Package ‘udpipe’

July 6, 2019

Type Package

Title Tokenization, Parts of Speech Tagging, Lemmatization and Dependency Parsing with the ‘UDPipe’ ‘NLP’ Toolkit

Version 0.8.3

Maintainer Jan Wijffels <jwijffels@bnosac.be>

Description This natural language processing toolkit provides language-agnostic 'tokenization', 'parts of speech tagging', 'lemmatization' and 'dependency parsing' of raw text. Next to text parsing, the package also allows you to train annotation models based on data of 'treebanks' in 'CoNLL-U' format as provided at <http://universaldependencies.org/format.html>. The techniques are explained in detail in the paper: 'Tokenizing, POS Tagging, Lemmatizing and Parsing UD 2.0 with UDpipe', available at <doi:10.18653/v1/K17-3009>.

as.data.frame.udpipe_connlu

Convert the result of udpipe_annotate to a tidy data frame

Description

Convert the result of udpipe_annotate to a tidy data frame

Usage

## S3 method for class 'udpipe_connlu'
as.data.frame(x, ...)

Arguments

x an object of class udpipe_connlu as returned by udpipe_annotate

... currently not used

Value

a data.frame with columns doc_id, paragraph_id, sentence_id, sentence, token_id, token, lemma, upos, xpos, feats, head_token_id, dep_rel, deps, misc

The columns paragraph_id, sentence_id are integers, the other fields are character data in UTF-8 encoding.

To get more information on these fields, visit http://universaldependencies.org/format.html or look at udpipe.

See Also

udpipe_annotate
Examples

```r
model <- udpipe_download_model(language = "dutch-lassysmall")

if(!model$download_failed){

    ud_dutch <- udpipe_load_model(model$file_model)
txt <- c("Ik ben de weg kwijt, kunt u me zeggen waar de Lange Wapper ligt? Jazeker meneer", "Het gaat vooruit, het gaat verbazend goed vooruit")
x <- udpipe_annotate(ud_dutch, x = txt)
x <- as.data.frame(x)
head(x)
}
```

```r
## cleanup for CRAN only - you probably want to keep your model if you have downloaded it
if(file.exists(model$file_model)) file.remove(model$file_model)
```

---

**as.matrix.cooccurrence**

_Convert the result of cooccurrence to a sparse matrix_

### Description

Convert the result of `cooccurrence` to a sparse matrix.

### Usage

```r
## S3 method for class 'cooccurrence'
as.matrix(x, ...)
```

### Arguments

- `x` an object of class `cooccurrence` as returned by `cooccurrence`
- `...` not used

### Value

a sparse matrix with in the rows and columns the terms and in the cells how many times the cooccurrence occurred

### See Also

`cooccurrence`
Examples

```R
data(brussels_reviews_anno)
# By document, which lemma's co-occur
x <- subset(brussels_reviews_anno, xpos %in% c("NN", "JJ") & language %in% "fr")
x <- cooccurrence(x, group = "doc_id", term = "lemma")
x <- as.matrix(x)
dim(x)
x[1:3, 1:3]
```

as_conllu  

Convert a data.frame to CONLL-U format

Description

If you have a data.frame with annotations containing 1 row per token, you can convert it to CONLL-U format with this function. The data frame is required to have the following columns: doc_id, sentence_id, sentence, token_id, token and optionally has the following columns: lemma, upos, xpos, feats, head_token_id, dep_rel, deps, misc. Where these fields have the following meaning

- **doc_id**: the identifier of the document
- **sentence_id**: the identifier of the sentence
- **sentence**: the text of the sentence for which this token is part of
- **token_id**: Word index, integer starting at 1 for each new sentence; may be a range for multi-word tokens; may be a decimal number for empty nodes.
- **token**: Word form or punctuation symbol.
- **lemma**: Lemma or stem of word form.
- **upos**: Universal part-of-speech tag.
- **xpos**: Language-specific part-of-speech tag; underscore if not available.
- **feats**: List of morphological features from the universal feature inventory or from a defined language-specific extension; underscore if not available.
- **head_token_id**: Head of the current word, which is either a value of token_id or zero (0).
- **dep_rel**: Universal dependency relation to the HEAD (root iff HEAD = 0) or a defined language-specific subtype of one.
- **deps**: Enhanced dependency graph in the form of a list of head-deprel pairs.
- **misc**: Any other annotation.

The tokens in the data.frame should be ordered as they appear in the sentence.

Usage

```R
as_conllu(x)
```
Arguments

x a data.frame with columns doc_id, sentence_id, sentence, token_id, token, lemma, upos, xpos, feats, head_token_id, deprel, dep_rel, misc

Value

a character string of length 1 containing the data.frame in CONLL-U format. See the example. You can easily save this to disk for processing in other applications.

References

http://universaldependencies.org/format.html

Examples

file_conllu <- system.file(package = "udpipe", "dummydata", "traindata.conllu")
x <- udpipe_read_conllu(file_conllu)
str(x)
conllu <- as_conllu(x)
cat(conllu)
## Not run:
## Write it to file, making sure it is in UTF-8
cat(as_conllu(x), file = file("annotations.conllu", encoding = "UTF-8"))
## End(Not run)

## Some fields are not mandatory, they will assumed to be NA
conllu <- as_conllu(x[, c('doc_id', 'sentence_id', 'sentence',
                          'token_id', 'token', 'upos')])
cat(conllu)

as_cooccurrence Convert a matrix to a co-occurrence data.frame

Description

Use this function to convert the cells of a matrix to a co-occurrence data.frame containing fields term1, term2 and cooc where each row of the resulting data.frame contains the value of a cell in the matrix if the cell is not empty.

Usage

as_cooccurrence(x)

Arguments

x a matrix or sparseMatrix
Value

a data.frame with columns term1, term2 and cooc where the data in cooc contain the content of the
cells in the matrix for the combination of term1 and term2

Examples

data(brussels_reviews_anno)
x <- subset(brussels_reviews_anno, language == "nl")
dtm <- document_term_frequencies(x = x, document = "doc_id", term = "token")
dtm <- document_term_matrix(dtm)

correlation <- dtm_cor(dtm)
cooc <- as_cooccurrence(correlation)
head(cooc)

as_phrasemachine

Convert Parts of Speech tags to one-letter tags which can be used to
identify phrases based on regular expressions

Description

Noun phrases are of common interest when doing natural language processing. Extracting noun
phrases from text can be done easily by defining a sequence of Parts of Speech tags. For example
this sequence of POS tags can be seen as a noun phrase: Adjective, Noun, Preposition, Noun.
This function recodes Universal POS tags to one of the following 1-letter tags, in order to simplify
writing regular expressions to find Parts of Speech sequences:

• A: adjective
• C: coordinating conjunction
• D: determiner
• M: modifier of verb
• N: noun or proper noun
• P: preposition
• O: other elements

After which identifying a simple noun phrase can be just expressed by using the following regular
expression (A|N)*N(P+D*(A|N)*N)* which basically says start with adjective or noun, another
noun, a preposition, determiner adjective or noun and next a noun again.

Usage

as_phrasemachine(x, type = c("upos", "penn-treebank"))
Arguments

- **x**: a character vector of POS tags for example by using `udpipe_annotate`.
- **type**: either 'upos' or 'penn-treebank' indicating to recode Universal Parts of Speech tags to the counterparts as described in the description, or to recode Parts of Speech tags as known in the Penn Treebank to the counterparts as described in the description.

Details

Value

The character vector `x` where the respective POS tags are replaced with one-letter tags.

See Also

- `phrases`

Examples

```r
as_phrasemachine(x)
```

as_word2vec

*Convert a matrix of word vectors to word2vec format*

Description

The word2vec format provides in the first line the dimension of the word vectors and in the following lines one has the elements of the wordvector where each line covers one word or token.

The function is basically a utility function which allows one to write wordvectors created with other R packages in the well-known word2vec format which is used by `udpipe_train` to train the dependency parser.

Usage

```r
as_word2vec(x)
```

Arguments

- **x**: a matrix with word vectors where the rownames indicate the word or token and the number of columns of the matrix indicate the side of the word vector.
Value

a character string of length 1 containing the word vectors in word2vec format which can be written to a file on disk

Examples

```r
wordvectors <- matrix(rnorm(1000), nrow = 100, ncol = 10)
rownames(wordvectors) <- sprintf("word%d", seq_len(nrow(wordvectors)))
wv <- as_word2vec(wordvectors)
cat(wv)

f <- file(tempfile(filename = "wv.txt"), encoding = "UTF-8")
cat(wv, file = f)
close(f)
```

**brussels_listings**

*Brussels AirBnB address locations available at www.insideairbnb.com*

Description

Data has been converted from UTF-8 to ASCII as in `iconv(x, from = "UTF-8", to = "ASCII/TRANSLIT")` in order to be able to comply to CRAN policies.

Source

http://data.insideairbnb.com/belgium/bru/brussels/2015-10-03/visualisations/listings.csv

See Also

`brussels_reviews, brussels_reviews_anno`

Examples

data(brussels_listings)
head(brussels_listings)
brussels_reviews

Reviews of AirBnB customers on Brussels address locations available at www.insideairbnb.com

More information: http://insideairbnb.com/get-the-data.html. The data contains 500 reviews in Spanish, 500 reviews in French and 500 reviews in Dutch. The data frame contains the field id (unique), listing_id which corresponds to the listing_id of the brussels_listings dataset and text fields feedback and language (identified with package clld2) Data has been converted from UTF-8 to ASCII as in iconv(x, from = "UTF-8", to = "ASCII//TRANSLIT") in order to be able to comply to CRAN policies.

Examples

```r
## brussels_reviews_anno
data(brussels_reviews_anno)
head(brussels_reviews_anno)
sort(table(brussels_reviews_anno$xpos))

## Not run:

## If you want to construct a similar dataset as the
## brussels_reviews_anno dataset based on the udpipe library, do as follows
##
library(udpipe)
library(data.table)
data(brussels_reviews)

## The brussels_reviews contains comments on Airbnb sites in 3 languages: es, fr and nl
table(brussels_reviews$language)
bxl_anno <- split(brussels_reviews, brussels_reviews$language)

## Annotate the Spanish comments
m <- udpipe_download_model(language = "spanish-ancora")
m <- udpipe_load_model(file = m$file_model)
bxl_anno$es <- udpipe_annotate(object = m, x = bxl_anno$es$feedback, doc_id = bxl_anno$es$id)

## Annotate the French comments
m <- udpipe_download_model(language = "french-partut")
m <- udpipe_load_model(file = m$file_model)
bxl_anno$fr <- udpipe_annotate(object = m, x = bxl_anno$fr$feedback, doc_id = bxl_anno$fr$id)

## Annotate the Dutch comments
m <- udpipe_download_model(language = "dutch-lassysmall")
m <- udpipe_load_model(file = m$file_model)
bxl_anno$nl <- udpipe_annotate(object = m, x = bxl_anno$nl$feedback, doc_id = bxl_anno$nl$id)

brussels_reviews_anno <- lapply(bxl_anno, as.data.frame)
brussels_reviews_anno <- rbindlist(brussels_reviews_anno)
str(brussels_reviews_anno)

## End(Not run)
```
Description

Annotated results of udpipe_annotate contain dependency parsing results which indicate how each word is linked to another word and the relation between these 2 words. This information is available in the fields token_id, head_token_id and dep_rel which indicates how each token is linked to the parent. The type of relation (dep_rel) is defined at http://universaldependencies.org/u/dep/index.html. For example in the text 'The economy is weak but the outlook is bright', the term economy is linked to weak as the term economy is the nominal subject of weak. This function adds the parent information to the annotated data.frame.

Usage

cbind_dependencies(x, type = c("parent", "child"))

Arguments

x a data.frame or data.table as returned by as.data.frame(udpipe_annotate(...))
type currently only possible value is 'parent', indicating to add the information of the head_token_id to the dataset

Details

Mark that the output which this function provides might possibly change in subsequent releases and is experimental.

Value

a data.frame/data.table in the same order of x where the token/lemma/upos/xpos information of the parent (head dependency) is added to the data.frame. See the examples.

Examples

```r
## Not run:
udmodel <- udpipe_download_model(language = "english-ewt")
udmodel <- udpipe_load_model(file = udmodel$file_model)
x <- udpipe_annotate(udmodel,
x = "The economy is weak but the outlook is bright")
x <- as.data.frame(x)
x[, c("token_id", "token", "head_token_id", "dep_rel")]
x <- cbind_dependencies(x, type = "parent")
nominals_subject <- subset(x, dep_rel %in% c("nsubj"))
nominals_subject <- nominals_subject[, c("dep_rel", "token", "token_parent")]
nominals_subject
```

## End(Not run)
cbind_morphological

Add morphological features to an annotated dataset

Description

The result of `udpipe_annotate` which is put into a data.frame returns a field called `feats` containing morphological features as defined at http://universaldependencies.org/u/feat/index.html. If there are several of these features, these are concatenated with the `|` symbol. This function extracts each of these morphological features separately and adds these as extra columns to the data.frame.

Usage

```r
cbind_morphological(x, term = "feats")
```

Arguments

- `x` a data.frame or data.table as returned by `as.data.frame(udpipe_annotate(...))`
- `term` the name of the field in `x` which contains the morphological features. Defaults to `"feats"`.

Value

`x` in the same order with extra columns added (at least the column has_morph is added indicating if any morphological features are present and as well extra columns for each possible morphological feature in the data).

Examples

```r
## Not run:
udmodel <- udpipe_download_model(language = "english-ewt")
udmodel <- udpipe_load_model(file = udmodel$file_model)
x <- udpipe_annotate(udmodel,
  x = "The economy is weak but the outlook is bright")
x <- as.data.frame(x)
x <- cbind_morphological(x, term = "feats")

## End(Not run)

f <- system.file(package = "udpipe", "dummydata", "traindata.conllu")
x <- udpipe_read_conllu(f)
x <- cbind_morphological(x, term = "feats")
```
Create a cooccurrence data.frame

Description

A cooccurrence data.frame indicates how many times each term co-occurs with another term.

There are 3 types of cooccurrences:

- Looking at which words are located in the same document/sentence/paragraph.
- Looking at which words are followed by another word
- Looking at which words are in the neighbourhood of the word as in follows the word within skipgram number of words

The output of the function gives a cooccurrence data.frame which contains the fields term1, term2 and cooc where cooc indicates how many times term1 and term2 co-occurred. This dataset can be constructed

- based upon a data frame where you look within a group (column of the data.frame) if 2 terms occurred in that group.
- based upon a vector of words in which case we look how many times each word is followed by another word.
- based upon a vector of words in which case we look how many times each word is followed by another word or is followed by another word if we skip a number of words in between.

You can also aggregate cooccurrences if you decide to do any of these 3 by a certain group and next want to have an overall aggregate.

Usage

```r
cooccurrence(x, order = TRUE, ...)
```

## S3 method for class 'character'
```r
cooprocessing(x, order = TRUE, ..., relevant = rep(TRUE, length(x)), skipgram = 0)
```

## S3 method for class 'cooccurrence'
```r
cooprocessing(x, order = TRUE, ...)
```

## S3 method for class 'data.frame'
```r
cooprocessing(x, order = TRUE, ..., group, term)
```

Arguments

- `x` either
• a data.frame where the data.frame contains 1 row per document/term, in which case you need to provide group and term where term is the column containing 1 term per row and group indicates something like a document id or document + sentence id. This uses cooccurrence.data.frame.
• a character vector with terms where one element contains 1 term. This uses cooccurrence.character.
• an object of class cooccurrence. This uses cooccurrence.cooccurrence.

order
logical indicating if we need to sort the output from high cooccurrences to low cooccurrences. Defaults to TRUE.

relevant
a logical vector of the same length as x, indicating if the word in x is relevant or not. This can be used to exclude stopwords from the cooccurrence calculation or selecting only nouns and adjectives to find cooccurrences along with each other (for example based on the Parts of Speech upos output from udpipe_annotate). Only used if calculating cooccurrences on x which is a character vector of words.

skipgram
integer of length 1, indicating how far in the neighbourhood to look for words. skipgram is considered the maximum skip distance between words to calculate co-occurrences (where co-occurrences are of type skipgram-bigram, where a skipgram-bigram are 2 words which occur at a distance of at most skipgram + 1 from each other). Only used if calculating cooccurrences on x which is a character vector of words.

group
character vector of columns in the data frame x indicating to calculate cooccurrences within these columns. This is typically a field like document id or a sentence identifier. To be used if x is a data.frame.

term
character string of a column in the data frame x, containing 1 term per row. To be used if x is a data.frame.

Value
a data.frame with columns term1, term2 and cooc indicating for the combination of term1 and term2 how many times this combination occurred.

Methods (by class)
• character: Create a cooccurrence data.frame based on a vector of terms
• cooccurrence: Aggregate co-occurrence statistics by summing the cooc by term/term2
• data.frame: Create a cooccurrence data.frame based on a data.frame where you look within a document / sentence / paragraph / group if terms co-occur

Examples
data(brussels_reviews_anno)

```r
## By document, which lemma's co-occur
x <- subset(brussels_reviews_anno, xpos %in% c("NN", "JJ") & language %in% "fr")
x <- cooccurrence(x, group = "doc_id", term = "lemma")
```
head(x)

## Which words follow each other
x <- c("A", "B", "A", "B", "C")
c0occurrence(x)

data(brussels_reviews_anno)
x <- subset(brussels_reviews_anno, language == "es")
x <- c0occurrence(x$lemma)
head(x)
x <- subset(brussels_reviews_anno, language == "es")
x <- c0occurrence(x$lemma, relevant = x$xpos %in% c("NN", "JJ"), skipgram = 4)
head(x)

## Which nouns follow each other in the same document
library(data.table)
x <- as.data.table(brussels_reviews_anno)
x <- subset(x, language == "nl" & xpos %in% c("NN"))
x <- x[, c0occurrence(lemma, order = FALSE), by = list(doc_id)]
head(x)

x_nodoc <- c0occurrence(x)
x_nodoc <- subset(x_nodoc, term1 != "appartement" & term2 != "appartement")
head(x_nodoc)

document_term_frequencies

**Aggregate a data.frame to the document/term level by calculating how many times a term occurs per document**

## Description

Aggregate a data.frame to the document/term level by calculating how many times a term occurs per document

## Usage

document_term_frequencies(x, document, ...)

## S3 method for class 'data.frame'
document_term_frequencies(x, document = colnames(x)[1],
                         term = colnames(x)[2], ...)

## S3 method for class 'character'
document_term_frequencies(x, document = paste("doc",
                         seq_along(x), sep = ""), split = "[[:space:][[:punct:][[:digit:]]+", ...)

```r
# Which words follow each other
x <- c("A", "B", "A", "B", "C")
c0occurrence(x)

data(brussels_reviews_anno)
x <- subset(brussels_reviews_anno, language == "es")
x <- c0occurrence(x$lemma)
head(x)
x <- subset(brussels_reviews_anno, language == "es")
x <- c0occurrence(x$lemma, relevant = x$xpos %in% c("NN", "JJ"), skipgram = 4)
head(x)

## Which nouns follow each other in the same document
library(data.table)
x <- as.data.table(brussels_reviews_anno)
x <- subset(x, language == "nl" & xpos %in% c("NN"))
x <- x[, c0occurrence(lemma, order = FALSE), by = list(doc_id)]
head(x)

x_nodoc <- c0occurrence(x)
x_nodoc <- subset(x_nodoc, term1 != "appartement" & term2 != "appartement")
head(x_nodoc)

document_term_frequencies

**Aggregate a data.frame to the document/term level by calculating how many times a term occurs per document**

## Description

Aggregate a data.frame to the document/term level by calculating how many times a term occurs per document

## Usage

document_term_frequencies(x, document, ...)

## S3 method for class 'data.frame'
document_term_frequencies(x, document = colnames(x)[1],
                         term = colnames(x)[2], ...)

## S3 method for class 'character'
document_term_frequencies(x, document = paste("doc",
                         seq_along(x), sep = ""), split = "[[:space:][[:punct:][[:digit:]]+", ...)
```
Arguments

x  a data.frame or data.table containing a field which can be considered as a document (defaults to the first column in x) and a field which can be considered as a term (defaults to the second column in x). If the dataset also contains a column called 'freq', this will be summed over instead of counting the number of rows occur by document/term combination.
If x is a character vector containing several terms, the text will be split by the argument split before doing the aggregation at the document/term level.
document  If x is a data.frame, the column in x which identifies a document. If x is a character vector then document is a vector of the same length as x where document[i] is the document id which corresponds to the text in x[i].
term  If x is a data.frame, the column in x which identifies a term. Defaults to the second column in x.
split  The regular expression to be used if x is a character vector. This will split the character vector x in pieces by the provides split argument. Defaults to splitting according to spaces/punctuations/digits.

Value

a data.table with columns doc_id, term, freq indicating how many times a term occurred in each document. If freq occurred in the input dataset the resulting data will have summed the freq. If freq is not in the dataset, will assume that freq is 1 for each row in the input dataset x.

Methods (by class)

• data.frame: Create a data.frame with one row per document/term combination indicating the frequency of the term in the document
• character: Create a data.frame with one row per document/term combination indicating the frequency of the term in the document

Examples

```r
## Calculate document_term_frequencies on a data.frame
##
data(brussels_reviews_anno)
x <- document_term_frequencies(brussels_reviews_anno[, , c("doc_id", "token")])
x <- document_term_frequencies(brussels_reviews_anno[, , c("doc_id", "lemma")])
str(x)

brussels_reviews_anno$my_doc_id <- paste(brussels_reviews_anno$doc_id,
                                          brussels_reviews_anno$sentence_id)
x <- document_term_frequencies(brussels_reviews_anno[, , c("my_doc_id", "lemma")])

## Calculate document_term_frequencies on a character vector
##
```
data(brussels_reviews)
x <- document_term_frequencies(x = brussels_reviews$feedback, document = brussels_reviews$id,
split = " ")
x <- document_term_frequencies(x = brussels_reviews$feedback, document = brussels_reviews$id,
split = "[:space:][:punct:][:digit:]+")

##
## document-term-frequencies on several fields to easily include bigram and trigrams
##
library(data.table)
x <- as.data.table(brussels_reviews_anno)
x <- x[, token_bigram := txt_nextgram(token, n = 2), by = list(doc_id, sentence_id)]
x <- x[, token_trigram := txt_nextgram(token, n = 3), by = list(doc_id, sentence_id)]
x <- document_term_frequencies(x = x,
document = "doc_id",
term = c("token", "token_bigram", "token_trigram"))
head(x)

document_term_frequencies_statistics

Add Term Frequency, Inverse Document Frequency and Okapi BM25
statistics to the output of document_term_frequencies

Description

Term frequency Inverse Document Frequency (tfidf) is calculated as the multiplication of

- Term Frequency (tf): how many times the word occurs in the document / how many words are
  in the document
- Inverse Document Frequency (idf): log(number of documents / number of documents where
  the term appears)

The Okapi BM25 statistic is calculated as the multiplication of the inverse document frequency and
the weighted term frequency as defined at https://en.wikipedia.org/wiki/Okapi_BM25.

Usage
document_term_frequencies_statistics(x, k = 1.2, b = 0.75)

Arguments

x a data.table as returned by document_term_frequencies containing the columns
doc_id, term and freq.

k parameter k1 of the Okapi BM25 ranking function as defined at https://en.

b parameter b of the Okapi BM25 ranking function as defined at https://en.
wikipedia.org/wiki/Okapi_BM25. Defaults to 0.5.
Value

a data.table with columns doc_id, term, freq and added to that the computed statistics tf, idf, tfidf, tf_bm25 and bm25.

Examples

data(brussels_reviews_anno)
x <- document_term_frequencies(brussels_reviews_anno[, c("doc_id", "token")])
x <- document_term_frequencies_statistics(x)
head(x)

document_term_matrix
Create a document/term matrix from a data.frame with 1 row per document/term

Description

Create a document/term matrix from a data.frame with 1 row per document/term as returned by document_term_frequencies

Usage

document_term_matrix(x, vocabulary, weight = "freq", ...)

## S3 method for class 'data.frame'
document_term_matrix(x, vocabulary, weight = "freq", ...)

## S3 method for class 'DocumentTermMatrix'
document_term_matrix(x, ...)

## S3 method for class 'TermDocumentMatrix'
document_term_matrix(x, ...)

## S3 method for class 'simple_triplet_matrix'
document_term_matrix(x, ...)

Arguments

x a data.frame with columns doc_id, term and freq indicating how many times a term occurred in that specific document. This is what document_term_frequencies returns. This data.frame will be reshaped to a matrix with 1 row per doc_id, the terms will be put in the columns and the freq in the matrix cells. Note that the column name to use for freq can be set in the weight argument.

vocabulary a character vector of terms which should be present in the document term matrix even if they did not occur in x
weight

... further arguments currently not used

Value

an sparse object of class dgCMatrix with in the rows the documents and in the columns the terms containing the frequencies provided in x extended with terms which were not in x but were provided in vocabulary. The rownames of this resulting object contain the doc_id from x

Methods (by class)

- data.frame: Construct a document term matrix from a data.frame with columns doc_id, term, freq
- DocumentTermMatrix: Convert an object of class DocumentTermMatrix from the tm package to a sparseMatrix
- TermDocumentMatrix: Convert an object of class TermDocumentMatrix from the tm package to a sparseMatrix with the documents in the rows and the terms in the columns
- simple_triplet_matrix: Convert an object of class simple_triplet_matrix from the slam package to a sparseMatrix

See Also

sparseMatrix, document_term_frequencies

Examples

```r
x <- data.frame(doc_id = c(1, 1, 2, 3, 4),
                term = c("A", "C", "Z", "X", "G"),
                freq = c(1, 5, 7, 10, 0))
document_term_matrix(x)
document_term_matrix(x, vocabulary = LETTERS)

## Example on larger dataset
data(brussels_reviews_anno)
x <- document_term_frequencies(brussels_reviews_anno[, c("doc_id", "lemma")])
dtm <- document_term_matrix(x)
dim(dtm)
x <- document_term_frequencies(brussels_reviews_anno[, c("doc_id", "lemma")])
x <- document_term_frequencies_statistics(x)
dtm <- document_term_matrix(x)
dtm <- document_term_matrix(x, weight = "freq")
dtm <- document_term_matrix(x, weight = "tf_idf")
dtm <- document_term_matrix(x, weight = "bm25")

## example showing the vocabulary argument
## allowing you to making sure terms which are not in the data are provided in the resulting dtm
allterms <- unique(x$term)
dtm <- document_term_matrix(head(x, 1000), vocabulary = allterms)
```
## Example adding bigrams/trigrams to the document term matrix
## Mark that this can also be done using ?dtm_cbind

```r
library(data.table)
x <- as.data.table(brussels_reviews_anno)
x <- x[, token_bigram := txt_nextgram(token, n = 2), by = list(doc_id, sentence_id)]
x <- x[, token_trigram := txt_nextgram(token, n = 3), by = list(doc_id, sentence_id)]
x <- document_term_frequencies(x = x,
   document = "doc_id",
   term = c("token", "token_bigram", "token_trigram"))
dtm <- document_term_matrix(x)
```

---

**dtmBind**

**Combine 2 document term matrices either by rows or by columns**

### Description

These 2 methods provide `cbind` and `rbind` functionality for sparse matrix objects which are returned by `document_term_matrix`.

In case of `dtm_cbind`, if the rows are not ordered in the same way in `x` and `y`, it will order them based on the rownames. If there are missing rows these will be filled with NA values. In case of `dtm_rbind`, if the columns are not ordered in the same way in `x` and `y`, it will order them based on the colnames. If there are missing columns these will be filled with NA values.

### Usage

```r
dtm_cbind(x, y)
dtm_rbind(x, y)
```

### Arguments

- `x` a sparse matrix such as a "dgTMatrix" object which is returned by `document_term_matrix`
- `y` a sparse matrix such as a "dgTMatrix" object which is returned by `document_term_matrix`

### Value

A sparse matrix where either rows are put below each other in case of `dtm_rbind` or columns are put next to each other in case of `dtm_cbind`

### See Also

`document_term_matrix`
**Examples**

```r
data(brussels_reviews_anno)
x <- brussels_reviews_anno

## rbind
dtm1 <- document_term_frequencies(x = subset(x, doc_id %in% c("10049756", "10284782")),
document = "doc_id", term = "token")
dtm1 <- document_term_matrix(dtm1)
dtm2 <- document_term_frequencies(x = subset(x, doc_id %in% c("10789408", "12285061", "35509091")),
document = "doc_id", term = "token")
dtm2 <- document_term_matrix(dtm2)
m <- dtm_rbind(dtm1, dtm2)
dim(m)

## cbind
library(data.table)
x <- as.data.table(brussels_reviews_anno)
x <- x[, token_bigram := txt_nextgram(token, n = 2), by = list(doc_id, sentence_id)]
dtm1 <- document_term_frequencies(x = x, document = "doc_id", term = c("token"))
dtm1 <- document_term_matrix(dtm1)
dtm2 <- document_term_frequencies(x = x, document = "doc_id", term = c("token_bigram"))
dtm2 <- document_term_matrix(dtm2)
m <- dtm_cbind(dtm1, dtm2)
dim(m)
m <- dtm_cbind(dtm1[-c(100, 999), ], dtm2[-1000,])
dim(m)
```

---

**dtm_colsums**

*Column sums and Row sums for document term matrices*

**Description**

Column sums and Row sums for document term matrices

**Usage**

```r
dtm_colsums(dtm)
dtm_rowsums(dtm)
```

**Arguments**

- **dtm** an object returned by `document_term_matrix`

**Value**

a vector of row/column sums with corresponding names
**dtm_cor**

**Examples**

```r
x <- data.frame(
  doc_id = c(1, 1, 2, 3, 4),
  term = c("A", "C", "Z", "X", "G"),
  freq = c(1, 5, 7, 10, 0))
dtm <- document_term_matrix(x)
x <- dtm_colsums(dtm)
x <- dtm_rowsums(dtm)
head(x)
```

---

**dtm_cor**

*Pearson Correlation for Sparse Matrices*

**Description**

Pearson Correlation for Sparse Matrices. More memory and time-efficient than `cor(as.matrix(x))`.

**Usage**

`dtm_cor(x)`

**Arguments**

- `x` A matrix, potentially a sparse matrix such as a "dgTMatrix" object which is returned by `document_term_matrix`.

**Value**

A correlation matrix.

**See Also**

`document_term_matrix`

**Examples**

```r
x <- data.frame(
  doc_id = c(1, 1, 2, 3, 4),
  term = c("A", "C", "Z", "X", "G"),
  freq = c(1, 5, 7, 10, 0))
dtm <- document_term_matrix(x)
dtm_cor(dtm)
```
**dtm_remove_lowfreq**

Remove terms occurring with low frequency from a Document-Term-Matrix and documents with no terms

### Description

Remove terms occurring with low frequency from a Document-Term-Matrix and documents with no terms

### Usage

```r
dtm_remove_lowfreq(dtm, minfreq = 5, maxterms, remove_emptydocs = TRUE)
```

### Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dtm</td>
<td>an object returned by <code>document_term_matrix</code></td>
</tr>
<tr>
<td>minfreq</td>
<td>integer with the minimum number of times the term should occur in order to keep the term</td>
</tr>
<tr>
<td>maxterms</td>
<td>integer indicating the maximum number of terms which should be kept in the dtm. The argument is optional.</td>
</tr>
<tr>
<td>remove_emptydocs</td>
<td>logical indicating to remove documents containing no more terms after the term removal is executed. Defaults to TRUE.</td>
</tr>
</tbody>
</table>

### Value

a sparse Matrix as returned by `sparseMatrix` where terms with low occurrence are removed and documents without any terms are also removed

### Examples

```r
data(brussels_reviews_anno)
x <- subset(brussels_reviews_anno, xpos == "NN")
x <- x[, c("doc_id", "lemma")]
x <- document_term_frequencies(x)
dtm <- document_term_matrix(x)

## Remove terms with low frequencies and documents with no terms
x <- dtm_remove_lowfreq(dtm, minfreq = 10)
dim(x)
x <- dtm_remove_lowfreq(dtm, minfreq = 10, maxterms = 25)
dim(x)
x <- dtm_remove_lowfreq(dtm, minfreq = 10, maxterms = 25, remove_emptydocs = FALSE)
dim(x)
```
dtm_remove_sparseterms

Remove terms with high sparsity from a Document-Term-Matrix

Description
Remove terms with high sparsity from a Document-Term-Matrix and remove documents with no terms.
Sparsity indicates in how many documents the term is not occurring.

Usage

dtm_remove_sparseterms(dtm, sparsity = 0.99, remove_emptydocs = TRUE)

Arguments

dtm an object returned by document_term_matrix

sparsity numeric in 0-1 range indicating the sparsity percent. Defaults to 0.99 meaning drop terms which occur in less than 1 percent of the documents.

remove_emptydocs logical indicating to remove documents containing no more terms after the term removal is executed. Defaults to TRUE.

Value

a sparse Matrix as returned by sparseMatrix where terms with high sparsity are removed and documents without any terms are also removed

Examples

data(brussels_reviews_anno)
x <- subset(brussels_reviews_anno, xpos == "NN")
x <- x[, c("doc_id", "lemma")]
x <- document_term_frequencies(x)
dtm <- document_term_matrix(x)

## Remove terms with low frequencies and documents with no terms
x <- dtm_remove_sparseterms(dtm, sparsity = 0.99)
dim(x)
x <- dtm_remove_sparseterms(dtm, sparsity = 0.99, remove_emptydocs = FALSE)
dim(x)
**dtm_remove_terms**

Remove terms from a Document-Term-Matrix and keep only documents which have at least some terms.

**Description**

Remove terms from a Document-Term-Matrix and keep only documents which have at least some terms.

**Usage**

```r
dtm_remove_terms(dtm, terms, remove_emptydocs = TRUE)
```

**Arguments**

- `dtm`: an object returned by `document_term_matrix`
- `terms`: a character vector of terms which are in `colnames(dtm)` and which should be removed
- `remove_emptydocs`: logical indicating to remove documents containing no more terms after the term removal is executed. Defaults to `TRUE`.

**Value**

A sparse Matrix as returned by `sparseMatrix` where the indicated terms are removed as well as documents with no terms whatsoever.

**Examples**

```r
data(brussels_reviews_anno)
x <- subset(brussels_reviews_anno, xpos == "NN")
x <- x[, c("doc_id", "lemma")]
x <- document_term_frequencies(x)
dtm <- document_term_matrix(x)
dim(dtm)
x <- dtm_remove_terms(dtm, terms = c("appartement", "casa", "centrum", "ciudad"))
dim(x)
x <- dtm_remove_terms(dtm, terms = c("appartement", "casa", "centrum", "ciudad"), remove_emptydocs = FALSE)
dim(x)
```
**dtm_remove_tfidf**

Remove terms from a Document-Term-Matrix and documents with no terms based on the term frequency inverse document frequency. Either giving in the maximum number of terms (argument `top`), the tfidf cutoff (argument `cutoff`) or a quantile (argument `prob`).

### Usage

```r
dtm_remove_tfidf(dtm, top, cutoff, prob, remove_emptydocs = TRUE)
```

### Arguments

- **dtm**: an object returned by `document_term_matrix`
- **top**: integer with the number of terms which should be kept as defined by the highest mean tfidf
- **cutoff**: numeric cutoff value to keep only terms in `dtm` where the tfidf obtained by `dtm_tfidf` is higher than this value
- **prob**: numeric quantile indicating to keep only terms in `dtm` where the tfidf obtained by `dtm_tfidf` is higher than the `prob` percent quantile
- **remove_emptydocs**: logical indicating to remove documents containing no more terms after the term removal is executed. Defaults to `TRUE`.

### Value

a sparse Matrix as returned by `sparseMatrix` where terms with high tfidf are kept and documents without any remaining terms are removed.

### Examples

```r
data(brussels_reviews_anno)
x <- subset(brussels_reviews_anno, xpos == "NN")
x <- x[, c("doc_id", "lemma")]
x <- document_term_frequencies(x)
dtm <- document_term_matrix(x)
dtm <- dtm_remove_tfidf(dtm, top=10)
dim(dtm)

## Keep only terms with high tfidf
x <- dtm_remove_tfidf(dtm, top=50)
dim(x)
x <- dtm_remove_tfidf(dtm, top=50, remove_emptydocs = FALSE)
dim(x)
```
## dtm_reverse

### Description

Inverse operation of the `document_term_matrix` function. Creates frequency table which contains 1 row per document/term.

### Usage

```r
dtm_reverse(x)
```

### Arguments

- `x` an object as returned by `document_term_matrix`

### Value

A data.frame with columns `doc_id`, `term` and `freq` where `freq` is just the value in each cell of the `x`

### See Also

`document_term_matrix`

### Examples

```r
x <- data.frame(
  doc_id = c(1, 1, 2, 3, 4),
  term = c("A", "C", "Z", "X", "G"),
  freq = c(1, 5, 7, 10, 0))
dtm <- document_term_matrix(x)
dtm_reverse(dtm)
```
**dtm_tfidf**

**Term Frequency - Inverse Document Frequency calculation**

**Description**

Term Frequency - Inverse Document Frequency calculation. Averaged by each term.

**Usage**

```r
dtm_tfidf(dtm)
```

**Arguments**

- `dtm` an object returned by `document_term_matrix`

**Value**

a vector with tfidf values, one for each term in the `dtm` matrix

**Examples**

```r
data(brussels_reviews_anno)
x <- subset(brussels_reviews_anno, xpos == "NN")
x <- x[, c("doc_id", "lemma")]
x <- document_term_frequencies(x)
dtm <- document_term_matrix(x)

## Calculate tfidf
tfidf <- dtm_tfidf(dtm)
hist(tfidf, breaks = "scott")
head(sort(tfidf, decreasing = TRUE))
head(sort(tfidf, decreasing = FALSE))
```

---

**keywords_collocation**

**Extract collocations - a sequence of terms which follow each other**

**Description**

Collocations are a sequence of words or terms that co-occur more often than would be expected by chance. Common collocation are adjectives + nouns, nouns followed by nouns, verbs and nouns, adverbs and adjectives, verbs and prepositional phrases or verbs and adverbs.

This function extracts relevant collocations and computes the following statistics on them which are indicators of how likely two terms are collocated compared to being independent.

- **PMI (pointwise mutual information):** \( \log_2\left(\frac{P(w_1w_2)}{P(w_1) P(w_2)}\right) \)
- **MD (mutual dependency):** \( \log_2\left(\frac{P(w_1w_2)^2}{P(w_1) P(w_2)}\right) \)
• LFMD (log-frequency biased mutual dependency): MD + log2(P(w1w2))

As natural language is non random - otherwise you wouldn’t understand what I’m saying, most of the combinations of terms are significant. That’s why these indicators of collocation are merely used to order the collocations.

Usage

```r
keywords_collocation(x, term, group, ngram_max = 2, n_min = 2, sep = " ")
collocation(x, term, group, ngram_max = 2, n_min = 2, sep = " ")
```

Arguments

- `x`: a data.frame with one row per term where the sequence of the terms correspond to the natural order of a text. The data frame `x` should also contain the columns provided in `term` and `group`.
- `term`: a character vector with 1 column from `x` which indicates the term.
- `group`: a character vector with 1 or several columns from `x` which indicates for example a document id or a sentence id. Collocations will be computed within this group in order not to find collocations across sentences or documents for example.
- `ngram_max`: integer indicating the size of the collocations. Defaults to 2, indicating to compute bigrams. If set to 3, will find collocations of bigrams and trigrams.
- `n_min`: integer indicating the frequency of how many times a collocation should at least occur in the data in order to be returned. Defaults to 2.
- `sep`: character string with the separator which will be used to paste together terms which are collocated. Defaults to a space: ` ' `. 

Value

A data.frame with columns

- `keyword`: the terms which are combined as a collocation
- `ngram`: the number of terms which are combined
- `left`: the left term of the collocation
- `right`: the right term of the collocation
- `freq`: the number of times the collocation occurred in the data
- `freq_left`: the number of times the left element of the collocation occurred in the data
- `freq_right`: the number of times the right element of the collocation occurred in the data
- `pmi`: the pointwise mutual information
- `md`: mutual dependency
- `lfmd`: log-frequency biased mutual dependency
**Examples**

```r
data(brussels_reviews_anno)
x <- subset(brussels_reviews_anno, language %in% "fr")
colloc <- keywords_collocation(x, term = "lemma", group = c("doc_id", "sentence_id"),
ngram_max = 3, n_min = 10)
head(colloc, 10)
```

```r
## Example on finding collocations of nouns preceded by an adjective
library(data.table)
x <- as.data.table(x)
x[, xpos_previous := txt_previous(xpos, n = 1), by = list(doc_id, sentence_id)]
x[, xpos_next := txt_next(xpos, n = 1), by = list(doc_id, sentence_id)]
x <- subset(x, (xpos %in% c("NN") & xpos_previous %in% c("JJ")) |
(xpos %in% c("JJ") & xpos_next %in% c("NN")))
colloc <- keywords_collocation(x, term = "lemma", group = c("doc_id", "sentence_id"),
ngram_max = 2, n_min = 2)
head(colloc)
```

**Keywords**

- **Extract phrases**

  - **Extract phrases - a sequence of terms which follow each other based on a sequence of Parts of Speech tags**

**Description**

This function allows to extract phrases, like simple noun phrases, complex noun phrases or any exact sequence of parts of speech tag patterns.

An example use case of this is to get all text where an adjective is followed by a noun or for example to get all phrases consisting of a preposition which is followed by a noun which is next followed by a verb. More complex patterns are shown in the details below.

**Usage**

```r
keywords_phrases(x, term = x, pattern, is_regex = FALSE, sep = " ",
ngram_max = 8, detailed = TRUE)
```

```r
phrases(x, term = x, pattern, is_regex = FALSE, sep = " ",
ngram_max = 8, detailed = TRUE)
```

**Arguments**

- **x**
  - a character vector of Parts of Speech tags where we want to locate a relevant sequence of POS tags as defined in pattern

- **term**
  - a character vector of the same length as x with the words or terms corresponding to the tags in x

- **pattern**
  - In case is_regex is set to FALSE, pattern should be a character vector with a sequence of POS tags to identify in x. The length of the character vector should be bigger than 1.
In case `is_regex` is set to TRUE, this should be a regular expressions which will be used on a concatenated version of `x` to identify the locations where these regular expression occur. See the examples below.

`is_regex` logical indicating if `pattern` can be considered as a regular expression or if it is just a character vector of POS tags. Defaults to FALSE, indicating `pattern` is not a regular expression.

`sep` character indicating how to collapse the phrase of terms which are found. Defaults to using a space.

`ngram_max` an integer indicating to allow phrases to be found up to `ngram` maximum number of terms following each other. Only used if `is_regex` is set to TRUE. Defaults to 8.

`detailed` logical indicating to return the exact positions where the phrase was found (set to TRUE) or just how many times each phrase is occurring (set to FALSE). Defaults to TRUE.

Details

Common phrases which you might be interested in and which can be supplied to `pattern` are

- Simple noun phrase: "(A(N)*N(P+(A(N)*N))*"
- Noun phrase with coordination conjunction: "((A(CA)*|N)*N((P(CP)*)+(D(CD)*)*(A(CA)*|N)*N)((P(CP)*)+(D(CD)*)*(A(CA)*|N)*N)+(M|V)*(C(M|V)*V(M|V)*)*)*)
- Verb phrase with coordination conjunction: "((A(CA)*|N)*N((P(CP)*)+(D(CD)*)*(A(CA)*|N)*N)((P(CP)*)+(D(CD)*)*(A(CA)*|N)*N)+(M|V)*(C(M|V)*V(M|V)*)*)*)

See the examples.

Mark that this functionality is also implemented in the phrasemachine package where it is implemented using plain R code, while the implementation in this package uses a more quick Rcpp implementation for extracting these kind of regular expression like phrases.

Value

If argument `detailed` is set to TRUE a data.frame with columns

- keyword: the phrase which corresponds to the collapsed terms of where the pattern was found
- ngram: the length of the phrase
- pattern: the pattern which was found
- start: the starting index of `x` where the pattern was found
- end: the ending index of `x` where the pattern was found

If argument `detailed` is set to FALSE will return aggregate frequency statistics in a data.frame containing the columns keyword, ngram and freq (how many time it is occurring)

head(np)

## Find noun phrases with the following regular expression: \(A|N\)+N(P+D+(A|N)+N)*
x$phrase_tag <- as_phrasemachine(x$xpos, type = "penn-treebank")
nounphrases <- keywords_phrases(x$phrase_tag, term = x$token,
                               pattern = "(A|N)+N(P+D+(A|N)+N)\|", is_regex = TRUE,
                               ngram_max = 4,
                               detailed = TRUE)
head(nounphrases, 10)
head(sort(table(nounphrases$keyword), decreasing=TRUE), 20)

## Find frequent sequences of POS tags
library(data.table)
x <- as.data.table(x)
x[, pos_sequence := txt_nextgram(x = xpos, n = 3), by = list(doc_id, sentence_id)]
tail(sort(table(x$pos_sequence)))
np <- keywords_phrases(x$xpos, term = x$token, pattern = c("IN", "DT", "NN"))
head(np)

keywords_rake  

---

Description

RAKE is a basic algorithm which tries to identify keywords in text. Keywords are defined as a sequence of words following one another.

The algorithm goes as follows.

- candidate keywords are extracted by looking to a contiguous sequence of words which do not contain irrelevant words
- a score is being calculated for each word which is part of any candidate keyword, this is done by
  - among the words of the candidate keywords, the algorithm looks how many times each word is occurring and how many times it co-occurs with other words
  - each word gets a score which is the ratio of the word degree (how many times it co-occurs with other words) to the word frequency
- a RAKE score for the full candidate keyword is calculated by summing up the scores of each of the words which define the candidate keyword

The resulting keywords are returned as a data.frame together with their RAKE score.
Usage

```r
keywords_rake(x, term, group, relevant = rep(TRUE, nrow(x)), ngram_max = 2, n_min = 2, sep = " ")
```

Arguments

- `x`: a data.frame with one row per term as returned by `as.data.frame(udpipe_annotate(...))`
- `term`: character string with a column in the data frame `x`, containing 1 term per row. To be used if `x` is a data.frame.
- `group`: a character vector with 1 or several columns from `x` which indicates for example a document id or a sentence id. Keywords will be computed within this group in order not to find keywords across sentences or documents for example.
- `relevant`: a logical vector of the same length as `nrow(x)`, indicating if the word in the corresponding row of `x` is relevant or not. This can be used to exclude stop-words from the keywords calculation or for selecting only nouns and adjectives to find keywords (for example based on the Parts of Speech `upos` output from `udpipe_annotate`).
- `ngram_max`: integer indicating the maximum number of words that there should be in each keyword
- `n_min`: integer indicating the frequency of how many times a keywords should at least occur in the data in order to be returned. Defaults to 2.
- `sep`: character string with the separator which will be used to paste together the terms which define the keywords. Defaults to a space: `' '`.

Value

- a data.frame with columns `keyword`, `ngram` and `rake` which is ordered from low to high `rake`
  - `keyword`: the keyword
  - `ngram`: how many terms are in the keyword
  - `freq`: how many times did the keyword occur
  - `rake`: the ratio of the degree to the frequency as explained in the description, summed up for all words from the keyword

References

Examples

```r
data(brussels_reviews_anno)
x <- subset(brussels_reviews_anno, language == "nl")
keywords <- keywords_rake(x = x, term = "lemma", group = "doc_id",
                          relevant = x$upos %in% c("NN", "JJ"))
head(keywords)
```
Description
This function is similar to `paste` but works on a data.frame, hence `paste.data.frame`. It concatenates text belonging to groups of data together in one string. The function is the inverse operation of `strsplit.data.frame`.

Usage
`paste.data.frame(data, term, group, collapse = " ")`

Arguments
- `data`: a data.frame or data.table
- `term`: a string with a column name or a character vector of column names from `data` which you want to concatenate together using `paste`
- `group`: a string with a column name or a character vector of column names from `data` indicating identifiers of groups. The text in `term` will be concatenated by group.
- `collapse`: a character string that you want to use to collapse the text data together. Defaults to a single space.

Value
A data.frame with 1 row per group containing the columns from `group` and `term` where all the text in `term` for each group will be `paste-d` together, separated by the `collapse` argument.

See Also
`strsplit.data.frame`, `paste`

Examples
```r
data(brussels_reviews_anno, package = "udpipe")
head(brussels_reviews_anno)
x <- paste.data.frame(brussels_reviews_anno,
  term = "lemma",
  group = c("doc_id", "sentence_id"))
str(x)
x <- paste.data.frame(brussels_reviews_anno,
  group = c("doc_id", "sentence_id"))
```
predict.LDA_VEM

Predict method for an object of class LDA_VEM or class LDA_Gibbs

Description

Gives either the predictions to which topic a document belongs or the term posteriors by topic indicating which terms are emitted by each topic.

If you provide in newdata a document term matrix for which a document does not contain any text and hence does not have any terms with nonzero entries, the prediction will give as topic prediction NA values (see the examples).

Usage

## S3 method for class 'LDA_VEM'
predict(object, newdata, type = c("topics", "terms"),
        min_posterior = -1, min_terms = 0, labels, ...)

## S3 method for class 'LDA_Gibbs'
predict(object, newdata, type = c("topics", "terms"),
        min_posterior = -1, min_terms = 0, labels, ...)

Arguments

- **object**: an object of class LDA_VEM or LDA_Gibbs as returned by LDA from the topicmodels package
- **newdata**: a document/term matrix containing data for which to make a prediction
- **type**: either 'topic' or 'terms' for the topic predictions or the term posteriors
- **min_posterior**: numeric in 0-1 range to output only terms emitted by each topic which have a posterior probability equal or higher than min_posterior. Only used if type is 'terms'. Provide -1 if you want to keep all values.
- **min_terms**: integer indicating the minimum number of terms to keep in the output when type is 'terms'. Defaults to 0.
- **labels**: a character vector of the same length as the number of topics in the topic model. Indicating how to label the topics. Only valid for type = 'topic'. Defaults to topic_prob_001 up to topic_prob_999.
- **...**: further arguments passed on to topicmodels::posterior
Value

- in case of type = 'topic': a data.table with columns doc_id, topic (the topic number to which the document is assigned to), topic_label (the topic label) topic_prob (the posterior probability score for that topic), topic_probdiff_2nd (the probability score for that topic - the probability score for the 2nd highest topic) and the probability scores for each topic as indicated by topic_label

- in case of type = 'terms': a list of data.frames with columns term and prob, giving the posterior probability that each term is emitted by the topic

See Also

scores <- predict(mymodel, type = "topics", newdata = dtm)
```
strsplit.data.frame

Obtain a tokenised data frame by splitting text alongside a regular expression

Description

Obtain a tokenised data frame by splitting text alongside a regular expression. This is the inverse operation of paste.data.frame.

Usage

strsplit.data.frame(data, term, group, split = "[[:space:]][[:punct:]][[:digit:]]+")

Arguments

data a data.frame or data.table

term a character with a column name from data which you want to split into tokens

group a string with a column name or a character vector of column names from data indicating identifiers of groups. The text in term will be split into tokens by group.

split a regular expression indicating how to split the term column. Defaults to splitting by spaces, punctuation symbols or digits. This will be passed on to strsplit.

Value

A tokenised data frame containing one row per token. This data.frame has the columns from group and term where the text in column term will be split by the provided regular expression into tokens.

See Also

paste.data.frame, strsplit

Examples

data(brussels_reviews, package = "udpipe")
x <- strsplit.data.frame(brussels_reviews, term = "feedback", group = "id")
head(x)
x <- strsplit.data.frame(brussels_reviews,
    term = c("feedback"),
    group = c("listing_id", "language"))
head(x)
**txt Collapse**

**Collapse a character vector while removing missing data.**

**Description**

Collapse a character vector while removing missing data.

**Usage**

```r
txtCollapse(x, collapse = " ")
```

**Arguments**

- `x` a character vector
- `collapse` a character string to be used to collapse the vector. Defaults to a space: `' '`.

**Value**

a character vector of length 1 with the content of `x` collapsed using `paste`

**See Also**

`paste`

**Examples**

```r
txtCollapse(c(NA, "hello", "world", NA))
```

**txt Contains**

**Check if text contains a certain pattern**

**Description**

Look up text which has a certain pattern. This pattern lookup is performed by executing a regular expression using `grepl`.

**Usage**

```r
txtContains(x, patterns, value = FALSE, ignore.case = TRUE, ...)
```
Arguments

- **x**
  - a character vector with text
- **patterns**
  - a regular expression which might be contained in x, a vector of these or a list of pattern elements where the list elements include and exclude indicate to find a pattern in x while excluding elements which have another pattern
- **value**
  - logical, indicating to return the elements of x where the pattern was found or just a logical vector. Defaults to FALSE indicating to return a logical.
- **ignore.case**
  - logical, if set to FALSE, the pattern matching is case sensitive and if TRUE, case is ignored during matching. Passed on to `grep`
- **...**
  - other parameters which can be passed on to `grep` e.g. fixed/perl/useBytes

Value

A logical vector of the same length as x indicating if one of the patterns was found in x.
Or the vector of elements of x where the pattern was found in case argument value is set to TRUE.

See Also

grep

Examples

```r
x <- c("The cats are eating catfood",
       "Our cat is eating the catfood",
       "the dog eats catfood, he likes it")
txt_contains(x, patterns = c("cat", "dog"))
txt_contains(x, patterns = c("cat", "dog"), value = TRUE)
txt_contains(x, patterns = c("eats"), value = TRUE)
txt_contains(x, patterns = c("^The"), ignore.case = FALSE, value = TRUE)
txt_contains(x, patterns = list(include = c("cat"), exclude = c("dog")), value = TRUE)
txt contiene(x, "cat") & txt containes(x, "dog")
```

**txt_freq**

*Frequency statistics of elements in a vector*

Description

Frequency statistics of elements in a vector.

Usage

```r
txt_freq(x, exclude = c(NA, NaN), order = TRUE)
```
**Arguments**

- **x** a vector
- **exclude** logical indicating to exclude values from the table. Defaults to NA and NaN.
- **order** logical indicating to order the resulting dataset in order of frequency. Defaults to TRUE.

**Value**

A data.frame with columns key, freq and freq_pct indicating the how many times each value in the vector x is occurring.

**Examples**

```r
x <- sample(LETTERS, 1000, replace = TRUE)
txt_freq(x)
x <- factor(x, levels = LETTERS)
txt_freq(x, order = FALSE)
```

---

**txt_highlight**

*Highlight words in a character vector*

**Description**

Highlight words in a character vector. The words provided in **terms** are highlighted in the text by wrapping it around the following character: !!. So 'I like milk and sugar in my coffee' would give 'I like |milk| and sugar in my coffee' if you want to highlight the word milk.

**Usage**

```r
txt_highlight(x, terms)
```

**Arguments**

- **x** a character vector with text
- **terms** a vector of words to highlight which appear in x

**Value**

A character vector with the same length of x where the terms provided in **terms** are put in between !! to highlight them.

**Examples**

```r
x <- "I like milk and sugar in my coffee."
txt_highlight(x, terms = "sugar")
txt_highlight(x, terms = c("milk", "my"))
```
Get the n-th next element of a vector

Description

Get the n-th next element of a vector

Usage

\texttt{txt\_next(x, n = 1)}

Arguments

\begin{itemize}
  \item \texttt{x} \hspace{1cm} a character vector where each element is just 1 term or word
  \item \texttt{n} \hspace{1cm} an integer indicating how far to look next. Defaults to 1.
\end{itemize}

Value

a character vector of the same length of \texttt{x} with the next element

See Also

\texttt{shift}

Examples

\begin{verbatim}
x <- sprintf("%s%s", LETTERS, 1:26)
txt\_next(x, n = 1)

data.frame(word = x,
    word\_next1 = txt\_next(x, n = 1),
    word\_next2 = txt\_next(x, n = 2),
    stringsAsFactors = FALSE)
\end{verbatim}

Based on a vector with a word sequence, get n-grams (looking forward)

Description

If you have annotated your text using \texttt{udpipe\_annotate}, your text is tokenised in a sequence of words. Based on this vector of words in sequence getting n-grams comes down to looking at the next word and the subsequent word and so forth. These words can be pasted together to form an n-gram containing the current word, the next word up, the subsequent word, ...
**Usage**

```
txt_nextgram(x, n = 2, sep = " ")
```

**Arguments**

- `x`: a character vector where each element is just 1 term or word
- `n`: an integer indicating the ngram. Values of 1 will keep the x, a value of 2 will append the next term to the current term, a value of 3 will append the subsequent term and the term following that term to the current term
- `sep`: a character element indicating how to `paste` the subsequent words together

**Value**

a character vector of the same length of `x` with the n-grams

**See Also**

`paste`, `shift`

**Examples**

``` r
x <- sprintf("%s%s", LETTERS, 1:26)
txt_nextgram(x, n = 2)

data.frame(words = x,
           bigram = txt_nextgram(x, n = 2),
           trigram = txt_nextgram(x, n = 3, sep = "-"),
           quartogram = txt_nextgram(x, n = 4, sep = ""),
           stringsAsFactors = FALSE)

data.frame(x,
           bigram = txt_nextgram(x, n = 2, sep = "_"),
           stringsAsFactors = FALSE)
```

---

**txt_previous**

*Get the n-th previous element of a vector*

**Description**

Get the n-th previous element of a vector

**Usage**

```
txt_previous(x, n = 1)
```
Arguments

- `x`: a character vector where each element is just 1 term or word
- `n`: an integer indicating how far to look back. Defaults to 1.

Value

- a character vector of the same length of `x` with the previous element

See Also

- `shift`

Examples

```r
x <- sprintf("%s", LETTERS, 1:26)
txt_previousgram(x, n = 1)

data.frame(word = x,
            word_previous1 = txt_previousgram(x, n = 1),
            word_previous2 = txt_previousgram(x, n = 2),
            stringsAsFactors = FALSE)
```

### `txt_previousgram`

Based on a vector with a word sequence, get n-grams (looking backward)

Description

If you have annotated your text using `udpipe_annotate`, your text is tokenised in a sequence of words. Based on this vector of words in sequence getting n-grams comes down to looking at the previous word and the subsequent previous word and so forth. These words can be pasted together to form an n-gram containing the second previous word, the previous word, the current word ...

Usage

```r
txt_previousgram(x, n = 2, sep = " ")
```

Arguments

- `x`: a character vector where each element is just 1 term or word
- `n`: an integer indicating the ngram. Values of 1 will keep the x, a value of 2 will append the previous term to the current term, a value of 3 will append the second previous term and the previous term preceding the current term to the current term
- `sep`: a character element indicating how to `paste` the subsequent words together
Value

a character vector of the same length of x with the n-grams

See Also

paste, shift

Examples

```r
x <- sprintf("%s%s", LETTERS, 1:26)
txt_previousgram(x, n = 2)

data.frame(words = x,
    bigram = txt_previousgram(x, n = 2),
    trigram = txt_previousgram(x, n = 3, sep = "-"),
    quatrogram = txt_previousgram(x, n = 4, sep = ""),
    stringsAsFactors = FALSE)

data.frame(x,
    bigram = txt_previousgram(x, n = 2, sep = "-"),
    stringsAsFactors = FALSE)
```

---

txt_recode  Recode text to other categories

Description

Recode text to other categories. Values of x which correspond to from[i] will be recoded to to[i]

Usage

```r
txt_recode(x, from = c(), to = c())
```

Arguments

- **x**: a character vector
- **from**: a character vector with values of x which you want to recode
- **to**: a character vector with values of you want to use to recode to where you want to replace values of x which correspond to from[i] to to[i]

Value

a character vector of the same length of x where values of x which are given in from will be replaced by the corresponding element in to

See Also

match
Examples

```r
x <- c("NOUN", "VERB", "NOUN", "ADV")
txt_recode(x = x,
  from = c("VERB", "ADV"),
  to = c("conjugated verb", "adverb"))
```

---

**txt_recode_ngram**  
*Recode words with compound multi-word expressions*

**Description**

Replace in a character vector of tokens, tokens with compound multi-word expressions. So that `c("New", "York")` will be `c("New York", NA)`.

**Usage**

```r
txt_recode_ngram(x, compound, ngram, sep = " ")
```

**Arguments**

- **x**  
a character vector of words where you want to replace tokens with compound multi-word expressions. This is generally a character vector as returned by the token column of `as.data.frame(udpipe_anonate(txt))`

- **compound**  
a character vector of compound words multi-word expressions indicating terms which can be considered as one word. For example `c("New York", "Brussels Hoofdstedelijk Gewest")`

- **ngram**  
a integer vector of the same length as `compound` indicating how many terms there are in the specific compound multi-word expressions given by `compound`, where `compound[i]` contains `ngram[i]` words. So if `x` is `c("New York", "Brussels Hoofdstedelijk Gewest")` the `ngram` would be `c(2, 3)`

- **sep**  
separator used when the compounds were constructed by combining the words together into a compound multi-word expression. Defaults to a space: `" "`.

**Value**

the same character vector `x` where elements in `x` will be replaced by compound multi-word expression. If will give preference to replacing with compounds with higher ngrams if these occur. See the examples.

**See Also**

- `txt_nextgram`
Examples

```r
x <- c("I", "went", "to", "New", "York", "City", "on", "holiday", ".")
y <- txt_recode_ngram(x, compound = "New York", ngram = 2, sep = " ")
data.frame(x, y)

keyw <- data.frame(keyword = c("New-York", "New-York-City"), ngram = c(2, 3))
y <- txt_recode_ngram(x, compound = keyw$keyword, ngram = keyw$ngram, sep = "-")
data.frame(x, y)

## Example replacing adjectives followed by a noun with the full compound word
x <- subset(brussels_reviews_anno, language == "nl")
keyw <- keywords_phrases(x$xpos, term = x$token, pattern = "JJNN",
is_regex = TRUE, detailed = FALSE)
head(keyw)
x$term <- txt_recode_ngram(x$token, compound = keyw$keyword, ngram = keyw$ngram)
head(x[, c("token", "term", "xpos")], 12)
```

---

**txt_sample**

Boilerplate function to sample one element from a vector.

Description

Boilerplate function to sample one element from a vector.

Usage

txt_sample(x, na.exclude = TRUE, n = 1)

Arguments

- **x**: a vector
- **na.exclude**: logical indicating to remove NA values before taking a sample
- **n**: integer indicating the number of items to sample from x

Value

one element sampled from the vector x

See Also

- sample.int

Examples

txt_sample(c(NA, "hello", "world", NA))
Perform dictionary-based sentiment analysis on a tokenised data frame

Description

This function identifies words which have a positive/negative meaning, with the addition of some basic logic regarding occurrences of amplifiers/deamplifiers and negators in the neighbourhood of the word which has a positive/negative meaning.

- If a negator is occurring in the neighbourhood, positive becomes negative or vice versa.
- If amplifiers/deamplifiers occur in the neighbourhood, these amplifier weight is added to the sentiment polarity score.

This function took inspiration from qdap::polarity but was completely re-engineered to allow to calculate similar things on a udpipe-tokenised dataset. It works on a sentence level and the negator/amplification logic can not surpass a boundary defined by the PUNCT upos parts of speech tag.

Note that if you prefer to build a supervised model to perform sentiment scoring you might be interested in looking at the ruimtehol R package https://github.com/bnosac/ruimtehol instead.

Usage

txt_sentiment(x, term = "lemma", polarity_terms,
  polarity_negators = character(), polarity_amplifiers = character(),
  polarity_deamplifiers = character(), amplifier_weight = 0.8,
  n_before = 4, n_after = 2, constrain = FALSE)

Arguments

x
  a data.frame with the columns doc_id, paragraph_id, sentence_id, upos and the column as indicated in term. This is exactly what udpipe returns.

term
  a character string with the name of a column of x where you want to apply to sentiment scoring upon

polarity_terms
  data.frame containing terms which have positive or negative meaning. This data frame should contain the columns term and polarity where term is of type character and polarity can either be 1 or -1.

polarity_negators
  a character vector of words which will invert the meaning of the polarity_terms such that -1 becomes 1 and vice versa

polarity_amplifiers
  a character vector of words which amplify the polarity_terms

polarity_deamplifiers
  a character vector of words which deamplify the polarity_terms
amplifier_weight
weight which is added to the polarity score if an amplifier occurs in the neighbourhood

n_before
integer indicating how many words before the polarity_terms word one has to look to find negators/amplifiers/deamplifiers to apply its logic

n_after
integer indicating how many words after the polarity_terms word one has to look to find negators/amplifiers/deamplifiers to apply its logic

constrain
logical indicating to make sure the aggregated sentiment scores is between -1 and 1

Value

a list containing
- data: the x data.frame with 2 columns added: polarity and sentiment_polarity.
  - The column polarity being just the polarity column of the polarity_terms dataset corresponding to the polarity of the term you apply the sentiment scoring
  - The column sentiment_polarity is the value where the amplifier/de-amplifier/negator logic is applied on.
- overall: a data.frame with one row per doc_id containing the columns doc_id, sentences, terms, sentiment_polarity, terms_positive, terms_negative, terms_negation and terms_amplification providing the aggregate sentiment_polarity score of the dataset x by doc_id as well as the terminology causing the sentiment, the number of sentences and the number of non punctuation terms in the document.

Examples

x <- c("I do not like whatsoever when an R package has soo many dependencies.",
       "Making other people install java is annoying,
       as it is a really painful experience in classrooms.")

## Not run:
## Do the annotation to get the data.frame needed as input to txt_sentiment
anno <- udpipe(x, "english-gum")

## End(Not run)
anno <- data.frame(doc_id = c(rep("doc1", 14), rep("doc2", 18)),
                   paragraph_id = 1,
                   sentence_id = 1,
                   lemma = c("I", "do", "not", "like", "whatsoever",
                              "when", "an", "R", "package",
                              "has", "soo", "many", "dependencies", ",",
                              "Making", "other", "people", "install",
                              "java", "is", "annoying", ",", "as",
                              "it", "is", "a", "really", "painful",
                              "experience", "in", "classrooms", ","),
                   upos = c("PRON", "AUX", "PART", "VERB", "PRON",
                             "SCONJ", "DET", "PROPN", "NOUN", "VERB",
                             "ADV", "ADJ", "NOUN", "PUNCT",
                             "VERB", "ADJ", "NOUN", "ADJ", "NOUN",
                             "AUX", "VERB", "PUNCT", "SCONJ", "PRON",...)
Boilerplate function to cat only 1 element of a character vector.

Description

Boilerplate function to cat only 1 element of a character vector.

Usage

```r
txt_show(x)
```

Arguments

- `x` a character vector

Value

invisible

See Also

```r
txt_sample
```

Examples

```r
txt_show(c("hello \
\n\n world", "world \
\n\n hello"))
```
Description

This function allows to identify contiguous sequences of text which have the same label or which follow the IOB scheme. Named Entity Recognition or Chunking frequently follows the IOB tagging scheme where "B" means the token begins an entity, "I" means it is inside an entity, "E" means it is the end of an entity and "O" means it is not part of an entity. An example of such an annotation would be 'New', 'York', 'City', 'District' which can be tagged as 'B-LOC', 'I-LOC', 'I-LOC', 'E-LOC'. The function looks for such sequences which start with 'B-LOC' and combines all subsequent labels of the same tagging group into 1 category. This sequence of words also gets a unique identifier such that the terms 'New', 'York', 'City', 'District' would get the same sequence identifier.

Usage

txt_tagsequence(x, entities)

Arguments

x a character vector of categories in the sequence of occurring (e.g. B-LOC, I-LOC, I-PER, B-PER, O, O, B-PER)

entities a list of groups, where each list element contains

• start: A length 1 character string with the start element identifying a sequence start. E.g. 'B-LOC'

• labels: A character vector containing all the elements which are considered being part of a same labelling sequence, including the starting element. E.g. c('B-LOC', 'I-LOC', 'E-LOC')

The list name of the group defines the label that will be assigned to the entity. If entities is not provided each possible value of x is considered an entity. See the examples.

Value

a list with elements entity_id and entity where

• entity is a character vector of the same length as x containing entities, constructed by recoding x to the names of names(entities)

• entity_id is an integer vector of the same length as x containing unique identifiers identifying the compound label sequence such that e.g. the sequence 'B-LOC', 'I-LOC', 'I-LOC', 'E-LOC' (New York City District) would get the same entity_id identifier.

See the examples.
Examples

```r
x <- data.frame(
  token = c("The", "chairman", "of", "the", "Nakitoma", "Corporation", 
  "Donald", "Duck", "went", "skiing", 
  "in", "the", "Niagara", "Falls"),
  upos = c("DET", "NOUN", "ADP", "DET", "PROPN", "PROPN", 
  "PROPN", "PROPN", "VERB", "VERB", 
  "ADP", "DET", "PROPN", "PROPN"),
  label = c("O", "O", "O", "O", "B-ORG", "I-ORG", 
  "B-PERSON", "I-PERSON", "O", "O", 
  "O", "O", "B-LOCATION", "I-LOCATION"), stringsAsFactors = FALSE)
x[, c("sequence_id", "group")]) <- txt_tagsequence(x$upos)
x

## Define entity groups following the IOB scheme
## and combine B-LOC I-LOC I-LOC sequences as 1 group (e.g. New York City)
groups <- list(
  Location = list(start = "B-LOC", labels = c("B-LOC", "I-LOC", "E-LOC")),
  Organisation = list(start = "B-ORG", labels = c("B-ORG", "I-ORG", "E-ORG")),
  Person = list(start = "B-PER", labels = c("B-PER", "I-PER", "E-PER")),
  Misc = list(start = "B-MISC", labels = c("B-MISC", "I-MISC", "E-MISC")))
x[, c("entity_id", "entity")]) <- txt_tagsequence(x$label, groups)
x
```

udpipe

 Tokenising, Lemmatising, Tagging and Dependency Parsing of raw
text in TIF format

Description

Tokenising, Lemmatising, Tagging and Dependency Parsing of raw text in TIF format

Usage

`udpipe(x, object, parallel.cores = 1L, parallel.chunksize, ...)`

Arguments

- `x` either
  - a character vector: The character vector contains the text you want to tokenize, lemmatise, tag and perform dependency parsing. The names of the character vector indicate the document identifier.
  - a data.frame with columns `doc_id` and `text`: The text column contains the text you want to tokenize, lemmatise, tag and perform dependency parsing. The `doc_id` column indicates the document identifier.
  - a list of tokens: If you have already a tokenised list of tokens and you want to enrich it by lemmatising, tagging and performing dependency parsing. The names of the list indicate the document identifier.
All text data should be in UTF-8 encoding

object
either an object of class udpipe_model as returned by udpipe_load_model, the
path to the file on disk containing the udpipe model or the language as defined
by udpipe_download_model. If the language is provided, it will download the
model using udpipe_download_model.

parallel.cores
integer indicating the number of parallel cores to use to speed up the annotation.
Defaults to 1 (use only 1 single thread).
If more than 1 is specified, it uses parallel::mclapply (unix) or parallel::clusterApply
(windows) to run annotation in parallel. In order to do this on Windows it runs
first parallel::makeCluster to set up a local socket cluster, on unix it just uses
forking to parallelise the annotation.
Only set this if you have more than 1 CPU at disposal and you have large amount
of data to annotate as setting up a parallel backend also takes some time plus an-
notations will run in chunks set by parallel.chunksize and for each parallel
chunk the udpipe model will be loaded which takes also some time.
If parallel.cores is bigger than 1 and object is of class udpipe_model, it
will load the corresponding file from the model again in each parallel chunk.

parallel.chunkszize
integer with the size of the chunks of text to be annotated in parallel. If not
provided, defaults to the size of x divided by parallel.cores. Only used in
in case parallel.cores is bigger than 1.

...other elements to pass on to udpipe_annotate and udpipe_download_model

Value

da.data.frame with one row per doc_id and term_id containing all the tokens in the data, the lemma,
the part of speech tags, the morphological features and the dependency relationship along the to-
kens. The data.frame has the following fields:

• doc_id: The document identifier.
• paragraph_id: The paragraph identifier which is unique within each document.
• sentence_id: The sentence identifier which is unique within each document.
• sentence: The text of the sentence of the sentence_id.
• start: Integer index indicating in the original text where the token starts. Missing in case of
tokens part of multi-word tokens which are not in the text.
• end: Integer index indicating in the original text where the token ends. Missing in case of
tokens part of multi-word tokens which are not in the text.
• term_id: A row identifier which is unique within the doc_id identifier.
• token_id: Token index, integer starting at 1 for each new sentence. May be a range for multi-
word tokens or a decimal number for empty nodes.
• token: The token.
• lemma: The lemma of the token.
• upos: The universal parts of speech tag of the token. See http://universaldependencies.org/format.html
• xpos: The treebank-specific parts of speech tag of the token. See http://universaldependencies.org/format.html
• feats: The morphological features of the token, separated by |. See http://universaldependencies.org/format.html
• head_token_id: Indicating what is the token_id of the head of the token, indicating to which other token in the sentence it is related. See http://universaldependencies.org/format.html
• dep_rel: The type of relation the token has with the head_token_id. See http://universaldependencies.org/format.html
• deps: Enhanced dependency graph in the form of a list of head-deprel pairs. See http://universaldependencies.org/format.html
• misc: SpacesBefore/SpacesAfter/SpacesInToken spaces before/after/inside the token. Used to reconstruct the original text. See http://ufal.mff.cuni.cz/udpipe/users-manual

The columns paragraph_id, sentence_id, term_id, start, end are integers, the other fields are character data in UTF-8 encoding.

  ##
  ## TIF tagging: tag if x is a character vector, a data frame or a token sequence
  ##
udpipe_accuracy

Evaluate the accuracy of your UDPipe model on holdout data

Description

Get precision, recall and F1 measures on finding words / sentences / upos / xpos / features annotation as well as UAS and LAS dependency scores on holdout data in conllu format.

Usage

udpipe_accuracy(object, file_conllu, tokenizer = c("default", "none"),
  tagger = c("default", "none"), parser = c("default", "none"))

Arguments

object an object of class udpipe_model as returned by udpipe_load_model
file_conllu the full path to a file on disk containing holdout data in conllu format
tokenizer a character string of length 1, which is either ‘default’ or ‘none’
tagger a character string of length 1, which is either ‘default’ or ‘none’
parser a character string of length 1, which is either ‘default’ or ‘none’

Value

a list with 3 elements

• accuracy: A character vector with accuracy metrics.
• error: A character string with possible errors when calculating the accuracy metrics

## You can also directly pass on the language in the call to udpipe

```r
x <- udpipe("Dit werkt ook.", object = "dutch-lassysmall")
x <- udpipe(data.frame(doc_id = names(txt), text = txt, stringsAsFactors = FALSE),
  object = ud_dutch)
x <- udpipe(strsplit(txt, "[:space:][:punct:][:digit:]"),
  object = ud_dutch)
```

## cleanup for CRAN only - you probably want to keep your model if you have downloaded it

```r
if(file.exists(model$file_model)) file.remove(model$file_model)
```

---

udpipe_annotate  
**Tokenising, Lemmatising, Tagging and Dependency Parsing Annotation of raw text**

Description

Tokenising, Lemmatising, Tagging and Dependency Parsing Annotation of raw text

Usage

udpipe_annotate(object, x, doc_id = paste("doc", seq_along(x), sep = ""),
  tokenizer = "tokenizer", tagger = c("default", "none"),
  parser = c("default", "none"), trace = FALSE, ...)

---
**Arguments**

- **object** an object of class `udpipe_model` as returned by `udpipe_load_model`.
- **x** a character vector in UTF-8 encoding where each element of the character vector contains text which you like to tokenize, tag and perform dependency parsing.
- **doc_id** an identifier of a document with the same length as x. This should be a character vector. `doc_id[i]` corresponds to `x[i]`.
- **tokenizer** a character string of length 1, which is either 'tokenizer' (default udpipe tokenisation) or a character string with more complex tokenisation options as specified in [http://ufal.mff.cuni.cz/udpipe/users-manual](http://ufal.mff.cuni.cz/udpipe/users-manual) in which case tokenizer should be a character string where the options are put after each other using the semicolon as separation.
- **tagger** a character string of length 1, which is either 'default' (default udpipe POS tagging and lemmatisation) or 'none' (no POS tagging and lemmatisation needed) or a character string with more complex tagging options as specified in [http://ufal.mff.cuni.cz/udpipe/users-manual](http://ufal.mff.cuni.cz/udpipe/users-manual) in which case tagger should be a character string where the options are put after each other using the semicolon as separation.
- **parser** a character string of length 1, which is either 'default' (default udpipe dependency parsing) or 'none' (no dependency parsing needed) or a character string with more complex parsing options as specified in [http://ufal.mff.cuni.cz/udpipe/users-manual](http://ufal.mff.cuni.cz/udpipe/users-manual) in which case parser should be a character string where the options are put after each other using the semicolon as separation.
- **trace** A non-negative integer indicating to show progress on the annotation. If positive it prints out a message before each `trace` number of elements of `x` for which annotation is to be executed, allowing you to see how much of the text is already annotated. Defaults to FALSE (no progress shown).

**Value**

A list with 3 elements

- **x**: The `x` character vector with text.
- **conllu**: A character vector of length 1 containing the annotated result of the annotation flow in CONLL-U format. This format is explained at [http://universaldependencies.org/format.html](http://universaldependencies.org/format.html)
- **error**: A vector with the same length of `x` containing possible errors when annotating `x`.

## This can be done using iconv as follows for example
udpipe_annotate(ud_dutch, x = iconv('Ik drink melk bij mijn koffie.', to = "UTF-8"))
}

## cleanup for CRAN only - you probably want to keep your model if you have downloaded it
if(file.exists(model$file_model)) file.remove(model$file_model)
```
udpipe_download_model

Description

In order to show the settings which were used by the UDPipe community when building the models made available when using `udpipe_download_model`, the tokenizer settings used for the different treebanks are shown below, so that you can easily use this to retrain your model directly on the corresponding UD treebank which you can download at http://universaldependencies.org/ud-treebanks.

More information on how the models provided by the UDPipe community have been built are available at https://lindat.mff.cuni.cz/repository/xmlui/handle/11234/1-2364

udpipe_download_model  Download an UDPipe model provided by the UDPipe community for a specific language of choice

Description

Ready-made models for 65 languages trained on 94 treebanks from http://universaldependencies.org/ are provided to you. Some of these models were provided by the UDPipe community. Other models were build using this R package. You can either download these models manually in order to use it for annotation purposes or use `udpipe_download_model` to download these models for a specific language of choice. You have the following options:
Usage

model_dir = getwd(),
udpipe_model_repo = c("jwijffels/udpipe.models.ud.2.4", "jwijffels/udpipe.models.ud.2.3", "jwijffels/udpipe.models.ud.2.0", "jwijffels/udpipe.models.conll18.baseline", "bnosac/udpipe.models.ud"),
overwrite = TRUE, ...)

Arguments

language a character string with a Universal Dependencies treebank which was used to build the model. Possible values are:

Each language should have a treebank extension (e.g. english-ewt, russian-syntagrus, dutch-alpino, ...). If you do not provide a treebank extension (e.g. only english, russian, dutch), the function will use the default treebank of that language as was used in Universal Dependencies up to version 2.1.

model_dir  a path where the model will be downloaded to. Defaults to the current working directory

udpipe_model_repo  location where the models will be downloaded from. Either 'jwijffels/udpipe.models.ud.2.4', 'jwijffels/udpipe.models.ud.2.3', 'jwijffels/udpipe.models.ud.2.0', 'jwijffels/udpipe.models.conll18.baseline' or 'bnosac/udpipe.models.ud'. Defaults to 'jwijffels/udpipe.models.ud.2.4'.

- 'jwijffels/udpipe.models.ud.2.4' contains models released under the CC-BY-NC-SA license constructed on Universal Dependencies 2.4 data
- 'jwijffels/udpipe.models.ud.2.3' contains models released under the CC-BY-NC-SA license constructed on Universal Dependencies 2.3 data
- 'jwijffels/udpipe.models.ud.2.0' contains models released under the CC-BY-NC-SA license constructed on Universal Dependencies 2.0 data
- 'jwijffels/udpipe.models.conll18.baseline' contains models released under the CC-BY-NC-SA license constructed on Universal Dependencies 2.2 data for the 2018 conll shared task
- 'bnosac/udpipe.models.ud' contains models mainly released under the CC-BY-SA license constructed on Universal Dependencies 2.1 data, and some models released under the GPL-3 and LGPL-LR license

See the Details section for further information on which languages are available in each of these repositories.

overwrite  logical indicating to overwrite the file if the file was already downloaded. Defaults to TRUE indicating it will download the model and overwrite the file if the file already existed. If set to FALSE, the model will only be downloaded if it does not exist on disk yet in the model_dir folder.

...  currently not used

Details

The function allows you to download the following language models based on your setting of argument udpipe_model_repo:

- 'jwijffels/udpipe.models.ud.2.4': https://github.com/jwijffels/udpipe.models.ud.2.4
  - UDPipe models constructed on data from Universal Dependencies 2.4

license: CC-BY-SA-NC

• 'jwijffels/udpipe.models.ud.2.3': https://github.com/jwijffels/udpipe.models.ud.2.3

UDPipe models constructed on data from Universal Dependencies 2.3

UDPipe models constructed on data from Universal Dependencies 2.0
- slovak, slovenian-sst, slovenian, spanish-ancora, spanish, swedish-lines, swedish, tamil, turkish, ukranian, urdu, uyghur, vietnamese
  - license: CC-BY-SA-NC
- ‘jwijffels/udpipe.models.conll18.baseline’: https://github.com/jwijffels/udpipe.models.conll18.baseline
  - UDPipe models constructed on data from Universal Dependencies 2.2
  - license: CC-BY-SA-NC
  - UDPipe models constructed on data from Universal Dependencies 2.1
  - This repository contains models build with this R package on open data from Universal Dependencies 2.1 which allows for commercial usage. The license of these models is mostly CC-BY-SA. Visit that github repository for details on the licenses of the language of your choice. And contact www.bnosac.be if you need support on these models or require models tuned to your needs.
  - languages-treebanks: afrikaans, crotian, czech-cac, dutch, english, finnish, french-sequoia, irish, norwegian-bokmaal, persian, polish, portuguese, romanian, serbian, slovak, spannish-ancora, swedish
  - license: license is treebank-specific but mainly CC-BY-SA and GPL-3 and LGPL-LR
  - If you need to train models yourself for commercial purposes or if you want to improve models, you can easily do this with udpipe_train which is explained in detail in the package vignette.

Note that when you download these models, you comply to the license of your specific language model.

Value

A data.frame with 1 row and the following columns:

- language: The language as provided by the input parameter language
- file_model: The path to the file on disk where the model was downloaded to
- url: The URL where the model was downloaded from
- download_failed: A logical indicating if the download has failed or not due to internet connectivity issues
- download_message: A character string with the error message in case the downloading of the model failed

                           model_dir = tempdir())

x

# cleanup for CRAN
if(file.exists(x$file_model)) file.remove(x$file_model)
```
udpipe_load_model

Load an UDPipe model

Description

Load an UDPipe model so that it can be used in `udpipe_annotate`

Usage

`udpipe_load_model(file)`

Arguments

- `file`: full path to the model or the value returned by a call to `udpipe_download_model`

Value

An object of class `udpipe_model` which is a list with 2 elements
- `file`: The path to the model as provided by `file`
- `model`: An Rcpp-generated pointer to the loaded model which can be used in `udpipe_annotate`

References

See Also

`udpipe_annotate`, `udpipe_download_model`, `udpipe_train`

Examples

```r
## Not run:
x <- udpipe_download_model(language = "dutch-lassysmall")
x$file_model
ud_english <- udpipe_load_model(x$file_model)

x <- udpipe_download_model(language = "english")
x$file_model
ud_english <- udpipe_load_model(x$file_model)

x <- udpipe_download_model(language = "hebrew")
x$file_model
ud_hebrew <- udpipe_load_model(x$file_model)

## End(Not run)

x <- udpipe_download_model(language = "dutch-lassysmall", model_dir = tempdir())
```
udpipe_train

x$file_model
if(!x$download_failed){
  ud_dutch <- udpipe_load_model(x$file_model)
}

## cleanup for CRAN
if(file.exists(x$file_model)) file.remove(x$file_model)

udpipe_read_conllu  Read in a CONLL-U file as a data.frame

Description
Read in a CONLL-U file as a data.frame

Usage
udpipe_read_conllu(file)

Arguments
file a connection object or a character string with the location of the file

Value
a data.frame with columns doc_id, paragraph_id, sentence_id, sentence, token_id, token, lemma, upos, xpos, feats, head_token_id, deprel, dep_rel, misc

Examples
file_conllu <- system.file(package = "udpipe", "dummydata", "traindata.conllu")
x <- udpipe_read_conllu(file_conllu)
head(x)

udpipe_train  Train a UDPipe model

Description
Train a UDPipe model which allows to do Tokenization, Parts of Speech Tagging, Lemmatization and Dependency Parsing or a combination of those.

This function allows you to build models based on data in in CONLL-U format as described at http://universaldependencies.org/format.html. At the time of writing open data in CONLL-U format for 50 languages are available at http://universaldependencies.org/#ud-treebanks.
Most of these are distributed under the CC-BY-SA licence or the CC-BY-NC-SA license.

This function allows to build annotation tagger models based on these data in CONLL-U format, allowing you to have your own tagger model. This is relevant if you want to tune the tagger to your needs or if you don’t want to use ready-made models provided under the CC-BY-NC-SA license as shown at `udpipe_load_model`.

**Usage**

```r
udpipe_train(file = file.path(getwd(), "my_annotator.udpipe"),
             files_conllu_training, files_conllu_holdout = character(),
             annotation_tokenizer = "default", annotation_tagger = "default",
             annotation_parser = "default")
```

**Arguments**

- `file` full path where the model will be saved. The model will be stored as a binary file which `udpipe_load_model` can handle. Defaults to `"my_annotator.udpipe"` in the current working directory.
- `files_conllu_training` a character vector of files in CONLL-U format used for training the model
- `files_conllu_holdout` a character vector of files in CONLL-U format used for holdout evaluation of the model. This argument is optional.
- `annotation_tokenizer` a string containing options for the tokenizer. This can be either 'none' or 'default' or a list of options as mentioned in the UDPipe manual. See the vignette vignette("udpipe-train", package = "udpipe") or go directly to [http://ufal.mff.cuni.cz/udpipe/users-manual#model_training_tokenizer](http://ufal.mff.cuni.cz/udpipe/users-manual#model_training_tokenizer) for a full description of the options or see the examples below. Defaults to 'default'. If you specify 'none', the model will not be able to perform tokenization.
- `annotation_tagger` a string containing options for the pos tagger and lemmatiser. This can be either 'none' or 'default' or a list of options as mentioned in the UD Pipe manual. See the vignette vignette("udpipe-train", package = "udpipe") or go directly to [http://ufal.mff.cuni.cz/udpipe/users-manual#model_training_tagger](http://ufal.mff.cuni.cz/udpipe/users-manual#model_training_tagger) for a full description of the options or see the examples below. Defaults to 'default'. If you specify 'none', the model will not be able to perform POS tagging or lemmatization.
- `annotation_parser` a string containing options for the dependency parser. This can be either 'none' or 'default' or a list of options as mentioned in the UD Pipe manual. See the vignette vignette("udpipe-train", package = "udpipe") or go directly to [http://ufal.mff.cuni.cz/udpipe/users-manual#model_training_parser](http://ufal.mff.cuni.cz/udpipe/users-manual#model_training_parser) for a full description of the options or see the examples below. Defaults to 'default'. If you specify 'none', the model will not be able to perform dependency parsing.
Details

In order to train a model, you need to provide files which are in CONLL-U format in argument `files_conllu_training`. This can be a vector of files or just one file. If you do not have your own CONLL-U files, you can download files for your language of choice at [http://universaldependencies.org/ud-treebanks](http://universaldependencies.org/ud-treebanks).

At the time of writing open data in CONLL-U format for 50 languages are available at [http://universaldependencies.org/ud-treebanks](http://universaldependencies.org/ud-treebanks), namely for: ancient_greek, arabic, basque, belarusian, bulgarian, catalan, chinese, coptic, croatian, czech, danish, dutch, english, estonian, finnish, french, galician, german, gothic, greek, hebrew, hindi, hungarian, indonesian, irish, italian, japanese, kazakh, korean, latin, latvian, lithuanian, norwegian, old_church_slavonic, persian, polish, portuguese, romanian, russian, sanskrit, slovak, slovenian, spanish, swedish, tamil, turkish, ukrainian, urdu, uyghur, vietnamese.

Value

A list with elements
- `file`: The path to the model, which can be used in `udpipe_load_model`
- `annotation_tokenizer`: The input argument `annotation_tokenizer`
- `annotation_tagger`: The input argument `annotation_tagger`
- `annotation_parser`: The input argument `annotation_parser`
- `errors`: Messages from the UDPipe process indicating possible errors for example when passing the wrong arguments to the `annotation_tokenizer`, `annotation_tagger` or `annotation_parser`

Examples

```r
## You need to have a file on disk in CONLL-U format, taking the toy example file put in the package
file_conllu <- system.file(package = "udpipe", "dummydata", "traindata.conllu")
file_conllu

## Not run:
##
## This is a toy example showing how to build a model, it is not a good model whatsoever,
## because model building takes more than 5 seconds this model is saved also in
## the file at system.file(package = "udpipe", "dummydata", "toymodel.udpipe")
##
## m <- udpipe_train(file = "toymodel.udpipe", files_conllu_training = file_conllu,
## annotation_tokenizer = list(dimension = 16, epochs = 1, batch_size = 100, dropout = 0.7),
## annotation_tagger = list(iterations = 1, models = 1),
```
unique_identifier

Create a unique identifier for each combination of fields in a data frame

Description

Create a unique identifier for each combination of fields in a data frame. This unique identifier is unique for each combination of the elements of the fields. The generated identifier is like a primary key or a secondary key on a table. This is just a small wrapper around \texttt{frank}

Usage

\begin{verbatim}
unique_identifier(x, fields, start_from = 1L)
\end{verbatim}

Arguments

\begin{itemize}
\item \texttt{x} \hspace{1cm} a data.frame
\item \texttt{fields} \hspace{1cm} a character vector of columns from \texttt{x}
\item \texttt{start_from} \hspace{1cm} integer number indicating to start from that number onwards
\end{itemize}
Value

an integer vector of the same length as the number of rows in x containing the unique identifier

Examples

data(brussels_reviews_anno)
x <- brussels_reviews_anno
x$doc_sent_id <- unique_identifier(x, fields = c("doc_id", "sentence_id"))
head(x, 15)
range(x$doc_sent_id)
x$doc_sent_id <- unique_identifier(x, fields = c("doc_id", "sentence_id"), start_from = 10)
head(x, 15)
range(x$doc_sent_id)
