Package ‘timechange’

April 26, 2018

Title Efficient Changing of Date-Times
Version 0.0.1
Description Efficient routines for manipulation of date-time objects while accounting for time-zones and daylight saving times. The package includes utilities for updating of date-time components (year, month, day etc.), modification of time-zones, rounding of date-times, period addition and subtraction etc. Parts of the ‘CCTZ’ source code, released under the Apache 2.0 License, are included in this package. See <https://github.com/google/cctz> for more details.

Depends R (>= 3.3)
License GPL-3
Encoding UTF-8
Imports Rcpp (>= 0.12)
LinkingTo Rcpp
Suggests testthat, knitr
LazyData true

SystemRequirements A system with zoneinfo data (e.g. /usr/share/zoneinfo) as well as a recent-enough C++11 compiler (such as g++-4.8 or later). On Windows the zoneinfo included with R is used.

timechange-package Package timechange

Description

Utilities for efficient updating of date-times components while accounting for time-zones and daylight saving times. When it makes sense functions provide a refined control of what happens in ambiguous situations through roll_month and roll_dst arguments.

Author(s)

Vitalie Spinu (<spinuvit@gmail.com>)

time-zones Time-zone manipulation

Description

time_at_tz returns a date-time as it would appear in a different time zone. The actual moment of time measured does not change, just the time zone it is measured in. time_at_tz defaults to the Universal Coordinated time zone (UTC) when an unrecognized time zone is supplied.

time_force_tz returns the date-time that has the same clock time as input time, but in the new time zone. Although the new date-time has the same clock time (e.g. the same values in the seconds, minutes, hours, etc.) it is a different moment of time than the input date-time. Computation is vectorized over both time and tz arguments.

time_clock_at_tz retrieves day clock time in specified time zones. Computation is vectorized over both dt and tz arguments, tz defaults to the timezone of time.
**Usage**

- `time_at_tz(time, tz = "UTC")`
- `time_force_tz(time, tz = "UTC", tzout = tz[[1]], roll_dst = "boundary")`
- `time_clock_at_tz(time, tz = NULL, units = "secs")`

**Arguments**

- **time**: a date-time object (POSIXct, POSIXlt, Date) or a list of date-time objects. When a list, all contained elements are updated the new list is returned.
- **tz**: a character string containing the time zone to convert to. R must recognize the name contained in the string as a time zone on your system. For `time_force_tz` and `time_clock_at_tzs`, `tz` can be a vector of heterogeneous time-zones, in which case `time` and `tz` arguments are paired. If `time` and `tz` lengths differ, the smaller one is recycled according with usual R conventions.
- **tzout**: timezone of the output date-time vector. Meaningfull only when `tz` argument is a vector of heterogenuous time-zones. This argument is necessary because R date-time vectors cannot hold elements with different time-zones.
- **roll_dst**: same as in `time_add` which see.
- **units**: passed directly to `as.difftime()`.

**Value**

- a POSIXct object with the updated time zone

**Examples**

```r
x <- as.POSIXct("2009-08-07 00:00:00", tz = "America/New_York")
time_at_tz(x, "UTC")
time_force_tz(x, "UTC")
time_force_tz(x, "Europe/Amsterdam")

## DST skip:

y <- as.POSIXct("2010-03-14 02:05:05", tz = "UTC")
time_force_tz(y, "America/New_York", roll = "boundary")
time_force_tz(y, "America/New_York", roll = "first")
time_force_tz(y, "America/New_York", roll = "last")
time_force_tz(y, "America/New_York", roll = "NA")

## Heterogeneous time-zones:

x <- as.POSIXct(c("2009-08-07 00:00:01", "2009-08-07 01:02:03"), tz = "UTC")
time_force_tz(x, tz = c("America/New_York", "Europe/Amsterdam"))
time_force_tz(x, tz = c("America/New_York", "Europe/Amsterdam"), tzout = "America/New_York")
x <- as.POSIXct("2009-08-07 00:00:01", tz = "UTC")
```
**Description**

Add periods to date-time objects. Periods track the change in the "clock time" between two civil times. They are measured in common civil time units: years, months, days, hours, minutes, and seconds.

Arithmetic operations with multiple period units (years, months etc) are applied in decreasing size order, from year to second. Thus `time_add(x, months = 1, days = 3)` first adds 1 to `x` and then 3 days.

Generally period arithmetic is undefined due to the irregular nature of civil time and complexities with DST transitions. `timechange` allows for a refined control of what happens when an addition of irregular periods (years, months, days) results in "unclear" date.

Let's start with an example. What happens when you add "1 month 3 days" to "2000-01-31 01:02:03"? `timechange` operates by applying larger periods first. First months are added `1 month + 1 day` which results in non-existent time of `2000-03-01 01:02:03`. Here the `roll_month` adjustment kicks in:

- **skip** - no adjustment is done to the simple arithmetic operations (the gap is skipped as if it's not there. Thus, `2000-01-31 01:02:03 + 1 month + 3 days` is equivalent to `2000-01-01 01:02:03 + 1 month + 31 days + 3 days` resulting in `2000-03-05 01:02:03`.
- **NA** - if any of the intermediate additions result in non-existent dates `NA` is produced. This is how arithmetic in lubridate operates.
- **boundary** - if an intermediate computation falls in a gap, the date is adjusted to the next valid time. Thus, `2000-01-31 01:02:03 + month = 2000-03-01 00:00:00`.
- **next** - is like `boundary` but preserves the smaller units. Thus, `2000-01-31 01:02:03 + 1 month = 2000-02-28 01:02:03`.
- **prev** - is like `next` but instead of rolling forward to the first day of the month, it rolls back to the last valid day of the previous month. Thus, `2000-01-31 01:02:03 + 1 month = 2000-02-28 01:02:03`. This is the default.
Usage

time_add(time, periods = NULL, years = NULL, months = NULL, weeks = NULL, days = NULL, hours = NULL, minutes = NULL, seconds = NULL, roll_month = "last", roll_dst = "first")

time_subtract(time, periods = NULL, years = NULL, months = NULL, weeks = NULL, days = NULL, hours = NULL, minutes = NULL, seconds = NULL, roll_month = "last", roll_dst = "last")

Arguments

time               date-time object
periods            string of units to add/subtract (not yet implemented) or a named list of the form
                   list(years = 1, months = 2, ...).
years, months,     Units to be added to time. Each unit except for seconds must be expressed as
weeks, days, hours, integer values.
minutes, seconds

roll_month         controls how addition of months and years behaves when standard arithmetic
                   rules exceed limits of the resulting date’s month. See "Details" for the descrip-
                   tion of possible values.
roll_dst           controls how to adjust the updated time if it falls within a DST transition intervals. See the "Details".

Examples

# Addition

## Month gap
x <- as.POSIXct("2000-01-31 01:02:03", tz = "America/Chicago")
time_add(x, months = 1, roll_month = "first")
time_add(x, months = 1, roll_month = "last")
time_add(x, months = 1, roll_month = "boundary")
time_add(x, months = 1, roll_month = "skip")
time_add(x, months = 1, roll_month = "NA")
time_add(x, months = 1, days = 3, roll_month = "first")
time_add(x, months = 1, days = 3, roll_month = "last")
time_add(x, months = 1, days = 3, roll_month = "boundary")
time_add(x, months = 1, days = 3, roll_month = "skip")
time_add(x, months = 1, days = 3, roll_month = "NA")

## DST gap
x <- as.POSIXct("2010-03-14 01:02:03", tz = "America/Chicago")
time_add(x, hours = 1, minutes = 50, roll_dst = "first")
time_add(x, hours = 1, minutes = 50, roll_dst = "last")
time_add(x, hours = 1, minutes = 50, roll_dst = "boundary")
time_add(x, hours = 1, minutes = 50, roll_dst = "skip")
time_add(x, hours = 1, minutes = 50, roll_dst = "NA")
Description

timechange provides rounding to the nearest unit or multiple of a unit. Units can be specified flexibly as strings; all common abbreviations are supported - secs, min, mins, 2 minutes, 3 years, 2s, 1d etc.

time_round() takes a date-time object and rounds it to the nearest value of the specified time unit. For rounding date-times which is exactly halfway between two consecutive units, the convention is to round up. Note that this is in line with the behavior of R's base::round.POSIXt() function but does not follow the convention of the base base::round() function which "rounds to the even digit" per IEC 60559.

time_floor takes a date-time object and rounds it down to the nearest boundary of the specified time unit.

time_ceiling() takes a date-time object and rounds it up to the nearest boundary of the specified time unit.

Usage

time_round(time, unit = "second", week_start = getOption("week_start", 1))

time_floor(time, unit = "seconds", week_start = getOption("week_start", 1))

time_ceiling(time, unit = "seconds", change_on_boundary = inherits(time, "Date"), week_start = getOption("week_start", 1))

## SUBTRACTION

### Month gap

```r
x <- as.POSIXct("2000-03-31 01:02:03", tz = "America/Chicago")
time_subtract(x, months = 1, roll_month = "first")
time_subtract(x, months = 1, roll_month = "last")
time_subtract(x, months = 1, roll_month = "boundary")
time_subtract(x, months = 1, roll_month = "skip")
time_subtract(x, months = 1, roll_month = "NA")
time_subtract(x, months = 1, days = 3, roll_month = "first")
time_subtract(x, months = 1, days = 3, roll_month = "last")
time_subtract(x, months = 1, days = 3, roll_month = "boundary")
time_subtract(x, months = 1, days = 3, roll_month = "skip")
time_subtract(x, months = 1, days = 3, roll_month = "NA")
```

### DST gap

```r
y <- as.POSIXct("2010-03-15 01:02:03", tz = "America/Chicago")
time_subtract(y, hours = 22, minutes = 50, roll_dst = "first")
time_subtract(y, hours = 22, minutes = 50, roll_dst = "last")
time_subtract(y, hours = 22, minutes = 50, roll_dst = "boundary")
time_subtract(y, hours = 22, minutes = 50, roll_dst = "skip")
time_subtract(y, hours = 22, minutes = 50, roll_dst = "NA")
```
Arguments

time  a date-time vector (Date, POSIXct or POSIXlt)
unit  a character string specifying a time unit or a multiple of a unit. Valid base
      periods for civil time rounding are second, minute, hour, day, week, month,
      bimonth, quarter, season, halfyear and year. The only unit for absolute
      time rounding is a second. Other absolute units can be achieved with multiples
      of a second ("60a", "3600a" etc). See "Details" and examples. Arbitrary unique
      English abbreviations are allowed. With one letter abbreviations are supported,
      including the strftime formats "y", "m", "d", "M", "H", "S". Multi-unit round-
      ing of weeks is currently not supported.
week_start  when unit is weeks specify the reference day. Defaults to 1 (Monday).
change_on_boundary  If NULL (the default) don’t change instants on the boundary (time_ceiling(ymd_hms('2000-01-01 00:00:00'), 'month') is 2000-01-01 00:00:00), but round up Date objects to the next boundary
          (time_ceiling(ymd("2000-01-01"), "month") is "2000-02-01"). When
          TRUE, instants on the boundary are rounded up to the next boundary. When
          FALSE, date-time on the boundary are never rounded up (this was the default for
          lubridate prior to v1.6.0. See section Rounding Up Date Objects below for
          more details.

Value

An object of the same class as the input object. When input is a Date object and unit is smaller than
day a POSIXct object is returned.

Civil Time vs Absolute Time rounding

Rounding in civil time is done on actual clock time (ymdHMS) and is affected by civil time irregu-
larities like DST. One important characteristic of civil time rounding is that floor (ceiling) does not
produce civil times that are bigger (smaller) than the rounded civil time.

Absolute time rounding (with aseconds) is done on the absolute time (number of seconds since
origin), Thus, rounding of aseconds allows for fractional seconds and multi-units larger than 60.
See examples of rounding around DST transition where rounding in civil time does not give same
result as rounding with the corresponding X aseconds.

Please note that absolute rounding to fractions smaller than 1ms will result to large precision errors
due to the floating point representation of the POSIXct objects.

Ceiling of Date objects

By default rounding up Date objects follows 3 steps:

1. Convert to an instant representing lower bound of the Date: 2000-01-01 --> 2000-01-01 00:00:00
2. Round up to the next closest rounding unit boundary. For example, if the rounding unit is
   month then next closest boundary of 2000-01-01 is 2000-02-01 00:00:00.
   The motivation for this is that the "partial" 2000-01-01 is conceptually an interval (2000-01-01 00:00:00
   – 2000-01-02 00:00:00) and the day hasn’t started clocking yet at the exact boundary
   00:00:00. Thus, it seems wrong to round up a day to its lower boundary.
The behavior on the boundary can be changed by setting `change_on_boundary` to a non-NULL value.

3. If rounding unit is smaller than a day, return the instant from step 2 (POSIXct), otherwise convert to and return a `Date` object.

Examples

```r
## print fractional seconds
options(digits.secs=6)

x <- as.POSIXct("2009-08-03 12:01:59.23")
time_round(x, ".5 asec")
time_round(x, "sec")
time_round(x, "second")
time_round(x, "asecond")
time_round(x, "minute")
time_round(x, "5 mins")
time_round(x, "5M")  # "M" for minute "m" for month
time_round(x, "hour")
time_round(x, "2 hours")
time_round(x, "2H")
time_round(x, "day")
time_round(x, "week")
time_round(x, "month")
time_round(x, "bimonth")
time_round(x, "quarter") == time_round(x, "3 months")
time_round(x, "halfyear")
time_round(x, "year")

x <- as.POSIXct("2009-08-03 12:01:59.23")
time_floor(x, ".1 asec")
time_floor(x, "second")
time_floor(x, "minute")
time_floor(x, "M")
time_floor(x, "hour")
time_floor(x, "day")
time_floor(x, "week")
time_floor(x, "m")
time_floor(x, "month")
time_floor(x, "bimonth")
time_floor(x, "quarter")
time_floor(x, "season")
time_floor(x, "halfyear")
time_floor(x, "year")

x <- as.POSIXct("2009-08-03 12:01:59.23")
time_ceiling(x, ".0 asec")
```
time_update

Update components of a date-time object

description

time_update returns a date-time with the specified elements updated. Elements not specified will be left unchanged.
Usage

time_update(time, updates = NULL, year = NULL, month = NULL,
yday = NULL, day = NULL, mday = NULL, wday = NULL, hour = NULL,
minute = NULL, second = NULL, tz = NULL, roll_month = "last",
roll_dst = "boundary", week_start = getOption("week_start", 1))

Arguments

time a date-time object
updates a string specification of components to be updated (not implemented yet) or a
named list of components.
year, month, yday, wday, mday, day, hour, minute, second
components of the date-time to be updated. day is equivalent to mday. All except
second will be converted to integer.
tz time zone component (a singleton character vector)
roll_month, roll_dst
See time_add().
week_start week starting day (Default is 1, Monday). Set week_start option to change this
globally.

Value

a date object with the requested elements updated. The object will retain its original class unless
the original class is Date and at least one of the hour, minute, second or tz is supplied, in which
case a POSIXct object is returned.

Examples

date <- as.Date("2009-02-10")
time_update(date, year = 2010, month = 1, mday = 1)
time_update(date, year = 2010, month = 13, mday = 1)
time_update(date, minute = 10, second = 3)
time_update(date, minute = 10, second = 3, tz = "America/New_York")
