocks and allows you to control how the groups are viewed whether they span the entire table or are nested as a column.

### Usage

```r
row_grp_plan(..., label_loc = element_row_grp_loc(location = "indented"))
```

### Arguments

- `...` Row group structure objects separated by commas
- `label_loc` `element_row_grp_loc()` object specifying location

### Value

- `row_grp_plan` object

### See Also

- `row_grp_structure()` for more details on how to specify row group structures, `element_block()` for more details on how to specify spacing between each group, `element_row_grp_loc()` for more details on how to specify whether row group titles span the entire table or collapse.

**Link to related article**
Examples

```r
## single grouping variable example
sample_grp_plan <- row_grp_plan(
  row_grp_structure(group_val = c("A","C"),
                    element_block(post_space = "---")),
  row_grp_structure(group_val = c("B"),
                    element_block(post_space = " ")),
  label_loc = element_row_grp_loc(location = "column")
)

## example with multiple grouping variables
sample_grp_plan <- row_grp_plan(
  row_grp_structure(group_val = list(grp1 = "A", grp2 = "b"),
                    element_block(post_space = " ")),
  label_loc = element_row_grp_loc(location = "spanning")
)
```

---

**row_grp_structure**  
Row Group Structure Object

**Description**

Function needed to create a row_grp_structure object, which is a building block of `row_grp_plan()`

**Usage**

```r
row_grp_structure(group_val = "default", element_block)
```

**Arguments**

- `group_val`  
  A string or a named list of strings which represent the value of group should be when the given fmt is implemented

- `element_block`  
  `element_block()` object to define the block styling

**Value**

`row_grp_structure` object

**See Also**

- `row_grp_plan()` for more details on how to group row group structures.  
- `element_block()` for more details on how to specify spacing between each group.

**Link to related article**
## Examples

```r
## single grouping variable example
row_grp_structure(group_val = c("A","C"), element_block(post_space = "---"))

## example with multiple grouping variables
row_grp_structure(group_val = list(grp1 = "A", grp2 = "b"), element_block(post_space = " "))
```

---

### tfrmt

**Table Format**

**Description**

tfrmt, or "table format" is a way to pre-define the non-data components of your tables, and how the data will be handled once added: i.e. title, footers, headers, span headers, and cell formats. In addition, tfrmt's can be layered, building from one table format to the next. For cases where only one value can be used, the newly defined tfrmt accepts the latest tfrmt

**Usage**

tfrmt(
  tfrmt_obj,  
  group = vars(),  
  label = quo(),  
  param = quo(),  
  value = quo(),  
  column = vars(),  
  title,  
  subtitle,  
  row_grp_plan,  
  body_plan,  
  col_style_plan,  
  col_plan,  
  sorting_cols,  
  big_n,  
  footnote_plan,  
  page_plan,  
  ...  
)

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tfrmt_obj</td>
<td>a tfrmt object to base this new format off of</td>
</tr>
<tr>
<td>group</td>
<td>what are the grouping vars of the input dataset</td>
</tr>
<tr>
<td>label</td>
<td>what is the label column of the input dataset</td>
</tr>
<tr>
<td>param</td>
<td>what is the param column of the input dataset</td>
</tr>
</tbody>
</table>
value what is the value column of the input dataset
column what is the column names column in the input dataset
title title of the table
subtitle subtitle of the table
row_grp_plan plan of the row groups blocking. Takes a row_grp_plan()
body_plan combination and formatting of the input data. Takes a body_plan()
col_style_plan how to style columns including alignment (left, right, character) and width. Takes a col_style_plan()
col_plan a col_plan object which is used to select, rename, and nest columns. Takes a col_plan()
sorting_cols which columns determine sorting of output
big_n how to format subject totals ("big Ns") for inclusion in the column labels. Takes a big_n_structure()
footnote_plan footnotes to be added to the table. Takes a footnote_plan()
page_plan pagination splits to be applied to the table. Takes a page_plan()
...
These dots are for future extensions and must be empty.

Details

NSE and Argument Evaluation:

- tfrmt allows users to pass vars, quo, and unquoted expressions to a variety of arguments, such as group, label, param, value, column, and sorting_cols. Users accustomed to tidyverse semantics should be familiar with this behaviour. However, there is an important behaviour difference between tfrmt and normal tidyverse functions. Because the data are not a part of tfrmt, it does not know when a value being passed to it is intended to be an unquoted expression representing a column name or an object from the environment. As such, it preferentially uses the value from the environment over preserving the entry as an expression. For example, if you have an object "my_object" in your environment with the value "Hello world", and try to create a tfrmt as tfrmt(column = my_object), it will take the value of "my_object" over assuming the column argument is an unquoted expression and view the entry to column as "Hello World". To pass "my_object" to tfrmt as a column name, use quotes around the value: tfrmt(column = "my_object").
- Additionally, unquoted expressions that match tfrmt’s other argument names can cause unexpected results. It is recommended to put quotes around the value as such: tfrmt(label = "group"). In this case, the quoting will prevent tfrmt from assigning its group input value to the label value.

Value

tfrmt object

  label_loc = element_row_grp_loc(location = "column")
)
**tfrmt_n_pct**

*N Percent Template*

**Description**

This function creates an tfrmt for an n % table, so count based table. The parameter values for n and percent can be provided (by default it will assume n and pct). Additionally the ffmt_when for formatting the percent can be specified. By default 100% and 0% will not appear and everything between 99% and 100% and 0% and 1% will be rounded using greater than (>) and less than (<) signs respectively.

**Usage**

```r
tfrmt_n_pct(
  n = "n",
  pct = "pct",
  pct_ffmt_when = ffmt_when("==100" ~ ffmt(""), ">99" ~ ffmt(">99%"), "==0" ~ ",", "<1"
    ~ ffmt("<1%"), "TRUE" ~ ffmt("xx.x%")),
  tfrmt_obj = NULL
)
```

**Arguments**

- **n** name of count (n) value in the parameter column
- **pct** name of percent (pct) value in the parameter column
- **pct_ffmt_when** formatting to be used on the the percent values
- **tfrmt_obj** an optional tfrmt object to layer

**Value**

tfrmt object

**Examples**

```r
print_mock_gt(tfrmt_n_pct())
```
**tfrmt_sigdig**

*Create tfrmt object from significant digits spec*

**Description**

This function creates a tfrmt based on significant digits specifications for group/label values. The input data spec provided to `sigdig_df` will contain group/label value specifications. `tfrmt_sigdig` assumes that these columns are group columns unless otherwise specified. The user may optionally choose to pass the names of the group and/or label columns as arguments to the function.

**Usage**

```r
tfrmt_sigdig(
  sigdig_df,
  group = vars(),
  label = quo(),
  param_defaults = param_set(),
  missing = NULL,
  tfrmt_obj = NULL,
  ...
)
```

**Arguments**

- `sigdig_df` data frame containing significant digits formatting spec. Has 1 record per group/label value, and columns for relevant group and/or label variables, as well as a numeric column `sigdig` containing the significant digits rounding to be applied in addition to the default. If unique group/label values are represented in multiple rows, this will result in only one of the `sigdig` values being carried through in implementation.
- `group` what are the grouping vars of the input dataset
- `label` what is the label column of the input dataset
- `param_defaults` Option to override or add to default parameters.
- `missing` missing option to be included in all tfrmts
- `tfrmt_obj` an optional tfrmt object to layer
- `...` These dots are for future extensions and must be empty.

**Details**

**Formats covered:**

Currently covers specifications for `frmt` and `frmt_combine`. `frmt_when` not supported and must be supplied in additional tfrmt that is layered on.

**Group/label variables:**

If the group/label variables are not provided to the arguments, the body_plan will be constructed from the input data with the following behaviour:
• If no group or label are supplied, it will be assumed that all columns in the input data are
group columns.
• If a label variable is provided, but nothing is specified for group, any leftover columns (i.e.
not matching sigdig or the supplied label variable name) in the input data will be assumed
to be group columns.
• If any group variable is provided, any leftover columns (i.e. not matching sigdig or the
supplied group/label variable) will be disregarded.

Value

tfrmt object with a body_plan constructed based on the significant digits data spec and param-level
significant digits defaults.

Examples

```r
sig_input <- tibble::tribble(
  ~group1, ~group2, ~sigdig,
  "CHEMISTRY", ".default", 3,
  "CHEMISTRY", "ALBUMIN", 1,
  "CHEMISTRY", "CALCIUM", 1,
  ".default", ".default", 2
)

# Subset data for the example
data <- dplyr::filter(data_labs, group2 == "BASOPHILS", col1 %in% c("Placebo", "Xanomeline Low Dose"))
tfrmt_sigdig(sigdig_df = sig_input,
  group = vars(group1, group2),
  label = rowlbl,
  param_defaults = param_set("[n]\" = NA)) %>%
tfrmt(column = vars(col1, col2),
  param = param,
  value = value,
  sorting_cols = vars(ord1, ord2, ord3),
  col_plan = col_plan(-starts_with("ord\"))) %>%
print_to_gt(.data = data)
```

---

**tfrmt_to_json**

*Print to JSON*

**Description**

Print to JSON

**Usage**

`tfrmt_to_json(tfrmt, path = NULL)`
Arguments

  tfrmt       tfrmt to print
  path        file path to save JSON to. If not provided the JSON will just print to the console

Value

  JSON

Examples

  tfrmt(
      label = label,
      column = column,
      param = param,
      value=value) %>%
  tfrmt_to_json()

update_group  Remap group values in a tfrmt

Description

Remap group values in a tfrmt

Usage

  update_group(tfrmt, ...)

Arguments

  tfrmt       a tfrmt
  ...         Use new_name = old_name to rename selected variables

Value

  A tfrmt with the group variables updated in all places
tfrmt object with updated groups#'

Examples

  tfrmt_spec <- tfrmt(
      group = c(group1, group2),
      body_plan = body_plan(
          fmt_structure(
              group_val = list(group2 = "value"),
              label_val = ".default",
              fmt("XXX")
          )
      )
  )
frmt_structure(
  group_val = list(group1 = "value", group2 = "value"),
  label_val = ".default",
  frmt("XXX")
) %>%
update_group(New_Group = group1)
