Package ‘tsDyn’

January 26, 2023

Type Package

Title Nonlinear Time Series Models with Regime Switching

Version 11.0.4

Date 2023-01-26

Depends R (>= 3.5.0)

Imports mnormt, mgcv, nnet, tseriesChaos, tseries, utils, vars, urca,
forecast, MASS, Matrix, foreach, methods

Suggests sm, scatterplot3d, rgl, tidyverse, rugarch

Maintainer Matthieu Stigler <Matthieu.Stigler@gmail.com>

Description Implements nonlinear autoregressive (AR) time series models. For univariate series, a non-parametric approach is available through additive nonlinear AR. Parametric modeling and testing for regime switching dynamics is available when the transition is either direct (TAR: threshold AR) or smooth (STAR: smooth transition AR, LSTAR). For multivariate series, one can estimate a range of TVAR or threshold cointegration TVECM models with two or three regimes. Tests can be conducted for TVAR as well as for TVECM (Hansen and Seo 2002 and Seo 2006).

Getting started with the tsDyn package

Description

Getting started with the tsDyn package

Details

This package provides some tools inspired by nonlinear dynamics for the analysis-modelling of observed time series.

For loading the package, type:

```
library(tsDyn)
```

A good place to start learning the package usage, is the vignette. It contains a more detailed guide on package contents, and an applied case study. At the R prompt, write:

```
vignette("tsDyn")
```

For a full list of functions exported by the package, type:

```
ls("package:tsDyn")
```

There is also an experimental GUI for built-in NLAR models. Call it with:

```
nlarDialog(timeSeries)
```

where `timeSeries` is an available time series object.

Each exported function has a corresponding man page (some man pages are in common to more functions). Display it by typing

```
help(functionName)
```
**Author(s)**
Antonio, Fabio Di Narzo

**See Also**
- `availableModels` for listing all currently available NLAR models
- `autopairs, autotriples, autotriples.rgl` for graphical exploratory functions
- `llar, delta, delta.lin` for nonlinearity checking tools

---

**aar**  
*Additive nonlinear autoregressive model*

**Description**
Additive nonlinear autoregressive model.

**Usage**
```r
aar(x, m, d=1, steps=d, series)
```

**Arguments**
- `x`: time series
- `m, d, steps`: embedding dimension, time delay, forecasting steps
- `series`: time series name (optional)

**Details**
Nonparametric additive autoregressive model of the form:

\[ x_{t+s} = \mu + \sum_{j=1}^{m} s_j(x_{t-(j-1)d}) \]

where \( s_j \) are nonparametric univariate functions of lagged time series values. They are represented by cubic regression splines. \( s_j \) are estimated together with their level of smoothing using routines in the `mgcv` package (see references).

**Value**
An object of class `nlar`, subclass `aar`, i.e. a list with mostly internal structures for the fitted `gam` object.

**Author(s)**
Antonio, Fabio Di Narzo
accuracy_stat

References

Wood and Augustin, GAMs with integrated model selection using penalized regression splines and

Examples

#fit an AAR model:
mod <- aar(log(lynx), m=3)
#Summary informations:
summary(mod)
#Diagnostic plots:
plot(mod)

accuracy_stat

Forecasting accuracy measures.

Description

Compute forecasting accuracies. This is very similar to the accuracy method form forecast.

Usage

accuracy_stat(object, ...)

## Default S3 method:
accuracy_stat(object, true, ...)

## S3 method for class 'pred_roll'
accuracy_stat(object, w, ...)

Arguments

object A data-frame, matrix, or object of class pred_roll

... Not used currently.

true If object is just a matrix or data-frame, true values to be compared to should be supplied

w Optional. For objects of class pred_roll containing multiple variables, user can specify the way to aggregate the specific x-step-ahead into the ‘all’ category

Details

The function works either for a simple data.frame or for objects pred_roll. For simple data.frames, the argument true, i.e. a data frame containing the true values, has to be provided. For pred_roll objects, the true values are contained in the object, so no need (nor possibility) to provide the true values.
addRegime

Value

A data-frame containing the forecasting accuracy measures.

Author(s)

Matthieu Stigler

Examples

## univariate:
mod_ar <- linear(lynx[1:100], m=1)
mod_ar_pred <- predict_rolling(mod_ar, newdata=lynx[101:114])
accuracy_stat(object=mod_ar_pred$pred, true=mod_ar_pred$true)

## multivariate
data(barry)
mod_var <- lineVar(barry, lag=1)
mod_var_pred <- predict_rolling(object=mod_var, nroll=10, n.ahead=1:3)
accuracy_stat(object=mod_var_pred)
accuracy_stat(object=mod_var_pred, w=c(0.7, 0.2, 0.1))

Description

addRegime test

Usage

addRegime(object, ...)

Arguments

object fitted model object with at least 2 regimes
... arguments to and from other methods

Value

A list containing the p-value of the F statistic and a boolean, true if there is some remaining nonlinearity and false otherwise.
## ar_mean

**Long-term mean of an AR(p) process**

### Description

Computes the long term mean of an AR process.

### Usage

```r
ar_mean(object, ...)  
```

#### S3 method for class 'linear'

```r
ar_mean(object, ...)  
```

#### S3 method for class 'setar'

```r
ar_mean(object, ...)  
```

#### S3 method for class 'lstar'

```r
ar_mean(object, ...)  
```

### Arguments

- **object**
  - an object of class **linear**, **setar** or **lstar**
- **...**
  - unused argument
Details

The function computes the long-term mean of an AR(p) process, or of the corresponding sub-regimes in SETAR or LSTAR model. There are three possible cases:

No constant nor trend  The LT mean is 0
constant  The LT mean is given by const/(1-sum(AR coefs))
Trend  The LT mean is not defined

Examples

```r
## estimate a (linear) AR, a SETAR and a LSTAR
lin_cst_l1 <- linear(lh, m = 1, include = "const")
set_cst_l1 <- setar(lh, m = 1, include = "const")
lst_cst_l1 <- lstar(lh, m = 1, include = "const", trace = FALSE)

ar_mean(lin_cst_l1)
ar_mean(set_cst_l1)
ar_mean(lst_cst_l1)
```

autopairs

Bivariate time series plots

Description

Bivariate time series plots: scatterplots, directed lines and kernel density estimations using functions in the sm package.

Usage

```r
autopairs(
  x,
  lag = 1,
  h,
  type = c("levels", "persp", "image", "lines", "points", "regression")
)
```

Arguments

- **x**: time series
- **lag**: time lag
- **h**: kernel window (useful only for kernel estimations)
- **type**: type of plot: contour levels, perspective plots, image, directed lines, points or points with superposed kernel regression
Details

Bivariate time series plots: scatterplots, directed lines and kernel density and regression functions estimations using functions in the package sm. In particular, for kernel density estimation sm.density is used, with smoothing parameter h defaulting to hnorm. For kernel regression, sm.regression is used.

Value

None. Plots are produced on the default graphical device.

Author(s)

Wrappers to sm by Antonio, Fabio Di Narzo

See Also

For finer control on density estimation, consider using directly sm.density and, especially, sm.ts.pdf from package sm.

Examples

```r
x <- log10(lynx)
autopairs(x, lag=2, type="lines")
```

Description

Trivariate time series plots: kernel autoregression using functions in the sm package

Usage

```r
autotriples(
  x,
  lags = 1:2,
  h,
  type = c("levels", "persp", "image", "lines", "points")
)
```

Arguments

- **x**: time series
- **lags**: vector of regressors lags
- **h**: kernel window
- **type**: type of plot: contour levels, perspective plots, image
Details

This function displays trivariate time series plots, i.e. kernel regression of \(x[t - lags[1]], x[t - lags[2]]\) against \(x[t]\) using functions in the package sm. In particular, sm.regression is used, with smoothing parameter defaulting to \(hnorm(x)\).

Value

None. Plots are produced on the default graphical device.

Author(s)

Wrappers to sm by Antonio, Fabio Di Narzo

See Also

For finer control on kernel regression, consider using directly sm.regression and, especially, sm.autoregression in package sm.

Examples

autotriples(log(lynx))
autotriples(log(lynx), type="persp")
autotriples(log(lynx), type="image")

---

autotriples.rgl          Interactive trivariate time series plots

Description

Interactive trivariate time series plots

Usage

autotriples.rgl(x, lags = 1:2, type = c("lines", "points"))

Arguments

- \(x\) time series
- \(lags\) vector of regressors lags
- \(type\) type of plot: contour levels, perspective plots, image

Details

This function displays interactive trivariate time series plots \(x[t-lags[1]], x[t-lags[2]]\) against \(x[t]\) using the interactive rgl device.
availableModels

Value

None. A plot is produced on the current rgl device.

Author(s)

Wrapper to `sm` and GUI by Antonio, Fabio Di Narzo

See Also

`autotriples` for 3d visualization via `scatterplot3d` package and for kernel post-processing of the cloud for nonparametric autoregression functions estimates.

Examples

```r
if(interactive())
  autotriples.rgl(log(lynx))
```

<table>
<thead>
<tr>
<th>availableModels</th>
<th>Available models</th>
</tr>
</thead>
</table>

Description

Available built-in time series models

Usage

`availableModels()`

Details

Return the list of built-in available `nlar` time series models

Value

A character vector containing built-in time series models. For help on a specific model, type: `help(modelName)`.

Author(s)

Antonio, Fabio Di Narzo

Examples

`availableModels()`
**barry**

*Time series of PPI used as example in Bierens and Martins (2010)*

**Description**

This data set contains the series used by *Bierens and Martins* for testing for PPI between Canada and US.

**Usage**

```r
data(barry)
```

**Format**

A data frame with 324 monthly observations, ranging from 1973:M1 until 1999:M12.

- `dolcan` Exchange rate US/Can dollar.
- `cpiUSA` US Consumer Price Index.
- `cpiCAN` Canada Consumer Price Index.

**Author(s)**

Matthieu Stigler

**Source**

Bierens, H. and Martins, L. (2010), Time Varying Cointegration,

---

**BBCTest**

*Test of unit root against SETAR alternative*

**Description**

Test of unit root against a stationnary three regime SETAR alternative

**Usage**

```r
BBCTest(
  x,
  m,
  series,
  testStat = c("LR", "Wald", "LM"),
  trim = 0.1,
  grid = c("minPerc", "minObs")
)
```
**Arguments**

- `x`: time series
- `m`: Number of lags under the alternative
- `series`: time series name (optional)
- `testStat`: Type of test statistic to use
- `trim`: trimming parameter indicating the minimal percentage of observations in each regime
- `grid`: Whether a minimal number of percentage or observations should be imposed.

**Details**

ODO

**Value**

A object of class "BBC2004Test" containing:

- The value of the sup Test
- The version of test used (either Wald, LM or LR).

**Author(s)**

Matthieu Stigler

**References**

**See Also**

`setarTest` for a test with stationarity as a null.

**Examples**

```r
BBCTest(lynx, m=3, test="Wald", grid="minPerc")
```
charac_root  

Characteristic roots of the AR coefficients

Description

Computes the (inverse) characteristic roots of the auto-regressive coefficients. To be stationary, the values should be outside the unit circle. The function here returns the modulus of the roots.

Usage

\[
\text{charac\_root}(\text{object, \ldots})
\]

## S3 method for class 'nlar'
\[
\text{charac\_root}(\text{object, \ldots})
\]

Arguments

- **object**: object of class nlar
- ... currently unused

Details

Computes the roots of the polynomial \((1, -\phi)\) using function `polyroot`.

Value

a data.frame, with the modulus of the roots. For models with multiple regimes (setar, lstar, star), one column per regime.

Examples

```r
mod.ar <- linear(lh, m = 5, include = "const")
mod.setar <- setar(lh, m = 5, include = "const")

charac_root(mod.ar)
charac_root(mod.setar)
```

coefB  

Extract cointegration parameters A, B and PI

Description

Extract parameters in VECM: adjustment coefficients A, cointegrating coefficients B, or the composite matrix PI.
Usage

coeB(object, ...)

## S3 method for class 'VECM'
coeB(object, ...)

## S3 method for class 'ca.jo'
coeB(object, r = 1, normalize = TRUE, ...)

coeA(object, ...)

## S3 method for class 'VECM'
coeA(object, ...)

## S3 method for class 'ca.jo'
coeA(object, r = 1, normalize = TRUE, ...)

coePI(object, ...)

Arguments

object An object of class VECM, ca.jo
r The cointegrating rank
normalize Whether to normalize the A/B coefficients. See details
... Further arguments passed to methods

Details

The functions extract the parameters from a VECM with \( K \) variables and rank \( r \):

- **A** Adjustment coefficients, of dim \( K \times r \)
- **B** Cointegrating coefficients, of dim \( K \times r \)
- **Pi** Matrix \( \Pi = AB' \), of dim \( K \times K \)

Coefficients are extracted from a VECM in package tsDyn, or from a VECM obtained in package urca from ca.jo or cajorls.

Note that by default, the A and B coefficients returned are normalized (see below). This is the case for results obtained from VECMLineVar and cajorls, while for ca.jo, the user has the choice (but normalize=TRUE by default), in which case the rank \( r \) is also to be specified. The normalization is the Phillips triangular representation, as suggested by Johansen (1995, p. 72), standardising the first \( r \times r \) coefficients to \( I_r \):

- **B** \( B_{norm} = B(c'B)^{-1} \) with \( c = (I_r, 0_{K-r,r})' \)
- **A** \( A_{norm} = AB'c \)

Finally, note that the function also apply to objects obtained from tests of class ca.jo.test (from blrtest etc...). Care should be taken however, since the normalization might override the restrictions imposed.
Value

A matrix containing the coefficients

Author(s)

Matthieu Stigler

References

Examples

data(barry)
vecm <- VECM(barry, lag=1, estim="ML")
vecm_r2 <- VECM(barry, lag=1, estim="ML", r=2)

## extract coefficients:
coefA(vecm)
coefB(vecm)
coefPI(vecm)
coefB(vecm_r2)
coefPI(vecm_r2)

## Beta-Restricted VECM:
beta_vecm2 <- coefB(vecm_r2)
beta_vecm2[3,2] <- 0.02
vecm_r2_rest <- VECM(barry, lag=1, estim="ML", r=2, beta=beta_vecm2)
round(coefB(vecm_r2_rest),5)

## Package vars/urca
if(require(urca)){
  vecm_ur <- ca.jo(barry, K=2)
  coefB(vecm_ur)
  coefB(vecm_ur, r=2)
  coefB(cajorls(vecm_ur, r=2))
  all.equal(coefB(vecm), coefB(vecm_ur), check.attributes=FALSE)
  all.equal(coefB(vecm_r2), coefB(vecm_ur, r=2), check.attributes=FALSE)
}

---

delta  

delta test of conditional independence

Description

delta statistic of conditional independence and associated bootstrap test
**Usage**

\[\text{delta}(x, m, d = 1, \text{eps})\]

\[
\text{delta.test}(
  
  x,
  
  m = 2:3,
  
  d = 1,
  
  eps = \text{seq}(0.5 \times \text{sd}(x), 2 \times \text{sd}(x), \text{length} = 4),
  
  B = 49
)
\]

**Arguments**

- **x**: time series
- **m**: vector of embedding dimensions
- **d**: time delay
- **eps**: vector of length scales
- **B**: number of bootstrap replications

**Details**

delta statistic of conditional independence and associated bootstrap test. For details, see Manzan(2003).

**Value**

delta returns the computed delta statistic. delta.test returns the bootstrap based 1-sided p-value.

**Warning**

Results are sensible to the choice of the window eps. So, try the test for a grid of m and eps values. Also, be aware of the course of dimensionality: m can’t be too high for relatively small time series. See references for further details.

**Author(s)**

Antonio, Fabio Di Narzo

delta test for nonlinearity: \texttt{delta.lin.test}
Examples

delta(log10(lynx), m=3, eps=sd(log10(lynx)))

delta.lin

delta test of linearity

Description

delta test of linearity based on conditional mutual information

Usage

delta.lin(x, m, d = 1)

delta.lin.test(
  x,
  m = 2:3,
  d = 1,
  eps = seq(0.5 * sd(x), 2 * sd(x), length = 4),
  B = 49
)

Arguments

x  time series
m  vector of embedding dimensions
d  time delay
eps  vector of length scales
B  number of bootstrap replications

Details

delta test of linearity based on conditional mutual information

Value

delta.lin returns the parametrically estimated delta statistic for the given time series (assuming linearity). delta.lin.test returns the bootstrap based 1-sided p-value. The test statistic is the difference between the parametric and nonparametric delta estimators.

Author(s)

Antonio, Fabio Di Narzo
References

Examples

delta.lin(log10(lynx), m=3)

---

Description

Use the `fevd` function from package `vars` to compute the forecast error variance decomposition of a VAR(p) or VECM for `n.ahead` steps.

Usage

```r
## S3 method for class 'nlVar'
fevd(x, n.ahead = 10, ...)
```

Arguments

- `x`: Object of class ‘VAR’ generated by `lineVar()`, or an object of class ‘VECM’ generated by `VECM()`
- `n.ahead`: Integer specifying the number of steps.
- `...`: Currently not used.

Details

The function converts the VAR or VECM computed by package tsDyn into an object of class ‘vec2var’, on which then the `fevd` method is applied. For details, see package `vars`.

Value

A list with class attribute ‘var fevd’ of length K holding the forecast error variances as matrices.

Author(s)

Bernhard Pfaff

References

fitted.nlVar

See Also

plot for the plot method. lineVar, VECM for the models.

Examples

data(zeroyld)
mod_vecm <- VECM(zeroyld, lag = 2)
fevd(mod_vecm, n.ahead = 5)

Description

Returns the fitted values of the model, either as computed in the model, or back to the original series level.

Usage

## S3 method for class 'nlVar'
fitted(object, level = c("model", "original"), ...)

Arguments

object An object of class ‘nlVar’: generated by VECM or lineVar.
level How to return the fitted values. See below.
... Currently not used.

Details

In case of a VAR in differences, in ADF specification, or a VECM, the fitted values are actually in differences. With the option level="original", the function returns the series in the original level.

For VAR in levels, the two arguments are evidently the same and hence it is not taken into account, returning a warning.

Value

A matrix.

Author(s)

Matthieu Stigler
getTh

Examples

```r
## estimate models
data(barry)

ve <- VECM(barry, lag=2)
va <- lineVar(barry, lag=1)
va_diff <- lineVar(barry, lag=1, I="diff")
va_ADF <- lineVar(barry, lag=1, I="ADF")

## get fitted values:
tail(fitted(ve))
tail(fitted(ve, level="original"))
tail(fitted(va))
tail(fitted(object=va, level="original"))
tail(fitted(va_diff))
tail(fitted(object=va_diff, level="original"))
tail(fitted(va_ADF))
tail(fitted(object=va_ADF, level="original"))
```

---

getTh

*Extract threshold(s) coefficient*

Description

Extract threshold coefficient(s)

Usage

```r
getTh(object, ...)
```

Arguments

- **object**: object of class `setar`, `summary.setar`, `nlVar`
- **...**: additional arguments to `getTh`

Value

Threshold value.
Author(s)

Matthieu Stigler

Examples

```r
set <- setar(lynx, m=3)
getTh(set)
getTh(summary(set))
```

---

**GIRF**

*Generalized Impulse response Function (GIRF)*

---

**Description**

Generates a GIRF for multiple innovations and histories

**Usage**

```r
GIRF(object, n.ahead, seed = NULL, ...)
```

## S3 method for class 'setar'

```r
GIRF(
  object,
  n.ahead = 10,
  seed = NULL,
  n.hist = 20,
  n.shock = 20,
  R = 10,
  hist_li = NULL,
  shock_li = NULL,
  ...
)
```

## S3 method for class 'linear'

```r
GIRF(
  object,
  n.ahead = 10,
  seed = NULL,
  n.hist = 20,
  n.shock = 20,
  R = 10,
  hist_li = NULL,
  shock_li = NULL,
  ...
)
```
## S3 method for class 'nlVar'

GIRF(
  object,
  n.ahead = 10,
  seed = NULL,
  n.hist = 20,
  n.shock = 20,
  R = 10,
  hist_li = NULL,
  shock_li = NULL,
  ...
)

## S3 method for class 'GIRF_df'

plot(
  x,
  plot_type = c("density", "line"),
  n.ahead = c(1, 5, 10),
  var = unique(x$var)[1],
  n_simu = c(1, 2),
  ...
)

Arguments

- **object**: An object of class `linear`, `setar` or `nlVar` (TVAR, TVECM)
- **n.ahead**: The number of steps ahead to compute
- **seed**: Optional, the seed for the random numbers
- **n.hist**: The number of past histories to consider. Should be high, ideally size of data (minus lags).
- **n.shock**: The number of actual shocks to consider
- **R**: The number of draws to use for the n.ahead innovations
- **hist_li**: Optional, a list of histories (each of same length as lags in the model). If not provided, n.hist histories will be randomly drawn for the original series.
- **shock_li**: Optional, a list of innovations. If not provided, n.shock shocks will be randomly drawn from the estimated residuals.
- **x**: Output of girf
- **plot_type**: Plot: density (for each n.ahead), or line (for multipe n_simu)?
- **var**: Plot: which variable to plot?
- **n_simu**: Line plot: which simulation to plot?
- **...**: Further arguments passed to specific methods.
Details

In a nonlinear model, the Impulse response Function (IRF) is not time-, scale- and sign-invariant as in linear models. To address this, Koop et al (1996) introduced the Generalized Impulse response Function (GIRF):

\[ GIRF(h, \delta, \omega_{t-1}) = E[y_{t+h} | \epsilon_t = \delta, \epsilon_{t+h} = 0, \omega_{t-1}] - E[y_{t+h} | \epsilon_t = 0, \epsilon_{t+h} = 0, \omega_{t-1}] \]

It is the difference between two conditional expectations, one containing the shock of interest, the second one averaging it out. The averaging-out is done by comparing against random innovations (unlike the IRF, which compares against innovation 0). The parameter R corresponds to the number of times this is done.

The GIRF as defined here depends on the particular shock, as well as on the history. Koop et al (1996) suggest to draw multiple combinations of histories and innovations. This is done with arguments n.hist and n.shock (or, alternatively, provide one of, or both, hist_li and hist_sli as list of histories and shocks).

The output is a data-frame containing the two average paths for each combinations of shocks and histories.

Value

A data-frame, with:

- **n_simu**: Id for the simulation (total number is n.hist times n.shock)
- **hist, shock**: History and shock used in the nth simulation
- **n.ahead**: The forecasting horizon. Note the shocks happens at time 0
- **var**: The variable (on which the shock happens, corresponds hence to the response argument in irf)
- **sim_1, sim_2**: The average (over R times) simulation with the specific shock (sim_1) or with random shocks (sim_2).
- **girf**: The difference between sim_1 and sim_2

**IIPUs**

**US monthly industrial production from Hansen (1999)**

### Description

This data, used as example in Hansen (1999), contains the US monthly industrial production.

### Usage

IIPUs

### Format

A monthly time series of class ts starting in January 1960 and ending in September 1997. Note that the series ends at 1997 and not 1998 as in the paper of Hansen, even if the data was taken from hisite and the graph is exactly the same.

### Source

### Examples

```
data(IIPUs)
end(IIPUs) #not same date as in the paper

## Figure 2 in paper (p. 555)
plot(IIPUs)
```
## Table 1 in paper (p. 556)

```r
ar_1 <- linear(IIPUs, m=16)
coef(summary(ar_1))[, 1:2]
deviance(ar_1)
```

## Table 2 in paper (p. 559)

```r
set_1 <- setar(IIPUs, m=16, thDelay=5, trim=0.1)
tsdyn finds another threshold, with a better SSR:
getTh(set_1)
deviance(set_1)
```

## Table 4 in paper (p. 561)

```r
set_2 <- setar(IIPUs, m=16, thDelay=5, trim=0.1, nthresh =2)
getTh(set_2)
deviance(set_2)
```

### most of the results agree, except constant in the low regime which has opposed signs!

```r
set_2_CO <- coef(summary(set_2))[1:2]
cbind(set_2_CO[1:17,], set_1_CO[18:34,])
```

### this is obviously a error in Hansen, see:

```r
XX<-embed(IIPUs, 17)
Y<-XX[,1]
X<-XX[,-1]
dummyDown<-ifelse(X[,6]<= -2.5, 1,0)
sum(dummyDown)
M<-cbind(1*dummyDown,X*dummyDown)
lm(Y~M-1)
```

### setar test (takes long to compute, even with small nboot)

```r
# Not run:
test_1 <- setarTest(IIPUs, m=16, thDelay=5, nboot=10)
# because of the discrepency. test1vs2 does not correspond, test 1vs3 conforms
test_1$Ftests ## compare with Table 2 (F12) and Table 4 (F13, F23)
supply(test_1)

setarTest(IIPUs, m=16, thDelay=5, nboot=10, test="2vs3")
# test 2vs3 is also different of the version in the article (27)
```

## End(Not run)

### results from the test is stored in: setarTest_IIPUs_results
data(setarTest_IIPUs_results)

### Table 5 and 6

```r
test_1vs <- setarTest_IIPUs_results$test_1
```
## Table 7
```
test_2vs <- setarTest_IIPUs_results$test_2
test_2vs
plot(test_2vs)
```

---

### irf.linear

**Impulse response function**

#### Description

Compute the impulse response coefficients (IRF) of a VAR(p) (or transformed VECM to VAR(p)) for \( n \) ahead steps. For TVECM and TVAR model, argument `regime` offers regime-specific IRF.

#### Usage

```r
## S3 method for class 'linear'
irf(
  x,
  impulse = NULL,
  response = NULL,
  n.ahead = 10,
  ortho = TRUE,
  cumulative = FALSE,
  boot = TRUE,
  ci = 0.95,
  runs = 100,
  seed = NULL,
  ...
)

## S3 method for class 'setar'
irf(
  x,
  impulse = NULL,
  response = NULL,
  n.ahead = 10,
  ortho = TRUE,
  cumulative = FALSE,
  boot = TRUE,
  ci = 0.95,
  runs = 100,
  seed = NULL,
  regime = c("L", "M", "H"),
  ...
)
```
## S3 method for class 'ar'

`irf`

```r
x,
impulse = NULL,
response = NULL,
n.ahead = 10,
ortho = TRUE,
cumulative = FALSE,
boot = TRUE,
ci = 0.95,
runs = 100,
seed = NULL,
...
```

## S3 method for class 'VAR'

`irf`

```r
x,
impulse = NULL,
response = NULL,
n.ahead = 10,
ortho = TRUE,
cumulative = FALSE,
boot = TRUE,
ci = 0.95,
runs = 100,
seed = NULL,
...
```

## S3 method for class 'VECM'

`irf`

```r
x,
impulse = NULL,
response = NULL,
n.ahead = 10,
ortho = TRUE,
cumulative = FALSE,
boot = TRUE,
ci = 0.95,
runs = 100,
seed = NULL,
...
```

## S3 method for class 'TVEC'

`irf`

```r
x,
impulse = NULL,
response = NULL,
n.ahead = 10,
ortho = TRUE,
cumulative = FALSE,
boot = TRUE,
ci = 0.95,
runs = 100,
seed = NULL,
...
```
Arguments

x                       Object of class ‘VAR’: generated by lineVar(), or object of class ‘VECM’: generated by VECM().
impulse, response          Not used!
n.ahead                   Integer specifying the steps.
ortho                     Logical, if TRUE (the default) the orthogonalised impulse response coefficients are computed.
cumulative                Logical, if TRUE the cumulated impulse response coefficients are computed. The default value is false.
boot, ci, runs, seed      Arguments for the bootstrap, see irf.varest
...                      Currently not used.
regime                    For a setar model, which regime (L, M or H) to produce IRF for?
Value

A list of class 'varirf' see `irf.varest`

Examples

data(barry)

## For VAR
mod_var <- lineVar(barry, lag = 2)
irf(mod_var, impulse = "dolcan", response = c("dolcan", "cpiUSA", "cpiCAN"), boot = FALSE)

## For VECM
mod_VECM <- VECM(barry, lag = 2, estim="ML", r=2)
irf(mod_VECM, impulse = "dolcan", response = c("dolcan", "cpiUSA", "cpiCAN"), boot = FALSE)

Description

Generic NLAR linearity test

Usage

`isLinear(object, ...)`

Arguments

  `object` fitted time series model
  `...` arguments to and from other methods

Author(s)

A. F. Di Narzo
KapShinTest

Test of unit root against SETAR alternative with

Description
Test of unit root against a stationary 3 regime SETAR alternative with random walk in the inner regime

Usage
KapShinTest(x, m=1, series, include = c("none", "const", "trend", "both"),
c=3, delta=0.5, points=NULL, minObsMid=10,
trick=c("for", "apply", "mapply"), trace=FALSE)

Arguments
  x time series
  m Number of lags under the alternative
  series time series name (optional)
  include Whether data should be raw, de-meaned or de-meaned and de-trended
  c Argument for the grid search. See details
  delta Argument for the grid search. See details
  points Points for the grid search. See details
  minObsMid Minimal number of observations in the inner regime
  trick type of internal function used
  trace should additional infos be printed? (logical)

Details
This function is currently spurious.

Value
A object of class KapShin2006Test containing:

  statistic The three (SupW, AvgW, ExpW) test statistics computed
  case Whether the data was transformed, corresponds to input argument include
  series The name of the series

Author(s)
Matthieu Stigler
See Also

BBCTest for a similar test. setarTest for a test with stationarity as a null.

Examples

KapShinTest(lynx, m=1, trace=FALSE, include="none", points=10)

lags.select  Selection of the lag with Information criterion.

Description

Selection of the cointegrating rank and the lags with Information criterion (AIC, BIC).

Usage

lags.select(
  data, 
  lag.max = 10, 
  include = c("const", "trend", "none", "both"), 
  fitMeasure = c("SSR", "LL"), 
  sameSample = TRUE 
)

Arguments

data  multivariate time series.
lag.max  Maximum number of lags to investigate.
include  Type of deterministic regressors to include.
fitMeasure  Whether the AIC/BIC should be based on the full likelihood, or just the SSR. See explanations in logLik.VECM.
sameSample  Logical. Whether the data should be shortened so that the AIC/BIC are estimated on the same sample. Default to TRUE.

Details

This function selects the lag according to AIC, BIC and Hannan-Quinn.

Value

An object of class rank.select, with ‘print’ and ‘summary’ methods, containing among other the matrices of AIC/BIC/HQ.

Author(s)

Matthieu Stigler
See Also

- rank.select, the underlying function, to estimate the rank also.
- VARselect in package vars, does basically the same.

Examples

```r
data(barry)

#
rk_sel <- lags.select(barry)
rk_sel
summary(rk_sel)
```

LINEAR Linear AutoRegressive models

Description

AR(m) model

Usage

```r
linear(x, m, d=1, steps=d, series, include = c( "const", "trend","none","both"),
type=c("level", "diff", "ADF"), warn_root=TRUE)
```

Arguments

- **x**: time series
- **m, d, steps**: embedding dimension, time delay, forecasting steps
- **series**: time series name (optional)
- **include**: Type of deterministic regressors to include
- **type**: Whether the variable is taken is level, difference or a mix (diff y=y-1, diff lags) as in the ADF test
- **warn_root**: Whether to check (and warn) for roots outside the unit circle?

Details

AR(m) model:

\[ x_{t+s} = \phi_0 + \phi_1 x_t + \phi_2 x_{t-d} + \cdots + \phi_m x_{t-(m-1)d} + \epsilon_{t+s} \]
Value
A `nlar` object, linear subclass.

Author(s)
Antonio, Fabio Di Narzo

See Also
`nlar` for fitting this and other models to time series data

Examples
```r
# fit an AR(2) model
mod.linear <- linear(log(lynx), m=2)
mod.linear
summary(mod.linear)
```

Description
Estimate either a VAR or a VECM.

Usage
```r
lineVar(
data,            # multivariate time series (first row being first=oldest value)
lag,             # Number of lags to include in each regime
r = 1,           # Number of cointegrating relationships
include = c("const", "trend", "none", "both"),
model = c("VAR", "VECM"),
I = c("level", "diff", "ADF"),
beta = NULL,     # Type of deterministic regressors to include
estim = c("2OLS", "ML"),
LRinclude = c("none", "const", "trend", "both"),
exogen = NULL)
```

Arguments
- `data`: multivariate time series (first row being first=oldest value)
- `lag`: Number of lags to include in each regime
- `r`: Number of cointegrating relationships
- `include`: Type of deterministic regressors to include
Model to estimate. Either a VAR or a VECM

For VAR only: whether in the VAR the variables are to be taken in levels (original series) or in difference, or similarly to the univariate ADF case.

for VECM only: user-specified cointegrating value. If NULL, will be estimated using the estimator specified in estim

Type of estimator for the VECM: '2OLS' for the two-step approach or 'ML' for Johansen MLE

Possibility to include in the long-run relationship and the ECT a trend, a, constant, etc. Can also be a matrix with exogeneous regressors

Inclusion of exogenous variables (first row being first=oldest value). Is either of same size than data (then automatically cut) or than end-sample.

This function provides basic functionalities for VAR and VECM models. More comprehensive functions are in package vars. A few differences appear in the VECM estimation:

Engle-Granger estimator The Engle-Granger estimator is available

Presentation Results are printed in a different ways, using a matrix form

latex export The matrix of coefficients can be exported to latex, with or without standard-values and significance stars

Two estimators are available: the Engle-Granger two-steps approach (2OLS) or the Johansen (ML). For the 2OLS, deterministic regressors (or external variables if LRinclude is of class numeric) can be added for the estimation of the cointegrating value and for the ECT. This is only working when the beta value is not pre-specified.

The argument beta is only for VECM, look at the specific help page for more details.

Fitted model data

Matthieu Stigler

VECM which is just a wrapper for lineVar(..., model="VECM"). Methods predict.VAR, VARrep, regime, irf and toLatex.

TVAR and TVECM for the corresponding threshold models. linear for the univariate AR model.
Examples

```r
data(zeroyld)

# Fit a VAR
VAR <- lineVar(zeroyld, lag=1)
VAR
summary(VAR)

# compare results with package vars:
if(require(vars)) {
  a<-VAR(zeroyld, p=1)
  coef_vars <- t(sapply(coef(a), function(x) x[,c(3,1,2),1]))
  all.equal(coef(VAR), coef_vars, check.attributes=FALSE)
}

### VECM
VECM.EG <- lineVar(zeroyld, lag=2, model="VECM")
VECM.EG
summary(VECM.EG)

VECM.ML <- lineVar(zeroyld, lag=2, model="VECM", estim="ML")
VECM.ML
summary(VECM.ML)

### Check Johansen MLE
myVECM <- lineVar(zeroyld, lag=1, include="const", model="VECM", estim="ML")
summary(myVECM, digits=7)
# comparing with vars package
if(require(vars)){
a<-ca.jo(zeroyld, spec="trans")
summary(a)
# same answer also!
}

### export to Latex
toLatex(VECM.EG)
toLatex(summary(VECM.EG))
options("show.signif.stars"=FALSE)
toLatex(summary(VECM.EG), parenthese="Pvalue")
options("show.signif.stars"=TRUE)
```

llar

Locally linear model
Description

Casdagli test of nonlinearity via locally linear forecasts

Usage

\texttt{llar}(x, m, d = 1, steps = d, series, eps.min = sd(x)/2, 
eps.max = diff(range(x)), neps = 30, trace = 0)

\texttt{llar.predict}(x, m, d=1, steps=d, series, n.ahead=1, 
eps=stop(“you must specify a window value”),
onvoid=c(“fail”,”enlarge”), r = 20, trace=1)

\texttt{llar.fitted}(x, m, d=1, steps=d, series, eps, trace=0)

Arguments

\texttt{x} \hspace{1cm} \text{time series}
\texttt{m, d, steps} \hspace{1cm} \text{embedding dimension, time delay, forecasting steps}
\texttt{series} \hspace{1cm} \text{time series name (optional)}
\texttt{n.ahead} \hspace{1cm} \text{n. of steps ahead to forecast}
\texttt{eps.min, eps.max} \hspace{1cm} \text{min and max neighbourhood size}
\texttt{neps} \hspace{1cm} \text{number of neighbourhood levels along which iterate}
\texttt{eps} \hspace{1cm} \text{neighbourhood size}
\texttt{onvoid} \hspace{1cm} \text{what to do in case of an isolated point: stop or enlarge neighbourhood size by an r\%}
\texttt{r} \hspace{1cm} \text{if an isolated point is found, enlarge neighbourhood window by r\%}
\texttt{trace} \hspace{1cm} \text{tracing level: 0, 1 or more than 1 for \texttt{llar}, 0 or 1 for \texttt{llar.predict}}

Details

\texttt{llar} does the Casdagli test of non-linearity. Given the embedding state-space (of dimension \texttt{m} and time delay \texttt{d}) obtained from time series \texttt{series}, for a sequence of distance values \texttt{eps}, the relative error made by forecasting time series values with a linear autoregressive model estimated on points closer than \texttt{eps} is computed. If minimum error is reached at relatively small length scales, a global linear model may be inappropriate (using current embedding parameters). This was suggested by Casdagli(1991) as a test for non-linearity.

\texttt{llar.predict} tries to extend the given time series by \texttt{n.ahead} points by iteratively fitting locally (in the embedding space of dimension \texttt{m} and time delay \texttt{d}) a linear model. If the spatial neighbourhood window is too small, your time series last point would be probably isolated. You can ask to automatically enlarge the window \texttt{eps} by a factor of r\% sequentially, until enough neighbours are found for fitting the linear model.

\texttt{llar.fitted} gives out-of-sample fitted values from locally linear models.
Value

llar gives an object of class 'llar'. I.e., a list of components:

- **RMSE**: vector of relative errors
- **eps**: vector of neighbourhood sizes (in the same order of RMSE)
- **frac**: vector of fractions of the time series used for RMSE computation
- **avfound**: vector of average number of neighbours for each point in the time series which can be plotted using the plot method, and transformed to a regular data.frame with the `as.data.frame` function.

Function `llar.forecast` gives the vector of n steps ahead locally linear iterated forecasts. Function `llar.fitted` gives out-of-sample fitted values from locally linear models.

Warning

For long time series, this can be slow, especially for relatively big neighbourhood sizes.

Note

The C implementation was re-adapted from that in the TISEAN package ("ll-ar" routine, see references). However, here the euclidean norm is used, in place of the max-norm.

Author(s)

Antonio, Fabio Di Narzo

References

Examples

```r
res <- llar(log(lynx), m=3, neps=7)
plot(res)

x.new <- llar.predict(log(lynx), n.ahead=20, m=3, eps=1, onvoid="enlarge", r=5)
lag.plot(x.new, labels=FALSE)

x.fitted <- llar.fitted(log(lynx), m=3, eps=1)
lag.plot(x.fitted, labels=FALSE)
```
Description

Log-Likelihood method for VAR and VECM models.

Usage

```r
## S3 method for class 'nlVar'
logLik(object, ...)  
## S3 method for class 'VECM'
logLik(object, r, ...)
```

Arguments

- `object`: object of class `VAR` computed by `lineVar`, or class `VECM` computed by `VECM`.
- `...`: additional arguments to `logLik`.
- `r`: The cointegrating rank. By default the rank specified in the call to `VECM`, but can be set differently by user.

Details

For a VAR, the Log-Likelihood is computed as in Luetkepohl (2006) equ. 3.4.5 (p. 89) and Juselius (2006) p. 56:

\[
LL = -(TK/2) \log(2\pi) - (T/2) \log |\Sigma| - (1/2) \sum_{i=1}^{T} \left[(y_t - A' x_t)' \Sigma^{-1}(y_t - A' x_t)\right]
\]

Where \(\Sigma\) is the Variance matrix of residuals, and \(x_t\) is the matrix stacking the regressors (lags and deterministic).

However, we use a computationally simpler version:

\[
LL = -(TK/2) \log(2\pi) - (T/2) \log |\Sigma| - (TK/2)
\]

(Note that Hamilton (1994) 11.1.10, p. 293 gives \(+ (T/2) \log |\Sigma^{-1}|\), which is the same as \(-(T/2) \log |\Sigma|\).

For VECM, the Log-Likelihood is computed in two different ways, depending on whether the `VECM` was estimated with ML (Johansen) or 2OLS (Engle and Granger).

When the model is estimated with ML, the LL is computed as in Hamilton (1994) 20.2.10 (p. 637):

\[
LL = -(TK/2) \log(2\pi) - (TK/2) - (T/2) \log |\Sigma_{UU}| - (T/2) \sum_{i=1}^{r} \log(1 - \hat{\lambda}_i)
\]
Where $\Sigma_{UU}$ is the variance matrix of residuals from the first auxiliary regression, i.e. regressing $\Delta y_t$ on a constant and lags, $\Delta y_{t-1}, \ldots, \Delta y_{t-p}$. $\lambda_i$ are the eigenvalues from the $\Sigma_{VV}^{-1} \Sigma_{VU} \Sigma_{UU}^{-1} \Sigma_{UV}$, see 20.2.9 in Hamilton (1994).

When the model is estimated with 2OLS, the LL is computed as:

$$LL = \log |\Sigma|$$

Where $\Sigma$ is the variance matrix of residuals from the the VECM model. There is hence no correspondence between the LL from the VECM computed with 2OLS or ML.

Value
Log-Likelihood value.

LSTAR  
Logistic Smooth Transition AutoRegressive model

Description
Logistic Smooth Transition AutoRegressive model.
Usage

\texttt{lstar(x, m, d=1, steps=d, series, mL, mH, thDelay, thVar, th, gamma, trace=TRUE, include = c("const", "trend","none", "both"), control=list(), starting.control=list())}

Arguments

\begin{itemize}
\item \texttt{x} \hspace{1cm} \text{time series}
\item \texttt{m, d, steps} \hspace{1cm} \text{embedding dimension, time delay, forecasting steps}
\item \texttt{series} \hspace{1cm} \text{time series name (optional)}
\item \texttt{mL} \hspace{1cm} \text{autoregressive order for 'low' regime (default: m). Must be \leq m}
\item \texttt{mH} \hspace{1cm} \text{autoregressive order for 'high' regime (default: m). Must be \leq m}
\item \texttt{thDelay} \hspace{1cm} 'time delay' for the threshold variable (as multiple of embedding time delay d)
\item \texttt{mTh} \hspace{1cm} \text{coefficients for the lagged time series, to obtain the threshold variable}
\item \texttt{thVar} \hspace{1cm} \text{external threshold variable}
\item \texttt{th, gamma} \hspace{1cm} \text{starting values for coefficients in the LSTAR model. If missing, a grid search is performed}
\item \texttt{trace} \hspace{1cm} \text{should additional infos be printed? (logical)}
\item \texttt{include} \hspace{1cm} \text{Type of deterministic regressors to include}
\item \texttt{control} \hspace{1cm} \text{further arguments to be passed as control list to \texttt{optim}}
\item \texttt{starting.control} \hspace{1cm} \text{further arguments for the grid search (dimension, bounds). See details below.}
\end{itemize}

Details

\[ x_{t+s} = \left( \phi_{1,0} + \phi_{1,1} x_t + \phi_{1,2} x_{t-d} + \cdots + \phi_{1,mL} x_{t-(mL-1)d} \right) G(z_t, th, \gamma) + \left( \phi_{2,0} + \phi_{2,1} x_t + \phi_{2,2} x_{t-d} + \cdots + \phi_{2,mH} x_{t-(mH-1)d} \right) \]

with \( z \) the threshold variable, and \( G \) the logistic function, computed as \texttt{plogis(q, location = th, scale = 1/gamma)}, so see \texttt{plogis} documentation for details on the logistic function formulation and parameters meanings. The threshold variable can alternatively be specified by:

\begin{itemize}
\item \texttt{mTh} \hspace{1cm} \( z[t] = x[t] mTh[1] + x[t-d] mTh[2] + \cdots + x[t-(m-1)d] mTh[m] \)
\item \texttt{thDelay} \hspace{1cm} \( z[t] = x[t - thDelay * d] \)
\item \texttt{thVar} \hspace{1cm} \( z[t] = thVar[1] \)
\end{itemize}

Note that if starting values for phi1 and phi2 are provided, isn’t necessary to specify mL and mH. Further, the user has to specify only one parameter between mTh, thDelay and thVar for indicating the threshold variable.

Estimation of the transition parameters \( th \) and \( gamma \), as well as the regression parameters \( phi1 \) and \( phi2 \), is done using concentrated least squares, as suggested in \textit{Leybourne et al. (1996)}.

Given \( th \) and \( gamma \), the model is linear, so regression coefficients can be obtained as usual by OLS. So the nonlinear numerical search needs only to be done for \( th \) and \( gamma \); the regression parameters are then recovered by OLS again from the optimal \( th \) and \( gamma \).
For the nonlinear estimation of the parameters $th$ and $gamma$, the program uses the optim function, with optimization method BFGS using the analytical gradient. For the estimation of standard values, optim is re-run using the complete Least Squares objective function, and the standard errors are obtained by inverting the hessian. You can pass further arguments to optim directly with the control list argument. For instance, the option maxit maybe useful when there are convergence issues (see examples).

Starting parameters are obtained doing a simple two-dimensional grid-search over $th$ and $gamma$. Parameters of the grid (interval for the values, dimension of the grid) can be passed to starting.control.

- nTh: The number of threshold values ($th$) in the grid. Defaults to 200
- nGamma: The number of smoothing values ($gamma$) in the grid. Defaults to 40
- trim: The minimal percentage of observations in each regime. Defaults to 10% (possible threshold values are between the 0.1 and 0.9 quantile)
- gammaInt: The lower and higher smoothing values of the grid. Defaults to c(1,40)
- thInt: The lower and higher threshold values of the grid. When not specified (default, i.e NA), the interval are the trim quantiles above.

Value

An object of class nlar, subclass lstar, i.e. a list with fitted model informations.

Author(s)

Antonio, Fabio Di Narzo

References

See Also

plot.lstar for details on plots produced for this model from the plot generic.

Examples

#fit a LSTAR model. Note 'maxit': slow convergence
mod.lstar <- lstar(log10(lynx), m=2, mTh=c(0,1), control=list(maxit=3000))
mod.lstar

#fit a LSTAR model without a constant in both regimes.
mod.lstar2 <- lstar(log10(lynx), m=1, include="none")
mod.lstar2
# Note in example below that the initial grid search seems to be too narrow.
# Extend it, and evaluate more values (slow!):  
controls <- list(gammaInt=c(1,2000), nGamma=50)  
mod.lstar3 <- lstar(log10(lynx), m=1, include="none", starting.control=controls)  
mod.lstar3

# a few methods for lstar:  
summary(mod.lstar)  
residuals(mod.lstar)  
AIC(mod.lstar)  
BIC(mod.lstar)  
plot(mod.lstar)  
predict(mod.lstar, n.ahead=5)

### m.unrate

**Monthly US unemployment**

**Description**

**Usage**

```r
data(m.unrate)
```

**Format**

zoo object

**Source**

**References**

MakeThSpec  

*Specification of the threshold search*

**Description**

This optional function allows the user to set different restrictions for the threshold grid search in function `selectSETAR`.

**Usage**

```r
MakeThSpec(
  ngrid = c("All", "Half", "Third", "Quarter"),
  exact = NULL,
  int = c("from", "to"),
  around = "val",
  ...
)
```

**Arguments**

- `ngrid`  
  The number of values to search for
- `exact`  
  The user give an exact threshold value
- `int`  
  The user gives an interval to search inside
- `around`  
  The user gives an point to search around
- `...`  
  currently unused

**Details**

This function is just to check the inputs for the specification of the grid search. If not provided, the search will be in the biggest interval (`ngrid = "All"`) between the minimum and maximum values. The user can reduce it by giving setting "Half" (only every two points is taken) and so on, or setting a number.

The search can also be made around a point, or between two points. When between a point, the argument `ngrid` is still used, whereas for around, a value of 30 is taken as default value if `ngrid` is not specified by user.

**Value**

The input values are given as output after checking for consistency (only one of exact/int/around should be given).

Matthieu Stigler
MAPE

Mean Absolute Percent Error

Description

Generic function to compute the Mean Absolute Percent Error of a fitted model.

Usage

MAPE(object, ...)

## Default S3 method:
MAPE(object, ...)

Arguments

  object          object of class nlar.fit
  ...             additional arguments to MAPE

See Also

selectSETAR

Examples

sun<-(sqrt(sunspot.year+1)-1)*2
selectSETAR(sun, m=3, th=MakeThSpec(exact=10.40967), criterion="SSR", d=1, thDelay=0:2,
              plot=FALSE, nthresh=1)
# when pre-sepcified value does not correspond, function will search nearest value
selectSETAR(sun, m=3, th=MakeThSpec(exact=10.4), criterion="SSR", d=1, thDelay=0:2,
              plot=FALSE, nthresh=1)
# search around:
selectSETAR(sun, m=3, th=MakeThSpec(around=10.40967, ngrid=20), criterion="SSR", d=1, thDelay=0:2,
              plot=FALSE, nthresh=1)
# search in an interval
selectSETAR(sun, m=3, th=MakeThSpec(int=c(10, 11), ngrid=20), criterion="SSR", d=1, thDelay=0:2,
              plot=FALSE, nthresh=1)
# reduce size of the grid:
selectSETAR(sun, m=3, th=MakeThSpec(ngrid="Half"), criterion="SSR", d=1, thDelay=0:2,
              plot=FALSE, nthresh=1)

# 2 thresholds:
selectSETAR(sun, m=3, th=MakeThSpec(ngrid="Half"), criterion="SSR", d=1, thDelay=0:2,
              plot=FALSE, nthresh=2)
Value

Computed Mean Absolute Percent Error for the fitted model.

Author(s)

Antonio, Fabio Di Narzo

Description

Generic function to compute the Mean Squared Error of a fitted model.

Usage

mse(object, ...)

# Default S3 method:
mse(object, ...)

Arguments

object object of class nlar.fit
... additional arguments to mse

Value

Computed MSE for the fitted model.

Author(s)

Antonio, Fabio Di Narzo
Description

Generic ‘nlar’ methods. Method ‘nlar’ is described in a separate page: nlar

Usage

## S3 method for class 'nlar'
coef(object, ...)

## S3 method for class 'nlar'
fitted(object, ...)

## S3 method for class 'nlar'
residuals(object, initVal = TRUE, timeAttr = TRUE, ...)

## S3 method for class 'nlar'
deviance(object, ...)

## S3 method for class 'nlar'
mse(object, ...)

## S3 method for class 'nlar'
AIC(object, k = 2, ...)

## S3 method for class 'nlar'
BIC(object, ...)

## S3 method for class 'nlar'

plot(mod.setar)
Neural Network nonlinear autoregressive model

Description

Neural Network nonlinear autoregressive model.

Usage

nnetTs(x, m, d = 1, steps = d, series, size, control = list(trace = FALSE))

Arguments

x
time series
m, d, steps embedding dimension, time delay, forecasting steps
series time series name (optional)
size number of hidden units in the neural network
control control list to be passed to nnet::nnet optimizer

Details

Neural network model with 1 hidden layer and linear output:

\[ x_{t+s} = \beta_0 + \sum_{j=1}^{D} \beta_j g(\gamma_{0j}) + \sum_{i=1}^{m} \gamma_{ij} x_{t-(i-1)d} \]

Model is estimated using the nnet function in nnet package. Optimization is done via the BFGS method of optim. Note that for this model, no additional model-specific summary and plot methods are made available from this package.

Value

An object of class nlar, subclass nnetTs, i.e. a list with mostly nnet::nnet internal structures.

Author(s)

Antonio, Fabio Di Narzo

References

Examples

```r
# fit a Neural Network model
mod.nnet <- nnetTs(log(lynx), m=2, size=3)
mod.nnet
```

plot methods

Plotting methods for SETAR and LSTAR subclasses

Description

Plotting methods ‘setar’ and ‘lstar’ subclasses

Usage

```r
## S3 method for class 'setar'
plot(x, ask=interactive(), legend=FALSE, regSwStart, regSwStop, ...)

## S3 method for class 'lstar'
plot(x, ask=interactive(), legend=FALSE, regSwStart, regSwStop, ...)
```

Arguments

- `x`: fitted ‘setar’ or ‘lstar’ object
- `ask`: graphical option. See `par`
- `legend`: Should a legend be plotted? (logical)
- `regSwStart`, `regSwStop`: optional starting and stopping time indices for regime switching plot
- `...`: further arguments to be passed to and from other methods

Details

These plot methods produce a plot which gives to you an idea of the behaviour of the fitted model. Firstly, if embedding dimension is, say, `m`, scatterplots are produced. On the x axis you have the lagged time series values. On the y axis the ‘response’ time series values. Observed points are represented with different colors-symbols depending on the level of the threshold variable. Specifically, for the setar model, black means ‘low regime’, red means ‘high regime’. For the lstar model, where the self-threshold variable is continuous, threshold values are grouped in 5 different zones with the same number of points in each. Note that if more than 300 points are to be plotted, they all share the same symbol, and regimes can be distinguished only by color. If you want, by specifying `legend=TRUE` a legend is added at the upper-left corner of each scatterplot. To each scatterplot, a dashed line is superposed, which links subsequent fitted values.

Finally, a new time series plot is produced, with lines segments coloured depending on the regime (colors meanings are the same of those in the preceding scatterplots). Optionally, you can specify a starting and ending time indices, for zooming on a particular segment of the time series.

plot_ECT

Description
This plot shows how variables in a (T)VECM respond to deviations from the long-term equilibrium

Usage
plot_ECT(x, add.legend = TRUE, legend.location = "topright", ...)

Arguments
x
object of class VECM or TVECM

add.legend
logical. Whether to add a legend?

legend.location
character. Location of the legend, see legend

...
arguments passed to the initial plot call, see plot

Value
a plot, and invisibly the underlying data.frame, containing the ECT and the response for each variable

Examples
data(zeroyld)
vec_l1 <- VECM(zeroyldMeta[, c("long.run", "short.run")], lag =1)
tvec_l1 <- TVECM(zeroyldMeta[, c("long.run", "short.run")], lag =1,
plot = FALSE, trace = FALSE, th1 = list(exact = -1.263))

plot_ECT(vec_l1)
plot_ECT(tvec_l1, legend.location = "bottomright")
### predict.nlar

**Predict method for objects of class 'nlar'.**

**Description**

Forecasting a non-linear model object of general class 'nlar', including 'setar' and 'star'.

**Usage**

```r
## S3 method for class 'nlar'
predict(
  object,
  newdata,
  n.ahead = 1,
  type = c("naive", "MC", "bootstrap", "block-bootstrap"),
  nboot = 100,
  ci = 0.95,
  block.size = 3,
  boot1Zero = TRUE,
  seed = NULL,
  ...
)
```

**Arguments**

- `object` An object of class 'nlar'; generated by `setar()` or `lstar()`.
- `newdata` Optional. A new data frame to predict from.
- `n.ahead` An integer specifying the number of forecast steps.
- `type` Type of forecasting method used. See details.
- `nboot` The number of replications for type MC or bootstrap.
- `ci` The forecast confidence interval (available only with types MC and bootstrap).
- `block.size` The block size when the block-bootstrap is used.
- `boot1Zero` Whether the first innovation for MC/bootstrap should be set to zero.
- `seed` Optional, the seed for the random generation.
- `...` Further arguments passed to the internal 'oneStep' function. Mainly argument 'thVar' if an external threshold variable was provided.

**Details**

The forecasts are obtained recursively from the estimated model. Given that the models are non-linear, ignoring the residuals in the 2- and more steps ahead forecasts leads to biased forecasts (so-called naive). Different resampling methods, averaging `n.boot` times over future residuals, are available:

- **naive** No residuals
MC  Monte-Carlo method, where residuals are taken from a normal distribution, with a standard
deviation equal to the residuals sd.

**bootstrap**  Residuals are resampled from the empirical residuals from the model.

**block-bootstrap**  Same as bootstrap, but residuals are resampled in block, with size block.size

The **MC** and **bootstrap** methods correspond to equations 3.90 and 3.91 of Franses and van Dijk
(2000, p. 121). The bootstrap/MC is initiated either from the first forecast, n.ahead=1 (set with boot1zero to TRUE), or from the second only.

When the forecast method is based on resampling, forecast intervals are available. These are ob-
tained simply as empirical ci quantiles of the resampled forecasts (cf Method 2 in Franses and van
Dijk, 2000, p. 122).

**Value**

A ‘ts’ object, or, in the case of MC/bootstrap, a list containing the prediction (pred) and the forecast
standard errors (se).

**Author(s)**

Matthieu Stigler

**See Also**

The model fitting functions **setar**, **lstar**.

A more sophisticated predict function, allowing to do sub-sample rolling predictions: **predict_rolling**.

**Examples**

```r
x.train <- window(log10(lynx), end = 1924)
x.test <- window(log10(lynx), start = 1925)

### Use different forecasting methods:
mod.set <- setar(x.train, m=2, thDelay=0)
pred_setar_naive <- predict(mod.set, n.ahead=10)
pred_setar_boot <- predict(mod.set, n.ahead=10, type="bootstrap", n.boot=200)
pred_setar_Bboot <- predict(mod.set, n.ahead=10, type="block-bootstrap", n.boot=200)
pred_setar_MC <- predict(mod.set, n.ahead=10, type="bootstrap", n.boot=200)

## Plot to compare results:
pred_range <- range(pred_setar_naive, pred_setar_boot$pred, pred_setar_MC$pred, na.rm=TRUE)
plot(x.test, ylim=pred_range, main="Comparison of forecasts methods from same SETAR")
lines(pred_setar_naive, lty=2, col=2)
```
lines(pred_setar_boot$pred, lty=3, col=3)
lines(pred_setar_Bboot$pred, lty=4, col=4)
lines(pred_setar_MC$pred, lty=5, col=5)

legend(“bottomleft”, leg=legLabels, lty=1:5, col=1:5)

------

predict.TVAR

Predict method for objects of class ‘VAR’, ‘VECM’ or ‘TVAR’

Description

Forecasting the level of a series estimated by ‘VAR’ / ‘VECM’ or ‘TVAR’

Usage

## S3 method for class ‘TVAR’
predict(object, newdata, n.ahead = 5, newdataTrendStart, ...)

## S3 method for class ‘VAR’
predict(object, newdata, n.ahead = 5, newdataTrendStart, exoPred = NULL, ...)

Arguments

object            An object of class ‘VAR’, ‘VECM’ or ‘TVAR’
newdata           Optional. A new data frame to predict from. This should contain lags of the level of the original series. See Details.
n.ahead           An integer specifying the number of forecast steps.
newdataTrendStart  If ‘newdata’ is provided by the user, and the estimated model includes a trend, this argument specifies where the trend should start
...                Arguments passed to the unexported ‘VAR.gen’ or ‘TVAR.gen’ function
exoPred           vector/matrix of predictions for the exogeneous variable(s) (with ‘n.ahead’ rows). Only for ‘VAR’/‘VECM’, not for ‘TVAR’.

Details

The forecasts are obtained recursively, and are for the levels of the series.

When providing newdata, newdata has to be ordered chronologically, so that the first row/element is the earliest value.

For VECM, the forecasts are obtained by transforming the VECM to a VAR (using function VARrep). Note that a VECM(lag=p) corresponds to a VAR(lag=p+1), so that if the user provides newdata for a VECM(lag=p), newdata should actually contain p+1 rows.
Value

A matrix of predicted values.

Author(s)

Matthieu Stigler

See Also

lineVar and VECM.VARrep

A more sophisticated predict function, allowing to do sub-sample rolling predictions: predict_rolling.

Examples

data(barry)
barry_in <- head(barry, -5)
barry_out <- tail(barry, 5)

mod_vecm <- VECM(barry_in, lag=2)
mod_var <- lineVar(barry_in, lag=3)
mod_tvar <- TVAR(barry_in, lag=3, nthresh=1, thDelay=1)

pred_vecm <- predict(mod_vecm)
pred_var <- predict(mod_var)
pred_tvar <- predict(mod_tvar)

## compare forecasts on a plot
n <- 30
plot(1:n, tail(barry[,1], n), type="l", xlab="t", ylim=c(0,n))
lines((n-5+1):n, pred_var[,1], lty=2, col=2)
lines((n-5+1):n, pred_vecm[,1], lty=2, col=3)
lines((n-5+1):n, pred_tvar[,1], lty=2, col=4)
legend("bottomright", lty=c(1,2,2,2), col=1:4, legend=c("true", "var", "vecm", "tvar"))

## example for newdata:
all.equal(predict(mod_vecm), predict(mod_vecm, newdata=barry[c(317, 318, 319),]))

predict_rolling Rolling forecasts

Description

Forecasts a VAR or VECM by discarding a part of the sample, and recursively generating a series of updated forecasts.
Usage

predict_rolling(object, ...)

## S3 method for class 'nlVar'
predict_rolling(object, nroll = 10, n.ahead = 1, refit.every, newdata, ...)

Arguments

object A linear object of class 'nlVar'; generated by lineVar or VECM.

... Currently not used.
nroll The number of rolling forecasts

n.ahead An integer specifying the number of forecast steps.

refit.every Determines every how many periods the model is re-estimated.

newdata In case the given model is already estimated on the sub-sample, the out-of-sample data can be provided with this argument. Note it should contain observations to predict the first values, that are also contained in the in-sample.

Details

This function allows to check the out-of sample forecasting accuracy by estimating the model on a sub-sample of the original, then making nroll forecasts of horizon n.ahead, each time by updating the sample. In other words, with a given model estimated on 100 observations, the function will estimate it on say 90 first obs (nroll=10), generate a say 1 step-ahead (n.ahead=1) from obs 90, then using true value 91 for to predict value at 92, etc, till the full sample is used.

Unlike with usual predict() methods, specifying n.ahead=2 will not generate a 1 step-ahead and a 2 step-ahead forecasts.

Note that while the forecasts are updated with new values, the model estimation is (by default) not updated. This can however be done with the argument fit.every, specifying at which frequency the model should be re-estimated. By setting it to 1 for example, each time a new observation is taken, the model is reestimated. This is similar to the ugarchroll in package rugarch.

Value

A matrix containing the forecasts.

Author(s)

Matthieu Stigler

See Also

predict.nlar for the standard predict function.
Examples

```r
data(barry)
## model estimated on full sample:
mod_vec <- VECM(barry, lag=2)
## generate 10 1-step-ahead forecasts:
pred_roll <- predict_rolling(mod_vec, nroll=10)
## plot the results:
plot(window(barry[,"dolcan"],start=1998), type="l", ylab="barry: dolcan")
pred_roll_ts <- ts(pred_roll$pred, start=time(barry)[nrow(barry)-10], freq=12)
lines(pred_roll_ts[,"dolcan"], col=2, lty=2)
legend("bottomright", lty=c(1,2), col=1:2, leg=c("True", "Fitted"))
title("Comparison of true and rolling 1-ahead forecasts\n")
```

---

**rank.select**

*Selection of the cointegrating rank with Information criterion.*

**Description**

Selection of the cointegrating rank and the lags with Information criterion (AIC, BIC).

**Usage**

```r
rank.select(
  data,
  lag.max = 10,
  r.max = ncol(data) - 1,
  include = c("const", "trend", "none", "both"),
  fitMeasure = c("SSR", "LL"),
  sameSample = TRUE,
  returnModels = FALSE
)
```

```r
## S3 method for class 'rank.select'
print(x, ...)  # S3 method for class 'rank.select'
as.data.frame(x, ...)  # S3 method for class 'rank.select'
summary(object, ...)  # S3 method for class 'rank.select'
```
Arguments

data: multivariate time series.
lag.max: Maximum number of lags to investigate.
r.max: Maximum rank to investigate.
include: Type of deterministic regressors to include. See VECM or lineVar.
fitMeasure: Whether the AIC/BIC should be based on the full likelihood, or just the SSR. See explanations in logLik.VECM.
sameSample: Logical. Whether the data should be shortened so that the AIC/BIC are estimated on the same sample. Default to TRUE.
returnModels: Logical, default to FALSE. Whether the output should also contain the list of each model computed.
x: The output from rank.select for the print method.
...: Unused.
object: The output from rank.select for the summary method.

Details

This function estimates the AIC, BIC and Hannan-Quinn for each rank (up to lags.max) and lags (up to lags.max). This method has been shown to be useful to select simultaneously the rank and the lags, see references.

Value

An object of class ‘rank.select’, with ‘print’ and ‘summary methods’, containing among other the matrices of AIC/BIC/HQ, the Likelihood, and best ranks according to each criterion.

Author(s)

Matthieu Stigler

References

620_05.html>.

---

rank.test

Test of the cointegrating rank

Description

Maximum-likelihood test of the cointegrating rank.

Usage

rank.test(vecm, type = c("eigen", "trace"), r_null, cval = 0.05)

## S3 method for class 'rank.test'
print(x, ...)

## S3 method for class 'rank.test'
summary(object, digits = max(1, getOption("digits") - 3), ...)

Arguments

vecm 'VECM' object computed with the function VECM.
type Type of test, either 'trace' or 'eigenvalue'. See details below.
r_null Rank to test specifically.
cval Critical value level for the automatic test.
x The output from rank.test for the print method.
... Unused.
object The output from rank.test for the summary method.
digits The number of digits to use in format.pval
Details

This function computes the two maximum-likelihood tests for the cointegration rank from Johansen (1996). Tests are:

**trace**  Test the hypothesis of rank ‘h’ against rank ‘K’, i.e. against the alternative that the system is stationary.

**eigenvalue**  Test the hypothesis of rank ‘h’ against rank ‘h+1’.

The test works for five specifications of the deterministic terms as in Doornik et al (1998), to be specified in the previous call to `VECM`:

- **Hqml**  Unrestricted constant and trend: use `include="both"`
- **Hl**  Unrestricted constant and restricted trend: use `include="const"` and `LRinclude="trend"`
- **Hlc**  Unrestricted constant and no trend: use `include="const"`
- **Hc**  Restricted constant and no trend: use `LRinclude="const"`
- **Hz**  No constant nor trend: use `include="none"`

Two testing procedures can be used:

**Specific test**  By specifying a value for ‘r_null’. The ‘pval’ value returned gives the specific p-value.

**Automatic test**  If not value is specified for ‘r_null’, the function makes a simple automatic test: returns the rank (slot ‘r’) of the first test not rejected (level specified by arg `cval`) as recommend i.a. in Doornik et al (1998, p. 544).

A full table with both test statistics and their respective p-values is given in the summary method.

P-values are obtained from the gamma approximation from Doornik (1998, 1999). Small sample values adjusted for the sample site are also available in the summary method. Note that the ‘effective sample size’ for the these values is different from output in gretl for example.

Value

An object of class ‘rank.test’, with ‘print’ and ‘summary methods’.

Comparison with urca

While `ca.jo` in package **urca** and `rank.test` both implement Johansen tests, there are a few differences:

- `rank.test` gives p-values, while `ca.jo` gives only critical values.
- `rank.test` allows for five different specifications of deterministic terms (see above), `ca.jo` for only three.
- `ca.jo` allows for seasonal and exogenous regressors, which is not available in `rank.test`.
- The lag is specified differently: K from `ca.jo` corresponds to lag+1 in `rank.test`.

Author(s)

Matthieu Stigler
References

See Also

VECM for estimating a VECM. rank.select to estimate the rank based on information criteria.
ca.jo in package urca for another implementation of Johansen cointegration test (see section ‘Comparison with urca’ for more infos).

Examples

data(barry)

## estimate the VECM with Johansen!
ve <- VECM(barry, lag=1, estim="ML")

## specific test:
ve_test_spec <- rank.test(ve, r_null=1)
ve_test_spec_tr <- rank.test(ve, r_null=1, type="trace")

ve_test_spec
ve_test_spec_tr

## No specific test: automatic method
ve_test_unspec <- rank.test(ve)
ve_test_unspec_tr <- rank.test(ve, type="trace")

ve_test_unspec
ve_test_unspec_tr

## summary method: output will be same for all types/test procedure:
summary(ve_test_unspec_tr)

## The function works for many specification of the VECM(), try:
rank.test(VECM(barry, lag=3, estim="ML"))
rank.test(VECM(barry, lag=3, include="both", estim="ML"))
rank.test(VECM(barry, lag=3, LRinclude="const", estim="ML"))

## Note that the tests are simple likelihood ratio, and hence can be obtained also manually:
-2*(logLik(ve, r=1)-logLik(ve, r=2)) # eigen test, 1 against 2
-2*(logLik(ve, r=1)-logLik(ve, r=3)) # eigen test, 1 against 3
regime 

Extract a variable showing the regime

Description

This function allows to extract the indicator variable specifying the regime in which the process is at time t.

Usage

regime(object, initVal = TRUE, timeAttr = TRUE, series = NULL, ...)

## S3 method for class 'lstar'
regime(object, initVal = TRUE, timeAttr = TRUE, series, discretize = TRUE, ...)

Arguments

- **object**
  - object of class setar or nlVar
- **initVal**
  - Logical. Whether the NA initial values should be returned. Default to TRUE.
- **timeAttr**
  - Logical. Whether the time attributes should be returned. Default to TRUE.
- **series**
  - Optional. A numeric vector to classify according to the model.
- **...**
  - additional arguments to regime
- **discretize**
  - logical (default TRUE) whether the series are discretized to 1,2, or whether regime probabilities are returned.

Value

Time series of same attributes as input to setar.

Author(s)

Matthieu Stigler

Examples

```r
set <- setar(lynx, m=3)
regime(set)
regime(set, time=FALSE, initVal=FALSE)
plot(regime(set))
```
**resample_vec**  

**Resampling schemes**

**Description**
Bootstrap a vector according to multiple resampling schemes: resampling, block resampling, Wild bootstrap.

**Usage**
```
resample_vec(
  x,
  boot.scheme = c("resample", "resample_block", "wild1", "wild2", "check"),
  seed = NULL,
  block.size = 2
)
```

**Arguments**
- **x** A numeric vector
- **boot.scheme** The type of resampling scheme used, see Details
- **seed** the seed used, see `set.seed`
- **block.size** for the `resample_block` scheme, the size of the blocks.

**Details**
This function offers various bootstrap/resampling schemes:
- **resample** Resampling with replacement
- **resample_block** Resampling contiguous observations (blocks) with replacement. Use argument `block.size`
- **wild1** Wild bootstrap: do not resample, but add a N(0,1) distribution to each value
- **wild12** Wild bootstrap: same, but add instead -1 or 1.

**resVar**  

**Residual variance**

**Description**
Extracts the global and regime-dependent variance of the residuals

**Usage**
```
resVar(x, adj=c("OLS", "ML"))
```
Arguments

x  setar object
adj  Degrees of freedom adjustment for the variance

Details

The degree of freedom adjustment in the formula for the variance is the number of parameters when adj="OLS" or zero when adj="ML".

Value

A vector containing:

Total  The residual variance of the full sample
L, (M), H  The residual variance of the lower (L), middle (if two thresholds) (M) and higher (H) regimes

Author(s)

Matthieu Stigler

#Lynx model as in Tong (1980, p. 387)
mod.setar <- setar(log10(lynx), mL=7, mH=2, thDelay=1, th=3.116)
summary(mod.setar)
#coefficients are same for lower regime but differ for higher
resVar(mod.setar, adj="ML")
#variance or the residuals is same for lower regime but differ for higher regime and hence for total

#Lynx model as in Tong (1980, p. 405)
mod.setar2 <- setar(log10(lynx), mL=1, mH=7, thDelay=1, nthresh=2, th=c(2.373, 3.154))
round(coefficients(mod.setar2),3)
resVar(mod.setar2, adj="ML")
selectHyperParms

Automatic selection of model hyper-parameters

Description

Automatic selection of model hyper-parameters

Usage

selectLSTAR(x, m, d=1, steps=d, mL = 1:m, mH = 1:m, thDelay=0:(m-1),
    fast=TRUE, trace=FALSE)
selectNNET(x, m, d=1, steps=d, size=1:(m+1), maxit=1e3, trace=FALSE)

Arguments

x
m, d, steps
mL, mH
thDelay
size
maxit
fast
trace

time series
embedding parameters. For their meanings, see help about nlar
Vector of ‘low’ and ‘high’ regimes autoregressive orders
Vector of ‘threshold delay’ values
Vector of numbers of hidden units in the nnet model
Max. number of iterations for each model estimation
For LSTAR selection, whether a fast algorithm using starting values fro previous
models should be used
Logical. Whether informations from each model should be returned.

Details

Functions for automatic selection of LSTAR and NNET models hyper parameters. An exhaustive
search over all possible combinations of values of specified hyper-parameters is performed. Em-
bedding parameters m, d, steps are kept fixed.
Selection criterion is the usual AIC.
For the LSTAR model, two methods are offered:
fast=FALSE  Each model is run separately, each time using the full grid search for starting values.
fast=TRUE  Only the first model is run with a full grid search, while the subsequent use the first
model results for their starting values.

Value

A data-frame, with columns giving hyper-parameter values and the computed AIC for each row
(only the best 10s are returned)

Author(s)

Antonio, Fabio Di Narzo
Examples

```r
llnyx <- log10(lynx)
selectLSTAR(llnyx, m=2)
selectNNET(llnyx, m=3, size=1:5)
```

selectSETAR
Automatic selection of SETAR hyper-parameters

Description
Automatic selection of SETAR hyper-parameters

Usage

```r
selectSETAR(x, m, d=1, steps=d, series, mL, mH, mM, thDelay=0, mTh, thVar,
th=MakeThSpec(), trace=TRUE, include = c("const", "trend", "none", "both"),
common=c("none", "include", "lags", "both"), model=c("TAR", "MTAR"),
ML=seq_len(mL), MH=seq_len(mH), MM=seq_len(mM), nthresh=1, trim=0.15,
criterion = c("pooled-AIC", "AIC", "BIC", "SSR"), plot=TRUE,
max.iter=2, type=c("level", "diff", "ADF"), same.lags=FALSE,
restriction=c("none", "OuterSymAll", "OuterSymTh"), hpc=c("none", "foreach")
```

Arguments

- `x` (time series)
- `m, d, steps` (embedding parameters. For their meanings, see help about `nlar`
- `series` (time series name (optional))
- `mL, mH, mM` (autoregressive order for ‘low’ (mL) ‘middle’ (mM, only useful if nthresh=2) and ‘high’ (mH) regime (default values: m). Must be <=m. Alternatively, you can specify ML)
- `thDelay` (Vector of possible ‘threshold delay’ values to check for)
- `mTh` (coefficients for the lagged time series, to obtain the threshold variable)
- `thVar` (external threshold variable)
- `th` (Different specifications of the grid search, to pre-specify a value or set the number of points to search. See `MakeThSpec`)
- `trace` (should additional infos be printed? (logical))
- `include` (Type of deterministic regressors to include)
- `common` (Indicates which elements are common to all regimes: no, only the include variables, the lags or both)
- `model` (Currently not implemented)
- `ML, MM, MH` (vector of lags for order for ‘low’ (ML) ‘middle’ (MM, only useful if nthresh=2) and ‘high’ (MH)regime. Max must be <=m)
- `nthresh` (Number of threshold of the model)
trimming parameter indicating the minimal percentage of observations in each regime. Default to 0.15

criterion Model selection criterion

plot Should a plot showing the criterion values be printed? (logical)

max.iter Number of iterations for the algorithm

type Whether the variable is taken is level, difference or a mix (diff y= y-1, diff lags) as in the ADF test

same.lags Logical. When AIC or pooled-AIC is used and arg m is given, should it search for same number of lags in each regime (TRUE) or allow for different (FALSE) lags in each regime. Different lags involves more computation

restriction Restriction on the threshold. OuterSymAll will take a symmetric threshold and symmetric coefficients for outer regimes. OuterSymTh currently unavailable

hpc Possibility to run the bootstrap on parallel core. See details

Details

Routine for automatic selection of SETAR models hyper parameters.

An exhaustive search over all possible combinations of values of specified hyper-parameters is performed. Thus the threshold delay, the number of lags in each regime and the threshold value are computed.

Embedding parameters d, steps are kept fixed.

Possible criteria are the usual SSR, AIC and a pooled AIC formula: $AIC(\text{lowregimemodel}) + AIC(\text{highregimemodel})$. The default criterion is the pooled AIC formula. SSR criterion can’t be used to compare models with different lags.

When two thresholds($nthresh=2$) have to be computed, the search for the second is made conditional on results for first threshold as suggested in Gonzalo and Pittarakis (2002). Refinements can be obtained by using max.iter (first threshold being re-estimated based on the second one). If SSR is used, the number of lags in the inner regime is either the same if only arg m was given, otherwise it has to be pre-specified. Criterion AIC can be used to determine the number of lags in the inner regime, whereas pooled-AIC is currently not implemented for $nthresh=2$.

By default, all threshold values excluding the upper and lower trim of the threshold values are taken as potential threshold. restriction can be made with arg th. See function MakeThSpec.

With the argument hpc, the heavy grid search can be run on parallel cores, thus alleviating the time of computation. Preliminary results indicate however that the length of the series must be very considerable in order that the parallel code becomes advantageous. To use it, the user needs simply to choose a package (among doMC, doMPI, doSNOW or doRedis) and register the backend. See the vignette for more details.

Value

An object of class selectSETAR (print and plot methods) with:

res A data-frame, with columns giving hyper-parameter values and the computed AIC for each row (only the best 10/5s are returned)

res2 Same as res, returned if $nthresh=2$ otherwise set to NULL
bests estimated hyper-parameters
th, firstBests, bests2th, ML, MM, MH
estimated parameters, from first and conditional search
criterion, nthresh, same.lags
returns args given by user
allTh all threshold values and corresponding criterion from first search

Author(s)
Antonio, Fabio Di Narzo and Stigler, Matthieu

selectSETAR(llynx, m=2)
#Suggested model is the following:
setar(llynx, m=2, thDelay=1, th=3.4)
```

Self Exciting Threshold AutoRegressive model

Description

Self Exciting Threshold AutoRegressive model.

Usage

```r
setar(x, m, d=1, steps=d, series, mL, mM, mH, thDelay=0, mTh, thVar, th, trace=FALSE, nested=FALSE, include = c( "const", "trend","none", "both"), common=c("none", "include","lags","both"), model=c("TAR", "MTAR"), ML=seq_len(mL), MM=seq_len(mM), MH=seq_len(mH), nthresh=1, trim=0.15, type=c("level", "diff","ADF"), restriction=c("none","OuterSymAll","OuterSymTh")
```
Arguments

x  time series
m, d, steps embedding dimension, time delay, forecasting steps
series time series name (optional)
ML, MM, MH autoregressive order for ‘low’ (ML) ‘middle’ (MM, only useful if nthresh=2) and ‘high’ (MH) regime (default values: m). Must be <=m. Alternatively, you can specify ML
thDelay 'time delay' for the threshold variable (as multiple of embedding time delay d)
mTh coefficients for the lagged time series, to obtain the threshold variable
thVar external threshold variable
th threshold value (if missing, a search over a reasonable grid is tried)
trace should additional infos be printed? (logical)
include Type of deterministic regressors to include
common Indicates which elements are common to all regimes: no, only the include variables, the lags or both
ML, MM, MH vector of lags for order for ‘low’ (ML) ‘middle’ (MM, only useful if nthresh=2) and ‘high’ (MH) regime. Max must be <=m
model Whether the threshold variable is taken in levels (TAR) or differences (MTAR)
nthresh Number of threshold of the model
trim trimming parameter indicating the minimal percentage of observations in each regime. Default to 0.15
type Whether the variable is taken is level, difference or a mix (diff y = y-1, diff lags) as in the ADF test
restriction Restriction on the threshold. OuterSymAll will take a symmetric threshold and symmetric coefficients for outer regimes. OuterSymTh currently unavailable
nested Whether is this a nested call? (useful for correcting final model df)

Details
Self Exciting Threshold AutoRegressive model.

\[ X_{t+s} = x_{t+s} = \left( \phi_{1,0} + \phi_{1,1} x_t + \phi_{1,2} x_{t-d} + \cdots + \phi_{1,mL} x_{t-(mL-1)d} \right) I(z_t \leq th) + \left( \phi_{2,0} + \phi_{2,1} x_t + \phi_{2,2} x_{t-d} + \cdots + \phi_{2,mH} x_{t-(mH-1)d} \right) I(z_t > th) + \epsilon_t \]

with z the threshold variable. The threshold variable can alternatively be specified by (in that order):

\[ thDelay \quad z[t] = x[t - thDelay * d] \]
\[ mTh \quad z[t] = x[t] \cdot mTh[1] + x[t-d] \cdot mTh[2] + \cdots + x[t-(m-1)d] \cdot mTh[m] \]
\[ thVar \quad z[t] = thVar[t] \]

For fixed th and threshold variable, the model is linear, so phi1 and phi2 estimation can be done directly by CLS (Conditional Least Squares). Standard errors for phi1 and phi2 coefficients provided by the summary method for this model are taken from the linear regression theory, and are to be considered asymptotical.
Value

An object of class `nlar`, subclass `setar`

Examples

```r
# fit a SETAR model, with threshold as suggested in Tong(1990, p 377)
mod.setar <- setar(log10(lynx), m=2, thDelay=1, th=3.25)
mod.setar
summary(mod.setar)

## example in Tsay (2005)
data(m.unrate)
setar(diff(m.unrate), ML=c(2,3,4,12), MH=c(2,4,12), th=0.1, include="none")
```

Description

Simulate or bootstrap a Threshold AR (SETAR) The `setar.sim` function allows to simulate a SETAR model from scratch. The most important argument is the `B` argument, which should be a one row matrix, with first the constant/trend arguments, then the slope coefficients, and this for each regime (lower, middle, high). Other arguments such as `lag`, `nthresh` indicate the dimension of this matrix. As an example, a SETAR with 2 lags, 1 threshold, a constant, would have coefficient in the order: `c(const_L, phi_1_L, phi_2_L, const_H, phi_1_H, phi_2_H)` where L is for Lower regime, H for Higher.

`setar.boot` on the other side resample/bootstraps an existing setar output. It uses a recursive approach, reconstructing the series. Residuals from the original model are resampled using different bootstrap schemes, see `resample_vec`.
Usage

setar.boot(
  setarObject,
  boot.scheme = c("resample", "resample_block", "wild1", "wild2", "check"),
  seed = NULL,
  ...
)

linear.boot(
  linearObject,
  boot.scheme = c("resample", "resample_block", "wild1", "wild2", "check"),
  seed = NULL,
  ...
)

setar.sim(
  B,
  n = 200,
  lag = 1,
  include = c("const", "trend", "none", "both"),
  nthresh = 1,
  Thresh,
  starting = NULL,
  innov = rnorm(n),
  ...
)

linear.sim(
  B,
  n = 200,
  lag = 1,
  include = c("const", "trend", "none", "both"),
  starting = NULL,
  innov = rnorm(n),
  ...
)

Arguments

setarObject Bootstrap: the setar object to resample data from.
boot.scheme Bootstrap: which resampling scheme to use for the residuals. See resample_vec.
seed Bootstrap: seed used in the resampling
... additional arguments for the unexported setar.gen.
linearObject Bootstrap: the linear object to resample data from.
B Simulation: vector of coefficients to simulate from.
n Simulation: Number of observations to simulate.
setarTest

Thresh, nthresh, lag, include

Simulation: parameters for the SETAR to simulate. See setar for their description.

starting

Simulation: Starting values (same length as lag)

innov

Simulation: time series of innovations/residuals.

Value

a list with the simulated/bootstrapped data and the parameter matrix used.

Author(s)

Matthieu Stigler

##Simulation of a TAR with 1 threshold
TvarMat <- c(2.9,-0.4,-0.1,-1.5, 0.2,0.3)
sim<-setar.sim(B=TvarMat,lag=2, type="simul", nthresh=1, Thresh=2, starting=c(2.8,2.2))
mean(ifelse(sim>2,1,0)) #approximation of values over the threshold

#check the result
selectSETAR(sim, m=2)

##Bootstrap a TAR with two threshold (three regimes)
sun <- (sqrt(sunspot.year+1)-1)*2
sun_est <- setar(sun, nthresh=2, m=2)
sun_est_boot <- setar.boot(sun_est)
head(sun_est_boot)

##Check the bootstrap: with no resampling, is it the same series?
sun_est_boot <- setar.boot(sun_est, boot.scheme = "check")
all.equal(as.numeric(sun), sun_est_boot)
Usage

setarTest(
  x,
  m,
  thDelay = 0,
  trim = 0.1,
  include = c("const", "trend", "none", "both"),
  nboot = 10,
  test = c("1vs", "2vs3"),
  hpc = c("none", "foreach"),
  boot.scheme = c("resample", "resample_block", "wild1", "wild2", "check"),
  seed = NULL
)

Arguments

x      time series
m, thDelay  lag and 'time delay' for the threshold variable
trim   trimming parameter indicating the minimal percentage of observations in each regime
include Type of deterministic regressors to include: none, a constant, a trend, or constant and trend (both).
nboot number of bootstrap replications
test whether to test AR against SETAR, or SETAR(1 reg) against SETAR(2 reg)
hpc Possibility to run the bootstrap on parallel core. See details in
boot.scheme  Type of resampling scheme to use for the residuals. See resample_vec.
seed  Seed used in the bootstrap resampling TVECM.HStest

Details

Estimation of the first threshold parameter is made with CLS, a conditional search with one iteration is made for the second threshold. The F test comparing the residual sum of squares (SSR) of each model is computed.

\[ F_{ij} = T((S_i - S_j)/S_j) \]

where \( S_i \) is the SSR of the model with \( i \) regimes (and so \( i-1 \) thresholds).

Three test are available. The both first can be seen as linearity test, whereas the third can be seen as a specification test: once the 1vs2 or/and 1vs3 rejected the linearity and henceforth accepted the presence of a threshold, is a model with one or two thresholds preferable?

Test **1vs2**: Linear AR versus 1 threshold TAR

Test **1vs3**: Linear AR versus 2 thresholds TAR

Test **2vs3**: 1 threshold TAR versus 2 thresholds TAR

The two first tests are computed together and available with test="1vs". The third test is available with test="2vs3".
The homoskedastic bootstrap distribution is based on resampling the residuals from H0 model (ar for test 1vs, and setar(1) for test 2vs3), estimating the threshold parameter and then computing the Ftest, so it involves many computations and is pretty slow.

**Value**

A object of class "Hansen99Test" containing:

- **SSRs** The residual Sum of squares of model AR, 1 threshold TAR and 2 thresholds TAR
- **Ftests** The Ftest statistic for the test
- **PvalBoot** The bootstrap p-values for the test selected
- **CriticalValBoot** The critical values for the test selected
- **Ftestboot** All the F-test computed
- **firstBests, secBests** The thresholds for the original series, obtained from search for 1 thresh (firstBests) and conditional search for 2 thresh (secBests)
- **nboot,m** The number of bootstrap replications (nboot), the lags used (m)

STAR model

Description

STAR model fitting with automatic selection of the number of regimes based on LM tests.

Usage

```
star(x, m=2, noRegimes, d = 1, steps = d, series, rob = FALSE,
     mTh, thDelay, thVar, sig=0.05, trace=TRUE, control=list(), ...)
```

Arguments

- **x**: time series
- **m, d, steps**: embedding dimension, time delay, forecasting steps
- **noRegimes**: max number of regimes
- **series**: time series name (optional)
- **rob**: perform robust test (not implemented)
- **thDelay**: 'time delay' for the threshold variable (as multiple of embedding time delay d)
- **mTh**: coefficients for the lagged time series, to obtain the threshold variable
- **thVar**: external threshold variable
- **sig**: significance level for the tests to select the number of regimes.
- **control**: further arguments to be passed as control list to optim
- **trace**: should additional infos be printed out?
- **...**: currently unused

Details

The function star implements the iterative building strategy described in [1] to identify and estimate Smooth Transition Autoregressive models.

Value

star returns an object of class nlar, subclass star, i.e. a list with informations about the fitted model.

Multivariate Threshold Vector Autoregressive model

Description

Estimate a multivariate Threshold VAR (TVAR), either using lags as transition variable (default), or specifying an external variable.

Usage

TVAR(
    data,
    lag,
    include = c("const", "trend", "none", "both"),
    model = c("TAR", "MTAR"),
    commonInter = FALSE,
    nthresh = 1,
    thDelay = 1,
    mTh = 1,
    thVar,
    trim = 0.1,
    ngrid,
    gamma = NULL,
    around,
    plot = FALSE,
    dummyToBothRegimes = TRUE,
    trace = TRUE,
    trick = "for",
    max.iter = 2
)

Arguments

data | time series
lag | Number of lags to include in each regime
include | Type of deterministic regressors to include
model | Whether the transition variable is taken in levels (TAR) or difference (MTAR)
commonInter | Whether the deterministic regressors are regime specific (commonInter=FALSE) or not.
nthresh | Number of thresholds
thDelay | 'time delay' for the threshold variable (as multiple of embedding time delay d)
PLEASE NOTE that the notation is currently different to univariate models in tsDyn. The left side variable is taken at time t, and not t+1 as in univariate cases.
mTh | combination of variables with same lag order for the transition variable. Either a single value (indicating which variable to take) or a combination
thVar  Optional. External transition variable.
trim  trimming parameter indicating the minimal percentage of observations in each regime
ngrid  number of elements of the grid, especially for nthresh=3
gamma  prespecified threshold values
around  The grid search is restricted to ngrid values around this point. Especially useful for nthresh=3.
plot  Whether a plot showing the results of the grid search should be printed
dummyToBothRegimes  Whether the dummy in the one threshold model is applied to each regime or not.
trace  should additional infos be printed out?
trick  type of R function called: for or mapply
max.iter  Number of iterations for the algorithm

Details

For fixed th and threshold variable, the model is linear, so estimation can be done directly by CLS (Conditional Least Squares). The search of the parameters values is made upon a grid of potential values. So it is pretty slow.

nthresh=1: estimation of one threshold model (two regimes) upon a grid of ngrid values (default to ALL) possible thresholds and delays values.

nthresh=2: estimation of two thresholds model (three regimes) Conditional on the threshold found in model where nthresh=1, the second threshold is searched. When both are found, a second grid search is made with 30 values around each threshold.

nthresh=3: DOES NOT estimate a 3 thresholds model, but a 2 thresholds model with a whole grid over the thresholds parameters (so is really slow) with a given delay, is there rather to check the consistency of the method nthresh=2

Value

An object of class TVAR, with standard methods.

Author(s)

Matthieu Stigler

predict(tv)
c(AIC(tv), BIC(tv), logLik(tv))
```

### TVAR.LRtest

**Test of linearity**

**Description**

Multivariate extension of the linearity against threshold test from Hansen (1999) with bootstrap distribution

**Usage**

```r
TVAR.LRtest(
  data, 
  lag = 1, 
  trend = TRUE, 
  series, 
  thDelay = 1:m, 
  mTh = 1, 
  thVar, 
  nboot = 10, 
  plot = FALSE, 
  trim = 0.1, 
  test = c("1vs", "2vs3"), 
  model = c("TAR", "MTAR"), 
  hpc = c("none", "foreach"), 
  trace = FALSE, 
  check = FALSE
)
```

**Arguments**

- **data**: multivariate time series
- **lag**: Number of lags to include in each regime
- **trend**: whether a trend should be added
series name of the series
thDelay 'time delay' for the threshold variable (as multiple of embedding time delay d)
PLEASE NOTE that the notation is currently different to univariate models in tsDyn. The left side variable is taken at time t, and not t+1 as in univariate cases.
mTh combination of variables with same lag order for the transition variable. Either a single value (indicating which variable to take) or a combination
thVar external transition variable
nboot Number of bootstrap replications
plot Whether a plot showing the results of the grid search should be printed
trim trimming parameter indicating the minimal percentage of observations in each regime
test Type of usual and alternative hypothesis. See details
model Whether the threshold variable is taken in level (TAR) or difference (MTAR)
hpc Possibility to run the bootstrap on parallel core. See details in TVECM.HStest
trace should additional infos be printed? (logical)
check Possibility to check the function by no sampling: the test value should be the same as in the original data

Details

This test is just the multivariate extension proposed by Lo and Zivot of the linearity test of Hansen (1999). As in univariate case, estimation of the first threshold parameter is made with CLS, for the second threshold a conditional search with one iteration is made. Instead of a Ftest comparing the SSR for the univariate case, a Likelihood Ratio (LR) test comparing the covariance matrix of each model is computed.

\[ LR_{ij} = T(\ln(\det \hat{\Sigma}_i) - \ln(\det \hat{\Sigma}_j)) \]

where \( \hat{\Sigma}_i \) is the estimated covariance matrix of the model with i regimes (and so i-1 thresholds).

Three test are available. The both first can be seen as linearity test, whereas the third can be seen as a specification test: once the 1vs2 or/and 1vs3 rejected the linearity and henceforth accepted the presence of a threshold, is a model with one or two thresholds preferable?

Test 1vs2: Linear VAR versus 1 threshold TVAR
Test 1vs3: Linear VAR versus 2 threshold2 TVAR
Test 2vs3: 1 threshold TAR versus 2 threshold2 TAR

The both first are computed together and available with test="1vs". The third test is available with test="2vs3".

The homoskedastik bootstrap distribution is based on resampling the residuals from H0 model, estimating the threshold parameter and then computing the Ftest, so it involves many computations and is pretty slow.
TVAR.sim

Simulation of a multivariate Threshold Autoregressive model (TVAR)

Description

Simulate a multivariate Threshold VAR (TVAR)

Usage

```r
TVAR.sim(
  B,
  Thresh,
  nthresh = 1,
  n = 200,
  lag = 1,
  include = c("const", "trend", "none", "both"),
  thDelay = 1,
  mTh = 1,
```

Value

A list containing:
- The values of each LR test
- The bootstrap Pvalues and critical values for the test selected

Author(s)

Matthieu Stigler

References

See Also

`setarTest` for the univariate version. `OlsTVAR` for estimation of the model.

Examples

```r
data(zeroylld)
data<-zeroylld
tVAR.LRtest(data, lag=2, mTh=1, thDelay=1:2, nboot=3, plot=FALSE, trim=0.1, test="1vs")
```
starting = NULL,
innov = rmnorm(n, varcov = varcov),
varcov = diag(1, nrow(B)),
show.parMat = FALSE,
... )

TVAR.boot(
    TVARobject, 
    innov,
    seed,
    boot.scheme = c("resample", "wild1", "wild2", "check"),
    ... 
)

**Arguments**

- **B**  
  Matrix of coefficients to simulate
- **Thresh**  
  The threshold value(s). Vector of length nthresh
- **nthresh**  
  number of threshold (see details)
- **n**  
  Number of observations to create when type="simul"
- **lag**  
  Number of lags to include in each regime
- **include**  
  Type of deterministic regressors to include. NOT WORKING PROPERLY CURRENTLY if not const
- **thDelay**  
  'time delay' for the threshold variable (as multiple of embedding time delay d) PLEASE NOTE that the notation is currently different to univariate models in tsDyn. The left side variable is taken at time t, and not t+1 as in univariate cases.
- **mTh**  
  combination of variables with same lag order for the transition variable. Either a single value (indicating which variable to take) or a combination
- **starting**  
  Starting values (matrix of dimension lag x k). If not given, set to zero.
- **innov**  
  Innovations used for simulation. Should be matrix of dim n x k. By default multivariate normal. For the bootstrap case TVAR.boot, residuals are resampled if argument is missing.
- **varcov**  
  Variance-covariance matrix for the innovations. By default identity matrix.
- **show.parMat**  
  Logical. Should the parameter matrix be shown? Useful to understand how to give right input
- **...**  
  Further arguments passed to the underlying (un-exported) TVAR.gen function
- **TVARObject**  
  Object of class TVAR generated by function TVAR
- **seed**  
  Optional. Seed for the random resampling function.
- **boot.scheme**  
  The bootstrap scheme.
Details

This function offers the possibility to generate series following a TVAR.

By giving a matrix of coefficients, one can only simulate a VAR (nthresh=0) or TVAR (nthresh=1 or 2). One can have a specification with constant (default), trend, both or none (see arg include). Order in parameters is include/lags (VECM) and include/lags/include/lags for TVECM, hence, a matrix for a TVECM with 3 regimes, a const and a 2 lags would have 2 lines and 2*(1+4) columns. The innovations can be given by the user (a matrix of dim nxx, here n does not include the starting values!), by default it uses a multivariate normal distribution, with covariance matrix specified by varcov. The starting values (of dim lags x k) can be given. The user should take care for their choice, since it is not sure that the simulated values will cross the threshold even once.

The matrix 'B' has to be in the form: constant, trend, lags, then repeated if many regimes. In case of uncertainty, using who.parMat=TRUE will print the matrix as interpreted by the function, helping the user to feed the right input.

For the bootstrap, the function resamples data from a given TVAR model generated by TVAR, returning the resampled data. A residual recursive bootstrap is used, where one uses either a simple resampling, or the Wild bootstrap, either with a normal distribution (wild1) or inverting the sign randomly (wild2).

Value

A matrix with the simulated/bootstrapped series.

## TVAR.sim: Simulation of a TVAR with 1 threshold
B <- rbind(c(0.11928245, 1.00880447, -0.009974585, -0.089316, 0.95425564, 0.02592617),
          c(0.25283578, 0.09182279, 0.914763741, -0.0530613, 0.02248586, 0.94309347))
colnames(B) <- paste(rep(c("Const", "Lag_1_var1", "Lag_1_var2"), 2), c("Low", "High"), sep="_")
sim <- TVAR.sim(B=B, nthresh=1, n=500, mTh=1, Thresh=5, starting=matrix(c(5.2, 5.5), nrow=1))

# estimate the new serie
TVAR(sim, lag=1, dummyToBothRegimes=TRUE)
```
## TVAR.boot: Bootstrap a TVAR with two threshold (three regimes)

data(zeroyld)
serie <- zeroyld
mod <- TVAR(data=serie,lag=1, nthresh=1)
TVAR.boot(mod)

---

### Description

Estimate a Threshold Vector Error Correction model (VECM)

### Usage

```r
TVECM(
data,  
lag = 1,  
nthresh = 1,  
trim = 0.05,  
ngridBeta = 50,  
ngridTh = 50,  
plot = TRUE,  
th1 = list(exact = NULL, int = c("from", "to"), around = "val"),  
th2 = list(exact = NULL, int = c("from", "to"), around = "val"),  
beta = list(exact = NULL, int = c("from", "to"), around = c("val", "by")),  
restr = c("none", "equal", "signOp"),  
common = c("All", "only_ECT"),  
include = c("const", "trend", "none", "both"),  
dummyToBothRegimes = TRUE,  
beta0 = 0,  
methodMapply = FALSE,  
trace = TRUE
)
```

### Arguments

- **data**: time series
- **lag**: Number of lags to include in each regime
- **nthresh**: number of threshold (see details)
- **trim**: trimming parameter indicating the minimal percentage of observations in each regime
- **ngridBeta**: number of elements to search for the cointegrating value
- **ngridTh**: number of elements to search for the threshold value
- **plot**: Whether the grid with the SSR of each threshold should be plotted.
th1  different possibilities to pre-specify an exact value, an interval or a central point for the search of the threshold (or first threshold if nthresh=2)
th2  different possibilities to pre-specify an exact value or a central point for the search of the second threshold (used only if nthresh=2)
beta different possibilities to pre-specify an exact value, an interval or a central point for the search of the cointegrating value
restr Currently not available
common Whether the regime-specific dynamics are only for the ECT or for the ECT and the lags
include Type of deterministic regressors to include
dummyToBothRegimes Whether the dummy in the one threshold model is applied to each regime or not.
beta0 Additional regressors to include in the cointegrating relation
methodMapply only for programming. Is to make the choice between a for loop or mapply implementation
trace should additional infos be printed? (logical)

Details

For fixed threshold and cointegrating vector, the model is linear, so estimation of the regression parameters can be done directly by CLS (Conditional Least Squares). The search of the threshold and cointegrating parameters values which minimize the residual sum of squares (SSR) is made on a grid of potential values. For specification of the grids, see below.

The function can estimate one as well as two thresholds:

nthresh=1: estimation of one threshold model (two regimes) upon a grid of ngridTh values (default to ALL) possible thresholds and delays values.

nthresh=2: estimation of two thresholds model (three regimes). Conditional on the threshold found in model where nthresh=1, the second threshold is searched. When both are found, a second grid search is made with 30 values around each threshold.

The model can be either with a threshold effect on all variables ("All") or only on the error correction term (ECT) (argument "only ECT"). In the second case, the value for the middle threshold is taken a null, as in Balke and Fomby (1997).

The grid for the threshold parameters can be set in different ways, through the argument th1, th2 and beta:

exact:  Pre-specified value (for beta: cointegrating vector will be c(1,-beta))
int:  Specify an interval (of length ngridTh) in which to search.
around:  Specify to take ngridTh points around the value given.

The default is to do an interval search. Interval bounds for the threshold interval are simply the trim and 1-trim percents of the sorted error correction term. For the cointegrating parameter, bounds of the interval are obtained from the (OLS) confidence interval of the linear cointegration case. It is often found however that this interval is too tight. It is hence recommended to inspect the plot of the grid search.
Value
Fitted model data

TVECM.HS

Test of linear cointegration vs threshold cointegration

Description
Tests the null of linear cointegration against threshold cointegration following Hansen and Seo (2002). Fixed regressor and residual bootstrap are available.
Usage

```
TVECM.HStest(data, lag=1, ngridTh=300, trim=0.05,
nboot=100, fixed.beta=NULL, intercept=TRUE,
boot.type=c("FixedReg", "ResBoot"),
hpc=c("none", "foreach"))
```

Arguments

- **data**: Time series
- **lag**: Number of lags to include in each regime
- **ngridTh**: Number of threshold grid points to evaluate the optimal threshold.
- **trim**: Trimming parameter indicating the minimal percentage of observations in each regime
- **nboot**: Number of bootstrap replications
- **fixed.beta**: Numeric. User pre-specified cointegrating value, as in VECM (i.e. cointegrating vector will be c(1, -beta.fixed)). When NULL (default), the value is estimated from the linear VECM.
- **intercept**: Logical. Whether an intercept has to be included in the VECM
- **boot.type**: Character. Type of bootstrap simulation (only if nboot>0)
- **hpc**: Possibility to run the bootstrap on parallel core. See details

Details

This test follows the implementation done by Hansen and Seo (2002). The cointegrating value is estimated from the linear VECM. Then, conditional on this value, the LM test is run for a range of different threshold values. The maximum of those LM test values is reported.

Two bootstrap are available: a fixed regressor, as well as a usual residual bootstrap (using the function `TVECM.sim`).

Available methods are `print()`, `summary()` and `plot()`.

With the argument `hpc`, the burdensome bootstrap replication can be run on parallel cores, thus alleviating the time of computation. The user needs simply to choose a package (among doMC, doMPI, doSNOW or doRedis) and register the backend. See the vignette for more details.

Value

A list containing diverse values:

- **stat**: The sup-LM statistic.
- **values**: The whole LM values.
- **PValBoot**: The bootstrap p-value
- **CriticalValBoot**: The bootstrap critical values
- **allBoots**: The boot sup-LM values
- **args**: Some user given args (nboot, boot.type)
Reproducibility

Comparison with original paper is made difficult as values of the test are not shown in the paper, only their critical values, which depend on random bootstrap.

Comparison is done with the GAUSS code available on the page of Bruce Hansen. Running tar_ci, we have the same sup-LM value when lags=1 and lags=2, a higher value with lag=3. When the test is run with pre-specified beta values, we have different results, sometimes higher but also smaller sup-LM value.

TVECM.SeoTest

No cointegration vs threshold cointegration test

Description
Test the null of no cointegration against threshold cointegration with bootstrap distribution of Seo (2006)

Usage
TVECM.SeoTest(
  data, 
  lag, 
  beta, 
  trim = 0.1, 
  nboot, 
  plot = FALSE, 
  hpc = c("none", "foreach"), 
  check = FALSE 
)

Arguments
- **data**: time series
- **lag**: Number of lags to include in each regime
- **beta**: Pre-specified cointegrating value (i.e. cointegrating vector will be c(1, -beta))
- **trim**: trimming parameter indicating the minimal percentage of observations in each regime
- **nboot**: Number of bootstrap replications
- **plot**: Whether a grid with the SSR of each threshold should be printed
- **hpc**: Possibility to run the bootstrap on parallel core. See details in `TVECM.HStest`
- **check**: Possibility to check the function by no sampling: the test value should be the same as in the original data

Details
For this test, the cointegrating value has to be specified by the user.
The model used is one where the threshold effect concerns only the cointegrating vector, and only in the outer regimes.
Due to the presence of parameters unidentified under the null hypothesis, the test employed is a Sup-Wald test, that means that for each combination of the thresholds, a Wald Test is computed and the supremum of all tests is taken. For each bootstrap replication, this approach is taken, so that the test is really slow.

**Value**

- A list containing diverse informations:
  - Estimated threshold parameters and usual slope parameters.
  - Value of the test.
  - Critical and Pvalue from bootstrap distribution.

# As the function takes long long time to be executed, we show in in don't run environement
## Not run:
data(zeroyld)
#can be useful to check whether the bootstrap is working:
#without sampling, results of boot should be same as original
#this is indeed not always the case due to floating point algorithm
TVECM.SeoTest(zeroyld,lag=2, beta=1, trim=0.1,nboot=2, plot=FALSE,check=TRUE)

#then run the function:
TVECM.SeoTest(zeroyld,lag=2, beta=1, trim=0.1,nboot=100, plot=FALSE,check=FALSE)
## End(Not run)
```
TVECM.sim

Simulation and bootstrap a VECM or bivariate TVECM

**Description**

Estimate or bootstraps a multivariate Threshold VAR

**Usage**

```r
TVECM.sim(
  B,
  n = 200,
  lag = 1,
  include = c("const", "trend", "none", "both"),
  beta,
  nthresh = 1,
  Thresh,
  starting = NULL,
  innov = rmnorm(n, varcov = diag(1, nrow(B))),
  show.parMat = FALSE,
  returnStarting = FALSE,
  ...
)

VECM.sim(
  B,
  n = 200,
  lag = 1,
  include = c("const", "trend", "none", "both"),
  beta,
  starting = NULL,
  innov = rmnorm(n, varcov = diag(1, nrow(B))),
  show.parMat = FALSE,
  returnStarting = FALSE,
  ...
)

VECM.boot(
  object,
  boot.scheme = c("resample", "resample_block", "wild1", "wild2", "check"),
  seed = NULL,
  ...
)

TVECM.boot(
  object,
  boot.scheme = c("resample", "resample_block", "wild1", "wild2", "check"),
  ...
seed = NULL,
...
)

Arguments

B  Simulation: Matrix of coefficients to simulate
n  Simulation: Number of observations to simulate.
beta  The cointegrating value
Thresh, nthresh, lag, include
Simulation: parameters for the VECM/TVECM to simulate. See TVECM for their description.
starting  Simulation: Starting values (same length as lag = 1)
innov  Simulation: time series of innovations/residuals.
show.parMat  Logical. Whether to show how the parameter matrix B is interpreted.
returnStarting  Logical. Whether to return the starting values.
...  additional arguments for the unexported TVECM.gen.
object  Object computed by function TVECM or linear VECM
boot.scheme  Bootstrap: which resampling scheme to use for the residuals. See resample_vec.
seed  Bootstrap: seed used in the resampling

Details

This function offers the possibility to generate series following a VECM/TVECM from two approaches: bootstrap or simulation. VECM.sim is just a wrapper for TVECM.sim.

When the argument matrix is given, one can only simulate a VECM (nthresh=0) or TVECM (nthresh=1 or 2). One can have a specification with constant ("const"), "trend", "both" or "none" (see argument include). Order for the parameters is ECT/include/lags for VECM and ECT1/include1/lags1/ECT2/include2/lags2 for TVECM. To be sure that once is using it correctly, setting show.parMat = TRUE will show the matrix of parameters together with their values and names.

The argument beta is the cointegrating value on the right side of the long-run relationship, and hence the function use the vector (1,-beta). The innov argument specifies the innovations. It should be given as a matrix of dim nxk, (here n does not include the starting values!), by default it uses a multivariate normal distribution, with covariance matrix specified by varcov.

The starting values (of dim lags x k) can be given through argument starting. The user should take care for their choice, since it is not sure that the simulated values will cross the threshold even once. Notice that only one cointegrating value is allowed. User interested in simulating a VECM with more cointegrating values should do use the VAR representation and use TVAR.sim.

The second possibility is to bootstrap series. This is done on a object generated by TVECM (or VECM). A simple residual bootstrap is done, or one can simulate a series with the same parameter matrix and with normal distributed residuals (with variance pre-specified), corresponding to Monte-carlo simulations.

One can alternatively give only the series, and then the function will call internally TVECM.
Value

A matrix with the simulated/bootstrapped series.

### Description

This data, used as example in Caner and Hansen (2001), contains the monthly US adult male unemployment from 1956 to 1999.

### Usage

```r
data(UsUnemp)
```

### Format

A monthly time series of class ts starting in January 1956 and ending in August 1999.

### Source

---

### VAR.sim

**Simulate or bootstrap a VAR model**

### Description

Allow to either simulate from scratch (by providing coefficients) or bootstrap from an estimated VAR model.

### Usage

```r
VAR.sim(
  B,
  n = 200,
  lag = 1,
  include = c("const", "trend", "none", "both"),
  starting = NULL,
  innov = rmnorm(n, varcov = varcov),
  varcov = diag(1, nrow(B)),
  show.parMat = FALSE,
  returnStarting = FALSE,
)```
VAR.boot(
  VARobject,
  boot.scheme = c("resample", "wild1", "wild2", "check"),
  seed,
  ...
)

Arguments

- B: Matrix of coefficients.
- n: Number of observations to simulate
- lag: Number of lags of the VAR to simulate
- include: Type of deterministic regressors to include in the VAR to simulate
- starting: Starting values (matrix of dimension lag x k) for the VAR to simulate. If not given, set to zero.
- innov: Innovations used for in the VAR to simulate. Should be matrix of dim n x k. By default multivariate normal.
- varcov: Variance-covariance matrix for the innovations. By default identity matrix.
- show.parMat: Logical. Should the parameter matrix be shown? Useful to understand how to give right input
- returnStarting: Whether starting values are returned. Default to FALSE
- ...: Further arguments passed to the underlying (un-exported) VAR.gen function
- VARobject: Object of class VAR generated by function lineVar
- boot.scheme: The bootstrap scheme. See details.
- seed: Optional. Seed for the random resampling function.

Details

For the bootstrap, the function resamples data from a given VAR model generated by lineVar, returning the resampled data. A residual recursive bootstrap is used, where one uses either a simple resampling, or the Wild bootstrap, either with a normal distribution (wild1) or inverting the sign randomly (wild2)

Value

A matrix with the resampled series.

# VAR model:
mod_var <- lineVar(barry, lag=2, I="diff")
VARrep(mod_var)

VECM

Estimation of Vector error correction model (VECM)

Description

Estimate a VECM by either Engle-Granger (2OLS) or Johansen (MLE) method.

Usage

VECM(
    data,
    lag,
    r = 1,
    include = c("const", "trend", "none", "both"),
    beta = NULL,
    estim = c("2OLS", "ML"),
    LRinclude = c("none", "const", "trend", "both"),
    exogen = NULL
)
VECM

Arguments

- **data**: multivariate time series (first row being first=oldest value)
- **lag**: Number of lags (in the VECM representation, see Details)
- **r**: Number of cointegrating relationships
- **include**: Type of deterministic regressors to include
- **beta**: for VECM only: user-specified cointegrating values, the cointegrating vector will be taken as: (1, -beta) If NULL, will be estimated using the estimator specified in `estim`
- **estim**: Type of estimator: 2OLS for the two-step approach or ML for Johansen MLE
- **LRinclude**: Type of deterministic regressors to include in the long-term relationship. Can also be a matrix with exogeneous regressors (2OLS only).
- **exogen**: Inclusion of exogenous variables (first row being first=oldest value). Is either of same size than data (then automatically cut) or than end-sample.

Details

This function is just a wrapper for the `lineVar`, with model="VECM".

More comprehensive functions for VECM are in package `vars`. Differences with that package are:

**Engle-Granger estimator** The Engle-Granger estimator is available

**Presentation** Results are printed in a different ways, using a matrix form

**latex export** The matrix of coefficients can be exported to latex, with or without standard-values and significance stars

**Prediction** The `predict` method contains a `newdata` argument allowing to compute rolling forecasts.

Two estimators are available: the Engle-Granger two step approach (2OLS) or the Johansen (ML). For the 2OLS, deterministic regressors (or external variables if `LRinclude` is of class numeric) can be added for the estimation of the cointegrating value and for the ECT. This is only working when the beta value is not pre-specified.

The arg beta is the cointegrating value, the cointegrating vector will be taken as: (1, -beta).

Note that the lag specification corresponds to the lags in the VECM representation, not in the VAR (as is done in package vars or software GRETL). Basically, a VAR with 2 lags corresponds here to a VECM with 1 lag. The lag can be set to 0, although some methods (irf, fevd) won’t work for this case.

#"The arg beta allows to specify constrained cointegrating values, leading to $\text{ECT} = \beta'X_{t-1}$. It should be specified as a $K \times r$ matrix. In case of $r = 1$, can also be specified as a vector. Note that the vector should be normalised, with the first value to 1, and the next values showing the opposite sign in the long-run relationship $-\beta$. In case the vector has $K - 1$ values, this is what `lineVar` is doing, setting $(1, -\beta)$. Note finally one should provide values for all the coefficients (eventually except for special case of r=1 and k-1), if you want to provide only part of the parameters, and let the others be estimated, look at the functions in package urca.

The eigenvector matrix $\beta$ is normalised using the Phillips triangular representation, see Hamilton (1994, p. 576) and Juselius (2006, p. 216), see `coefA` for more details.
Value
An object of class VECM (and higher classes VAR and nlVar) with methods:

**Usual methods:** Print, summary, residuals, fitted, vcov

**Fit criteria:** AIC, BIC, MAPE, mse, logLik (the latter only for models estimated with MLE)

**Prediction:** predict and predict_rolling

**coef extraction:** Extract cointegrating/adjustment coefficients, coefA, coefB, coefPI

**VAR/VECM methods:** Impulse response function (irf.VECM) and forecast error variance decomposition (fevd)

**LaTeX:** toLatex

Author(s)

Examples

data(zeroyld)
data<-zeroyld

#Fit a VECM with Engle-Granger 2OLS estimator:
vecm.eg<-VECM(zeroyld, lag=2)

#Fit a VECM with Johansen MLE estimator:
vecm.jo<-VECM(zeroyld, lag=2, estim="ML")

#compare results with package vars:
if(require(vars)) {
  data(finland)
  #check long coint values
  all.equal(VECM(finland, lag=2, estim="ML", r=2)$model.specific$beta,
    cajorls(ca.jo(finland, K=3, spec="transitory"), r=2) $beta, check.attributes=FALSE)
  # check OLS parameters
  all.equal(t(coefficients(VECM(finland, lag=2, estim="ML", r=2))),
    coefficients(ajorls(ca.jo(finland, K=3, spec="transitory"), r=2)$rlm), check.attributes=FALSE)
}

VECM_symbolic

Virtual VECM model

Description

Pedagogical tool to create a symbolic VECM model, i.e. just for representation purpose.

Usage

VECM_symbolic(
  alpha,
  beta,
  lags,
  inc,
  include = c("none", "const", "trend", "both")
)

Arguments

alpha Matrix of alpha speed adjustment coefficients.
beta Matrix of alpha, cointegrating coefficients.
lags Matrix containing the lags coefficients.
inc Matrix containing the include (see following arg.) coefficients.
include Character indicating the type of deterministic term included, if any.

Value

An object of class ‘VECM’, without however any data.

Examples

a<-matrix(c(-0.4, 0.1), ncol=1)
b<-matrix(c(1, -2), ncol=2)
# VECM_symb(alpha=a, beta=t(b))
d<- VECM_symbolic(alpha=a, beta=t(b))
VARrep(d)
d<- VECM_symbolic(alpha=a, beta=t(b), lags=matrix(0, ncol=2, nrow=2))
VARrep(d)
LagMat <- matrix(c(0.1, 0.3, 0.1, 0.2), ncol=2, nrow=2)
incMat <- matrix(c(0.5, 0.1), ncol=1)
d3<- VECM_symbolic(alpha=a, beta=t(b), lags=LagMat, inc=incMat, include="const")
VARrep(d3)

**zeroyl**

**zeroyl time series**

---

**Description**

**Usage**

`zeroyl`

`zeroylMeta`

**Format**

`zeroyl` contains two variables, while `zeroylMeta` contains also `Year` and `Month` columns.

`zeroyl` is a data frame with 482 observations and 2 variables:

<table>
<thead>
<tr>
<th>short.run</th>
<th>numeric</th>
<th>Short term, 12 month</th>
</tr>
</thead>
<tbody>
<tr>
<td>long.run</td>
<td>numeric</td>
<td>Long term, 120 month</td>
</tr>
</tbody>
</table>

**Source**

The data can be downloaded from: [http://www.ssc.wisc.edu/~bhansen/progs/joe_02r.zip](http://www.ssc.wisc.edu/~bhansen/progs/joe_02r.zip).

The authors themselves took the data from the webpage of Huston McCulloch: [https://www.asc.ohio-state.edu/mcculloch.2/ts/mcckwon/mccull.htm](https://www.asc.ohio-state.edu/mcculloch.2/ts/mcckwon/mccull.htm)

**See Also**

`TVECM.HStest`: Hansen and Seo test.

`TVECM` for estimating a TVECM.
Examples

data(zeroyldMeta)
plot(zeroyldMeta$Date, zeroyldMeta$short.run, type = "l", xlab = "Date", ylab = "Rate")
lines(zeroyldMeta$Date, zeroyldMeta$long.run, lty = 2)
legend("topleft", lty = c(1, 2), legend = c("Short rate: 12 months", "Long rate: 120 months"))
